"While I was in Sackett's shop the other day McMillan came in and asked for money between pay days. Sackett heard him and went for him. Rated him soundly for being in need of money and so careless of the future as to have to draw pay for present necessities. Found he had not been sick, nor had any of his folks, nor had he taken a trip to the seashore, nor bought bonds or real estate—bought nothing. Sackett began to look sick and disgusted. Went and fished out old pay rolls, etc., and showed Mack that he had received and spent more money in the last twelve years than any small store-keeper in the whole town could possibly have made. McMillan couldn't say anything, but it made him feel rich to see what money had gone through his fingers, and awful poor to see what had not stuck to them. Sackett got mad as he thought of

the thing, and finally told Mack he could not draw any pay, but he would lend him $10 for a week; 'but mind you,' added he, 'I am going to make an example of you. There's some excuse for a lazy drunkard with a slouchy wife, or for a smart young chap who dresses and lives proudly, but there's none for you. I never saw you with nice clothes on, and never saw yourself and family out enjoying an evening at a theatre or any other place. I will bet a quarter that you buy heavy sugar at a higher price than sawed block, and pay more for coal oil than I do, and pay more for your clothes. You get good pay, and I am bound that someone around this place shall make some money. If you and your wife, after studying common sense for a year, can't show me a certificate of deposit for $300 you shall earn your butterless bread in some other shop.'"

End View, Showing Progress of the Work.

### Compound and Simple Engines.

BY HUGH SHARP.

The compound system affords a simple and effective means of using steam expansively without the aid of any elaborate expansion-gear. Theoretically, the expansion of a given quantity of steam can be carried out with greater economy in more than one cylinder. The temperature and pressure of steam vary directly. Steam entering a cylinder at a pressure of 160 pounds to the square inch and expanded four times falls in temperature from 360 to 267 deg. Fahr. Towards the end of the stroke a certain amount of condensation takes place. The cylinder metal will become comparatively chilled, partly from radiation and partly from the cooling effects of the four-fold expansion. The inlet of high-pressure steam on the return stroke coming into contact with the cooler metal suffers an immediate fall in temperature and pressure. A double loss here ensues; the condensed steam on the dead side of the piston is re-evaporated owing to the reheating of the cylinder, which means increased back pressure, and to effect this the live steam has been deprived of a portion of its energy. The losses here noted could be reduced by maintaining a more constant pressure and temperature throughout the stroke by cutting off at the latest point practicable and exhausting at a pressure approximating closely to that of the steam as originally admitted. But this exhaust steam would still have stored up in it a large amount of useful energy which would be wasted by discharging it directly into the atmosphere; hence the utility of the low-pressure cylinder, which extracts the balance of this useful energy, and finally releases the steam at only a few pounds above atmospheric pressure. (The admission of steam in the high-pressure cylinder during the full stroke has only been assumed for purposes of illustration. It would seldom be desirable in practice).

From the foregoing it would appear that if expansion can be more economically carried out in two cylinders than one, owing to the lesser range of temperature in each cylinder, by increasing the number of cylinders, this range of temperature would be still further reduced, resulting in increased economy. Within certain limits this is true, and in marine engine practice, where a considerable number of moving parts can be tolerated, triple and quadruple expansion has given very favorable results. In locomotive practice, however, extreme simplicity of detail and the least possible number of moving parts are of the first importance. In a two-cylindered compound locomotive there is little more complication than in the simple, but it remains to be seen whether the employment of four cylinders will prove satisfactory in the long run. The initial cost of such engines is greater; the increased number of moving parts means increased liability to breakdowns, as well as extra wear and tear, and last, but not least, lubrication must be a considerable item in their working expenses.

The compound engine is having a boom in America just as it had in Europe ten years ago. The European boom was followed by a reaction, and compounding has been practically abandoned after being given an extended trial. Two or three years since, Mr. Webb, of the Northwestern Railway, who is one of the few English believers in the compound locomotive, backed one of his patent three-cylindered machines against a fine simple locomotive of the Southwestern. The latter had 19 x 26-inch cylinders and four 84-inch drivers, coupled, and was one of the type employed for working the Exeter Express. The compound was to perform the same duty on less coal and in quicker time. Both engines had about equal theoretical capacity, but when it came to actual practice the Webb engine was hopelessly beaten.

What coal it burnt on the trip was never divulged, but it arrived at Exeter an hour late in spite of the gallant efforts of its engineer and fireman to run to time. When it pulled up the smoke-box was white-hot and the smoke-stack partially melted. (The last two items are from an intelligent Southwestern engineer, who was very likely a member of a London "Ananias Club.") This does not prove that compounding is bad, though Webb's application of the principle is open to serious objections. But where the demands on an engine are variable, as they were throughout this journey, with its severe and frequent grades, the compound will not compete successfully with the simple unless it can be so arranged as to work as a simple on up-grades. This seems to have been ingeniously carried out in the Brooks and Pittsburgh compounds.

It was recently reported that a compound engine on the New York Central indicated one horse power an hour for each 3¼ pounds of coal burnt. This is certainly a good performance, but it has been beaten. In 1850 Sir Daniel Gooche's "Great Britain" exerted the same power on 2½ pounds of coke. Allowing coke to be, weight for weight, 6 per cent. superior to coal as a fuel, the balance is still greatly in favor of the English engine. The experiments during which this remarkable result was obtained were so carefully conducted that no error can have crept in. The engine at the time was cutting off at the seventh inch of the stroke of 24 inches

### Corrugated Pistons.

A Western inventor who has devoted much attention to increasing heating surface by means of corrugations and other protuberances, proposes to increase the area of a piston by the use of concentric corrugations. The writer wasted an hour on the man in trying to explain that the total pressure would not be greater than it would be on a plain surface. It proved to be a case of "a man convinced against his will is of the same opinion still."

Besides being a fallacy, the attempt to increase piston surface by grooves, corrugations and serrations is old, and comes up regularly, like inventions aiming at perpetual motion. It is in line with the tapering of plugs with the belief that less steam or water pressure would be exerted to drive them out.

---

They have had to use pilot plows in North Carolina this winter, the first in eight years.

For a full account see Zerah Colburn's "Locomotive Engineering," chap. XVII. The "Great Britain" was one of a number of similar engines built for the Great Western Broad-gauge Railway of seven feet. The cylinders were 18x24 inches, and were suspended with their steam-chests in the smoke-box; exhaust nozzle, 5½ inches internal diameter; total heating surface, 1,800 square feet; weight of engine alone, in working order, 91,800 pounds. It is not difficult to understand that such an engine would be light on coal. The cylinders and steam-chests were thoroughly protected; the large boiler was able to supply abundance of steam without being stimulated by a violent exhaust, and with the 5½-inch exhaust-nozzle back-pressure was practically *nil* when the engine was traveling at speed with an early cut-off. One of these engines, the "Lord of the Isles," is to be exhibited at the World's Fair. During its thirty-four years' active service it ran 1,000,000 miles with the original boiler.

It is safe to say that no compound engine has ever beaten the "Great Britain's" record. Compound engines may certainly be more economical than many of the simple, but this perhaps is not fairly attributable to the compound system alone. A bad feature and a very common one in American simple-engine practice is that of leaving the cylinder ends and steam-chests entirely unprotected. Such engines work at a great disadvantage, for in actual practice it has been ascertained that with imperfectly protected cylinders nothing is gained by cutting off earlier than half-stroke. If a higher rate of expansion is attempted condensation becomes so great, with consequent increased back-pressure, that an actual loss may ensue. There are two features in compound engines which are largely responsible for their economy—completely protected cylinders and a free exhaust. The complete protection of the cylinders is necessary, for any considerable condensation would cause a partial vacuum in the low-pressure cylinder near the end of the stroke. If a free exhaust were not provided back-pressure would exceed that on the live side of the piston. Another good effect of the free exhaust is the saving of some tons of fuel from being blown out of the stack in the course of a year.

A compound engine that can be worked as a simple when desired offers considerable advantages by doing away with the necessity of helping engines on extra steep grades. The capacity of the engine can be temporarily increased 40 to 50 per cent. by admitting steam into the low-pressure cylinder and using sand freely. Such engines are now working and are said to be satisfactory; there is a great danger, however, of their being abused in incompetent hands. But for ordinary express service a simple engine with thoroughly protected cylinders 20x24-in., 6½-ft. driving wheels, 1,600 sq. ft. heating surface and a 5-in. exhaust nozzle should be able to hold its own against any compound.

The heating surface may appear excessive, but this is a good fault; it makes an easy exhaust possible, and tends to prevent priming, which is the invariable result of an overworked boiler and a cause of serious loss.

*Abilene, Tex.*

## Setting Up Wedges, Keying Side-Rod Brasses and Tramming Engines.

BY G. K. W.

The question is frequently asked, what is the proper position for a locomotive engine to stand when the wedges are set up and side-rod brasses keyed?

In setting up wedges for right side of engine, would place engine on straight and level track, so right crank-pins would be on top quarter, then block in front of left driving-wheels, if wedge is back of driving-box; if wedge is in front of driving-box, would block back of driving-wheels; then give cylinders a little steam, so as to move driving-wheels hard against the blocks, and away from the wedges, on the side not blocked. If engine is dead—has no steam—pinch driving-wheels up to blocks hard, and away from wedges. Then get under engine, and set up all wedges on right side tight; make a mark on side of pedestal frame where top of wedges come to; then pull the wedges down a little, so boxes will be loose between wedge and shoe. It is a good idea to try the wedges to see that they are not up too tight, by putting a bar over the frame, and under the spring saddle, and pulling down on bar; if driving-box moves between wedge and shoe, wedge is not up too tight; or you can try them with two pinch bars, one on each side of driving-wheel, and push down on bars, if driving-box moves between wedge and shoe, wedge is not up too tight; if box is tight, pull wedge down until box moves. Take the blocks out from under the left driving-wheels, and block driving-wheels on right side, and proceed on left side same as on right side.

It sometimes happens that the flange on one driving-wheel will wear faster than the other on the same axle, caused by the driving-wheels not being in tram; the wheel with the worn flange is the one that is out of tram, and is always the rear one of the two driving-wheels on that axle, if the tires are all the same size; if not, they will wear bad, and the smallest driving-wheel will wear the fastest, as it has to slip to keep up with the other driving-wheel on that axle, and therefore wears faster.

A good way to find out how much one driving-wheel is out of tram, is to make a center punch mark between the frames on the back and in the center of cylinder saddle, then with a tram made out of a piece of ¼-in. pipe, one end with a sharp point, and on the other end a sliding point, to slip over the pipe, this point to be about 15 in. long, and at right angles to the pipe, and to be held in position by a thumb screw; put the straight point in center of punch mark between frames and set the sliding point to center of front, or main axle, on one side, then try it in center of same axle on the other side. If they tram the same that pair is correct, if they are out (don't tram the same) they should be made to tram together by changing the wedge and shoe so the two centers will tram the same—so both will be the same distance from center punch mark between frames, change which ever is easiest by moving one driving-wheel forward or the other backward. By getting the centers on both ends on the same axle the same distance from center punch mark on cylinder saddle between frames, the wheels will be parallel with

INTERIOR OF NEW SHOP—OLD SHOP ENTIRELY DESTROYED

track, and will not cut the flange. Before changing any wedge or shoe, all side-rod keys should be loosened, as changing the wedge or shoe changes the length of the side-rod. Then tram from the pair of driving-wheels that is correct to the back pair, and then to the front pair of driving-wheels, in a ten-wheel or consolidation engine; if any show out they should be made to tram correct with the others by changing the wedge and shoe.

It is best to have engine hot, under steam, when setting up wedges and keying side-rods, so all parts affected by heat are then in same condition as when in service.

Now that the wedges are up to their proper places, and driving-wheels tram correct, side-rod brasses can be keyed. If side-rods are put up as they should be when engine comes out of the "back shop" from general repairs, they will not need any work done on them for a long time. Just as soon as any side-rod brass on an eight-wheel engine is reduced, it will not be long before all will need reducing and rods lined up again.

Solid side-rods run without changing a long time, and do good work; that is evidence that side-rods can run without having brasses reduced every few weeks, although in a ten-wheel or consolidation engine the side-rod brass on the main pin will wear faster than any other, and will need reducing. Great care must be exercised in reducing all rod brasses. In reducing rod brasses, all except front end of main-rods should be left brass and brass; leave them loose enough so they can be keyed tight and not pinch the pin.

When putting up all rod brasses, avoid as much as possible leaving them loose between brass and end of strap, or stub end of rod, not depending on rod keys to keep brasses in place; have no lost motion between brass and key, so in case a key is lost the brasses cannot move any in strap; make the liners as thick as can be, so as to use as few as possible; brasses should be left brass and brass to do this; by so doing brasses will wear longer, and not get loose in strap.

As the front end of main-rod brass don't make a complete revolution on the cross-head pin, as on crank pins, this brass can be left a little open; the work done by the front end of main-rod brass is nearly a push and pull; this wear is only on front and back of cross-head pin, and that part of brass that wears with this part of pin; as this brass and pin wears it can be keyed, and not taken down and reduced every time it wears loose.

After reducing any rod-brass that goes on a crank-pin, it should be put in the rod strap (don't put strap on rod), and put on pin and key tight; have it move free on pin, but not over $\frac{1}{64}$ in. loose.

When an engine goes out of the "back shop" from general repairs, or gets new brasses, and the crank pins are new and round, a side-rod brass will need very little fitting; when a brass comes from the lathe it is round, and by filing or scraping it will not make it fit any better; if the pin is not round, or parallel, then it may need fitting. Back end of main-rod brasses should have a little filed off brass on top and bottom, as there is very little wear on that part of the brass, and when this brass is reduced, that part will bear heavy on pin and cause it to run hot.

Before putting up side-rods, place the engine on dead center on the side you are to key the side-rod brasses, and be careful that the engine stands on the exact dead center, on the side you are keying side-rod brasses, as this point is the most rigid, and side-rods should be free, so no strain will come on the rods when passing this point. Key the side-rod brass on main pin first for any engine, then the back and front for a ten-wheel or consolidation engine, be careful that you don't key the brasses so tight as to pinch the pin; leave them so they can be moved laterally on pin; move engine to dead center on the other side, and key that side the same, keying brass on main pin first.

Permit me to say here that the best mechanics are those that are the most observing, and we can all learn much by observing the results obtained from the way we do our work. Some persons advocate putting up side-rods on the "eights." I have got better results from putting them up on the dead centers.

### Wootz Steel.

A correspondent in Pittsburgh, Pa., writes: In last number of LOCOMOTIVE ENGINEERING mention is made of the famous Wootz steel of India. This steel has never been surpassed in quality, and it has been made almost since iron was first made into weapons.

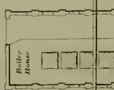
It appears to me that the Wootz steel takes away from Hornstman the credit of being the inventor or first maker of cast-steel. Wootz steel is made from a fine quality of native iron melted in crucibles containing a quantity of dried wood or leaves. The weight of the bloom is from one to three pounds. So it is merely a peculiar way of making cast-steel. It is still made and imported for certain purposes.

Indian steel is successfully imitated in Europe. Small pieces of very good Swedish iron are put in a crucible and covered with charcoal, the air being carefully excluded. This mass is exposed to heat until it turns dark gray carburet of iron. This is very brittle and is easily pulverized. When broken up fine it is mixed with alumina and subjected to a white heat, when it becomes white. A certain percentage, varying from $\frac{1}{8}$ to $\frac{1}{16}$, is then mixed with small pieces of good steel and the whole melted in a crucible. The product is a metal which passes for Wootz steel and is just as good for most purposes.

---

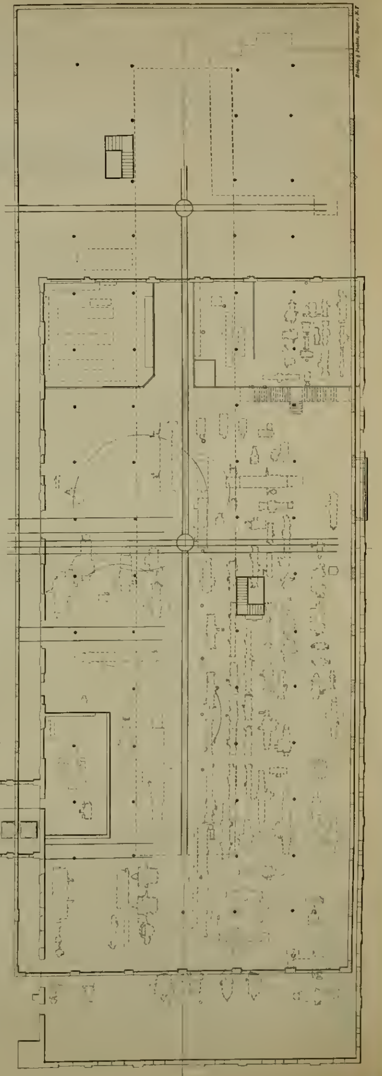
We learn from Mr. F. W. Johnstone, of the Mexican Central, that the note which appeared in LOCOMOTIVE ENGINEERING intimating that he wanted a few technical school graduates with the view of training them for official positions has had the effect of flooding him with applications. The difficulty experienced in the matter was that a young man's characteristics could not be judged from a letter of application or from references. Mr. Johnstone does not wish to invite men to come to the City of Mexico unless he feels fairly certain that they will prove successful, and so he is not likely to engage any applicants until he makes a trip to the United States and can meet the candidates for positions on his road.

The largest steam shovel in the world is digging phosphate in the mines at St. John's Island, near Charleston, S. C. Its weight is fifty-six tons. It can dig ten feet below its track and to a distance of thirty-five feet on either side. The dipper, which can swing through two-thirds of a circle, has a capacity of one and three-quarters cubic yards, and about two dipperfuls can be handled in a minute.



The Linde Ice Machine Co., of Chicago, recently made a test to find out whether or not more coal was consumed when using a smoke preventer. The same amount of coal was used in a given time with and without the smoke preventer, but it was claimed that a little more water was evaporated when running with the smoke preventer.

An engineer writing from the Pacific Coast says: An article in last year's issue was contributed by my wife, in which she stated that it was impossible to get anything out of me until I got through reading LOCOMOTIVE ENGINEERING. She is about right, but she forgot to add that to reverse the case would fit her as well as me, for she monopolizes the paper first.



## Notes from Brazil.

### The Brazilian Central Railway.

BY LEWIS GLEASON.

When that good and progressive man, the late Emperor Dom Pedro II, was ruler of Brazil, his pet hobby was the Dom Pedro Segunda Railway, now known as the "Central of Brazil," he succeeded in making it a first-class road. His successors have tried to follow his example and keep the road-bed and equipment in fairly good condition. The merchants of Rio, however, are not satisfied with the transportation facilities afforded them by the management of the road. Many and bitter are the letters published in the daily papers of the city from the shippers who cannot get their goods sent over the road within a reasonable time. As it is the only trunk line railroad having a terminus in the city, it has a monopoly of the shipping business destined for the interior. Consequently there is a continual freight blockade.

The terminal station is within the city limits, and easily reached from all parts of the city by several street car lines.

The building is a two-story structure containing the usual waiting rooms, ticket offices, etc Everything is so much like an ordinary American terminal station, a detailed description would be merely a repetition of what has been so many times described in regard to our home roads. Automatic switches are used in leads diverging from main lines to train sheds.

The rolling stock is of the American type, so far as the passenger department is concerned. Many of the coaches are built at the shops of the company, but the great majority were built in the States. No upholstery whatever is used in any class of the coaches. Cane makes the coolest and cleanest seat for this climate. The numerous insects with which this country is infested would find too good a hiding place in upholstery.

The principal shops of the company are located at Enghero de Deutra, a suburban town eight miles from the city station As you get off the cars at the very neat and well-kept station, a walk of about five hundred feet brings you to the office building. The building is a handsome two-story structure facing the railway lines, and separated from them by a very neatly-kept lawn, in which are numerous flower beds and fountains Inside the building cleanliness and neatness are apparent on every hand. The offices of the mechanical department are all situated in this building, that of the "Chefe de Locomotive" being a very handsome and neatly-furnished apartment

The superintendent of motive power, Dr Faire, I found to be a very courteous and polite gentleman, who personally conducted me through his extensive shops, where he has worked his way up from apprentice boy to chief

The shops of all the different departments are well stocked with modern tools and labor-saving machinery, a description of which would not interest the great majority of your readers, as they are just the same kind of tools they come in contact with every day. The shops and surroundings are so very much like those on well regulated home roads that a person almost forgets for the time being that he is under the Southern Cross, instead of the North Star. The appearance of the workmen, however, brings him to a sense of the fact that he is in a strange land and amidst strange people Black faces and swarthy complexions are around you, with a large sprinkling of whites, or as near white as a man can be who works around an engine, smithshop or foundry

I have seen some very fine work done here, both in machine, fitting and blacksmith work From the number of engines undergoing repairs (I was informed it was about their usual number), I don't think they will have a suspension or reduction of working hours very soon. No engines in service are kept at these shops except those employed switching. All the engines in road service are looked after at the "deposito" or roundhouse at San Diogo, one mile distant from City Station, of which I will have something to say later on.

I am informed that there are four hundred American built engines in service in this system, and as this is the principal shop, an idea may be conveyed that it is a busy one. All engines in road service are American built. The switching engines in Rio are either English or French They look as if they might at one time have been in road service, but they are behind the times, consequently they are eking out the last of their days, like so many of the men who run them in switching service.

In a corner of the pattern shop, mounted on a pedestal and apparently in excellent condition, is the engine "Baroneza," the first locomotive run in Brazil, built in Manchester, England, in 1852, inside connected 10-inch cylinders, 48 drivers, two pair connected, and weighs 10 tons. The only difference I see between this engine and modern-built English engines in service on the San Paulo Railway is in the items of weight and a cab (such as it is). The old "Baroneza" has no cab, however. The regulation spectacle plate is in its place.

As near as I could find out, the wages of the different classes of workmen vary very much. The best paid machinists get eight milreis per day If milreis were at their par value, this sum would be a little over four American dollars, but at the present rate of exchange it does not amount to more than two dollars and a quarter. Exchange is constantly fluctuating, but it does not exert much of an influence in the cost of living. A milrei has no more purchasing power at present, when exchange is fourteen pence, than it had when it was down to ten pence The cost of living in this country is much more expensive than in the States, more especially for clothing. It is true that a person does not need much clothing in this climate, yet what little is required costs about double what the same articles would cost in New York.

Although this is a government road, and all the employes are placed more or less through the influence of political partisans, yet the "committee man" is not an unknown quantity. The employes have their organization; while "the schoolmaster has been abroad" to a very large extent in the northern part of this immense continent, the southern portion has also felt his influence.

I noticed that the engine that furnishes power to the wood-working shop is of American manufacture and of the Corliss type; the builder, however, either from modesty or other motives, failed to put his name thereon; he therefore misses a first-class chance to get a free advertisement through the columns of your paper.

After having made the rounds of the shops I was shown through the storehouse. Everything requisite for any part of the working of the road can be found here, all of the best quality, and the money value represented must be enormous.

I am under many obligations to Dr. Faire for his courtesy, and also for a pass to ride on his engines; to the chief draughtsman (whose name I unfortunately forget) I am also indebted for his attentions.

I visited the "deposito" or roundhouse at San Diogo, Here I found a substantial brick building of twenty-six stalls, to which is attached machine and blacksmith shop, with a sufficient force employed to keep up running repairs in all engines in road service, also the switching engines. The "chefe de deposito" or general foreman, Mr. Gustave Bion, I found to be a very pleasant and intelligent man, who acquired his mechanical training in France, of which country he is a native

There were twelve engines in the house at the time of my visit, all American built Amongst the number was a four cylinder compound, 8-wheel passenger, named after the President of the Brazilian Republic, "Floriana Peixoto," a very fine looking engine. The engines on this system will compare very favorably with any road in the States. Were I to enter into details concerning them it would make this article of more length than the editors would be willing to give place to.

I was glad to meet here an American engineer, named Samuel Edgar, a native of Ohio, and at one time on the Lake Shore road, he is pulling a passenger train out of Rio, and has been in the service for fifteen years.

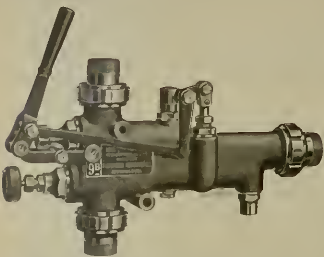
Engineers and firemen are divided into three classes, whose relative rank is designated by the number of gold lace bands on their caps, a first-class man wears three bands, the third-class man one. I am very favorably impressed with the neat uniform worn by the enginemen, trousers and blouse of blue material, with brass buttons, cap of navy pattern with the bands around it as before mentioned, with a circular piece in front in which is emblazoned a locomotive in gold lace; it gives the men a neat and tidy appearance. All train and engine crews are natives, with a few Spanish and Portuguese engineers, and one solitary American.

The pay of a first-class engineer is ten milreis a day, with a premium each month for economy in supplies and a clear record, that is, if he has no accident or breakdown

ON THE PACIFIC EXTENSION OF THE GREAT NORTHERN.

THE

# LOCOMOTIVE INSPIRATOR



These machines are especially constructed for, and adapted to railroad service and

## STANDARD FITTINGS

in common use. Modern locomotive service is more exacting in its demands, and requires a more efficient apparatus to meet its requirements, and we believe that these are met in this instrument more fully than ever before. It is simple in its construction, easily taken apart, and readily repaired at small cost.

It will lift water, or take it under a head, as desired. It will lift water when Inspirator and suction pipe are hot, or when water is at a temperature of 120 degrees Fahr., and deliver to boiler at steam pressure of 35 to 200 lbs. without adjustment.

It has a minimum capacity of less than 50 per cent. of its maximum by actual test and service.

**The Capacity increases with the increase of Steam Pressure up to 200 pounds.**

We guarantee it to be reliable and effective under all conditions and requirements of railroad service. Correspondence solicited.

**THE HANCOCK INSPIRATOR CO.,**
**BOSTON MASS.**

# AMERICAN ENGINEER AND RAILROAD JOURNAL.

*(Formerly Railroad and Engineering Journal.)*

**Among the Articles promised for 1893 are the following:**

## English and American Locomotives.

A series of critical articles describing and comparing the English and American Locomotive in detail, showing their points of resemblance and difference. These articles will be illustrated by general and very full detail drawings of a representative or typical locomotive of English, and one of American design.

## Contributions to Practical Railroad Information.

The very valuable series of articles under this head, by DRS. DUDLEY and PEASE, already published, will be supplemented by a new series describing methods of tests and analysis.

## Standard Locomotives and Stationary Engines.

Illustrated articles describing standard locomotives and stationary engines by the best builders, will appear from time to time.

## Progress in Flying Machines.

This series of articles, by Mr. O. Chanute, Past President Am. Soc. C. E., will be continued and concluded, and the author will show the scientific reasons upon which he, with Professor Langley and other eminent scientific men, base their belief in future success in navigating the air.

Very full notes on the COLUMBIAN EXPOSITION will be published. There will be given descriptions of **NEW ENGINEERING WORKS, NEW MACHINERY, SHOP METHODS** and **PLANTS**, both at home and abroad.

Particular attention will be paid to the department of **NEW PUBLICATIONS**, making it a current index to the best engineering literature.

All articles will be fully illustrated when the subject requires it.

The AMERICAN ENGINEER will aim to be as the JOURNAL has been, entirely independent in its criticisms and editorial discussions.

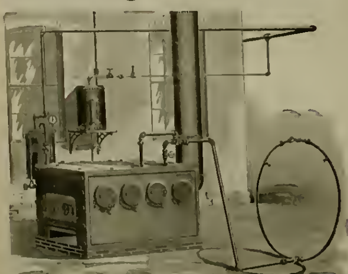
***Published Monthly at $3 per Year, Single Copies, 25 Cents.***

**M. N. FORNEY, Editor and Prop.,**
47 Cedar Street, New York.

# APPARATUS

FOR

# Heating, Setting and Removing Tires



A very complete arrangement for putting on new Tires or taking off old ones, without removing wheels from under the engine. Will do all the work connected with tire heating, setting, removing, shimming and replacing. With this apparatus and system of doing the work, less than one-tenth of the time is consumed, and the paint on the wheel centers is not injured.

**Send for Circulars and Prices.**

# PEDRICK & AYER,

**1001 and 1003 Hamilton St., Philadelphia, Pa.**

during the month. To all worthy and faithful engineers a two weeks' holiday each year is granted, with full pay. After a continuous service of twenty-one years a pension is granted of one-half pay.

A visit to these shops, or a ride over the road brings to view many ideas as to the utilization of worn out rails. As there is no market in this country for old rails and to ship them to a market would be too expensive, therefore they are used to the best possible advantage, in this and other systems in Brazil. They are used for fencing in right of way, telegraph and telephone poles, columns for sheds and station houses and several other purposes, for all of which they make a permanent and by no means a bad looking fabric.

A few words to the readers of this article who may have a thirst for life in foreign lands, as locomotive runners or otherwise, may not be out of place, to all such I have but one word to offer "Don't!" You who are accustomed to run or fire locomotives in the States have the best that can be expected in your respective positions. After a rather extended tour in other countries I consider the States is the best place for either runner or fireman, or any other person connected with train service, not alone from a financial point of view, but from a climatic also. Blizzards and snow storms in the winter season I know are not pleasant things, neither is it pleasant to be in a continual state of perspiration, from which there is no relief, no cool season to look forward to, by way of relaxation; furthermore, my experience in South America leads me to the conclusion that a man misses all or nearly all the comforts for which life is worth living.

Brazil is a grand and beautiful country for those who can endure its climate. Its soil will produce every plant known to the botanist, except those that are indigenous to the Arctic regions. The labor question is the great obstacle to advancement; while the Latin races stand the climate fairly well as out-door laborers, the black man is more at home under its hot sun.

But the negroes of Brazil (like their Northern brethren) since their liberation from slavery, flock into the towns, and as a few days' work each week is sufficient to provide them with food, they do not worry themselves much as to providing for a "rainy day." On account of the scarcity and high price of common labor, the Brazilians are trying to introduce Chinese emigration.

In closing, I wish to speak of the honesty and sobriety of the Brazilian people; if robberies are committed they are gradually traced to some vagabond foreigner, principally West India negroes, and a drunken Brazilian is rarely seen.

*Rio de Janeiro, Brazil.*

## An Interesting Exhibit.

The London and Northwestern Railway Company of England will make a highly interesting display at the Columbian Exposition. Mr. Geo. Chesworth, who will have charge of the exhibit, has arrived in Chicago and is making the necessary arrangements. The exhibit will consist of one of the latest type of Webb compound locomotives and a representative passenger train of the cars now in use on the line. A full size working model of Stephenson's "Rocket," an engraving of which appeared in the December number of LOCOMOTIVE ENGINEERING, will be there. Our readers will remember that the "Rocket" was the first locomotive made with a fire-box and tubular boiler, the combination that makes high speed a possibility. The engine took the prize offered by the Liverpool and Manchester Railway Co. in 1829 for the most successful locomotive. Another curiosity of the London and Northwestern exhibit will be Trevithick's locomotive of 1804. Trevithick is credited by English people as having been the inventor of the high-pressure steam engine, although Oliver Evans in this country worked earlier than Trevithick, and did more than any other early inventor to make a success of the high-pressure engine.

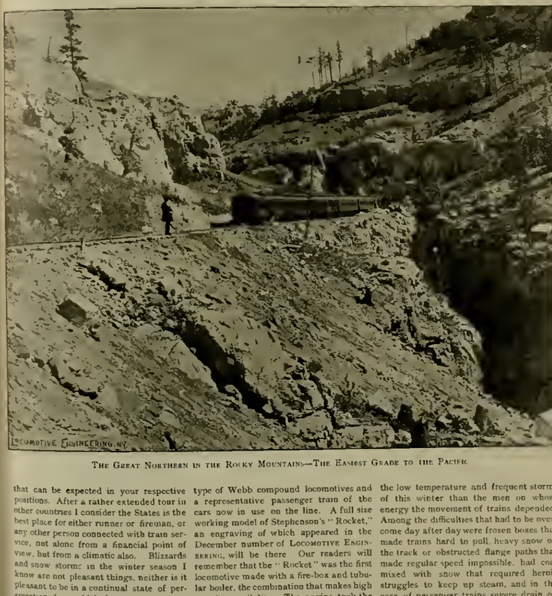
There will be in the exhibit a good representation of the signal and interlocking system used by the London and Northwestern people.

We are informed that the New York Central people made an effort to have the London and Northwestern locomotive pull its train of cars over the Vanderbilt lines, but the required consent was not given.

## An Old-Fashioned Winter.

We have heard a good deal of talk this season about the glories of an old-fashioned winter. The parties who become enthusiastic on this theme are those who do not endure any suffering or discomfort from weather, no matter how cold or stormy it may be. Among that large portion of our readers who work in poorly-heated shops or have to face storm and stress of weather in the cabs of locomotives there is a sentiment entertained that old-fashioned winters are not nearly so pleasant as fancy has painted them. Unless it be the poor people who are unable to procure coal or clothes to keep themselves and children warm, there is no class of men who have suffered more from the low temperature and frequent storms of this winter than the men on whose energy the movement of trains depended. Among the difficulties that had to be overcome day after day were frozen boxes that made trains hard to pull, heavy snow on the track or obstructed flange paths that made regular speed impossible, bad coal mixed with snow that required heroic struggles to keep up steam, and in the case of passenger trains severe drain on the boiler to keep the cars warm. And still in train dispatchers' offices and in superintendents' rooms we have frequently heard querulous complaints because Jones or Smith were not making time. It is much easier to figure on keeping time in a comfortable office that storm and tempest do not reach than it is to do the thing in actual service.

The men who are responsible for keeping the motive power and cars in running order are another class that are not enthusiastic about old-fashioned winters. In a letter to the writer, one of this class draws a picture that is edifying. He writes: "This winter has almost discouraged me. You can look back and remember the last winter when you were foreman, what a terrible time we had then with half the engines we now have and less than half the business to contend with. But this winter has been harder still. Every headquarters of motive power in the Western country is blocked up with broken engines that accumulate faster than they can be repaired. If the weather will only moderate for two weeks I can get my head above water, but if it keeps like what it has been for the last month the look-out will be grim. We have broken driving axles, bent and twisted rods, broken crank-pins, fractured wheels, and everything else imaginable broken or out of shape. We have had to replace four sets of driving-wheels within the last month, and still they come. But I try to console myself as the Irishman did during the great failure of the potato crop. Feeling very blue he went over to his neighbor's field and returned, quite cheerful, saying, 'Thank God, my friend's potatoes are worse than mine.'"



THE GREAT NORTHERN IN THE ROCKY MOUNTAINS—THE EASIEST GRADE TO THE PACIFIC.

## Compound Locomotive Building.

The Committee of the Railway Master Mechanics' Association, investigating the subject of compound locomotives, have received information that 314 of the Vauclain compound are in service on sixty railroads. Eleven of the roads are in foreign countries. The Baldwin Works have orders for ninety-three more of these engines.

The Rhode Island Locomotive Works report having built or having in course of construction thirty-nine compound locomotives, thirty of which are of the two-cylinder type and nine of the Johnstone design.

The Schenectady Locomotive Works report having compound locomotives of the two-cylinder type running on seven railroads. The number in service is about forty.

The Brooks Locomotive Works have built two compounds, one with two cylinders, and the others with four cylinders, set tandem. Rogers' have built one, Pittsburgh one, Cooke one—all of the two-cylinder design.

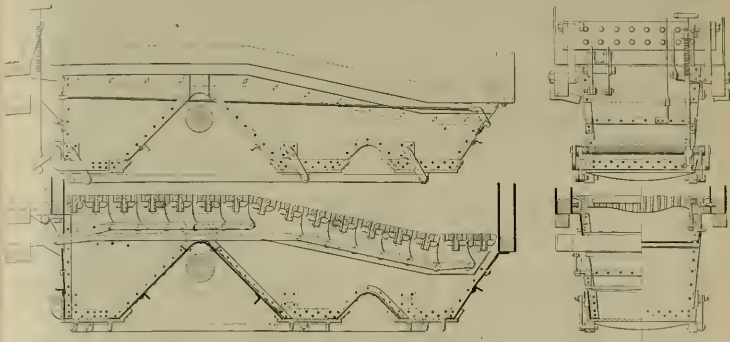
In addition to these there is the Webb compound, belonging to the Pennsylvania Railroad, and one which they built for themselves at Altoona. The Old Colony have built one compound and have one in course of construction. The Chicago, Burlington & Quincy have built one compound.

The inter-continental railway commission has had prepared for the World's Fair a fac-simile in miniature of Central and South America to show the surveys of the proposed railroad intended to unite the systems of North and South America. The work was done by E. E. Court of the Hydrographic Office, and is a faithful representation of the topography of the countries named. It is about twenty-five feet long, and will be sent to the World's Fair as a part of the government exhibit. In addition to the lines surveyed for the railroad the map also shows the routes of the present and prospective steamship lines from North to South America, with the names of their terminal ports and intermediate stopping points, if any.

An article in a Chicago paper says that Lafayette Truman, a locomotive engineer on the Erie, has had the misfortune to kill twenty-two persons since he has been running an engine. In no case has he been considered to blame for the accidents. Most of the killing has been done at level crossings and to persons walking the track. It is quite conceivable that the most careful kind of an engineer should have a run of bad luck of this kind. Every railroad man knows about engines that are always in trouble without there being any apparent reason for it. The same species of hard luck often follows the men running engines.

## Boon's Self-Dumping Ash Pan.

The accompanying engraving shows the arrangements of a self-dumping ash pan designed by Mr. J. N. Boon, and used on certain classes of locomotives on the West Shore Railroad. The ash pan, as will be seen by the cut, is formed into hoppers



Self-Dumping Ash Pan.

are closed by cast-iron sliding doors. These doors are operated by levers worked by a screw and wheel located in the cab. This form of ash pan gives great satisfaction to the men in charge of the engines, and often saves valuable time at stations. Cleaning the ash pans in the old way is getting to be such an inconvenient operation with the numerous attachments that prevent a man from getting under the engine, that a self-dumping pan seems to be greatly needed.

## "Engineer" Applied to Engine Runner.

A correspondent writes: "I see in this month's issue an article of an objection raised by some of the members of the Am. S. M. E., relative to the term 'engineer' being applied to enginemen. These same men seem to forget that bright men can be found in our ranks, and some very poor ones amongst the men with the parchment and differential calculus (in their mind) and that some of our engine-drivers can give them a point or two on that score. I should like to see the gentlemen that design our engines for us come out on the desert where I am at work, with poor coal and the water full of solids, get on any engine and train and make time as we do every day.

"It recalls to my memory a case that came under my observation some years ago, of a mechanical engineer wanting to run an engine. The superintendent of motive power gave him a Baldwin in first-class condition. She had old style Sellers injectors and very sensitive, so our Mr. Engineer *Brown*, as we shall call him, failed to get very much water into the boiler, in fact did not know if he had any when he shut off the throttle. Making a hasty exit from the cab, he left the fireman of five months' experience to find it for him. Returning after some time, he asked, 'How's her water, is she full?' He was discharged for incompetency. That was a case where the fireman was the engineer and the mechanical man the runner. He ran from a bad case of water, a sure case of hydrophobia. I think if some of our mechanical engineers would peruse the pages of Locomotive Engineering for any length of time, they could do so to advantage, and learn how to run an engine. It teaches them how to handle the air-brake now, and later on it will probably tell them how to get water in a boiler and keep it there."

## The Butler's Sand Dryer.

The sand dryer shown in the annexed engraving was designed by Mr. L. M. Butler, master mechanic of the New York, Providence & Boston, and used by him in the engine houses belonging to the road. Sand drying is a troublesome business on all roads, but it is a necessity, and unless it is done well it had better not be done at all. This dryer accomplishes the work properly with the least possible expenditure of heat, and requires very little more attention than the filling of the hopper with wet sand. The drying, as can be seen by the engraving, is done by steam pipes. The sand on getting dry falls into a screen set on an angle. The sand passes through this, and the gravel and impurities pass along the screen and are collected in a bin provided for the purpose. We commend this sand dryer to all the master mechanics who are wrestling with the crude appliances generally used for doing this work.

Butler's Sand Dryer.

The directors of the Columbian Exposition have created an official bureau of public comfort for the purpose of contributing to the convenience of visitors. The officials connected with this bureau arrange for the accommodation of visitors to the Exposition, procuring for them hotel and all other conveniences required. Full particulars may be obtained by application to W. Marsh Kasson, Chicago.

## A Rule With a Purpose.

General Superintendent C. D. McKelvey, of the N. Y., S. & W., has a rule in his book of train rules that a brakeman, after throwing a switch, must walk away about 15 or 20 feet and remain there until the train passes over the switch.

This rule seemed to be a very foolish one to many of the men, who did not hesitate to condemn it as "red tape."

Recently a brakeman, who probably hurried because he was cold, threw a switch under the last car in a train and let the last truck on to the ties.

When he went to see the superintendent the first question asked was

"Were you fifteen feet from the switch?"

"No, sir."

"If you had been could you have thrown that truck off the track?"

"No, sir. I could never see any reason for that rule, but I do now. I see what it is for. Yes, it's a good thing."

"You fellows don't seem to pay any attention to a rule until it saves your own life or the disobedience of it kills some one. I will not punish you for this offense, but I want you and all the men on the road to understand that the next man who ignores that rule will get a vacation."

We have issued a new pocket premium list, giving the cash commission rates and a list of premiums for getting up clubs to Locomotive Engineering. We have some 400 club raisers now, and we propose to have as many more. The book will be sent free.

## Griffith's New Engine.

We lately had the pleasure of examining a remarkably handsome light wheel passenger engine designed by Fred B. Griffith, master mechanic of the Delaware, Lackawanna & Western, and built under his supervision in the shops at Buffalo. The engine has cylinders 19x24 inches, and driving wheels 72½ inches diameter on the tread. To supply steam there are 1624.2 square feet of heating surface, of which 158.7 feet are in the firebox. The boiler is of the wagon-top variety, with the firebox set above the frames, and is made to stand a working pressure of 180 pounds to the square inch. The boiler is 56 inches diameter at the smallest ring. There are 251 2-inch flues, 12 feet 1½ inches long. All the outside sheets are ½-inch steel. The circumferential seams are double riveted, with 4½ inches lap, while the longitudinal seams are single riveted, with covering strips, and two reenforcing rows of ¾ rivets. The crown sheet is supported by crown bars and sling stays. The firebox is 124¼ inches long inside and 42¼ inches wide, with water-bar grates, having a total area of 36.4 square feet. The mud-ring is double riveted. The new type of Boies wheel, with solid steel center, is used for engine truck and tender trucks. The engine is reported to steam very freely and to ride so well that all the men want one just like her. Some of the new big engines are awful hard for the crews.

The Toledo & Ann Arbor are getting ten heavy engines built at Baldwin's.

## Practical Letters from Practical Men.

Facts Wanted. There's a glut of Opinions.

Write on one side of the paper, state your point plainly and briefly, and then quit. We supply the generalities. No letters noticed unless name and address accompany.

### The History of Gauge Making.

*Editors:*

In your issue of August, 1892, in an article on "Settling the Size of an Inch" you recount the history of gauge making in this country, but not completely. The American Standard Gauge Works at Philadelphia were the first to introduce this art here as a regular manufacture, and long before Messrs. Pratt & Whitney made any gauges, had supplied a number of large works, not less than fifty, with not only gauging implements but machines for measuring work, corrective gauges, calipers and other implements.

These works were founded or started in 18[illegible], eighteen years from the time the writer took up the subject and made standard gauges now in use. The standards were derived from careful sources in England and the Coast Survey here in this country, on the Whitworth "touch" system instead of visual, and are believed to be as accurate as any in the world at this time unless, perhaps, it be the late standards produced at Paris by the international commission.

The American Standard Gauge Works were removed to Wilmington, Delaware, in 18[illegible], and are now owned by Messrs. James A. Taylor & Co., who will no doubt, if requested, furnish additional particulars of the manufacture.

More than 50,000 fixed calipers have been made and sold for one thing, and I much doubt if any other company in this country has made half as many. The business is conducted in a quiet manner but has a history much more interesting than the facts you have related.

JOHN RICHARDS.

*San Francisco, Cal.*

### To Foremen Blacksmiths.

*Editors:*

I am very glad to notice in your recent issues that the question of railroad blacksmithing is being taken up and discussed by the craft. I noted with interest the articles by Mr. Lottes on handling steel and the construction of proper fires for this work. The question of handling steel properly to get the best results is, in my opinion, one that requires great care and study on the part of the workman and a great watchfulness on the part of the foreman of the smith shop. This care and watchfulness has been largely neglected by both the workman and the foreman in the past. I think, however, that a discussion on this and other questions through LOCOMOTIVE ENGINEERING would obviate this to a large extent.

What is the matter with an organization of the foreman blacksmiths of the different locomotive and railroad shops of this great country? This would bring about a better understanding of the best methods, not only of handling the different grades of steel, but would also bring about the best and most economical methods for the manufacturing and repairing of the different forgings now in use on our engines and cars, which would cause a large saving in maintenance of motive power and rolling stock.

I think that such an organization of blacksmith foremen would assist largely in bringing about a better understanding as to the most practical methods of doing work under different conditions and circumstances that exist in different parts of the country which many of us know very little or nothing of at present. Many of our craft have some good ideas, and with those good ideas are usually some very poor ones. My notion is that if we could exchange ideas, one with the other, in a short time we would be able to separate the wheat from the chaff, and by this means our trade, one that requires as much skill as any other, would make rapid strides forward instead of going backward, as many think we are now doing.

An organization such as I suggest would meet with the approval of our superior officers in the mechanical departments; they are, I am glad to say, progressive men, and any means whereby the cost of maintenance of rolling stock can be lessened without a corresponding reduction in the life and service of the same will be hailed by them with delight. I would like to hear from some of the foremen through the columns of your paper, or any others—not excepting the editors.

*Brainard, Minn.*

### That Blind Washer Under the Brake-Valve on Second Engine of a Double-header.

*Editors:*

In the last number of your paper, Mr. Bruce asks whether it would be considered good practice to put a blind washer in the train-pipe connection to the engineer's valve in case the pump on the second engine of a double-header should stop working and permit a reduction of the main drum pressure and consequent lifting of the rotary valve. This is supposing, of course, that there is no stop-cock in the train-pipe connection.

I must say I do not see any other good way out of the difficulty. It is a case wherein the best instruction would seem to be, "Do anything not positively destructive of the apparatus in order to make the brake work," for running without

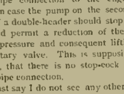

Fig. 1.

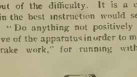

Fig. 2.

brakes is pretty risky business these days of fast time and heavy traffic, and it is especially risky in a case where the office supposes that the train is using air brakes.

The only objection I can see to this suggestion is the possibility of the washer being allowed to remain in the train-pipe through the forgetfulness of some of the men; but this does not seem serious, in view of the fact that the brake could not be used either in taking the engine in or out of the house, and the cause of the trouble certainly would be discovered before the engine was allowed to go out into service again.

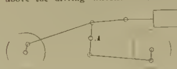
PAUL SYNNESTVEDT.

*Chicago, Ill.*

### An Odd Locomotive.

*Editors:*

A few years ago in the Cumberland Valley yard at Harrisburg, Pa., there was an odd-looking locomotive called the "Utility." I think she was built by Seth Wilmarth, South Boston, and he built some good ones too. The peculiarity about this engine was her connections. She had horizontal cylinders, but they were located above the driving wheels. Power was



transmitted to the wheels through the lever *A*, which was pivoted on the frame. Who can tell us something about her and send LOCOMOTIVE ENGINEERING a cut or photo of same.

W. DE SANNO.

*Indianapolis, Ind.*

### Tempering Tools—Advantages of Uniform Sizes.

*Editors:*

The toolsmith who tries to satisfy his employer and the mechanics at the same time has considerable of a contract on his hands.

It would take a world of argument, however, to convince the average master mechanic or general foreman of the advantage of having on hand a large stock of standard sizes of tools all hardened and ground ready for use.

This can be done by numbering the tools and have one man do all the grinding and keep the stock, so that when a machinist or boiler-maker wants a tool dressed he can exchange his worn or broken one for a new one and not lose any time, keeping his machine in service all the time.

The only sensible argument against this plan is the one of first cost—it ties up a little money in steel. But steel once on hand, the plan saves it, because the toolsmith is not changing a parting tool to a finishing tool, and *vice versa*.

The thing to do is to get the tools ground uniform; this can best be done by one of the tool-grinding machines, Sellers or Gisholt; both of these machine builders send out a chart with their machines that shows a cut of each kind of tool and tells where to move the stops to grind that particular shape; tools ground this way are always alike and uniform.

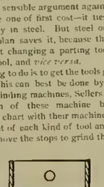


Fig. 3.
Section of Lead Pot.

With a system of this kind the toolsmith can do a good job on tools, if he knows how, and do it in less time, because he generally gets a dozen or two of the same number to do at a time, or, say he gets six different numbers, and twelve of each, he can build him a fire which is most suitable for the work, such as you see in Fig. 1, with back closed.

For all lathe and planer tools a system of this kind makes it a great deal pleasanter for the smith and all hands that have to depend on him for their tools.

It does away with the practice of having three or four men standing around the tool fire all day. Another benefit is, that as the tools are forged they go to the machine shop to be ground and come back in lots of from 50 to 100, and the toolsmith can again take advantage of this by beating his tools in hot lead for hardening, by having a fire with a lead pot in it, as represented in Fig. 2. The lead pot may be made of gas pipe from 4 to 10 inches in diameter and from 10 to 20 inches deep, as represented in Fig. 3. You can heat at least four ordinary tools, such as lathe and planer tools, or chisels, drills and calking tools, where you would be heating one in any other way, and not injure the steel, if you keep your lead at the proper heat and properly covered with fine charcoal, which is put in to keep the hot lead from forming a scum on top, and it will also prevent your lead from sticking to the steel to a certain extent, which is a very important point in hardening such tools as are not intended to be ground after they are hardened. For if you allow the lead to stick to your steel it will show on your steel after you take it out of whatever you quench it in by leaving it full of what blacksmiths generally call "pock-marks," which show very plain after you polish your steel, and looks as though you had overheated it or raised a heavy scale on it. This may not be any particular injury to steel, but it looks bad.

*Madison, Wis.* W. G. LOTTES.

### Testing Stay-Bolts.

*Editors:*

I noticed an article in your paper about the fallibility of the hammer test for stay-bolts, and write to give you a pointer from the practical field.

I have been for some years testing stay-bolts on the Wisconsin Central, and must say that I have the first time yet to mark a bolt as broken that was not found so.

No boiler-maker can rely on the hammer test alone, because if a bolt be broken in the sheet, or even outside of it, and still the ends are firmly pressed together, the hammer will not always tell the truth, but if you put hydrostatic pressure on the boiler, of, say 60 pounds, the sheets will spring apart enough to separate the ends of the broken stay and the hammer finds it at once.

The difference in the radius of the firebox sheet and the shell at the top of the side sheet causes a great many broken bolts in the upper forward corners, and long practice is necessary to enable a man to find them when broken, especially if the boiler is cold and without pressure.

I believe, however, that any company can rely on the hammer test when used in connection with the hydrostatic test.

THOMAS MCCANN.

*Waukesha, Wis.*

### Hollow Stays.

*Editors:*

I have been asked by several foremen boiler-makers, readers of your journal, to give my opinion on and experience with hollow stay-bolts. I presume they mean by hollow stay-bolts a bolt hollow its full length. If so, I am in favor of the hollow bolt in preference to a system of drilling a hole in outside end of bolt, as is done by many railroad shops, for the reason that drilling weakens the bolt at a point where the bolt has to bear the most strain, and very seldom you will find hole drilled in center of bolt. I have seen part of the thread on sheet drilled away, as it is hard to keep drill in center of bolt after bolt has been hammered.

There seems to be very little thought given by boiler-builders to vertical expansion of fireboxes in locomotive boilers, and expansion is the weak point in radial stay boilers, as the firebox sheets, being lighter and exposed to the heat, will expand more rapidly when a new fire has been started in firebox than the outer sheets, that are in most parts exposed to the atmosphere. This has a tendency to strip thread on crown sheet or stay-bolt, or both, pressing bolt through crown or bending bolt. I gave this as my reason when asked by a foreman boiler-maker from Kansas, why flue-sheet in radial stay-boilers crack at top above flue holes.

He wrote me a short time ago that my

theory was correct, as he had tested the matter by drilling a hole in wagon top over the flue-sheet and put in a stuffing-box, through which he passed a rod until it rested on crown sheet. He went in boiler to see that center point at end of rod was in center mark made in crown sheet; this done, he fired up, and when boiler began to show steam, crown sheet had raised rod ⅛ inch, and when boiler showed 50 pounds it went back, or, as I would say, the outer sheet came up to it. This is why I advocate a flexible bolt, as stay-bolts in sides of firebox have this expansion and contraction. I do not mean that a bolt drilled its full length would be flexible, as I contend that a bolt so drilled has the best of the metal drilled away, and the cutting of the thread on outside takes all the springy part away. I have used for over a year a mandrel rolled hollow stay-bolt, made by the Falls Hollow Stay-bolt Company, which comes nearer filling the bill than anything I have seen yet, as by their process they compress the iron externally and internally, and it can truly be said to be elastic, as I have found by testing.

JAMES HERON.

*Chicago, Ill.*

### Forging Locomotive Frames—Handy Blacksmith Tools.

*Editors:*

In my last article I dwelt somewhat on side-rods; in the present article I will direct attention to locomotive frames, and will endeavor to point out one particular agency upon the texture of the chief anatomy of the locomotive, in so far as blacksmiths are concerned, *viz.*, structural imperfections.

As regards the proper length in welding the lower brace of frame, experience and observation have demonstrated that in many instances no attention is given to tension, thus destroying that equilibrium or state of rest produced by the mutual action of the particles in the construction of the frame in welding the lower brace of the frame proper. Before this operation everything is practically normal. For illustration, before the lower brace is welded draw a straight line on the side of top of frame and draw a parallel line on lower brace, then draw perpendicular lines on the inner jaws, intersecting the parallel lines, thus describing a rectangle; now, after the weld is performed try your lines, and if you are working for "general results" nine chances out of ten your lines will assume the shape of a trapezoid. A more practical way is to make a fine tram mark on the lower part of each inner jaw and tram before you make your weld.

I have seen frames after they were welded and cold show a shortage of from ⅛ in. to $\frac{3}{16}$ in. between the tram marks, in many instances in making new frames a sheet-iron template is the only thing used, the only consideration being enough stock for planer and slotter.

Under the circumstances let us take into account the deflection caused by a transverse strain, or, practically speaking, a breaking strain on the upper inside corners of the inner jaws.

Here we have a continuous strain and, in addition to this, violent shocks or concussions which are transmitted to the weakest points—the upper inside corners of inner jaws—resulting in a broken pedestal caused by undue strain.

It is only within about twenty years that much attention has been given to the invention of machinery and minor devices for saving labor in the smith shop. During all the years the blacksmith having skill and ability was obliged to create or produce out of his own hands, so to speak. But the art of forging, like everything else, must keep up with the procession.

A great deal of the work of fashioning wrought-iron, which formerly required the smith's skill, is now done by machinery. There is no doubt that most of the forging belonging to a locomotive can be done by ingenious contrivances far more accurately and in many respects with less abuse to metal, to say nothing as to capacity of production.

I present herewith illustrations of some blacksmith-shop tools which are in successful operation.

Fig. 1 represents a tool for making clamps belonging to switch-chairs or "rail-heads." It is in the form of a mold; the number of pieces that can be stamped or pressed is only a question of how many can be heated and handled. The edge to be trimmed when cold with power shears.

Fig. 3 represents a valuable tool for making clamps or binders for railroad frogs. *A* represents punch sliding on two

Fig. 1

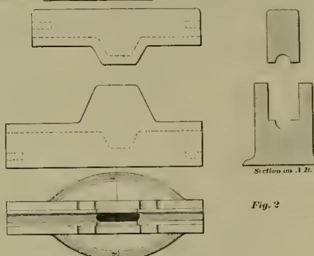

Fig. 2

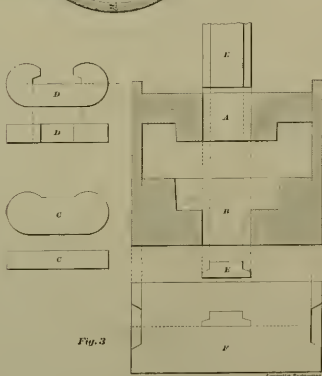

Fig. 3

dovetailed guides. *B* the die, *C* the blank after the first operation of punch *A*. *D* represents the blank after the second and last operation by punch *E*. *F* represents a top view. In my opinion, the best material for frog-clamps is a very mild, ductile steel, and its having nearly like strength in both directions of its plate.

GEO. T. HINKENS.

*Gladstone, Minn.*

### That Tool-Hardening Matter.

*Editors:*

In February number of LOCOMOTIVE ENGINEERING, wherein you published my article on "Hardening Tools," leaving soft center, either your printer or myself omitted two words which greatly changes what is meant. It should have read: "I reduced or hammered the steel to a certain degree, and that has a refining effect, at any rate, *it did not* increase the carbon," instead of "at any rate it increased the carbon."

I thought I would call your attention to the error lest your readers might think that I believed that I discovered a new process for putting carbon into steel.

GEO. F. HINKEN

*Gladstone, Minn.*

### That New Driving-Box.

*Editors:*

Allow me to say a little in regard to the proposed new frame and driving-box.

I quite agree with Mr. De Sanno that the movable wedge for taking up the wear of driving-boxes could be dispensed with, but do not think it would be necessary to make such a change in frames as Mr. De S. proposes.

I think that with good materials and careful fitting the present style of frames would do. It might simplify the work if the jaws were parallel. The feature of the new frame providing a double wearing surface is very good. It has been found necessary with the present style of frame and box to let shoe and wedge fit loosely between flanges of box, and in addition to this to widen space between flanges at top and bottom making it slightly bell-shaped, this is done to prevent flanges of boxes being broken by engine passing over uneven track, as is well known. It is not uncommon to see springs carrying one side of engine considerably higher than the other owing to unequal strength; this would tilt boxes of the new style, throwing bearing on one edge and thereby cause severe heating, unless some means are provided for the self-adjustment of boxes, as in the present style.

It is hard to tell what would be the result of an engine with the new frame and box passing over a Wharton switch, where one wheel is raised high enough for flange to pass over main rail in going in side track; this would throw a severe strain on box and studs. Then, again, in a machine that has to do the work that is expected of a locomotive, and the shocks it has to stand, I think the fewer parts and joints it is made up of the better. It will be seen that the proposed new style provides us four extra joints for each box. Take it all around, I do not think this would be very good company for the solid rod, as I am afraid it would tend to offset the good qualities of the rod.

*Sanford, Fla.* A. DIXBY.

### How to Tell Mushet's Steel by the Emery Wheel.

*Editors:*

I want to call the attention of brother machinists to a trick worth knowing, *i. e.*, how to tell Mushet's steel after tools get old, mixed up with other tools, or in some other way lose their identity. I do this on the emery wheel.

Mushet's will throw a stream of dull red fire when ground, and without flying sparks. Ordinary steel throws brighter sparks and more of a shower of them. Cast-iron grinds something like Mushet's, but still has brighter sparks.

I don't like Mushet's so well for wrought-iron and soft steel as for cast-iron, and for the roughing cut on tire it is "best and goes farthest." CALIPERS.

*Mt. Savage, Md.*

### Traveling Crane in Havelock Shop (B. & M. R. in N.) Near Lincoln, Neb.

*Editors:*

The machine shop of the above-named company, located at Havelock, Neb., is 400 feet long. A standard gauge track is laid the entire length of the shop, along each side of which the heavy tools are located and served by one crane, of which the following is a description.

This crane is operated by a pair of reversible engines, run by compressed air, at a pressure of 60 to 80 pounds per square inch. The engine power is communicated to the front axle by friction, as shown on plan. The car is moved by turning the lowest three-way cock, admitting air to the cylinders of the engines. The reversing valve is so arranged that the engines are always in back motion, and by pressing the foot lever on platform air is admitted to the opposite end of reversing cylinder working tumbling shaft and the motion changed. The operator stands on the platform attached to mast and from this position controls all movements of the crane. The swing motion is performed by turning second three-way cock, which admits air to the cylinder under the car, operating rack and pinion in connection with mast of crane.

Raising and lowering is controlled by upper three-way cock, which admits air to the lifting cylinder, 13 inches in diameter and 7 feet stroke, at top of crane.

The air storage is distributed as follows: one main reservoir 42 inches in diameter and 6 feet high, three nine-inch tubes, supported over lifting cylinder and suitably connected, mast, stay and jib connected by openings in tubes and castings as shown in section; all are connected with service pipe, which is fastened to mast and to which are attached throttle, swing, lifting and reversing valves, gauge and alarm whistle. Different sizes of hose are used where flexibility in connection is required. This arrangement stores 85 cubic feet of air on crane, which is sufficient to permit of the crane being run out of shop to platform, or cars, pick up a pair of heavy driv-

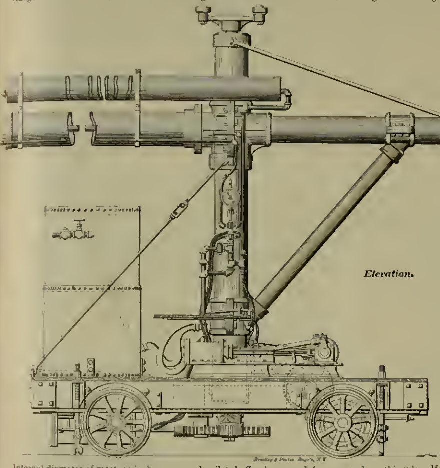
ers, a cylinder or other heavy casting, and take same into the shop to a machine or otherwise, as desired. The air is supplied by a Norwalk air compressor and convenient pipes and couplings are placed in shop for charging crane when necessary.

Capacity of crane, 4 tons.
Maximum lift, 7 feet.
Air pressure, 60 to 80 pounds.
Air storage capacity, 85 cubic feet.
Diameter of wheels, 28 inches.
Gauge of track, 4 feet 8½ inches.



*Elevation.*

Internal diameter of mast, 13 inches.
Internal diameter of jib, 10 inches.
Internal diameter of stay, 6 inches.
Internal diameter of air tubes, 9 inches.
Internal diameter of air reservoir, 42 inches.
Internal diameter of lifting cylinder, 13 inches.
Total height above rail, 15 feet 10 inches.

As will be noticed in section, an internal tube 4½ inches in diameter is rolled into ends forming jib, acting as a guide to piston rod and chain; and leaving the surrounding area for air storage. The same method is also employed where piston rod passes through mast.

The rollers on castings on top of crane receive a double channel iron between them, which is fastened to girders in the shop and act as a steady to crane when serving machines. For outside use, when necessary, there are four adjustable rail clamps, two on each side at ends of car, to be used for taking side lift.

The special features of this crane are its adaptability to the large variety of lifting and carrying in locomotive shops, being independent of external power.

This crane was designed and built at the company's shop at Plattsmouth, Neb.

D. HAWKSWORTH,
Superintendent Motive Power.

### An Injector Problem.

*Editors:*

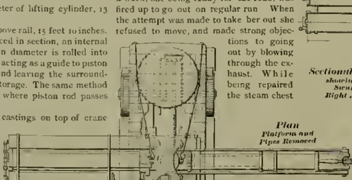
I am running a Baldwin engine with saddle tank, feed boiler with two Rue injectors. During the recent cold weather my injectors refused to work. I made an investigation and found plenty of water in tank, injectors all right, steam-pipe, discharge-pipe and overflow all right—everything all right, from tank to boiler. Now, what was the reason it would not work?

*Houtzdale, Pa.* C. L. DENNIS.

### A Peculiar Accident.

*Editors:*

An engine once collided with some freight cars with the usual result, front end, pilot, buffer beam and frames used up. Her cylinder and steam-chest casing were not injured. The collision happened not far from the roundhouse. She was towed in without disconnecting. In about a week, she being ready for the road, was fired up to go out on regular run. When the attempt was made to take her out she refused to move, and made strong objections to going out by blowing through the exhaust. While being repaired the steam chest covers were taken up and everything found all right, but on her refusal to move under steam the cylinder-heads were taken off, when the lower half of both piston heads were found to be broken off. The piston heads were of the solid type. One piston rod was slightly bent, the other one was straight.



*Plan*
*Platform and Pipes Removed*

What broke those heads?

My theory is that he plugged her so hard she filled the cylinders with water. Cylinder-heads were not started.

W. DE SANNO.
*Indianapolis, Ind.*

### An Unfair Rule.

*Editors:*

The item on page 63 of February relative to, or headed, "Southern California Engineers," is what I want to make some inquiries about. You are in favor of such rules, but I do not think you would indorse them if you were a freight man. Usually when an engine in passenger service gives out her place is filled with a freight engine. The regular man assigned to this run takes her out. What will the man do who is assigned to this regular freight engine? Of course he will be obliged to lay off. I am in favor of the old men having the preference, but not to that extent. This rule gives them full time, year in and year out, and gives freight men a living when their engines are not required on first-class runs. I have worked under this rule for two years, and nothing has ever been introduced on the Chicago & Erie that has ever kicked up so much disturbance among the men as this rule. If you can say anything in defence to this I would be pleased to hear from you.

### What Was Wrong with This Air Signal?

*Editors:*

I coupled on to a train of eight passenger cars sometime ago and the conductor could not blow the air-whistle from any car but the one next to the tank. We examined all cocks in the train line, found them all open, had to run that way to destination. When we arrived at destination we coupled on to the opposite end of the train, the whistle acted the same way, that is, would only blow from car next to tank. What was the matter.

### Why Do These Valves Break?

*Editors:*

I would like to ask through the medium of your paper what causes the wings of the lower discharge-valve of the 6-inch air-pump to break, the upper discharge-valve being in good shape, and the left not excessive. I have seen several cases of this kind, but have been unable to find a cause or construct a theory.

Yours truly,
*Winona, Minn.* G. S. HALE.

### A Question for Runners.

*Editors:*

Please allow me to ask if the pump governor can get into such a condition as to cause an emergency application of the brakes after a slight reduction in service stop, say just enough to cover the leakage groove? Also, do we run brake-valve in running position to get excess pressure only, or for safety? In other words, could an accident happen while running the brake-valve in released position that could not possibly happen while running it in running position? "NYPANO."

*Meadville, Pa.*

### Who Knows? Difference Between Freight and Passenger Brakes.

*Editors:*

Referring to an article in February journal relative to difference between Westinghouse freight and passenger triples.

The feed-groove in a freight triple is only about one-half the width of a groove in a passenger triple. The reason for this, I would judge, is to prevent auxiliaries on forward cars of a long freight train from filling before those on rear cars. After forward auxiliaries were charged to maximum pressure, there would be danger of setting brakes on forward cars by rear auxiliaries taking air from train-pipe, especially when engineer's valve was in running position, or on lap.

*Nashville, Tenn.* J. A. JISSON.

*Editors:*

In answer to Mr. Synnestvedt's question, would say a standard, quick-action freight triple valve and a standard, quick-action passenger triple valve in some respects are exactly the same, as many of the parts are interchangeable. The only difference is in the length and width and size of cavity of slide valve No. 3 (see Fig. 9, Plate 3, of the Westinghouse instruction book) and the diameter of ports "*R*" and "*P*" in the valve seat.

In the passenger triple valve the cavity "*N*" in slide valve is a little larger and the face of valve is about 1/8-in. larger both ways, and ports "*R*" and "*P*" in the valve seat are 1/16-in. larger than in the freight triple valve. The passenger brake cylinder being of larger diameter than the freight brake cylinder, the ports in passenger triple valves are made larger so that when both kinds are used in one train the brakes can be applied and released more evenly than if both triple valves were alike. On some roads they take out the emergency valve piston No. 8, and put a small brass bushing in its place. When this is done, it is to prevent brakes from being applied too severely where the old

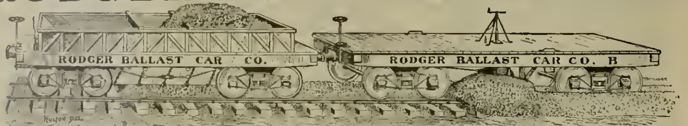
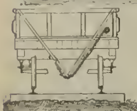
# RODGER * BALLAST * CARS.





These cars are 31 feet long, and are built either 50,000 or 60,000 lb capacity, M. C. B. Standard. They carry from 18 to 20 cubic yards of gravel or broken stone. In using them no ballast is thrown in the ditch and none is wasted, as the precise amount of ballast needed can always be discharged. A train of 25 cars, carrying 500 yards of ballast can be unloaded and the ballast distributed, leaving the track perfectly cleared and flanged, as shown in the cuts, in from 12 to 15 minutes. This is all done by the regular train service (a conductor and two brakemen); no extra help being required. The track is perfectly cleaned by the spreader, so that a train can immediately pass over it at any rate of speed, without meeting any obstruction. No aprons are needed; no wire cables are used. There is no shoveling ballast from between the cars and no cleaning the tracks with shovels. The ballast is left between the ties and on their ends, directly in position for tamping when the track is raised, without being shoveled in from the ditch. The average saving per mile, in the amount of ballast needed to make a "raise" of 10 or 12 inches, will be about 400 yards, and often far exceeds this. The total saving per mile in material, labor, time, use of cars, saving in transportation, etc., is found to amount, in gravel, to from $250 to $400, and in broken stone it often amounts to $500.

These cars are in use on the Great Northern Ry., the Illinois Central, the Gulf, Colorado & Santa Fe, the Chicago & Eastern Illinois, the Penn. Lines West, and other roads.

Detailed information will be furnished by circular by addressing the

M. E. WATTS.

*West Nanticoke, Pa.*

THE ANSWERS.

*Editors :*

The difference between the Westinghouse freight triple valve and the standard passenger triple valve is in the port openings. The freight or passenger triple valve must not be used in the opposite service for the reason that in making an emergency application of the brake the air would not equalize and close the check valve between the auxiliary reservoir and the brake cylinder. Therefore the triple valves must correspond with the different sized brake-cylinders, in order that the brakes on all cars may work in harmony in the same service.

"NYPANO."

*Meadville, Pa.*

*Editors :*

The difference is mainly one of size, due to the fact that the passenger reservoir and cylinder are larger than those used in freight service.

It is necessary that both freight and passenger brakes be so constructed that they can be used together in the same train.

They should act together both in application and release.

Because of the difference in size of the reservoirs and cylinders, the port through which the air passes must also differ. Hence the passenger triple is larger than the freight in the following parts .

1. The feed groove from the train-pipe to the reservoir.

2 The ports from the reservoir to the cylinder.

3. The feed valve controlling the graduation.

4 The recessed cavity in the bottom of the slide valve and the co-acting ports.

5. The slide valve.

Besides these differences the passenger triple valve has a threaded exhaust port on one side only, whereas the freight triple has one on each side. This is for the connection to the pressure-retaining valve which is not used on the majority of passenger cars, but almost always found on freight.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

### That Tank Brake.

*Editors :*

Concerning the problem propounded in your last issue on a tender brake-lever arrangement, I should like to say a few words.

If the point *E*, shown as the middle of the cylinder-lever, is a fixed fulcrum, the braking power cannot be figured at all, for a lever cannot operate at all with two fulcra, and that would be approximately the condition of affairs after the slack on one or the other truck had been taken up by movement of the piston. The arrangement shown is such that nearly the whole braking power would be thrown on either one truck or the other as the slack was looser on one truck or the other. Mathematics is an accurate science, and cannot be applied to guess-work such as would be necessary to get any idea of the strains brought on any of these brake-beams. It the fulcrum *E* be taken out and the cylinder-lever allowed to swing or pivot on the end of the rod *B*, as a fulcrum, then the strains can be calculated.

This calculation I have made, but as it does not meet the conditions of the problem as given, I shall not insert it unless some one wants it.

I notice also that the piston travel is given, and should like to ask whether the 50 pounds specified is reservoir pressure before equalization, or full equalized pressure.

Except in determining the equalization, the travel is not necessary, as its only practical effect is in altering slightly the position of the levers with reference to the angle they make with the rods.

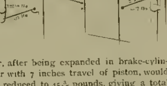
It might also be noted that if the slack on the back truck be taken up tightly, there would be great danger of breaking the beams on that truck. Let us hear from Mr. Gonware again on these points.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

*Editors :*

Allow me to offer a solution of the strange brake-rig-for-tender problem that appeared in the last issue of your paper. I base my calculation on 50 pounds train-pipe pressure, a 12 x 30 inch reservoir, and an 8-inch brake-cylinder. This volume of



air, after being expanded in brake-cylinder with 7 inches travel of piston, would be reduced to $45\frac{3}{16}$ pounds, giving a total pressure on piston of 2,275.25 pounds. The forces applied at the different points will be shown in the sketch.

*Sanford, Fla.*

A. DERBY.

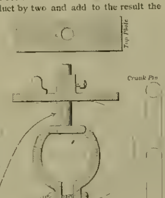
### A Tool for Setting Eccentrics.

*Editors :*

In your last issue a reader wants to know something about laying out keyways for eccentrics before they go under the engine. I made a special tool for this purpose that works very well ; this for a class of engines where the line of eccentric rod connections is on a line with axial line of cylinder.

To plumb, I scribe a circle on the end of axle the diameter of the pin and with a double plumb line set pin directly over center of axle as shown in sketch, and then block the driver. Now I put my tool on the axle between the eccentrics and level the top plate and then fasten secure , you will see the clamp bears on the axle in three places.

I have a rule for setting the top plate the proper distance above the axle, as follows Subtract the diameter of the axle from the diameter of eccentric, divide the product by two and add to the result the



amount of lap and lead—the result will be proper distance to set plate above the axle, as shown by arrows. Example : Diameter of axle, 7½ inches ; diameter of eccentric, 16 inches .

$7\frac{1}{2}$—16=$8\frac{1}{2}$÷2=$4\frac{1}{4}$ <lap 1" lead $\frac{1}{16}$"=$5\frac{5}{16}$.

I now move the eccentrics up until they touch the top plate, and lay out my keyways. I also use this device where line of motion is not paralleled to axial line of cylinders.

F. WELLS.

*Frankfort, N. Y.*

[Our correspondent's device requires the putting on of the eccentrics, while the plan shown by F. S Hill does not, and can be used any time after the axle has been quartered for keyway, and before the wheels are keyed on a new axle.]

### Campbell's Valve Setting.

*Editors :*

In your February issue Mr Campbell tells your readers why centers for valve-setting are taken from the rods instead of wheel covers. He also *tries* to tell how to set valves, and succeeds in one about as well as in the other.

Most machinists when setting valves by pinching try to get the engine on a piece of track that is somewhere near level, for it is no worse to have the wheels drop into a hole and away from the tram center than it is to have them carry the center along with them while leaving the links suspended to the frames, which they will do if the track is uneven, and thus change the length of the blades.

One advantage in using a center on the side-rod is in putting it on the top of the rod and having a tram bent on one end only (thus ⌈) ; this will be found quite convenient when working at night, as it gives you the use of one hand to hold a torch, otherwise I could never see as it made any difference which you used.

In telling how to set valves he says that he catches the centers on one side and uses the quarters on the other. Will he please tell how he finds the amount of lead on that side, or changes it if necessary.

I never was able to set an eccentric without getting the dead center. Will he call his niggers back and have them pinch five minutes more, or will his machinist and foreman do it ?

He gives "the boys a nut to crack" in telling them how to keep the eccentrics and blades proper for a long time by putting a liner in the front of the main wheels, but does not tell them that if they put liners in the main shoes they will have to do the same with the rest of the wheels or else change the length of all the rods.

I think every one of your readers will admit that it is easier work and less of it to shorten the eccentric blades, especially if the engines are slim gauge, as they are on the H., E. & W. Texas.

F. C. CHARLES.

*Cedar Rapids, Iowa.*

### Using Air on Head End of Train, M., K. & T. Instructions.

*Editors :*

In perusing your valuable paper I learn more and more every month. There is one subject of great importance which, if discussed in your paper by other roads and by experienced men, would probably benefit M., K. & T. men.

Some time ago the M , K. & T. put up bulletin orders forbidding engineers to use air only in cases of emergency ; it must be coupled up and in condition for use, but must not be used unless in emergency. Brakemen will not set brakes among airs. So, in going up to water tanks or following trains, before brakeman can go from seat on fireman's side over train to first brake behind air, we are in a close place and it becomes necessary to lay brake-valve around in emergency, so all our stops are emergency stops, which is hard on brakes, cars and everything generally. The cause of this order was on account of trains breaking in two behind air and running together, which was laid to air, which I claim had nothing to do with it. I know that a train going over the road with 6 cars air in good working order can be handled to perfection, making all stops and slowing up and down all hills, and if train crews attend to their duty when train breaks off they will not collide.

I will ask some of your correspondents where brakemen ride on their roads. Here on a train equipped with six or eight or even four cars of air, we handle trains perfectly and head brakeman rides on fireman's seat, in his way, and engineer has to fire him out or ask him "if they are all coming." Sometimes he will look out, but it's owing to what kind of weather it is outside whether he will venture his head out or not. If the M , K. & T. R R. will put up a bulletin like this, and enforce it, engineers will use their own judgment in using and handling air and trains and will keep sharp lookout on approaching places where they expect to stop or slow up, and head brakeman should be on top of train and be sure that all are together and conductor and rear brakeman should be out on top of train and be ready to notify head man if train has parted, and engineer, fireman and each brakeman and conductor shall be held responsible for trains running together when parted. I have handled air trains and broke in two in close places, but have never let them collide, and I attribute it to carefulness and watchfulness and making head brakeman keep a close watch. On a dark, rainy night train crews will not even look out, and it is necessary that the darker the night the more carefully should they be strung out on top at every stopping place and be able to help keep train together. Brakemen should look the train over for cracked pins and links

Where officials do not know how to run or pull trains themselves they should be willing to leave such things to the judgment of the men—retaining in service only such men as can "get there" and show results.

M. K. & T.

*Dennison, Texas.*

### The Pontiac Slipper.

*Editors :*

Answering Pontiac, Mich. I should judge from the description of the 15 in. x 22 in. locomotive engine complained of, that there may be many reasons for the engine acting in the manner complained of by Pontiac It may be the engine is over-cylindered with a short lap valve, lots of swap, as the boys call it. The fault may be with a set of hard, slippery driving tires, or too much counter-balance in driving wheels, or perhaps the counter-balance unevenly distributed. With either of these things the engine will act as complained of. I would advise Pontiac to test his engine, see that the driving wheels are not twisted on driving axles, or that the driving axles or crank pins are not bent Counterbalance the driving wheels against ⅔ the reciprocating weights, take off driving tires and anneal same. If the engine valves are line and line inside, put in a set with $\frac{1}{32}$ in. inside lap, and a longer outside lap ; I think the trouble will be removed. If the engine is found all right as regards axles, tires, crank pins and counter-balances, which I have every reason to doubt, try a valve with ⅛ in. to ¼ in. more outside lap, I think the ghost will disappear

*Cedar Rapids, Iowa*

OBSERVER.

### Front Brasses Filed Open.

*Editors :*

Answering W. De Sanno The philosophy of filing front end main rod brasses open, is to avoid filing brasses often. It is the practice in a great many places to file front end main rod brasses open in joints, and are run successfully with care. I approve of filing all connecting-rod brasses to key close in joints.

*Cedar Rapids, Iowa.*

OBSERVER.

A correspondent sends us some interesting notes about the career of Mr. H. A. Whitney, whose retirement from the position of mechanical superintendent of the Intercolonial Railway of Canada we mentioned in a recent issue. Mr Whitney had been in the railway service for over forty years, thirty-five of which had been on the Intercolonial. He began railway work as fireman in 1852, and five years later went to the Intercolonial as engineer, when the road was only thirty miles long. Rising slowly through various grades he reached the head of the mechanical department of the road, which has now 1,200 miles of track. He was highly popular with the rank and file on the system and was entertained at a banquet by the engineers, firemen and machinists when he left.

Part V of the Consolidated Car Heating Company's Catalogue has reached us. It treats of coil and disc drum systems and baggage-car equipment. It forms a comprehensive hand-book on the subjects treated.

## The Greater Santa Fe Trail.

[EDITORIAL CORRESPONDENCE.]

A PIONEER TRADE CENTER.

One of the oldest routes of intercommunication in the United States was the Santa Fé trail. The ancient city of Santa Fé, built by the Spaniards shortly after they took possession of Mexico, was the storehouse of trade for a civilized region long before any permanent settlement was made in the Atlantic States. The town was built on a spot that rendered it a natural distributing point for trade, besides the center of supplies for a district which supported a thriving population.

When the settlement of colonists on the eastern seaboard developed so that the people had something to sell, they naturally looked for a market in the Southwest. There are always enterprising spirits ready to push the gospel of trade to the remotest markets of the earth, and there was not wanting men ready and willing to undertake the transporting of merchandise by mule or wagon over the vast territory that intervenes between the Missouri River and the Rocky Mountains. The route adopted was that presenting the fewest physical difficulties, at the same time providing means of subsistence for man and beast. This was the Santa Fé trail.

MORE DANGEROUS THAN FREIGHT-BRAKING.

In the whole history of human endeavor there are few pages that display more stirring and dramatic scenes than the experiences of those who carried on the work of transporting merchandise over the Santa Fé trail. The men who engaged in this early line of express business took their lives in their hands, and every day of their tedious journey were liable to be called upon to meet death in its most terrible forms. The most stupendous difficulties that animate and inanimate nature could present had to be overcome. Treacherous rivers had to be crossed with the crudest floating apparatus, savage lurking foes haunted the trail, and animals scarcely less ferocious than the human enemies were often encountered. Thirst and hunger had often to be endured in the long journey over the arid plains, and the terrors of storm and tempest were frequently increased by the precarious foothold provided on paths that wound round shelves of giddy precipices. But over storm-swept plains, over almost impassable mountains and through fearful gorges these pioneers of trade forced their foot-trains and led the way to more imposing methods of transit.

ENTERPRISING RAILROAD BUILDERS.

When the daring enterprise of joining the Atlantic States to the Pacific slope by the friendly bonds of a transcontinental railroad was first advocated the Santa Fé trail was urged as the natural route. Surveys were made which proved that the route was one of the best that could be followed, but considerations other than engineering ones sent the first railroad another way. Even while railroad men were almost unanimous that one railroad would be sufficient for all business that could be offered for transportation between the Atlantic and Pacific States for half a century to come, men with clearer vision were ready to venture their means in building a railroad over the Santa Fé trail. For this purpose the Atchison, Topeka & Santa Fé Railroad Company was organized in 1863. The enterprise made little progress for a few years, but by 1873 360 miles of the road was completed and the State of Colorado reached. Through the hard times which followed the panic of 1873 it was difficult raising money to push railroads into the wilderness, but this road kept pushing out its terminals year after year till not only the original goal, Santa Fé, was reached, but remote territory traversed never dreamt of by the organizers of the company. This is the modern Santa Fé trail.

THE ATCHISON, TOPEKA & SANTA FE SYSTEM.

The new and greater trail is wonderful in many ways—wonderful for the number and extent of its tentacles, wonderful for the vast territory it traverses and wonderful for the revivifying influences it is exerting on the communities reached by its lines. The lines twist over Kansas like the tracings of an intricate web. One terminus is in Chicago, another is in Guaymas in Mexico, half way down the Gulf of California. A leg goes to Galveston on the Gulf of Mexico, and it gives direct connection with Salt Lake City, in Utah. Los Angeles in Southern California is the Western terminus, and there are many smaller terminal points that are now the jumping off place while waiting for additions to the track that will lead to new fields.

This railroad system has nearly 10,000 miles of track extending through fourteen States and Territories. The corporation owns over 1,300 locomotives and about 40,000 cars. Its track drops to the sea level in three different States, and in Colorado crosses a mountain at an altitude of 11,528 feet—over two miles in the air.

PASO DEL NORTE, MEXICO, RAILWAY STATION.

OUT WITH AN INSPECTION PARTY.

In September and November last the writer spent three weeks on the Atchison, Topeka & Santa Fé system. The time was too short to see more than a few of the main line trunks, but it was long enough to give the impression that the whole of the lines could not be thoroughly explored in less than a year. Three or four days were spent with a party out on an inspection tour. The principal members of the party were General Superintendent Nickerson, Superintendent of Motive Power Player and the superintendents, engineers and road masters of the division under inspection. A special train was used and it was stopped at every bridge, culvert and shop, or any other place where cuts or embankments were likely to be out of order. The work was very thoroughly done. Those interested went down beneath every bridge and carefully examined the condition of the structure and of the foundations. The track was kept under constant scrutiny, and where rails or ties were considered unsatisfactory, stoppages were made and orders issued for renewals or repairs. The roundhouses, car repair shops and yards and every place where maintenance of any material was to be found came in for attention. Slovenliness or indications of waste brought down upon the devoted head of the man responsible sneers and reproaches that were not likely to be forgotten soon. The party managed to get over the road at the rate of 100 miles a day.

This practice of constant inspection by heads of departments keeps the men in charge vigilant, and there is very little cause for complaint about yards or shops being dirty. The policy followed is to convert all scrap into money or into new metal with the least possible delay, and there is very little idle capital to be found lying around in the shape of overgrown scrap heaps.

OVER THE MAIN LINE.

From Topeka westward we were the guests of Mr. Player in a "business car." All through Kansas, Colorado and New Mexico he followed the inspection practice at every place where there was an engine-house or car-repair shed. If the train stopped only fifteen minutes, a run was made to the engine-house or repair-yard, and it was wonderful how orderly every place was. Even in the most remote parts of New Mexico, where workmen are hard to hold and where order and cleanliness are notable for their absence about the houses of the people, the railroad establishments were examples of neatness that gave practical preaching of a gospel badly needed on the frontiers of civilization.

MODERN METHODS OF THANKING BENEFACTORS.

I had been over the Santa Fé route before, and was fairly familiar with the appearance of the country, but there has been wonderful development within the last twelve years. Vast stretches that in 1880 offered merely a scanty herbage for stock during a portion of the year are now covered with fertile farms that raise bountiful crops of wheat, corn, alfalfa and other kinds of agricultural riches. A wise English statesman once received great praise for saying that, "the man who made two blades of grass grow where only one had grown before was a benefactor to mankind." If our people were to take that view of human actions, they would credit railroad companies with being the greatest benefactors of the human race. Just reflect on the vast increase of comfortable homes due to the railroads stretching out into the unbroken prairies of the West. Praise has little part in the reward they receive f r the favors done. Modern ideas of freedom tend to the abuse of anything that stands higher than the average individual. A railroad company is the most conspicuous embodiment of capital, and many of those who have gained the most by its enterprise are ready to howl against its receiving common justice. This is becoming the American way of requiting favors enjoyed.

ENCOURAGING BUSINESS.

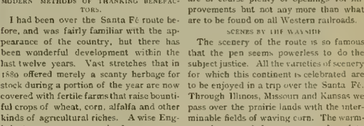
The present management of the Atchison, Topeka and Santa Fé are following a most enlightened policy of encouraging the development of the natural resources within reach of the company's lines. All sorts of mining enterprises are developing rapidly, advantageous rates being given for the transportation of the products to market. But the most striking line of development is in agricultural and horticultural products. The soil of many districts of Kansas, Colorado, New Mexico, Texas, Arizona and California contains in great riches the constituents that sustain vegetation, but the elements have lain dormant for centuries for want of water. Irrigation works are now supplying this want, and vast tracts that seldom receive a shower of rain are supplied with all the water needed for raising fruit and cereals. Under this influence the desert is really coming to blossom as the rose.

WELL EQUIPPED FOR TRAIN RUNNING.

The railroad is surprisingly well equipped for handling the growing traffic of its numerous feeders and far-reaching connections. The rolling stock compares favorably with anything to be seen anywhere. A large percentage of the freight cars have air-brakes, and through trains of stock and perishable freight or time merchandise are pushed along faster than passenger trains. The track of the main line from Chicago to Los Angeles is nearly all maintained in shape that makes express speed perfectly safe. Long stretches of the track are laid on stone ballast, on broken slag or on good clean gravel. The worst ballast used is sand and there is not much of that. There are of course plenty of openings for improvements but not any more than what are to be found on all Western railroads.

SCENES BY THE WAYSIDE.

The scenery of the route is so famous that the pen seems powerless to do the subject justice. All the varieties of scenery for which this continent is celebrated are to be enjoyed in a trip over the Santa Fé. Through Illinois, Missouri and Kansas we pass over the prairie lands with the interminable fields of waving corn. The warmest admirers of the prairie are forced to admit that it grows monotonous to the eye, but even in this respect the prairie is improving. Twelve years ago one could ride for hours in Kansas without seeing brush or brake to vary the sameness of the view. Now there are groves and plantations of trees everywhere dotted over the country, and many of the grove marked hillsides are pretty as the rural landscapes that painters have made familiar to art admirers.



IN THE STATION COURT, PASO DEL NORTE, MEXICO.

When Colorado is reached the scenery, animate and inanimate, becomes of a more picturesque type. The dignified Mexican who tamps gravel under the track and handles the tamping rod as if it were a spear is picturesque with his broad sombrero and red shirt; the adobe houses, with chattering brunettes squatting about the door, their scanty garments thrown on with an eye to pleasing effect that displays the innate taste for the decorative part of art inherited by so many of the race

to which Bartolomé Esteban Murillo belonged; the loose-limbed Mexican basking in the sun, galloping on the skinny bronco, or performing laboring work with the dignity of a nobleman, are common sights of the mountain regions. These, with women, large and small, lolling around, their humble apparel worked out for supreme display, the swarthy faced urchins clad in little more than their own sense of native modesty, the demure donkeys that appear to be intimate members of every household, the flocks of goats and the general sleepiness that prevails tell the traveler that he has found a different character of civilization from that established by the restless denizens of the Atlantic States. The peaks and gorges, the rock broken torrents and silver lakes and all the novelties of mountain scenery are pleasant to look upon, but they do not by any means monopolize the sights picturesque to be seen on the Greater Santa Fé trail.

A. S.

### Kingsland Shops.

The Delaware, Lackawanna & Western are getting five locomotives built at Cooke's, two of them 8-wheelers and three moguls for handling the heavy milk trains run into New York. There is talk of making some badly needed extensions of the shops at Kingsland. They have only eight stalls for doing the work for 160 locomotives, so the work is done at great disadvantage. Part of the roundhouse is taken up for a paint shop and for the repairing of tenders, and the running engines are crowded out of doors. A new building for paint and tender shop is among the improvements planned. They have got a number of new tools in the machine shop lately but a few more could be used to advantage. Mr. Lewis is putting heavier frames in the locomotives as fast as he can get the work done and he finds that the change reduces the repair bills very much. He is using a great many cast-steel driving-axle-boxes and speaks very highly of their durability. A liner of brass is put inside the box to prevent cutting the wheel-hub and an oil hole is drilled through the top of the box to supply lubrication to the rubbing plate. The wear is very small.

They expect to put an electric lighting plant into the shops this season. When this is done an electric motor will be employed for moving the transfer table.

### The Latest "Rotary" Wheel.

The engraving shown herewith was made direct from a photograph taken in the locomotive works of Henschel & Son, at Cassel, Germany, who are the European builders of the greatest American snow shoveler.

This wheel is the first of a new design, and is 18 inches narrower than the old wheels, but having the same capacity. The center cone is short and curves directly into the vanes of the wheel. Part of the depth is saved by flattening the channels at the back; this gives them a broader bearing, with more rivets to the disc, and does not decrease the capacity, as it merely changes the shape.

The knives have a chisel near the outer hinge that keeps a four-inch ring cut out of the snow ahead of the breast, so that it is easier for the knives to cut it out.

The German builders are quite proud of their work on this device.

### A Wholesale President.

There are some positions in railroad life in which a man appears to be more influential than the President of the United States. As an illustration of this we might instance Mr. Allan Manvel, president of the Atchison, Topeka & Santa Fé, who according to the *Railway Age* is a director in fifty-four railroad companies and president of forty-nine of them.

### Manipulating Boiler Plates.

A great deal has been written of late on the behavior of steel plates when worked at the blue heat point, also more or less concerning the mysterious cracking of firebox sheets, and more or less blame laid at the door of the manufacturer; whereas, the punishment the steel has received at the hands of the boiler-maker, has well-nigh been lost sight of, and in this day of cheap first cost a great many bad practices have crept in unawares, until now it is quite common to hear of firebox plates being punched, and in the hurry, very little attention has been paid to annealing, so that the following from a noted authority, Thos W. Traill, F. E. R. N., engineer surveyor-in-chief to the London Board of Trade, is both instructive and timely.

PLATES WHICH HAVE BEEN HEATED OR WORKED.

Plates which are not heated uniformly in one operation, or heated and worked, no matter how they may be heated, should after such treatment be immediately and in one operation heated to a bright red, and allowed to cool gradually. When this has not been done, plates have in many instances cracked, sometimes within an hour; in other cases hours and days, and even weeks and months, have elapsed before the plate cracked; in some cases they have cracked without being touched at the time; while in others they have cracked when struck a slight blow, the plates being of a mild description—that is, of moderate tensile strength, and having good elongation. The failures which have taken place with steel plates of good quality have in nearly all cases been traced to the treatment which they received, and in every case when the plate had been satisfactorily proved to be of good quality before it had been heated or worked, improper usage or want of proper treatment had been the cause of failure. Steel should not be worked when hot below a red heat.

FLANGING.

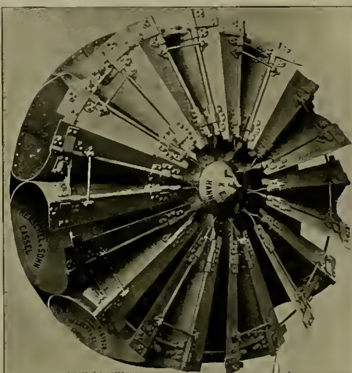
All flanging, so far as practicable, should be done in one operation; hydraulic appliances are the most desirable, and the plate immediately after it has been flanged should be heated to a bright red and allowed to cool gradually.

DRILLING AND NOT PUNCHING.

Plates should not be punched, as such treatment has been found not only to impair the strength of the material, but also to make it dangerously unreliable, which is much more serious than if it only reduced the tensile strength. With suitable drilling appliances, boilers can be constructed at less cost than by the barbarous method of punching the holes; and no boiler works can now be considered as a first-class establishment which has not suitable appliances for drilling the holes in place. It has been proved in several good boiler works, that the cost of construction is less when the holes are drilled by suitable machines than when they are punched. Good machines can be obtained which will soon repay the outlay and ultimately effect a saving of labor; moreover a reliable and safe boiler can be turned out instead of one in which, when the holes are punched, no confidence can be placed, and which may explode without giving warning, through the material having been ruined by punching.

PUNCHING AND BORING.

Punching plates and afterward boring them is not recommended, but if this is done care should be taken that a sufficient quantity is bored out so as to remove as far as possible the very injurious effect of punching. It is found that when ½-inch plate is punched $\frac{9}{16}$-inch it requires to be bored out to fully $\frac{11}{16}$-inches, and a 1-inch plate punched $1\frac{1}{16}$ inch requires to be bored out to $1\frac{3}{16}$ inches to remove the pernicious effect of the punch on the plates, and consequently plates of greater thickness require to have more bored out so as to remove the injurious effects of punching. There is nothing gained by punching and afterward boring, and there is also more or less risk of the injury done by the punch not being removed, and therefore such a barbarous tool as a punch should never be used to steel plates.



"ROTARY" WHEEL, AS BUILT IN GERMANY.

PUNCHING AND ANNEALING.

Punching plates and afterward annealing them is decidedly an objectionable method, and before it is done the special assent of the engineer inspector should be obtained; if he assents, it is essential that he should satisfy himself that the annealing is done perfectly and in a properly constructed furnace.

LOCAL HEATING.

Local heating of the plates is very objectionable, and should be avoided, as many plates have failed from having been so treated. If this be not attended to, serious accidents are likely to result

ANNEALING

All plates that are punched, flanged, or locally heated, should be carefully annealed after being so treated. The plates should be heated all over at one operation in a properly constructed furnace, and then allowed to cool gradually.

BENDING PLATES WHEN COLD.

Plates should be bent when they are cold to the required curvature for cylindrical shells, receivers and domes, etc. Plates which will not stand bending when cold should not be used, there are rolls well adapted for such work, being capable of bending large plates, and thicker than any yet used for shells of boilers.

STEEL SERVICEABLE AND RELIABLE.

Notwithstanding the peculiarities of mild steel, it is a material which may be used with safety and advantage, if proper precautions be taken and due consideration given to these peculiarities; possibly it has fewer infirmities than iron; and there can be no doubt that it is a better and more serviceable material for general use in the construction of boilers.

### Profit Sharing.

H. K. Porter & Co., Pittsburgh, distributed a share of profits to their employés last month. Along with the notice the following circular was issued

"We are especially gratified that the amount distributed is not decreased, as we supposed it would have to be. The conditions of business the past year have been very trying, and in many respects discouraging. Prices were less throughout the year than in 1891, and the output for the first six months was very small, but as soon as the demand increased the output largely increased, and by your efficient co-operation, so soon as you had the opportunity to put it forth, we largely recovered the lost ground. This proves to us what we believed before, that practical co-operation is a positive benefit to every one of us, and that it pays us partly, if not fully, in the item of dollars and cents, to make this distribution. We have often said to you that it is only on this basis that we can hope to make such distribution a permanent annual thing. But such reasonable return to us only makes us the more gratified to recognize your efficient and cheerful service, and to be able to give you this additional remuneration for your faithful labor. We hope that in receiving this sum, each one of you is conscious of having deserved it by having rendered the best service in his power, and that the money will be a positive good to each one, and to all dependent upon you."

Brake slack adjusters are passing through the Patent Office in a manner that rivals the car-coupler. Among recent inventions of this kind we notice as well worthy of notice a brake slack adjuster invented by William W. Holmes, and assigned to the Consolidated Brake Adjuster Company, Chicago. It has a threaded connecting-rod, on which there is a ratchet, operated by a reciprocating pawl. When a certain degree of slack is worn the pawl engages the ratchet and moves it, taking up the lost motion. The device looks as if it would do the work automatically.

The rates of pay of engineers and firemen on Western roads are, for firemen, \$2.25 per day of eight and a quarter hours for the first half year, \$2.50 per day for the second half year, and \$2.75 for the third year and after, for engineers \$3.50 per day of eight and a quarter hours for the first half year, \$3.75 for the second half year and increasing 25 cents per day per year for the next three years until for the fourth and succeeding years the rate of pay is to be \$4.50 per day.—*Engineer.* Not quite. This is the proposed pay on the Chicago Elevated. No doubt if this pay was offered on a surface road for eight and a quarter hours work, they would have to open an application bureau.

All traveling engineers should correspond with W. O. Thompson, Secretary of the new Traveling Engineers' Association, at Elkhart, Ind.

## ? A. What You Want to Know. ? A.

Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.

(23) A C S. Hoisington, Kan., asks

In locomotive practice, why does the go-ahead eccentric follow the crank-pin when engine is running ahead. *A.*—This is a foolish question—the eccentric follows the pin because it must be in this position to move the valve at the proper time. It follows the pin only in engines having a rocker.

(24) B. R. M., Scranton, Pa., writes

I have found that several kinds of steel are self-hardening. What ingredient or physical property causes this? *A.*—This self-hardening property is caused by peculiar combinations, carbon, manganese and tungsten in the steel Chromium also appears in some kinds of steel to be used as a mixture which gives the self-hardening property

(25) F. S., Brooklyn, says:

What would be the bore of a low-pressure cylinder for a compound engine if the high-pressure cylinder is 11¼ x 20 inches *A.*—That depends on the ratio of cylinders required. A common ratio is to have the low-pressure twice the area of the high-pressure piston. In that case the diameter of the low-pressure cylinder would be 15.9 inches

(26) M. B. O., Sheldon, Ia., writes

Please advise through columns of your paper as to the practicability of taking a course of mechanics through the Correspondence School of Mechanics, Scranton, Pa *A.*—We receive many letters asking for advice on this question, and we take this opportunity of answering publicly that we consider the course of instruction given by the school named as being both practicable and valuable. We are acquainted with parties who are taking the course and they speak in the highest terms about the help they are receiving.

(27) C. A. R., Syracuse, N. Y., writes

I heard the expression, "the efficiency of a firebox," made use of, and I am at a loss to understand what it implies. Please help me out. *A.*—The expression is used to indicate several things. For instance, the firebox may be very small or quite large in proportion to the boiler. In such cases the efficiency of the firebox in relation to the boiler is estimated or speculated about. The expression is used in another way in estimating the heat generated in the firebox as compared with the total heat in the fuel burned.

(28) W B., Philadelphia, says

We have some compound locomotives on the road, and one of our shop men who has been at a mechanical school argues that steam-jackets are necessary for the cylinders of compound engines. I have never heard of steam-jackets being used with locomotives, and I should like to know if they are of much value *A.*—Steam-jackets have been repeatedly tried on locomotives, but without showing any advantage The ability of the steam-jacket is doubtful, except with engines having low piston speed. A locomotive is a poor subject for a steam-jacket. If the condensed water is not removed quickly the jacket becomes a condenser instead of a means of keeping the cylinder hot.

(29) A. J. Ford, Sedalia, Mo., writes

We have several Baldwin ten-wheel engines here that have eccentrics on shaft of front driving-wheels; these engines have several times been towed in, owing to something happening that required all side-rods coming down. Many of our runners claim that these engines, under above condition, would bring themselves in the same as if eccentrics were on main shaft. *A.*—Engines of this class have been brought in without side-rods, where the distance was short, but it is bad railroading, they are liable to slip and become helpless at once. When engines having eccentrics on other than the main driver are crippled so as to require the taking down of side-rods, they should be towed in. It is taking the fewest chances.

(30) W. J. B., Houston, Texas, writes

1. If the valve of engine having link motion could be made to open half as quick again as at present, and you should work at 12 inches, how near would cylinder pressure come to boiler pressure. Would the cut-off at 12 inches make the engine as strong as the slow motion at 18 inches? *A.*—So much depends on piston speed, size and shape of steam-pipes that no positive answer can be given to these questions The chances are that the working of the engine would not be changed materially. 2. When an engine cuts off at 6 inches with $\frac{5}{16}$-in. lead, and a change should be made reducing this lead to $\frac{5}{32}$-in., maintaining the same port opening, how much would this increase the engine's speed, and would it reduce the fuel account? *A.*—It would not increase the speed any, and the likelihood is that the fuel consumption would be increased. The effect of changes of this character could not be settled except by experiment.

(31) L. M., Cheyenne, Wyo., writes

I am informed that red lead and white lead are both the same substance, oxide of lead. What causes the difference in their appearance? *A.*—They are not the same substance. Red lead is oxide of lead, the other is carbonate of lead. Red lead is made by keeping a thin layer of melted lead on a reverberatory furnace and passing the gases from the combustion of coal over its surface. This action converts the lead into litharge, which is protoxide of lead. This compound is then taken out, ground and thoroughly washed to take out metallic lead and foreign substances. The mass is then returned to the reverberatory furnace and again subjected to a current of corbonic dioxide which converts it into red lead. This is oxide of lead. To make white lead the litharge is washed in water until it is converted into an impalpable paste. A certain quantity of chloride of sodium (common salt) is then mixed with it which precipitates an insoluble chloride of lead. This is allowed to settle and is treated with carbonic dioxide which converts it into white lead

(32) H. F. M. P., Fort Madison, writes:

After reading three books on mechanics I am still at a loss to understand the "Law of Falling Bodies," viz. "Under the influence of gravity alone, all bodies fall with equal rapidity." For if you take the penny and feather experiment and make the feather of the same area as the penny, then in an exhausted air chamber, they will both fall in the same time, but in the atmosphere the penny will reach the ground first owing to the resistance of the air being greater on the feather than the coin, now why should the feather offer more resistance to the air than the penny, both being of the same area? For if the resistance of air is not dependent on the size of the surface of a body, but on the weight, then how is it that we have a common velocity for all falling bodies, namely 32.5 feet per second? If this number applies only to bodies in a vacuum, then what good is it in actual practice when every body will have a different velocity? *A.*—Why a light body of equal area does not fall as fast against the air resistance as a heavy body involves a question in dynamics. The heavy body immediately after starting to fall has more energy to push itself through the air than the light body

(33) L. K., Truro, N. S., writes

1. Please explain the meaning of working steam expansively? *A.*—This cannot be done within the space available in this column. It will be found explained fully in a chapter beginning on page 353 in Sinclair's Locomotive Engine Running. 2. What is a Corliss engine? *A.*—One of the best class of automatic engines. Particulars of construction can be found in any modern book on the steam engine. 3. Is there any difference of weight on the truck of an ordinary eight-wheel engine when pulling a train up a grade from what there is when running down the same? *A.*—Yes. There is a little more weight on the truck when the engine is descending a grade. 4. Is a ten-wheel engine harder to slip than an eight-wheeler with the same weight on the driving-wheels and same size of cylinders? *A.*—No. Not if the driving-wheels are of the same size 5. Why will an ordinary Mack injector not work hot water? *A.*—For two reasons. 1. Because the steam from the hot water prevents the injector from creating a vacuum to raise the water. 2 Because the hot water will not condense the steam passing through the injector, and unless the steam is all condensed the water will not be solid enough to maintain the velocity which puts it into the boiler

(34) P. M McC., East Mauch Chunk, Pa., writes

We have about 20 engines equipped with the Allan Richardson balanced valve I am running one. Why is it they will not run free shut off going down hill? The one I am running will not make over 20 miles per hour on 90 feet grade. The rest act the same way; they also work the fire pretty hard when fire door is shut. *A.*—The action of the valves spoken of is not far different from a plain D-valve. When the lever is in its corner the action of the piston tends to draw air out of the steam chest and force it out of the nozzles. If there is a relief valve on chest there is no doubt that more air is thus pumped through the cylinders and this causes the draft on the fire. If there was no relief valve on chest there would be a partial vacuum there as the piston receded, but this would instantly be supplied with air through the exhaust port and nozzle, when the piston neared the end of the stroke, and the exhaust port was opened This movement of air back and forth from the cylinder to the exhaust passages never caused any great trouble in the old engines, and is, we think, better than drawing a large quantity of cold air through the chest and cylinders. Some mechanics advocate large cylinder cocks that can act as relief cock, and some contend that these should be run wide open, but this would be annoying, to say the least, and apt to carry into the cylinders a great deal of sand and other ballast Just what prevents the engine from running down hill we can't see, unless the lever cannot be run in the corner, in this case the port would close before the piston reached the end of its stroke, and the air ahead of it would be compressed enough to retard very seriously. With an ordinary valve it would simply be lifted off the seat; the balanced valve cannot lift more than 1-16, if that There are hundreds of engines equipped with balanced valve that run down hill freely; from this we are led to believe that there is some local cause that does most of the mischief for which the valves are blamed.

### High Train Speed of the Future.

An article on railway development has been contributed to the New York *Commercial Advertiser* by Vice-President Webb, of the New York Central, from which we quote

"I have no doubt at all that early in the next century there will be a number of trains on some of the greater roads whose schedule time will call for as much as 100 miles an hour. I have no doubt that a traveler early in the next century will be able to get his breakfast in New York and his evening dinner in Chicago.

"We have already learned how to construct locomotives which are capable of making ninety miles and more an hour, and we have learned how best to utilize their enormous powers. Given the perfect locomotive—and we have nearly secured the perfect machine of this sort—we need only two or three other conditions. There must be a perfectly constructed track and roadbed. It must have inappreciable grades and very slight curves. It must be so made as to be elastic and yet withstand easily the strain caused by high speed Then we must have a perfect signal system. That I am sure will be developed.

"The block system of to-day is sufficiently thorough to make the high rates of speed attained by trains on my own road for instance, possible. There should be no grade crossings—these eat up time dreadfully sometimes—and passenger cars must be light but very strong, and the number of them limited to a high-speed train. We need the best coal and, of course, highly trained employes. With these conditions—and they are sure to be obtained early in the next century—I feel safe in saying that regularly scheduled daily trains running 100 miles an hour will be advertised by many of the railway companies.

"The question of safety and of popularity will be no more considered than are the same questions when a person enters an ordinary express train of the present time. With the conditions that I have described above, a train running 100 miles an hour is just as safe as one running forty. In either case, if an accident happens it is likely to prove disastrous. The tendency of the time is toward rapid travel, and it has already been discovered that these fast trains are not an experiment, but are put on the roads in response to a public demand."

### Never Touched It.

"When Irvin Baker was on the Park, remarked the old-timer as he lit his pipe, "I heard him git even with Jim Kirk, the master mechanic. Jim allers objected to the boys callin' the Mason-Fairlies 'Jim-Crows.'

"These little yard-wide engines were loaded down with a Nesbith stack, a balloon thing with a sub-treasury for sparks and a 36-inch cone with a wrought-iron petticoat to it—awfullest thing you ever see to git sparks through.

"Well, one morning Baker brung one of 'em into Leadville and left her for the hostler. Kirk was in town, and went to the roundhouse, when Baker went up to the house to borrow enough hemp from some Rio Grande feller to pack—the Park never bought nothin'—Kirk was waiting for him.

"'Did you look this engine over when you come in?' says he.

"'I allus look over a "Crow." They'r liable to lose something.'

"'Well, just look at that truck wheel, got six inches broke out of the rim, wonder you didn't go into the Arkansas.'

"'That don't hurt nothin', don't touch.

"'Don't hurt? don't touch?—what 'd'y mean?'

"'Well, sir, when you'r workin' her hard up the hill the exhaust hits that cone so hard it kinder lifts up the front end so's the wheels don't touch 'ceptin' on curves.'"

The practice of admitting the feed-water in the back end of locomotive boilers, which has been tried so often with unsatisfactory results, has been adopted by Mr. W A Foster, of the Fall Brook Railway, under a peculiar arrangement. The usual plan has been to convey the cold water to the front of the boiler in a pipe, which soon gets choked up with sediment and scale. Mr. Foster employes a capacious trough to convey the water, which can be used a long time before filling up. He speaks highly about the performance of the engines that are equipped with this improvement

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK·

VOL. VI, No. 4. NEW YORK, APRIL, 1893. 20 Cts. Monthly, $2.00 Per Year.

## Group of Members of Association of Railway Locomotive Engineers of Great Britain.

Superintendents of motive-power, master mechanics and masters of machinery are unknown in the British Isles

They call the head of the motive-power department a Locomotive Engineer and the man we call locomotive engineer is there called a driver.

There are not so many railroads nor so many officers of this rank in that small country as in this, and the group here shown is small compared with the yearly assembly to "be took" at our annual Master Mechanics' meetings.

This picture was taken at the last meeting of the British Association at Red Bank, over Grassmere, England, June 24, 1892, and shows an intelligent-looking lot of railroaders.

Commencing at the left the men may be identified as follows

*Front Row.*—J. H Hosgood, Barry Docks & Railways; J A. F. Aspinall, Lancashire & Yorkshire, T G. Clayton, Midland Railway (Carriage & Wagon Dept.); J. C. Park, Great Northern, of Ireland, W. Wainwright, South Eastern (Carriage & Wagon Dept.); W Dean, Great Western; H A Ivatt, Great Southern & Western of Ireland, J. Stirling (Sec. of Association), South Eastern Railway.

*Second Row.*—T. H Riches, Taff Vale Railway; B. Malcolm, Belfast & Northern Counties; J. J. Hanbury, Metropolitan Railway, R. J. Billinton, London, Brighton & South Coast Railway, S W. Johnson, Midland Railway; W. Adams (President of Asso.), London & South Western Railway; James Manson, Glasgow & South Western Railway.

*Back Row.*—Hugh McColl, Secretary's Clerk; R. Mason, Furness Railway, T. Whitelegg, London, Tilbury & South End Railway; M. Stirling, Hull, Barnsley & West Riding Junction, T Parker, Manchester, Sheffield & Lincolnshire Railway, M. Atock, Midland Great Western Railway, W. Kirtley, London, Chatham & Dover Railway, F. Attock, Lancashire & Yorkshire (Carriage & Wagon Dept.).

Two of the best-known heads of railway mechanical departments in Great Britain are not shown. Mr. F. W. Webb, of the London & Northwestern, was away, and Patrick Sterling of the Great Northern was sick at the time of the meeting.

MEN IN CHARGE OF THE ROLLING STOCK OF THE RAILWAYS OF GREAT BRITAIN.

---

The authorities who control the rate-making power on our railroads are making a bold front to convey the impression that no demoralization of rates will happen in connection with the rush toward Chicago. In fact, superficial observers would conclude that full fares are liable to be charged both ways. In the meantime, tourist companies in the British Isles are advertising rates of first-class passage from Liverpool to Chicago and return for $85, including meals, sleeping-car berths and entrance to the World's Fair. We calculate that $10 of this sum would be devoted to railroad fare from the seaboard to Chicago and back. It is all right to encourage foreign visitors, but it seems passing strange that our own people are threatened with the exaction of high rates. In this connection it would be interesting to find out on what plea of justice immigrants can get from New York to Chicago for $7, while residents here pay double the sum when willing to accept the same dirty accommodation.

## Some Experience with Balanced Slide-Valves.

BY JOHN H. COOPER, M. E.

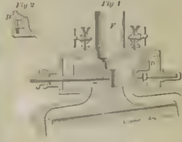
Patents and plans for balanced slide-valves exist in great number. Few of them have realized the hopes of their inventors, and fewer still have made commercial successes. Complexity having reigned supreme in the make-up of many, brought such to early failure, and some that were simple enough neither disburdened the valve, prevented leakage nor endured the service, all of which results they were designed to accomplish.

The triple problem of least leakage, least friction, coupled with greatest endurance, is difficult of solution. If any form of balancing device applied to a slide-valve can lay any claims to simplicity of construction, correctness of principle and sustained ease of working, that which is defined and illustrated in the following review has at least features that promise well for these.

In the year 1851, M. Desgrange applied a steam-packed ring to the back of a plain slide-valve, which was used for steam distribution in the cylinders of locomotives as built by the Messrs Buddicom & Co. of Rouen (for detailed account of which see *Armengaud, Publication Industriell*, Vol. 8)

This ring and valve are shown in section in Figs 1 and 2, the ring is fitted to an annular groove formed in the back of

Fig 2 Fig 1



the slide-valve against the outer rim of which it is packed tight to prevent leakage into the interior which forms the exhaust way to the pipe *P* above the valve, communicating with the stack in the usual way

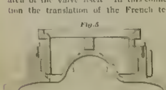
There is no exhaust port on the ported face of the cylinder casting.

The peculiarity of this ring, to which attention is called, is the increased diameter like a flange, of the part *D*, which comes in contact with the under face of the steam-chest cover, the same being surfaced to a parallel plane with the working valve face on the cylinder casting

The inside of this ring is turned out to a diameter about equal to the outside diameter of the packed part in the valve, shown distinctly in Fig 2 of the *Armengaud* illustrations The result of this form is to expose a certain amount of the surface of the ring to the upward pressure of the live steam in the steam-chest, surrounding it an area which is just equal to the surface of the ring in contact with the cover, into which the fluid pressure creeps from the steam-chest, and for this reason it would seem to maintain a steam-tight joint between the steam-chest and exhaust-pipe, the one pressure being equal to the other and opposed to it, the whole arrangement forming a balanced ring floating in the steam

The next point to be determined is the relative area of this balanced ring to the area of the valve itself In this connection the translation of the French text

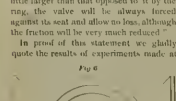
Fig.5



says "If it be arranged in such a manner that the surface of the slide-valve be a little larger than that opposed to it by the ring, the valve will be always forced against its seat and allow no loss, although the friction will be very much reduced"

In proof of this statement we gladly quote the results of experiments made at

Fig 6



Boulogne, which showed a saving of $\frac{1}{12}$ of the coke used for steaming, by the use of this form of valve over the ordinary steam-burdened slide-valves, when everything else remained the same

In the March number of the *Journal of the Franklin Institute*, for 1870, is an article on the theory and practice of the slide-valve (by Thomas Adams, C E, of England) which was read before the Institute in May, 1869

Mr Adams' experiments were numerous, were tried under varying circumstances on locomotives in use, and during long periods of time

His treatment of the subject reads as if by one working in earnest for the solution of a difficult problem Mr. Adams says he discovered the law of balance between two free surfaces wholly in molecular contact when immersed in steam. The benefits of this law are realized when the area of contact is opposed by an exactly equal area of the same fluid pressure In plain terms Mr Adams says that steam will go between two surfaces in ordinary contact when it has free access to the joint and cannot be kept out until a counter pressure be applied which is equal to the area of the surface multiplied by the steam pressure upon it.

In Mr Adams' valve we have the same form and proportions of ring as found in the Desgrange valve, which were applied fifteen years before

Your writer repeated the Adams form of balancing ring in a design of valve arranged as shown in Figs 3, 4 and 5, which present a longitudinal section, a

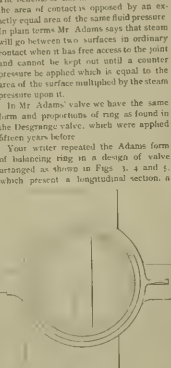


Fig 4

transverse section, and a plan of a twin valve, that is, two of these in reversed position on the valve stem were used in a long steam-chest, having short steam-ports at the extreme ends of the cylinder, and beside each an exhaust-port which are united into one common exhaust-pipe.

The overhung joint surface and flange are plainly seen, and this little trick is the key to the secret of this valve's success

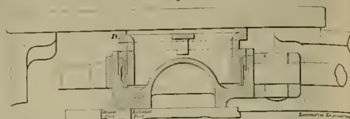
This packing-ring has a bar cast across its upper diameter with a pendant pin which is embraced by a spiral spring, resting upon the back of the valve, this is for holding the ring against the cover with a gentle pressure and is only of service when the steam is absent. This ring is steam-packed to the valve by the usual three-ring metallic packing, which is held in place by a bolted follower Live steam has access to the space behind these packing rings in order to balance them to the creeping pressure of the steam in the chest trying to get to the interior of the ring. This group of packing rings is turned smaller in diameter than the balancing rings, so as to hug it closely at all times

The valve can be lifted from its seat to give relief of pressure in the cylinder when necessary, and will readily return to its normal place without injury to any part. If there be any leakage into the interior it may be vented into the exhaust port or through the steam chest cover, making itself known to the engineer. The valve-stem yoke encircles the whole affair, and being freely fitted will also permit the valve to lift The bump formed in the walls of the exhaust way in the valve was a necessity of the space already provided by an existing steam chest, but it serves the purpose of additional strength to the valve, as well as vent to the exhausting steam.

Your writer, with his efficient draughtsman (A D. Emery), being a little enthusiastic in the matter of balancing side-valves at that time, endeavored to improve on the preceding designs, from which effort there issued a form of ring shown in Figs. 6 and 7, which we patented July 23, 1872, and to the description here following we call the reader's attention

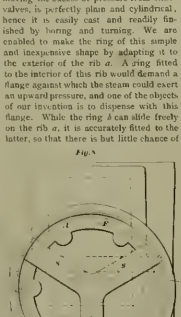
Our invention has for its object the im-

Fig.3



provement, both as regard simplicity in construction and practical efficiency, of disburdened slide-valves of a well-known type. The nature of our invention may be briefly described as follows, reference being had to the vertical section, Fig. 7, in the accompanying drawing, in which the line *A* represents the face of the steam-cylinder, *B*, the inner face of the steam chest cover, and *D* the slide-valve, on the back of which is cast an annular rib, *a*, adapted to the plain cylindrical ring *b*, the pressure of steam on the lower edge of the latter being exerted on an area equal to that of the upper edge of the ring, which bears against the steam-chest cover. The French patent of Desgrange (March 10, 1851) affords an early example of disburdened or so-called balanced slide-valves of this class It will be understood, therefore, that no new principle is involved in our invention, which is restricted to a specific construction of parts and adaptation of these parts to each other. The ring *b*, unlike the rings heretofore used for removing the excess of pressure from slide-valves, is perfectly plain and cylindrical, hence it is easily cast and readily finished by boring and turning. We are enabled to make the ring of this simple and inexpensive shape by adapting it to the exterior of the rib *a*. A ring fitted to the interior of this rib would demand a flange against which the steam could exert an upward pressure, and one of the objects of our invention is to dispense with this flange. While the ring *b* can slide freely on the rib *a*, it is accurately fitted to the latter, so that there is but little chance of

Fig. 8

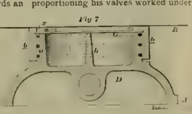


the steam penetrating between the two; but to prevent the possibility of such penetration of the steam, we place, in grooves formed in the rib *a*, light rings, which, owing to their expansible property, bear with a constant pressure against the interior of the ring *b*. In order to insure the contact of the ring against the steam-chest cover under all circumstances, a spring, *G*, bears upon a central projection, *h*, of the valve, extends across the annular rib *a*, and each end enters a groove in the ring *b*, upon which the spring exerts a constant upward pressure, the spring being always maintained in its proper position by its adaptation to recesses *x* in the upper edge of the annular rib. The rib *a* extends very nearly to the steam-chest cover, hence the valve is prevented from being forced from its seat when steam is excluded from the chest, and the movement of the engine is continued.

A noteworthy observation important to be made is, that Mr. Adams changed the construction as shown by his earlier valves, from equal areas of the balancing ring to an increased area of contact with the cover over that of the steam acting to lift the ring, with what results cannot here be given.

The precise proportions with reasons therefor were not gone into; the writer in proportioning his valves worked under the

Fig 7



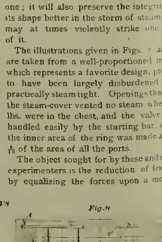
belief that all that detail had been well gone over, therefore, with confidence in the designs already established, the simpler form of valve-ring with equal areas was made and applied to several stationary mill engines with good results, prior to and during the year 1876.

Of course a thicker ring will wear longer and "stand the racket" better than a thin one; it will also preserve the integrity of its shape better in the storm of steam that may at times violently strike one side of it.

The illustrations given in Figs. 8 and 9 are taken from a well-proportioned model which represents a favorite design, proven to have been largely disburdened and practically steam tight. Openings through the steam-cover vented no steam when 80 lbs. were in the chest, and the valve was handled easily by the starting bar, when the inner area of the ring was made about $\frac{1}{16}$ of the area of all the ports.

The object sought for by these and other experimenters is the reduction of friction by equalizing the forces upon a moving

Fig.9



ring or sliding plate in fluid under pressure and they have tried to solve this problem in about the same manner and by very similar means.

Attempts were made early in steam-machinery time to get a perfectly balanced packing ring. Tredgold, in 1838, said "The rubbing surface of a piston must be pressed against the cylinder with a force at least equal to the pressure of the steam it confines, otherwise the surfaces would separate and the steam escape."

Very naturally, equal pressures of the same fluid when exactly opposed to each other would result in a complete relief of resistance to the sliding part, if *capillarity* did not interfere—a phenomenal force not suspected in this case—the existence of which could only be proven by experiment.

The weight of evidence presented by these authorities seems to favor the results of Prof S. W. Robinson's carefully conducted experiments and of Mr. Adams' later constructions, which point to the conclusion that the pressure in a joint, called the *creeping* pressure, is about half—per square inch—of the pressure of the same fluid when freely acting in an opposite direction.

Nevertheless, a practically tight and free working valve was made and used in 1872, by your writer as referred to above, and this was done by a balancing ring having equal and opposite areas exposed to the same fluid pressure.

Fig. 8 gives a plan of a plain *D* slide-valve *V*, to which a cylindrical ring, *B R*, is fitted. A section of the same is shown in Fig. 9, through the axis of the valve-stem, the opening for which is plainly seen at *L* on both views, with facings for the nuts upon the stem, by which latter the valve is adjusted and moved.

A circular rib is cast upon the back of the valve to which a follower *F* is fitted and bolted. The outer face of this rib is recessed for the reception of packing rings, two of them fitting against the inner face of the balanced ring, and one of them within the aforementioned two rings; all three are cut, fitted to break joints and are turned to set firmly against the inner face of the balanced ring, to which they are also assisted by steam from the steam-chest, which reaches a recess turned in the rib on the valve, back of the inside packing ring, through small drilled holes beneath the edge of the balanced ring, one of which is shown. The follower *F* keeps the packing rings in place in the same manner as is done for steam pistons.

UP IN THE WORLD. THE HIGHEST RAILWAY BRIDGE ON EARTH. ERIE RAILWAY.

The balanced ring has a groove turned in its inner face, into which the ends of three flat springs *S* project. These springs are bolted to the radiating tri-rib of the follower, the whole so fitted as to permit the balanced ring to play up and down a small distance upon the rib on the valve, and to have such a set to the springs as to maintain a gentle contact of the top edge of the ring to the steam-chest cover, to which it is made to fit steam-tight, and on which it will freely slide.

The normal position of the balanced ring is to *just touch* the face of the steam-chest cover when no steam is on.

This particular valve design is for a stationary engine, having the face of the valve vertical; in which case there would be no tendency of the ring to part from the steam-chest cover by gravity. With an horizontal valve face the *weight* of the ring must be carried by the springs

At *A*, the inner corner of the ring is turned out, this slightly reduces the contact area of its upper edge, giving the steam an advantage, by its pressure upward, on the lower edge, which has now become relatively greater, thus insuring contact and tightness of the ring to the cover.

It will be noticed that, so far as principle goes, this valve does not differ from the Adams or the Desgrange valve It simplifies and cheapens and offers a design more readily and effectively applied to existing conditions of cylinders and steam-chests, with which we have to deal.

This valve is shorter—motion-wise—at its middle than at its ends, this was done to admit steam and cut off the same *gradually*, the only object being to *quiet* the working of the engine, which it accomplished most effectually.

In some of Adams' valves for locomotives, two of these balancing rings were placed upon the back of one valve—one on each side of the stem.

Adams' valves were used on locomotives on several roads in England satisfactorily, as reported by *Engineering* for November 9, 1866.

It will be noticed that, for and upon locomotives, this form of equilibriated slide-valve was first tried.

Valves which have different strokes at different times should be fitted with a lip or flange to the top edges of their balanced rings, to be made wide enough to cover the difference of strokes, in order to prevent wearing a shoulder upon the working face of the steam-chest cover.

This whole subject is much a matter of history, and will serve as a lesson to those who intend to solve this difficult problem.

To the writer there are two details of a steam engine which, perhaps more than any other, because invisible while working, need careful designing and better workmanship; these are a free-running, yet always steam-tight, piston and a disburdened slide-valve, which shall act as a relief to compression in the cylinder and which will never leak steam during normal running.

*Philadelphia, Pa.*

### Growth of the Boring Tool.

A writer says "The first boring tool may be assumed to be an awl of some kind. Pliny states that Dædalus invented the gimlet in 1240 B. C. It was destitute of a screw point, but it may have had a hollow pod, and a cross-head forming a handle. Awls are shown in Egyptian tombs of 1700 and 1490 B. C The screw point was added to the gimlet in course of time, and within our own recollection the twisted shank, which makes it self-discharging. The hint was taken from the auger proper, which may be called a magnified gimlet, now that their specific features have become so closely assimilated in form and function. The auger (*terebra*) was a Greek tool From the early descriptions, the auger seems to have been considered a shipwrights' tool. It formerly had a curved, sharpened end, and a concavity to hold the chips; this was a pod auger. To this a lip was subsequently added for some kinds of boring, and in course of time the depression grew into a spiral, which allows the chips to escape while the boring proceeds, instead of withdrawing the tool as the pod becomes filled. The twisted auger is the American invention, and was made by Lilley, of Mansfield, Conn., about the beginning of the present century, and afterward by Gurley, of the same place. Augers may be classified as augers, annular augers, taper augers, augers with secondary bores, reamers, or countersinks, or having expansive cutters."

---

The Reading Railroad is celebrated in several ways, and the affairs of few railroad companies receive so much attention from newspapers. The most interesting thing about the road to us is the number of its boiler explosions The company owns about 700 locomotives, many of them very old, and it is difficult preventing some accidents to boilers, but having a boiler explosion every week or two indicates gross mismanagement in some quarter. There have been two boiler explosions on the Reading since our last issue was published, both resulting in loss of life. Explosions at rare intervals happen through gross carelessness of the engineer, but 99 per cent. of such disasters are caused by weakness due to deterioration which thorough inspection would detect It is a convenient explanation to say that a boiler explosion was due to low water, but low water very seldom causes an explosion, even when crown-sheets and upper tubes are destroyed. One railroad company we know of has had hundreds of crown-sheets burned and no explosion. Broken stay-bolts and furrowed sheets are what nearly always cause sudden rupture of sheets that start an explosion. This is preventable. It is a disgrace to the State of Pennsylvania that fatal boiler explosions happen weekly, and no successful effort is made to locate the responsibility for this species of murder.

The *Electrical Review* (New York) people have got out a special number of nearly seventy pages to celebrate the beginning of the tenth year of the paper. The number is handsomely illustrated and contains a great many interesting articles on electrical subjects. Parties interested in electrical matters would do well to send for this paper.

### To Help in Making Boilers Safe.

"Drilling the ends of stay-bolts is not a reliable means for detecting breakage," remarked a bright master mechanic during a recent visit to this office. "When breakage takes place," he continued, "the fracture is gradual, and leakage into the drilled opening is just sufficient to permit that so-called safe-guard to get filled solid with lime. The lime prevents leakage as completely as if the bolt was solid. Drilling the stay-bolts is a little worse than useless, because it makes the men in charge of the boilers neglect inspection and rely upon the holes to show when a stay-bolt breaks. The plan may be all right for roads that use soft water, but it is no use where the feed water is heavily charged with lime."

This statement was very much of a surprise, for we had heard the plan of drilling holes spoken of very favorably by master mechanics of Western roads. We incline to believe that the real lesson of this experience is not to rely implicitly upon any single method of detecting such a dangerous weakness to a boiler as broken stay-bolts. For a time the hammer tests were in great favor for the detection of broken stay-bolts, but observing men noted, when many fire-boxes had to be put in, that numerous stay-bolts were found broken, although they had passed the hammer test as giving sound. When this condition of things began to be realized there was a sudden reaction, and the hammer test was denounced as worse than useless. The real trouble was that the hammer test, like many another mechanical operation, is of no value when done by an unreliable workman. When performed by a skillful, conscientious man the hammer test is one of the best methods of finding out the condition of stay-bolts.

We incline to think that the drilled hole is a very useful aid in detecting broken stay-bolts, but it requires attention. If it is considered sufficient to drill the hole and let that go as a complete safeguard, without constant vigilant supervision, the plan is likely to fail. If fireboxes having the drilled stay-bolts are inspected minutely at short intervals, an expert will find indications that are likely to identify those that are broken. It is a good plan to employ a man as inspector who has brains enough to induce reasoning from effect to cause. One of the richest men on this continent laid the foundation of his fortune by reasoning from effect to cause in a case which others supposed to be trifling. He was almost a boy, but had found himself floated by the gold fever to California, and was sitting with a group of others beside a mountain stream eating a scanty lunch. The luck of the camp where he was had been wretched, and the place was supposed to be on the outside edge of the gold fields. As the party sat beside the stream the youngest noticed a cork floating past. He instantly reasoned, if a cork comes from the unknown regions above there must be civilized men there. So with his partner he started up stream next day and struck it rich.

The boiler inspector requires to have this faculty of acute reasoning. With an incompetent man a small congealed tear at the end of a stay-bolt hole means nothing, while a man of brains reasons that it has come from the inside and that therefore the bolt must be cracked. The same line of reasoning applies to all distortions of form that indicate internal breakage and to numerous other signs of weakness soon liable to become dangerous. There is too much tendency in railroad shops to assume that any boilermaker is competent to act as a boiler inspector. A man to fill this position successfully must be selected with much care and good judgment.

A good many railroad companies and locomotive builders have adopted the practice of making the stay-bolts flexible at the points where breakage occurs most readily, and we believe that no case of breakage has occurred where the bolts are made to adjust themselves to the movement of the sheets. This practice appears to be worthy of general adoption. But this or any other improvement ought not to lessen the stringency of inspection. Flexible bolts, drilled ends or hollow stay-bolts, the hammer test, the hot-water-pressure test and systematic inspection are all needed to make boilers safe under the intense working pressure becoming common.

### Re-keying on Eccentric Sheaves in Wheel-Shop.

BY A. A. MAVER.

There is no doubt the most reliable method of setting sheaves is to set them by the motion under each individual engine, but cutting key-ways under an engine is awkward, and therefore slow work, and often causes delay when the engine is otherwise ready to be hustled out of shop.

To set them in the wheel-shop to a staff marked by calculation is not always trustworthy, as there may be some peculiarity about the motion which will cause the position of sheaves to vary from the calculation.

We key on all our sheaves in the wheel-shop, and find it satisfactory practice.

Our method may not in all cases be so absolutely correct as the first mentioned, but I have never found it to vary from accuracy sufficient to be of practical importance, and it has advantages over the other which more than compensate for what it may lack in perfect accuracy.

We mark a staff for each class of engine from sheaves that have been set under the engine by the motion; a new engine or one that has been thoroughly repaired and with parts to standard is used for the purpose.

In order to make it quite clear, I will describe in detail our method of marking a staff for the use of wheel-shop.

We will suppose an engine has had thorough repair, a new driving-axle, and all parts to standard, the sheaves have been set by the motion, and the straps have been removed preparatory to taking off the sheaves to cut the key-ways. Before the sheaves are disturbed, we place one of the cranks on the forward center, and level center of crank with center of axle; we do this by describing a circle from center of axle the same diameter as that of the crank-pin at crank-hub, and then level by placing plumb square on crank-pin and to top of circle on axle. The staffs we use are 31 x 2¼ x ½ inch, made of well-dried cherry and varnished.

We now place one of these staffs level on two planks, which have been laid across the pit and under the forward gear-sheave. A line is then hung over this sheave with a weight at each end, a similar line is hung over the axle close to sheave, the staff is then marked with a square where the lines on the sheave touch its edge, the axle lines are marked in the same manner.

The crank is then put on the back center and leveled, the staff is reversed end for end, and the axle marks placed to the axle lines; the sheave line is then hung over the back gear sheave and in most cases it will be found to coincide with the forward gear sheave marks, but if they do not, mark the staff to the back gear lines. I herewith inclose a copy of one of our staffs where the marks do not coincide; in this case, were the back gear-sheaves set to the forward gear marks, the lead of the back gear would be double that of the forward gear. And herein lies the advantage of marking a staff from sheaves which have been set by the motion; for if there is any peculiarity it is discovered in this way.

The staff being marked as described is used in wheel-shop when keying on sheaves for this class.

A North Countryman, in describing how sheaves should be placed on axle in wheel-shop, used to say "Standin' between the wheels, mak' the richt crank-pin twal' o'clock, and iv the motion's indirec' set the throw of the back-gear sheave aboot twal' meenits to twal' an' the fore-gear sheave aboot twal' meenits past; reverse the posections on the left side," which is a fair guide when putting sheaves on axle, prior to finally setting by the lines and staff, each crank is then leveled in turn, the lines placed over sheave and axle and the staff placed with axle marks to axle lines, the sheave is then moved on axle until sheave lines coincide with sheave marks, and to this position it is keyed. Before closing I will mention another advantage in this practice.

An engine comes in with broken, bent or twisted driving-axles, requires a new one, the motion is half or partially worn, to set the sheaves accurately by this motion would necessitate its being overhauled, and to set them by it in its worn condition would mean resetting them next time the engine is generally repaired in order to give the proper lead.

By keying to standard we put them on precisely as they had been on the old axle.

*Grand Trunk Locomotive Works, Stratford, Ont.*

STAFF FOR SETTING ECCENTRICS.

### No Spark Arresters the Best Spark Arrester.

At the New York Railroad Club the question was discussed: Is any device using a netting a real spark arrester? If there were absolutely no laws on the subject except that roads should pay for damage done by fires caused by locomotives, would any of us use extension fronts or diamond stacks? The discussion turned principally on the merits of different kinds of spark arresters. Mr. Dixon, of the Rogers Locomotive Works, mentioned a case where he had seen an engine worked without any spark arrester, and he testified to the free steaming properties of the engines. Mr. Angus Sinclair had handled engines without any spark arresters what ever, and others with what are regarded as the best spark arresters. He never found a locomotive working hard that did not throw sparks, but he believed that an engine having no spark arresting obstructions to the draft could be made to steam with such large nozzles, that no more sparks would be thrown than what pass through the best spark arresters. Mr. D. H. Neale, who has had extended experience with engines with and without spark arresters, agreed with the views of Mr Sinclair.

THE CRACK FAST TRAIN OF IRELAND—THE DUBLIN-BELFAST MAIL.

### The Dublin-Belfast Mail.

The picture shown herewith explains the make-up of the fast mail between Dublin and the north of Ireland.

On the side of the first car can be seen a large iron frame covered with a heavy rope-net that is used to catch mail-sacks with. This device catches the sack so far from the side of the car that they are subject to severe shocks, and are often broken off.

The mail-cars are eight-wheeled, with a swiveling truck, with the exception of the rear one, which is an old-fashioned six-wheeler.

The engine is the regulation "single" used on all fast trains on the other side.

One of the firemen on the "smooth line" of the U. P.—the old New Orleans road—writes to say that, though it is claimed their road is behind on account of using the Fisher joints, they do beat the Rio Grande once in a while. He seems to think the reason they get away with the Rio Grande boys is because their diamond stacks do better than the "smooth bores."

### Sleeping Cars for the Masses.

The railroad companies expect to reap a golden harvest this season in carrying passengers to and from Chicago. An effort will be made to keep the rates sufficiently high to give the companies some profit on the business done, but the indications are that the minds of managers and general passenger agents will be exhausted scheming attractions intended to draw patronage. From what we have seen and heard of the novel attractions offered, we are under the impression that one of the best cards in the railroad pack is about to be neglected. Every effort is making to induce workmen and people of slender means to visit the World's Fair, but no railroad company is making systematic provision for carrying these people comfortably during a journey that lasts longer than a day. They must either sit up all night or pay the price of an ordinary sleeping car. Sleeping cars are not popular with the masses because they cannot afford to pay $2 for a berth, and sitting all night in a day-car is a hardship that many people dread to encounter. If a railroad company with a through line to Chicago would make clean, comfortable sleeping cars similar to the tourist cars run on some Western lines, and give this extra accommodation without charge, they would secure all the passenger travel they could accommodate.

This matter of sleeping-car accommodation is badly in want of reform. The lavish outlay for costly upholstery and the profusion of embellishments designed for mere display and to gratify snobbish tastes, keep up the expense of this accommodation, and is carrying the sleeping-car business away from the people and into the hands of the luxurious classes. The luxurious sleeping-car service has built up interests which oppose the introduction of less costly cars for the accommodation of people who cannot afford to pay high rates. The number of the latter class far exceeds the class which pays the prevailing rates, with or without a murmur. The wise policy for railroad companies to follow is that of accommodating the greatest number when the business pays. No attempt has ever been made to find out how well it would pay to give the common passenger decent night conveniences. The majority rules in this country, and some day the majority of travelers will make demands for justice in a fashion that will brook no refusal.

There is some talk among air-brake inspectors of forming an association of their own, but we doubt the wisdom of such a move. The Traveling Engineers' Association have offered the air-brake inspectors full membership in their order, and quite a number of them have already become members. Every air-brake specialist should write to W. O. Thompson, Secretary of the T. E. Association, Elkhart, Ind., for particulars and application blanks, and get into the new educational body at once.

### Brake Leverage.

BY WILL W. WOOD

The standard air-brake equipment is generally accepted as all right if the triple valve does its duty and the brake piston moves out with sufficient force; for instance, a 10-inch brake-piston should transmit to cylinder lever at its point of attachment a force of about 4,000 pounds full service application, and can be depended upon to do it every time at a two-thirds piston travel. There is great interest taken in the mechanism that supplies the power and little or none in the correct distribution of the braking power to the shoes. It may be too light and the road is not getting full benefit of the price paid for the equipment, or it may be the power is so great that wheels and the company's pocketbook are flattened.

THE PAST.—FINE (PASSENGER) WOOD BURNER OF THIRTY YEARS AGO. No. 1. SOUTH CAROLINA RY.

Sometimes one finds the push-rod attached direct to a *dead* cylinder-lever, in that case it is likely that the trucks at one end of the vehicle receive too much braking power and the other trucks too little.

The brake people guarantee that their brake pistons will push out with a certain force, but they cannot guarantee anything further unless their standards are followed to the wheels. The W. A. B. instruction book gives rules and formulæ for finding out just what a brake is doing. It may be simplified, however, as they refer to levers of three kinds and give four formulæ, when really there are but two kinds of levers and six formulæ are necessary to calculation.

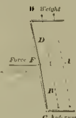
The instruction book shows a lever having power applied at an end, weight depending at opposite end and fulcrumed intermediately, and calling it a lever of the first kind, while the same lever, but with weight and fulcrum reversed, is called a lever of the second kind. Now, levers of the first and second kind may be classed as one, for it makes no difference in calculating their dimensions or power which of the second and third points of the lever is fulcrum or weight.

A cylinder-lever, for instance, at one end the push-rod connection is the point of power, the two pull-rods of the brake are connected with the lever and give the points of fulcrum, and weight and any problem relating to dimension or power of a cylinder-lever may be worked out per formula for either a lever of the first or second kind.

I would divide levers into but two classes and give six formulæ as there are six points, any one of which may be unknown, viz.: force, weight, fulcrum, length of lever, length of lever between force and weight and length of lever between weight and fulcrum. (Lever of the second kind.)

Any lever having force applied at an end I would class a lever of the second kind, indicating the point of leverage nearest the force as *weight* and the farthest point of leverage, *fulcrum*, thus:

When force is applied between the points of *fulcrum* and *weight* it is a lever of the third kind and the three points of leverage bear in the same direction. A brake-beam is a good illustration of a lever of this kind. The two brake-shoes are *fulcrum* and *weight*, but they do the same work and either may be called fulcrum or weight.

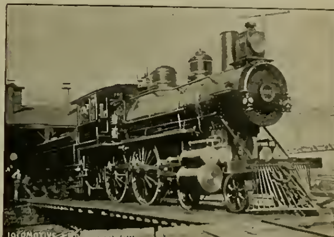


The complete formulæ for calculation of each kind of lever are

$$W = \frac{f \times b}{a} \qquad A = \frac{f \times b}{w}$$

$$F = \frac{w \times a}{b} \qquad B = \frac{w \times a}{f}$$

$$C = \frac{f \times d}{a} \qquad D = \frac{c \times a}{f}$$



THE PRESENT.—FASTEST ENGINE IN THE WORLD. No. 385. COMPOUND. CENTRAL R. R. OF N. J.

### California Redwood.

A visitor to the railroad car shops in California is apt to be struck with the splendid timber in use for car building purposes in the shape of redwood. This timber is remarkably good in all respects for car building, and it has the quality of being slow to ignite or burn, which ought to commend it for the building of passenger cars in the East as well as in the far West.

The people connected with wood-working in California appear all to be proud of the great redwood tree, which does not grow north of the State line. Its largest body, amounting to 500,000 acres, according to estimate, is in Humboldt county, extending about fifty miles north and south of Humboldt bay. This body contains more timber than all the other redwood forests in the State. Redwood has been manufactured on Humboldt bay for thirty-five years, the present output being about 200,000,000 feet in a year. Most of the lumber is marketed in San Francisco and the interior valleys of the State—though considerable shipments have been made to Australia, the Pacific islands and the west coast of South America. But with the exception of Eureka, the coast towns are built up in large part with other woods, redwood being mainly employed for finishing purposes. Eureka, however, is built up of redwood almost entirely, and is claimed to be the only city on the coast of any age that has not suffered seriously by fire. All the cities that have been swept by fire were constructed mainly of fir—so-called pine.

The trees are so large that in comparison logs of white pine are contemptuously designated poles. The redwood grows on every quality of soil in the State, on the river bottoms, on the tops of the highest ridges or on steep side hills, flourishing everywhere. Nothing definite can be told about the amount of redwood standing in Humboldt county, because in approximating it it would be necessary to estimate each quarter section separately, owing to local variations. Some estimates are gross exaggerations—others far below the truth. Quarter-section claims that will cut 16,000,000 feet, are by no means unusual, even on hill land, while a yield of 50,000 feet to the acre is called fair. Fifteen trees to such an acre would be very small for redwood. Some trees yield as high as 25,000 or 30,000 feet, while a single log, 12 or 14 feet long, often contains from 4,000 to 6,000 feet. It is a daily occurrence in the woods when steam engines and block and tackle are employed simply to roll over the larger logs, and fourteen or sixteen oxen will strain all their energies to haul three or four redwood logs down hill.

In the course of a report made to the general manager of the Cincinnati Southern on a test of simple and compound locomotives, Mr. James Meehan, superintendent of motive power, directs attention to the difference in evaporative power of good and inferior coal. He says the difference is 33 per cent. in favor of the good coal, and this is by no means offset by the difference in price. This is a subject that deserves much more consideration from railroad managers than it usually receives. It is quite common to find coal differing in heating power all the way from 25 to 50 per cent., and yet they will hesitate to pay 10 per cent. more for the superior coal.

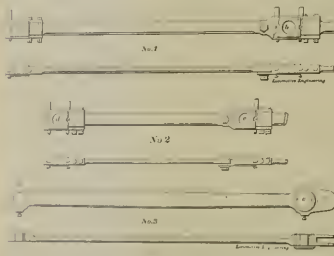
Did you ever try cleaning a greasy smoked head lamp chimney by filling it partly with clean sand, then holding your hand over one end fill nearly full of water, closing the other end likewise, shaking thoroughly, rinsing out with clean water, giving the outside a rubbing with your gritty hand while so doing. Try it once and you will be surprised at your job and the case with which you did it, after which you will throw no more dirty globes away because you cannot get them clean.

## Shop-Work—Side-Rods.

BY OBSERVER

In this day of improved locomotive construction we would almost be made to believe that the day of faulty design had become a thing of the past, but inasmuch as we have the locomotives of the past to contend with, practical experience has to determine the economy and convenience in repairs of the different constructions.

The inclosed sketches are side-rods of three different builds of six-wheeled connected 18 x 24-in. locomotives. No. 1 has adjusting keys on middle connection rod, which reduces the strength of strap at the part where strength is most needed. I have known of three locomotives with side rods constructed like sketch No. 1 to break strap through key-way at *A*, breaking driving-wheels on main axles, pulling driving-wheels partly off front axle, and in one case breaking main driving-wheels, and breaking pedestals and bottom braces out of main part of engine frame. During a few years' service of engines equipped with side-rods of this construction, twenty-five middle connection straps had to be replaced, as the straps were found to be cracked through corners of key-way at *A* and *B*. The new straps were constructed like No. 2, with adjusting keys on back strap, in no case where the middle connection straps were changed in construction from Fig. 1 to Fig. 2 had a middle connection-strap been broken.



Good service can be had by dispensing with inside adjusting keys and using the two outside keys, but it requires a little more care in adjusting rods.

Although No. 1 is defective in the construction of middle connection-straps, No. 2 also has its defects; the butt end of middle connecting-rods of No. 2 are smaller than butt end of rods in No. 1, and do not admit of as large crank-pins. The diameter of side-rod journals of middle connection of No. 1 are $4\frac{1}{4}$ in., where in No. 2 the diameter of crank-pin journals are but $4\frac{1}{2}$ in., the crank-pins are frequently broken with No. 2 rods, but no middle connections have been broken; the reverse is the case with No. 1.

Middle connection-straps are broken, but no crank-pin, by enlarging the butt end of connecting-rod, strap and crank-pin of No. 2 to dimensions of No. 1, and changing construction of strap of No. 1 to that of No. 2, better results will be obtained.

No. 3 is, in my judgment, the best construction of a locomotive side-rod; they are less expensive to make, are much easier to repair, and less expensive to maintain; they also have their defects. Engineers will neglect them, and, like every other part of machinery when neglected, they will run hot. When the brasses do run hot, the brass expands more than the eye of the rod, the brass becomes compressed in the eye of the rod when hot, and when cooled off the brass is loose in the eye and tight on the crank-pin. To repair the brass after having once run hot, the usual way is to put a liner around the brass, press the brass back into the eye of the rod and ream out hole in brass to fit crank-pin, but as the holes in eyes of rods are of a size all the way through, and the liner will wrinkle when the brass is being pressed into rod, it is rather a difficult operation to press a brass with liner into a solid side-rod and have the liner fit solid the length of the fit of brass in rod. If the hole in eye of side-rods were bored to a taper of $\frac{1}{8}$-in. to the foot, it would be much less work to repair brasses with liner.

It is not always convenient to get new brasses, it is good practice when connecting-rods are taken off for repairs to have them taken to the blacksmiths' shop, heated to a dull red heat and examined for cracks. A small crack can be found in this way when any other mode of inspection has failed to determine any defects.

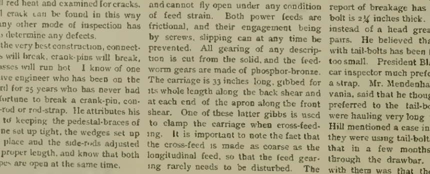
With the very best construction, connecting-rods will break, crank-pins will break, and brasses will run hot. I know of one locomotive engineer who has been on the footboard for 25 years who has never had the misfortune to break a crank-pin, connecting-rod or rod-strap. He attributes his success to keeping the pedestal-braces of his engine set up tight, the wedges set up in their place and the side-rods adjusted to their proper length, and know that both sand-pipes are open at the same time.

Not long ago, January 24th, so say three correspondents, a N. P. freight engine took a dive off the big ferryboat between Kalama and Hunters Landing, on the Columbia River. The train, a freight, was run on the boat and the crew went to lunch at the lunch-counter aboard, as is the custom. When nearly across it was discovered that the engine was missing. The story seems almost incredible, but it is vouched for by railroad men on the coast. How the engine could dive off the boat without the pilot seeing it, or the crew of boat or train not feeling the shock of her desertion, is more than we can understand.

## Bogert's Improved 20-inch Engine Lathe.

The annexed engraving illustrates Bogert's 20-inch engine lathe, a tool well worthy of the attention of railroad mechanics. Swing over top of cross-slide, $14\frac{3}{4}$ inches; length of bed shown, 10 feet 3 inches.

The head-stock has carefully fitted adjustable boxes, lined with the best phosphorized babbitt metal. The front bearing is $3\frac{1}{2}$ inches in diameter by $5\frac{5}{8}$ inches long, and its cap is held down and adjusted by four $\frac{3}{4}$-inch bolts. The live spindle of very hard crucible steel has, unless otherwise ordered, a $1\frac{1}{4}$-inch hole through its axis, carries a four-step cone for a $3\frac{1}{2}$-inch double belt, and a front gear $14\frac{1}{4}$ inches in diameter. Its end thrust is taken upon hardened tool-steel collars with sides ground perfectly parallel. The ratio of the back gearing is 12 to 1, which, taken in connection with the diameters chosen for the corresponding steps of the over-head and main cones, makes the speed of rotation of the live spindle decrease in exact geometrical ratio from the fastest to the slowest. A very accessible rocking device on the back end of the head-stock enables the direction of the feed to be instantly reversed without disturbing the change gears. The lead-screw is $1\frac{3}{16}$ inches in diameter, cut three threads to the inch, and is made as accurate in every way as practically possible. The usual variety of threads from one to sixteen per inch can be cut with the change gears without compounding. The thread of the lead-screw is used only for screw-cutting, the longitudinal and cross feeds being driven by means of a large key-way or spline. The half-nuts are opened and closed by one-third of a revolution of two single-threaded screws of large diameter, and cannot fly open under any condition of feed strain. Both power feeds are frictional, and their engagement being by screws, slipping can at any time be prevented. All gearing of any description is cut from the solid, and the feed-worm gears are made of phosphor-bronze. The carriage is 33 inches long, gibbed for its whole length along the back shear and at each end of the apron along the front shear. One of these latter gibbs is used to clamp the carriage when cross-feeding. It is important to note the fact that the cross-feed is made as coarse as the longitudinal feed, so that the feed gearing rarely needs to be disturbed. The cross-slide, $20\frac{1}{4}$ inches long, is fitted with one of Bogert's patent double-screw tool posts. A telescopic slide by its movement protects the cross-feed screw from chips in any position of the tool. The tail-stock may be set over, to line the centers, and is clamped to the bed by two $\frac{3}{4}$-inch bolts. The tail-stock spindle is $2\frac{3}{8}$ inches in diameter, and $10\frac{1}{2}$ inches long. The center-rest will admit work from $\frac{1}{2}$ of an inch to 9 inches in diameter, without change of jaws. The follow-rest is made either with adjustable jaws or with a split hole, to clamp bushings. Bogert's improved friction clutches and Bogert's improved method of oiling loose pulleys are features of the counter-shaft. Counter-shaft pulleys, 15 inches in diameter and 4-inch faces, should make from 160 to 180 revolutions per minute; the backing pulley should be run at least as fast as the latter speed for screw-cutting. When the nature of the work makes it necessary or desirable, Bogert's improved compound rest may be applied to the top of the cross-slide, without any change in its construction. Tapers up to four inches to the foot can be readily and accurately turned with Bogert's improved taper-turning attachment without disturbing the allignment of the centers. This device must be provided for in the construction of the lathe. The bed, owing to a proper distribution of metal, is stiff and rigid, its design and arrangement of cross-bracing being the result of the careful thought and experiment of years. In 1882 Mr. Bogert made the first drawing for a machine tool with its bed deeper in the middle than at the end, and in 1885 tapered the ends and at the same time brought the legs nearer together. His uniform practice in the case of lathes is to make the inside edge of the upper surface of one of the legs plumb with the front end of the head-stock, and locate the other leg the same distance from the other end of the bed. An elliptic curve to the lower edge of the middle portion makes the elevation symmetrical, and best provides for the strain of use.



NEW ENGINE LATHE. JOHN L. BOGERT, FLUSHING, L. I.

## Tail-bolt or Yoke?

There was a discussion at the New York Railroad Club on which offers the most security for automatic couplers, a tail-bolt or a yoke attachment? Mr. C. A. Smith, of the Union Trunk Line, said that they have about 2,000 cars equipped with a tail-bolt that has two keys and no head. They have been in use over two years and no report of breakage has been made. The bolt is $2\frac{1}{4}$ inches thick. The use of a key instead of a head greatly facilitates repairs. He believed that all the trouble with tail-bolts has been from making them too small. President Blackall said that his car inspector much preferred a tail-bolt to a strap. Mr. Mendenhall, of the Pennsylvania, said that he thought the strap was preferred to the tail-bolt on roads that were hauling very long trains. Secretary Hill mentioned a case in the South where they were using tail-bolts with small heads that in a few months wore their way through the drawbar. Another trouble with them was that the tail-bolt turned half round and the key dropped out. Mr. Montgomery had seen many tail-bolts broken but never a tail-yoke.

In almost every large railroad shop in Europe a visitor, who is allowed inside, is given a small print showing a ground plan of the works. On this is mapped the route that will be taken, into this shop and out and into that, until a complete circle is made. This path is shown by a dotted line and an occasional arrow. The plan seems a good one and is a nice memento for visitors to carry away. The different shops are marked, sizes are given, etc. Would not this plan pay in this country?

### Confusion about Meum and Tuum.

A report from Chicago that a smoke-stack 34 x 4 feet had been stolen, and that no clew to the thieves could be obtained, testifies to the purloining ability displayed in the windy metropolis. What we wonder at is that the thieves did not carry away the factory as well as the smoke-stack. There is a growing dullness of perception in not a few western communities as to the distinctions between "thine" and "mine." In New Mexico and southwestern States generally, there is a growing idea that railroad property belongs to those who care to take possession of it.

The Santa Fé Railroad Company have lately been wrestling with an organized band of robbers, consisting of trainmen, station agents and others, who stole freight by the wholesale. They used to stop trains at out-of-the-way points and take out of the cars any articles they could dispose of. In one case they tried to steal a grand piano, and had a wagon ready to carry it away, but there were not enough men on the train to lift the instrument. About fifty persons have been arrested for connection with this thieving set, but the sympathy of the people in New Mexico is so strongly in favor of those who despoil railroad companies that there is no likelihood of any conviction.

People in these parts consider it the duty of railroad companies to supply them with coal without charge. There was nearly a riot in one town when the Union Pacific fenced in their yards to prevent people from driving in to carry away coal any time they wanted a load. The better classes of western communities consider stealing coal by the wagon load to be slightly reprehensible, but for a poor man to wheel away a barrow load or to carry away a sackful is regarded as right and fair. A railroad company that would object to have coal carried away in small quantities of this kind is considered mean enough to put locks and bars on its freight-houses.

The junior philosopher of this journal once, in an unguarded hour, revealed how he had been duped by a verdant-looking ranchman in a coal operation. "Coming it strong" was never more brazenly imposed upon "Truthful James." Our J. P. had his engine in a yard in Colorado one evening, just before dark, and an innocent looking native of the plains came up and asked if the engineer would be so kind as to push a certain coal car up to the end of the yard. The J. P. was ready to oblige, and pushed the car to the point desired. In the morning he learned that the coal belonged to the company and the man wanted it set at a point where people would not be likely to see that he was stealing it. The car was empty when the sun rose upon the scene.

### Loose Nuts.

In an article which we published last month on diverse sizes of taps and dies, we pointed out some of the evils which result from the practice of ordering these articles different from the correct dimensions. We notice in a speech made by Mr. A. M Waitt, general master car builder of the Lake Shore Railway, at a club meeting, corroboration of some of the points made in our article. He says: "I have in my office two draft-timber bolts that were applied to a Lake Shore car a few weeks ago by a large connecting line that has adopted M. C. B. standards. The bolts are standard size, but the nuts are so loose that by just a little impetus they will unscrew over nearly two inches of thread. They are therefore in such condition that when the nut is screwed up a little jar will cause it to fall off."

This is what comes of making the tap a little larger than the standard size and the die a little smaller so that more service will be obtained from them before they wear out. Strange kind of economy this is. Every railroad track in the country is strewn with nuts that fall off cars and locomotives, and much of the slacking back is due to loose fits. We wonder how many expensive wrecks have been caused by the practice of using big taps and small dies for economy's sake? It would be a profitable theme for those who are trying to save money by deviating from standard sizes, to speculate on how many people have lost their lives in wrecks that were directly due to the loss of nuts or bolts that held running gear together. There is an old rhyme telling that, for want of a nail a shoe was lost and for want of a shoe the horse was lost, with many other expensive consequences. The nut on a car's running gear performs more important functions than the nail in the horse's hoof, and the consequences of this little member of the machine being badly secured are too serious to be trifled with.

---

Those who have seen composite car bolsters and transoms in use on cars running in extremely dry climates are not likely to be favorably impressed with any advantage of using a combination of wood and iron in one piece. The alternate shrinking and swelling of the wood disintegrates the parts made of material having so little natural unity as wood and iron, and the call for repairs is greatly magnified.

### Iron Tender Frames.

Metallic members are gradually forcing their way into use for all parts of railroad rolling stock, but there is intense reluctance displayed by many designers to change from the shrinking, rot-inclining wood to the firm and durable iron and steel. This is very well illustrated in the reluctance that so many railroad men display to adopting iron or steel frames for tenders and in the inexplicable clinging to wood for parts of trucks for which the material is conspicuously unsuitable. There are very few wooden tender frames now made by the leading locomotive builders, but a few railroad companies still specify them. How this is done shows the force of a tradition and shows how slowly fallacies are rooted out.

GREAT LOOP, COLORADO MIDLAND, WINDING UP THE ROCKIES NEAR HAGERMAN TUNNEL.

THE BIG TRESTLE ON THE GREAT LOOP, NEAR HAGERMAN TUNNEL COLORADO

At a Master Mechanics' convention many years ago, when iron tender frames were coming into use, a speaker criticised the practice on the grounds that iron tender frames would be difficult to repair in case of a wreck. There was the usual opposition to a radical change so well known among our conservative railroad men, and the objection that a wrecked iron tender frame would be costly to repair was accepted as an inspiration. The belief has passed as gospel ever since. Yet it is false doctrine, as any one may readily find out on roads where wrecks and well-designed iron tender frames are found in company. The metal tender frame stands wrecks much better than wooden ones, but if it did not that would be a poor argument against the material, for rolling stock is not designed with a view to making it successful in a wreck. The real test is how it behaves on the track. The metal tender frame has come to stay, and it is preparing the way for car frames being made of the same kind of material.

A committee of the Railway Master Mechanics' Association has just issued a circular calling for information about tender frames. We should like those who can speak from experience to send in all the facts in their possession about the relative value of wood and metal for tender frames. It would be well to mention how the iron tender frames behave in wrecks. The wooden one generally goes to pieces.

---

California has passed a law making it a misdemeanor for newspapers to claim more circulation than they have. We sincerely wish that this law could be passed in every State. If the newspapers of this country don't obtain money under false pretenses, in claiming ten times as much circulation as they have, we miss our guess.

## Causes of Breakage.

In the course of a discussion at one of the railroad club meetings some edifying information was given about the breakage of tail-bolts of draw-bars that to the reflective mechanic is applicable to all parts of machinery that are given to breaking. No means of attaching the draw-bar to the plates connecting with the draft timbers has been so simple and so satisfactory as the tail-bolt, especially when repairs have to be made. This attachment, with all its merits of simplicity, is gradually falling out of use, a complex yoke taking the place of a single round bolt. The change has been brought about by the tendency of the tail-bolt to break. It is not our purpose at present to discuss the short-sighted policy of abandoning a simple form for a complex one without exhausting all means to render the former as strong as the latter. Our subject is the cause of breakages generally.

There is no subject connected with the operating of machinery more important than how can all parts of a machine be made so that there will never be any failure from breakage? The problem is peculiarly important in its relation to machinery used in transportation, for the comfort and lives of those who travel by land or by sea are greatly dependent upon machinery and mechanical structures being free from breakage. The answer to the question of why a piece of machinery breaks, was covered in a reply given by the well-known mechanical engineer, Dr. Coleman Sellers, when asked at one of the Railway Master Mechanics' conventions, What is the cause of boiler explosions? He answered, because the sheets of the boiler are not strong enough to resist the pressure inside. That answer, of course, failed to explain why boiler-plates, which were strong enough yesterday, fail to-day. A kindred inquiry has been asked frequently during the past winter, viz. Why has a rod failed to-day which stood for years without showing the smallest sign of weakness?

When a skillful engineer designs a machine, he carefully studies every shock and strain that has to be resisted, and proportions all the parts to have a wide margin of strength. He calculates not only all the external forces that will come into action to disintegrate the machine, but also takes into consideration the molecular internal forces within the material employed and provides against their breaking influences. It might be supposed that a machine of this character would be like the one-horse shay, and would last until every part was worn out. This is not how it comes out in practice. Care in design tends to make machines and mechanical structures durable, but forces begin work on a machine the day it is put in operation which will sooner or later lead to breakage unless the proper remedies are provided.

The shocks and strains incident to railroad operating subject the leading parts of the machinery used to blows and pulls that strain the material beyond its elastic limit. When a load is put upon a bar it will stretch a certain distance in the same way that a rubber band or coil spring does, and on the load being removed the bar will go back to its original length. The limit within which a bar will endure a strain and return to its original length after the strain is taken off is called the elastic limit. When a bar or any other form of metal is strained beyond its elastic limit, it receives damage which if repeated often enough will result in breakage.

When engineers first began experimenting with the strength of material, it was believed that a bar was not injured in any way by sustaining loads within the elastic limit; but more experience proved that if loads within the elastic limit were applied and taken off many times breakage would ensue. From this it was concluded that a molecular change was induced in the metal by strains, even within the elastic limit, which seriously weakened it without making any apparent physical change on the article affected. This is spoken of among engineers as the fatigue of metal.

There are two distinct forms of stresses which machinery and structures are subjected to with very different results. Let us take a truss rod which is helping to support the roof of a building. A certain load is put upon this rod and it remains constantly there. That rod is carrying what is called a static load. On the other hand, we will take the load or strain which a crank-pin or connecting-rod must be strong enough to sustain. This load is constantly changing on and off. Engineers speak of this as a live load. It has been found that a bar or structure will endure a statical load much better than a live load.

Wöhler, an eminent German engineer and physicist who is a recognized authority on strength of material, made a great many experiments with bars of steel and iron, putting on and taking off the loads alternately, careful means being provided to record the exact results. It was found in every instance that the breaking stress of the material thus tested was away below the statical breaking load. A bar of steel having a tenacity under a steady load of 110,000 per square inch, broke under 64,000 pounds when the load was completely removed and replaced 170,000 times. The trend of the experiments went to show that a bar would break with an alternating stress of about one-third the statical breaking strength of the material if the repetitions of strain were sufficiently numerous. The test department of the Pennsylvania Railroad have repeatedly corroborated the correctness of Wöhler's discoveries regarding the effect of alternating stresses. There is still a great deal to be learned about the influences which reduce the original strength of metals; but there are numerous evidences tending to prove that so long as strains are below a certain portion of the elastic limit no damage or fatigue will ensue no matter how often the stresses may be applied.

The lessons of the experiments and discoveries are: Give a good margin of the calculated strength to material that has to withstand alternating loads, and keep the eyes of vigilant inspectors upon axles, crank-pins, rods and other parts that have to endure what is known to be a destructive character of service. Breakages like that of the tail-bolt referred to in the beginning of this article have been very common in railroads since the prevalent tendency to overload engines and cars came into vogue. Frequently the remedy is looked for in the wrong direction. We have lately found several railroad companies introducing the use of bronze eccentric straps because the cast-iron straps gave annoyance from breakage, and the same thing is going on with driving-axle boxes. This is substituting a strong material, but the purpose would be equally well accomplished by increasing the size of the piece made from cast-iron. We have in mind a road that was greatly troubled with valve stems breaking, and numerous fancy remedies were suggested without relief till a hard-headed foreman urged making the stems stronger, and that plan being tried the breakage ceased. If parties using tail-bolts in their couplers would strengthen the bolt instead of looking for complex remedies, the result would probably be more satisfactory in the repair yards. Where side-rods and crank-pins and rocker-arms and piston-rods keep breaking the chances are that a stronger article is needed, although in some cases vicious forms provide the conditions that cause breakage. A piston-rod made with a sharp shoulder puts a varying bending strain on one point which reaches up towards the elastic limit. Every bend given to the rod is a step towards destruction, and the end comes with as much certainty as the end of a division is reached in a given time at a certain speed. All other parts subject to breakage are controlled by similar influences. If the metal is distributed so that the strains are uniform, the article will be durable; if bad form concentrates strains on one point it will be short-lived. If the material employed is of good quality it will resist destructive strains longer than substances of inferior quality; but good material and perfect form will not long prevent breakage when the article is too weak for the strains to be borne.

## Safety Appliances Made Compulsory.

What has been popularly known as the Car Coupler bill has passed Congress at last and is now a law. The measure is much broader than the popular name for it indicates, as it provides that after January 1, 1898, every locomotive used moving interstate traffic must be provided with driver-brakes and appliances for operating a continuous train-brake, that all trains must have a sufficient number of power-brakes, so that the engineer can control the train without requiring brakemen to use hand-brakes.

In regard to couplers, the law requires that all cars must be equipped with couplers that act automatically by compact and which can be uncoupled without the switchmen going between the cars.

The hand-hold at the ends of cars, which is a standard of the Master Car Builders' Association, and which many friends of humanity have been vainly urging for general adoption, is made a compulsory attachment by the new law. The neglect of many railroad companies to provide this inexpensive safety appliance is one of the strongest arguments we know of in favor of compulsory legislation.

Another highly important enactment which ought not to have been necessary is in regard to the height of draw-bars. The law provides that within three months after the passage of the act, the American Railway Association is authorized to designate to the Interstate Commission the standard height of draw-bars for freight cars, and fix also the maximum variation from that standard height. There has been a standard height of draw-bar since 1872, but many railroad companies pay no attention to it, although the diverse height of draw-bars has been a fruitful cause of accidents in the coupling of cars.

The act provides that violations of its provisions will be punishable with a fine of $100 for each offense. It also exempts railroad employés from contributory negligence in case they are injured in the handling of locomotives or cars not provided with the appliances required in the act.

There is nothing in the new law which a railroad company wishing to be fair toward its employés and toward humanity ought to object to. Most railroad companies will find the law no hardship, because they are gradually meeting its provisions. Others will do nothing till the day of reckoning comes, and then they will raise demands for longer time. These are the kind of companies that bring all corporations into disrepute. They have struggled to prevent the Act from passing and they have delayed it for years. Companies of this kind do nothing to conserve life without the spur of compulsion. They deserve no consideration.

## Slow Progress of Standards.

Every railroad man who possesses business conceptions combined with mechanical knowledge is aware that one of the most desirable improvements that could be carried out on railroad rolling stock is the general adoption of standard parts so that the material for effecting repairs might always be at hand no matter how far a car might be away from its home yards. Nearly all railroad officers admit the advantages that would accrue from a reform of this kind, yet very few of those in authority are prepared to sacrifice the smallest tittle of prejudice to bring about uniformity. They are all willing that others should adopt their particular forms, but there is little disposition to give and take in the promotion of this good cause.

The railroad mechanical associations have been struggling for years to establish certain standards, but it is surprising how little good has been accomplished by the protracted efforts in this direction. Men contribute testimony to committees of investigation showing how great the advantages of standards and uniformity would be; they raise their voices in the conventions in favor of standards and vote for their adoption by letter-ballot, and then consider that their full duty has been performed. They use no effort whatever to make their own practice conform to the standards they have helped to establish. Of course in some instances the mechanical men cannot help themselves, because the policy of their companies is to hold to their own established forms no matter what the associations may do; but in many cases the failure to make progress towards standards is due to the apathy of the master car builders and master mechanics. This apathy is not worldly wise. More than one man has come to grief for neglect of this duty to his company, and others will fall by the wayside when their managements come to realize the losses due to the lack of enterprise that obstructs necessary improvements.

## Government Boiler Inspection.

On another page one of our correspondents discusses in a very fair spirit and intelligent fashion the subject of Government inspection of locomotive boilers. He sees no reason why locomotive boilers on railroads should be exempt from Government inspection and supervision when the boilers of steamers are subject to this kind of control. We entirely agree with this view of the case, and we cannot see why any other person should think differently. The lives of passengers on railroad trains are certainly as valuable as the lives of those who travel by steamers. The practice of requiring marine boilers to be systematically inspected by competent men has proved one of the best safeguards ever introduced, and it ought to be extended to all steam boilers. A change of this kind would be better for every one who comes within reach of a boiler. It would be a merciful thing to the men attending boilers, and in many cases it would benefit superintendents and owners.

## The Underpaid Mechanical Engineer.

Railroad companies have their own share of poorly paid employés, although, on the whole, railroad men are fully as well remunerated for their services as any class of workmen or officials going. We have lately been studying the pay received by the various classes in railroad service, and have concluded that the mechanical engineer is the worst paid man in the business, considering the training and education necessary for the position. There are only a few railroad companies that have ostensibly a mechanical engineer, but nearly every railroad company has a man performing a mechanical engineer's work without the title being attached to the duties. Railroads are too much in the barbarian era yet for scientific attainments to be treated with deserved respect; but the necessity for certain kinds of work being done scientifically—that is, according to correct principles—is slowly becoming recognized. The complexity of mechanism that tends towards simplicity or automatism in railroad operating is constantly calling for the services of a designer or semi-inventor as an attachment to every mechanical headquarters. Duties of this kind were formerly all done by the master mechanic, but they have now become too numerous for that official to perform. The next man in order is naturally the draughtsman. There is nothing in connection with train mechanism, signal apparatus, electrical appliances, or the thousand and one mechanical articles used on railroads that the draughtsman is not considered competent to design attachments for. He is supposed to have perfect knowledge concerning the strength of material, he must know how to calculate strains transmitted in the most complex of shapes; he must understand a great deal about heat, electricity, the behavior of gases under various circumstances, and a great variety of other knowledge must be in his possession for use at any moment. His daily duties require much manipulative skill, and the work he is called upon to perform as a designer requires the exercise of much good judgment and aptitude for displaying what some one calls "modifying power."

The education and training necessary to prepare a man for performing the high and diverse duties of a mechanical engineer are costly, but yet by perversity of judgment railroad officers nearly all consider that the work of a mechanical engineer is of small money value. Many brakemen and switchmen a few weeks away from working on the section receive better pay than men performing the scientific business of a mechanical engineer. We believe that nearly all heads of the mechanical departments who have to employ men to do the work of mechanical engineers appreciate the value of the services performed; but they cannot convince those above them that good salaries ought to be paid. There are too many officers on our railroads whose training has unfitted them to understand the value of scientific work. Clamor and brute force on one side and obedient stupidity on the other fulfills their idea of railroad service. This is the class that has made combination essential to those who were anxious to get in sight of fair play. It is passing away, but its influence helps to depress the market price of brains and knowlege.

## Disrespect to Railroad Managers.

Some points made by Col. N. S. Haines, president of the American Railway Association, in a pamphlet on legislation relating to railroad safety appliances, might be studied to advantage by the lawyers and public speakers who pretend to know more about railroad management than those raised to the business. Col. Haines rose from brakeman to be a railroad president. His views on railroad problems are therefore of the greatest value, yet they have not always been treated with respect when delivered before Congressional committees.

Concerning this object, he says: "If members of Congress who are lawyers could see before them a body of railroad managers undertaking to argue and decide issues involving fundamental principles of law, they would understand how they appear to railroad managers when they undertake to argue and decide fundamental questions in the operation of railways. Let a lawyer of recognized reputation appear before a Congressional committee and his views are received with respect, his words carry the weight of authority, but an expert railroad manager, who has acquired his experience by slow and laborious promotion from the lower ranks, and whose every word among his peers would carry conviction to their minds, will, in the same committee room, feel that his arguments have fallen on deaf ears, and perceive that his printed statements are not even read."

## Partial Car Repairs on Defect Cards.

A circular letter has been issued by Mr. A. M. Waitt, general master car builder of the Lake Shore & Michigan Southern, making proposals concerning defect cards, which appear to offer an easy solution of a difficult problem. Certain roads are requiring all cars having defective air-brakes that require immediate repairs to apply a separate card for each defect. This is likely to cause complications, disputes and delays, and some cars are likely to be all covered over with defect cards.

Mr. Waitt's plan of making partial repairs is to use one card for all repairs necessary, and when partial repairs are made to draw a red line through the words calling for the repairs that have been done. When this is done an M. C. B. card or preferably a special partial repair card, shall be filled out duplicating reading on the original card, with the same items crossed out as are shown thereon, this duplicate to accompany the bill for partial repairs as voucher.

The plan is simple and comprehensive, and we think it would be a wise plan for the M. C. B. Association to adopt it.

---

The Boston & Albany have lately put in service some freight cars with collarless journals, that are encouraging profanity among the Western connections of the road. During a recent visit to Buffalo we found among the car building and inspecting fraternity complete unanimity in condemnation of the new B. & A. axle and oil-box. The subject was like Banquo's ghost and would not be downed. Whatever subject of conversation was introduced drifted with certainty to the iniquities that have been inflicted upon other railroad men by the B. & A. axle. The side movement of the axle is supposed to be controlled by an end stop of wedge form. This wedge is reported to be regularly missing and the ends of the boxes are knocked out in consequence. We should advise friend Adams of the B. & A. to pay a visit to the interchange yards, Buffalo, Cleveland or Chicago, and he will learn something that is worth knowing.

## BOOK REVIEW.

SWITCH LAYOUTS AND CURVE EASEMENTS. By Augustus Torrey, *Railroad Gazette*, New York. Price, $1.

This useful little book is intended for the use of section foremen and assistant engineers, and is prepared in a shape simple enough to be understood by men of very limited education. The author, who is acting chief engineer of the Michigan Central Railroad, has prepared the book from the notes of his own practice. It consists of written directions given very plainly, and diagrams giving complete directions for section foremen. The publishers say that no similar book has ever been published before. It is an essentially practical and necessary manual for trackmen. We think that every young man ambitious to be a section foreman ought to make this book a pocket companion.

THE TABOR STEAM ENGINE INDICATOR. Ashcroft Mfg. Co., New York. $1.

The book is evidently the work of our well-known contributor, Mr. Harris Tabor, who is inventor of the indicator described. There is first an introduction telling about the purpose of a steam engine indicator, and then comes a clear, concise and interesting description of the Tabor instrument. After that comes a division or chapter devoted to "the management and care of the Tabor indicator," which is followed by a discourse on "the essential features of the indicator diagram." A chapter on "the uses to which the steam engine indicator may be applied," brings us to details of the every-day work done by the indicator, embracing valuable information on making tests of steam engines, and how to detect defects. In this chapter the author is unusually frank for a writer on indicators, and tells plainly what the indicator will not do as well as what its uses are. He says:

"The matter of leakage of valves and pistons in steam engines is one of importance. In the testing of engines it is often overlooked, and in the ordinary working of a large number of engines it is the cause of much waste of steam. It is quite a common belief that the indicator diagram is useful for the purpose of showing the condition of an engine in regard to leakage. This belief is erroneous. The diagram is useful for no such purpose. Leakage of steam, except in rare instances, has so little effect upon the lines of the diagram that it can scarcely be detected. The only satisfactory way to determine the tightness of an engine is to take it in hand when not in motion, apply a full boiler pressure to the valves placed in a closed position and to the piston as well, which is blocked for the purpose at some point away from the end of the stroke."

Railroad men will particularly value the portion devoted to "the use of the indicator on locomotives," and that where directions are given for "combining the diagram from compound engines." In the former chapter diagrams are given showing the distribution of steam in locomotives that have the valves set by measurement, and others where the valves are set by the indicator. The difference is very striking, and ought to be a strong argument in favor of more general use of the indicator on locomotives.

Besides the information referred to there are many useful facts about steam engine matters to be found in the book. There are of course methods of finding the horse-power from the diagram, methods of calculating the steam used and very carefully prepared tables relating to steam. A useful thing to find in a book relating to the indicator is a table giving the area of circles. The working of Amsler's polar planimeter is very plainly described in a fashion that will make the action of this useful instrument apparent to those who cannot get personal instruction in using the planimeter.

The publishers, who are manufacturers of the Tabor indicator, give the book with every instrument sold. To others a charge of $1 is made. It would be difficult to get the same volume of information at the low price named were the book not prepared in connection with a manufacturing business.

---

The Consolidated Car-Heating Co., of Albany, N. Y., have recently placed on the market a very efficient electric heater for electric street cars. This device is located under the seats, weighs but 14½ pounds for an entire car equipment. Mr. McElroy, the inventor of their leading features of steam heating, is the inventor. This heater is clean, instantly controlled and safe—a pity they cannot be used on our passenger coaches.

## PERSONAL.

Mr. J. J. Frey has been appointed general manager of the Atchison Topeka.

Mr. W. G. Tuller has been appointed purchasing agent for the Atchison, Topeka & Santa Fe.

Mr. T. F. Butler has been appointed master mechanic of the Pennsylvania road at Wellsville, O.

Benj. Parker, one of the oldest engineers on the Missouri Pacific, recently died at Little Rock, Ark.

Mr. H. E. Chipman has been appointed master mechanic of the Oregon Pacific, with office at Corvallis, Ore.

Mr. E. M. Neel has been appointed superintendent of the C. C. C. & St. L., with headquarters at Mattoon, Ill.

Mr. A. Tait has been appointed superintendent of the Guatemala Western, with headquarters at Retalhuleu.

Mr. Daniel Deeter has been appointed road foreman of engines of the main line of the Philadelphia & Reading.

Mr. E. P. Lord, superintendent of motive power of the Cleveland, Cincinnati, Chicago & St. Louis, has resigned.

Mr. Joseph McWilliams has been appointed superintendent of the Texas Central, with headquarters at Waco, Tex.

Mr. J. C. Slater has been appointed master mechanic of the Nevada Central, with headquarters at Battle Mountain, Nev.

Mr. J. Q. Van Winkle has been appointed general superintendent of the C. C. C. & St. L., with headquarters at Indianapolis.

Mr. C. H. Smith has been appointed general manager of the Pittsburgh, Marion & Chicago, with headquarters at New Lisbon, O.

Mr. G. W. Miller has been appointed general foreman of the locomotive shops belonging to the Pennsylvania, at Columbus, O.

Mr. T. L. Clarke has been appointed acting superintendent of the Atlantic & Western, with headquarters at Orange City, Fla.

Mr. S. M. Prevost has been appointed general manager of the Pennsylvania Railroad. He was formerly general superintendent.

Mr. G. E. Husted has been promoted from freight agent to be superintendent of the Lake Shore & Michigan Southern at Toledo, O.

Mr. Henry Gould has been promoted from assistant to acting superintendent of the New York Central, with headquarters at Buffalo, N. Y.

Mr. A. F. Priest has been appointed master mechanic of the Duluth, Messabe & Northern, with headquarters at Iron Junction, Minn.

Mr. Daniel Coxe, superintendent of motive power of the D. S. & S. Railroad, is spending the winter in Florida, being in delicate health.

Mr. G. E. Coleman has been appointed superintendent of the Owensboro Falls of Rough & Green River, with headquarters at Owensboro, Ky.

Mr. R. B. Agnew has been appointed superintendent of the Chicago, Rock Island & Pacific, with headquarters at Colorado Springs, Col.

Mr. E. McNeal, assistant to President Sage, of the Iowa Central, has been appointed general manager in place of Mr. C. A. Ackert, resigned.

Mr. A. J. Frasier has been promoted from train master to superintendent of the Alabama Great Southern, with headquarters at Birmingham, Ala.

Mr. H. A. Worcester has been promoted from train master to superintendent of the Lake Shore & Michigan Southern, with headquarters at Lansing, Mich.

Mr. A. B. Elliman has been appointed general manager of the Nevada Central, with office at Austin, Nev. He was previously treasurer for the company.

Mr. J. N. Sanborn has resigned the foremanship of the C. M. & St. P. roundhouse at Sioux City to accept the position of road foreman of engines for the J. C. Ry.

Mr. Charles H. Stanton has been appointed general superintendent of the New York & Massachusetts Railroad, with headquarters at Poughkeepsie, N. Y.

Mr. George P. Randolph has been appointed general traffic manager of the New York & New England. He was formerly a freight agent on the Philadelphia & Reading.

Mr. B. Fitzpatrick, master mechanic, has been transferred from Wellsville, O., to take charge of the Cleveland & Pittsburgh division shops of the Pennsylvania at Columbus, O.

Mr. Myron Cooper has been appointed master mechanic of the Seattle & Montana, Fairhaven & Southern and New Westminster Southern roads, with headquarters at Fairhaven, Wash.

W. D. McKelvey, who for some years has pulled the Chicago limited on the Pittsburgh division of the P. R. R., has been promoted to the position of roundhouse foreman at Altoona, Pa.

Mr. Otto Miller has been appointed superintendent of the Hutchinson & Southern with headquarters at Hutchinson, Kas. He was formerly a superintendent on the Chicago & Northwestern.

Mr. J. M. Keith has been appointed master mechanic of the Western Railway of Guatemala, with headquarters at Retalhuleu. Mr. Keith was for several years on the Mexican Central.

Mr. S. P. Bush has been promoted from the position of master mechanic of the Pittsburgh, Cincinnati & Chicago shops, at Columbus, O., to be superintendent of motive power at the same place.

Mr. George L. Potter, master mechanic of the Fort Wayne shops, has been promoted to be superintendent of motive power of the Northwest System of the Pennsylvania lines west of Pittsburgh.

Mr. Frank Bruce has been appointed master mechanic of the Montana Central, with headquarters at Great Falls, Mont. Mr. Bruce has been on the Great Northern lately and was formerly on the Santa Fe.

John McLellan, roundhouse foreman for the P. R. R. at Altoona, Pa., has been made master mechanic at Blairsville, in place of W. B. Norris, promoted. The men give "Jack" a good name and wish him success.

Mr. Walter R. Woodford has been appointed general superintendent of the Cleveland, Lorain & Wheeling, with office at Cleveland, O. He has been general superintendent of the Wheeling & Lake Erie for four years.

W. B. Norris, until now master mechanic of the West Penn. division of the P. R. R., at Blairsville, Pa., has been made assistant to H. D. Garrett, master mechanic at West Philadelphia. This is a promotion to larger responsibilities.

Mr. John Forster, for several years roundhouse foreman on the Atchison, Topeka & Santa Fe, at Fort Madison, Ia., has been promoted to be master mechanic of the Panhandle division of same road, with headquarters at Wellington, Kas.

Mr. W. H. Fry has been appointed superintendent of the car department of the New York New Haven & Hartford and Consolidated roads. Mr. Fry has been employed in the Pullman works for several years as superintendent of repairs.

Mr. J. P. Graham, who was appointed master mechanic of the Iowa Central some time ago, learned his trade on the C. C. C. & I. under L. S. Young. He has spent several years on the Pacific coast and rose to be master mechanic on a division of the Union Pacific.

Mr. Daniel B. Robinson has been elected first vice-president of the Atchison, Topeka & Santa Fe, and he will have charge of the operation of that system of roads. He is an excellent railroad man, and has pushed himself up from the bottom by the force of ability.

Mr. Charles Graham, Jr., master mechanic of the D. L. & W. Ry., makes a very neat job of worn valve-stems by fitting a copper tube over them. The ends of the tube fit snugly against the yoke and the socket of the valve-rod making a steam-tight joint. This plan prevents the weakening of the stem by continual wearing and turning down, as when the copper covering is worn badly it can be removed and a new one substituted without machine work and with very little expense.

The consolidation of the motive power and car departments of the Long Island Railroad has released Mr. W. H. McKaig from the position of master car builder. Mr. McKaig has experience which ought to make him a valuable man for some railroad company. He learned the business in Jackson & Sharp's, and had experience in some of the best car shops in the country. He was assistant foreman in the Pullman works for upwards of five years. He was two years M. C. B. on the Long Island road.

Mr. William Garstang has been appointed superintendent of motive power and machinery of the Cleveland, Cincinnati, Chicago & St. Louis in place of E. P. Lord, resigned. This is a case of a man returning to his old love, for Mr. Garstang never ceased to display a warm interest in the affairs of the C. C. C. & I., now part of the Big Four, from which he was taken to be superintendent of motive power of the Chesapeake & Ohio. Mr. Garstang was for years master mechanic in charge of the Brightwood shops of the C. C. C. & I. before going to Richmond. He is first vice-president of the Railway Master Mechanics' Association.

Mr. Theodore N. Ely, the well-known general superintendent of motive power, has been created chief of motive power by the directors, and his headquarters has been changed to the general office of the company, at Philadelphia. Mr. Ely will have general supervision of the mechanical department of all the Pennsylvania lines and it is understood that he will act as advisor to the presidents in all matters relating to machinery. Mr. Ely leaves Altoona universally regretted. Few heads of departments have been more popular, and he performed the delicate duties that connect the operative with the mechanical department of the Pennsylvania with much success. A most estimable characteristic about Mr. Ely has been his readiness to credit subordinates with work done. This has always insured an able and loyal staff of assistants and much of his success has been due to them.

A good illustration of the force of habit was displayed at a recent meeting of the New York Railroad Club. Mr. T. B. Purves, Jr., master mechanic of the Boston & Albany at East Albany, had been elected a member and was invited to speak. Mr Purves is a young man of pious proclivities with a taste for Sunday-school work, and he is superintendent of a Reformed Presbyterian (Auld Lichts) Sunday-school. On being called upon to speak at the club meeting, Mr. Purves began to catechise the members as to what they knew about boilers. He floored H. L. Leach, puzzled M. N. Forney, started A. E. Mitchell figuring, and put every other member upon the anxious seat, when his course was suddenly checked by a suggestion from President Blackall that he answer some of his questions himself. It was a new experience, but the introducing of Sunday-school methods into a club meeting was decidedly sensational.

Once in a great while it's comical to look like some one else. A. E. Mitchell, superintendent of motive power of the Erie, has a twin brother, a supervisor on the Pennsylvania's western lines. They say that when A. E. goes over the Pennsylvania the conductors just nod to him and put down the number of his brother's annual. He could make things interesting for his brother by charging meals "until I come up next week." It wouldn't be so funny if some cannibal recently dismissed by the supervisor took occasion to "get even" in an interview, and should happen to strike A. E. On the whole, when you are a twin it will pay to lead a strictly correct life and be careful that your brother tells no lies and makes no enemies. If we had a twin brother soliciting advertising, we should crawl under the table every time the door opened.

Mr. Edward B. Wall, for several years superintendent of motive power of the Pittsburgh, Cincinnati, Chicago & St. Louis, at Columbus, O., has been made assistant to the president of the Pennsylvania lines west of Pittsburgh, with headquarters in Chicago. Mr. Wall is peculiarly well fitted for his new duties, as he is an excellent organizer and a good executive officer, as any observing man could see who visited his headquarters. He is a graduate of the Stevens Institute of Technology. While at college he devoted much attention to car construction, and his learning in that direction led him into railroad employment. He has been a famous member of the Master Car Builders' Association, and has fought the battles of the Pennsylvania Railroad very successfully in different conventions. His efforts and skillful management did more than the labors of any other man to turn the vote of the Association in favor of a vertical plane coupler.

Mr. F. D. Casanave, who has been superintendent of motive power of the Fort Wayne divisions of the Pennsylvania Railroad since 1887, has been appointed general superintendent of motive power of the Pennsylvania Railroad, with headquarters at Altoona, Pa. Mr. Casanave served his apprenticeship in the Altoona shops, having begun there in 1862. He went through the usual course of instruction given to the Altoona apprentices. In 1876 he was promoted to be assistant master mechanic at Altoona. Five years later he was made master mechanic of the Fort Wayne shops. After holding that position five years he was made superintendent of motive power. We know of no man in the country who has such a good technical and mechanical training combined as Mr. Casanave. The successful establishing of the piece system of work on the Pennsylvania has been in a great measure due to his labors. He was offered by President McLeod the position of general superintendent of machinery of all the Reading lines a year ago, with a very high salary, and declined the place by the advice of the president of his road. He is chairman of the Arbitration Committee of the Master Car Builders' Association.

### How Could She, When She Couldn't?

Strange things happen when men make up their minds that they will happen, have got to happen and can't help happening.

It is now over twenty years since Superintendent Healy, of the Rhode Island Locomotive Works, built a passenger engine for the Old Colony; this engine had 17½ x 22-inch cylinders with a 5-foot wheel. The only innovation on the standard engines of the day was the trial of 2¼-inch tubes instead of 2-inch, there being about 160 of them.

Before the engine ever made a turn the general superintendent got onto the big flues and openly announced that the engine would never make the time with the Fall River boat train—for which she was built.

The master mechanic admitted that he didn't believe she would ever steam, and one by one the engineers shook their heads and allowed that she couldn't make it—because she couldn't. Then the firemen announced that no man could keep her hot and no one ought to expect they could.

The engine was doubted from the start. Everybody said she couldn't make the run—and she didn't.

She went on the road and was a failure from the start, and after eighteen months' service she was rebuilt. The general superintendent paid the Rhode Island Locomotive Works $1,000 extra for a new boiler (returning the old one) like the other except that it had 2-inch tubes.

He said he knew that the new boiler would steam and the engine make the time. The M. M. said he knew so, too, and the engineers and firemen agreed with them that now she was all right.

She was all right, steamed well and made the time—because everybody said she could and would.

Some months afterward John Thompson, general master mechanic of the Eastern Railway, wanted a 17-inch passenger engine, and wanted it as cheap as possible. He was induced to take the boiler discarded by the Old Colony (after being thoroughly repaired). None of the engineers knew the engine had an old boiler or flues larger than the ordinary. Mr. Thompson said she was a dandy and would just play with their fastest and heaviest express. The boys all counted on her as a good steamer—and a good steamer she was.

This engine never lacked for steam, did her work well, and as economically as the best engines on the road, and is in the service yet—running in sight of the scene of her former failure.

If a man at the bottom of a well made up his mind that he couldn't climb out, wouldn't climb out or wouldn't try to climb out, it is altogether likely he would stay there.

Many a device has been a success, and many a man won in the battle of life, because the inventor of the device or the man believed in his invention or himself; knew that if he had half a show he would "get there,"—and "got there."

Have faith in your ability to run your engine or fire it successfully. Make up your mind that it has got to *go*. Don't let any other man do what you failed to do, and because you failed have therefore decided couldn't be done.

### Power Required to Drive Wood-Working Machinery.

We have several times lately received inquiries about the amount of power required to drive wood-working machinery. On searching for information on the subject, we found that few people outside of those having the designing and placing of wood-working tools realize how much power is needed for these machines.

Some years ago Mr. William Lee Church, now of the firm of Westinghouse, Church, Kerr & Co., made some careful experiments to ascertain the power required to drive wood-working machinery, and the facts be made public are the most reliable data to be found on this important subject A somewhat curious feature of the test was that they demonstrated that more power is required to drive the tools than is needed for dressing the lumber. This of course is a characteristic of all machinery run at very high speed.

A 12-inch matcher running on 6-inch spruce called for about 15.25 horse-power. The same tool when running empty required 10 horse-power. It required 31.2 horse-power to start a 24-inch double surface planer, but after full speed had been attained the power required to keep up the velocity fell to 12.5 horse-power. A 14-inch rip saw cutting off 1-inch stuff called for 5½ horse-power, and almost the same power was required by a 24-inch circular resawing machine splitting 6-inch ... and it varies but a small fraction from the power required by a 60-inch circular resawing machine. Of course heavier ...ing would have greatly increased the resistance of the latter machine.

This information is a little limited, but it is good as far as it goes. If some enterprising superintendent in charge of a car shop would apply an indicator to his engine and take notes of the power required for the different machines, he would secure data that would be of much general interest.

A committee was appointed at the last meeting of the New York Railroad Club to put in form any suggestions regarding necessary changes on the Rules of Interchange of Cars. Mr A E Mitchell, superintendent of motive power of the Erie, is chairman of the committee. Anyone having suggestions of changes to propose should send particulars as soon as possible to Mr Mitchell.

The Southern & Southwestern Railway Club will meet at Atlanta on April 20th. The subjects to be brought forward for discussion are · Air Brake Practice ; Draft Rigging Appliances ; Soft Plugs for Crown Sheets of Fireboxes. Mr. George Morris, of the A French Spring Co., will read a paper bearing upon the second subject.

The Mt Vernon Car Mfg. Co. have just finished turning out 175 box cars, 75 coke cars and 10 caboose cars for the Monterey & Mexican Gulf R. R , Monterey, Mexico. They are now turning out 500 Illinois Central box cars, 1,000 Hicks stock cars, and have recently taken orders for 300 Louisville & Nashville box cars, 300 flat cars for the Monterey & Mexican Gulf R. R., Monterey, Mexico. This, with contracts on hand, will fill the company's capacity until August.

At the March meeting of the Western Railway Club Mr. F. C Cleaver, of the Terre Haute & Indianapolis, read a paper on a comparative test of simple engines and a compound built at the Pittsburgh Locomotive Works. The engines were of substantially the same size and the compound made a large saving of fuel over the others.

## Uneven Expansion of Long and Short Stay Bolts.

At a meeting of the New York Railroad Club, Mr. A. E. Mitchell made some remarks on the subject of Belpaire boilers, in which he enunciated a theory which may account for a well-known defeat of these boilers. He said Although we have none on our line, and I have never calculated the strains which come on them, I often wonder why the top row of stays should fail on Belpaire boilers, unless it is on account of the difference in the expansion of the top row of stay bolts and the lateral stays which run across the top of the firebox. In talking on this subject to one party some months ago, he gave this theory—that iron heated by steam will expand a certain amount—let us say for illustration one-thousandth of an inch to an inch in length. Now if the stay bolts are six inches long we get under the heat an elongation of .006. The top stay is running from side sheet to side sheet of the boiler—say 50 inches, is elongated the same distance per inch as the short stay, making a total 50 times greater than the other. This would naturally throw greater strain on those short side stay bolts, causing them to fail.

The Grant Locomotive Works of Chicago are full of orders but they are getting work done more slowly than they expected, the principal cause of delay being the want of good mechanics. The works are located in a district where houses are scarce, and which is not easily reached. Owing to this the men readily become discontented, and work is so plentiful in more convenient parts of the city that only fancy wages will keep them with the Grant Works.

The Hall signal system has been applied for the protection of trains on the Illinois Central Railroad, in the neighborhood of Chicago, and the trains for the World's Fair suburban business will be run under this system.

The Boston & Maine have given a large order to Pullman's people for passenger cars.

The next meeting of the New York Railroad Club, April 20th, will be a special car builders' meeting. The rules of interchange will be discussed and recommendations sent to the Master Car Builders' Association. There will be a short paper on practical car construction and a number of topical subjects on car repairs discussed. Everyone in the vicinity of New York who is interested in the building or maintenance of rolling stock ought to attend this meeting

## A Heavy Milling Machine.

The illustration on this page was made from a photograph of the largest milling machine we know anything about. This machine has been recently turned out by the Ingersoll Milling Machine Co., of Rockford, Ill.

The builders say they designed this tool especially for locomotive works and railroad shops, for such work as driving-boxes, cross-heads, shoes, wedges, connecting-rods, etc.

The machine looks more like a planer than a milling machine; the table is 36 inches wide and 8 feet long.

The feed motion is operated by friction, and the range of feed speeds is from 5 inches per minute down to $\frac{3}{16}$ of an inch per minute.

The spindle is 5¾ inches in diameter, bearings 25 inches long , it is back-geared 24 to 1, having a horizontal adjustment of 14 inches, and a vertical adjustment of 36 inches.

Cutters 15 inches in diameter and 30 inches long can be swung on this machine.

The cross-rail is graduated to read in thousandths, and can be raised by hand or power.

A piece 36 inches high can be milled in this machine, using a 6-inch cutter.

A pump is attached for throwing a stream of water on the tool while at work.

The machine weighs, complete, 22,000 pounds.

Using their special cutter, the makers of this machine state that they have milled cast-iron slabs 36 inches wide cutting $\frac{3}{16}$ inch deep, with a lineal feed of 3 inches per minute, removing by this operation 1,200 cubic inches of cast iron per hour. In other words, with one cut across the cast-iron slab, 36 inches square, they took off $\frac{3}{16}$ inch of the metal in twelve minutes.

We will be entirely out of February and March papers within a month ; no specimen copies of those months can be sent now. If you expect to make your file complete order back numbers now or you will be unable to get them ; we shall print no second editions.

The World's Fair business will promote many of the boys to pulling varnished cars. We hope they will all give satisfaction and be willing to go back to flats and gondolas in their turn.

We have just about 100 calendars left, if you want one drop us a postal card this month. Don't send after May 1st for we won't have one then

A report is current that Mr. A A. Robinson, who has resigned the position of second vice-president and general manager of the Atchison, Topeka & Santa Fe, is going to take a similar position in one of the Gould lines. It was generally expected, when President Manvel of the Santa Fe died, that Mr. A. A. Robinson would become president or at least first vice-president, for he has been a most successful manager. Mr. Robinson rose on the Santa Fe through the engineering department and looked after the construction of nearly 7,000 miles of railroads now forming that system. He has a surprisingly wide grasp of details and has the history of a great part of the vast properties forming the Santa Fe in his mind.

The Locomotive Educational Association, of Cedar Rapids, Ia., send us an invitation to attend their first annual ball and promise that we will have the opportunity to make good time around the hall without danger of collision. We are very grateful and should like much to witness the terpsichorean successes of old friends, but taking part in that species of train service is out of our line

Mr. J. W. Addis, who has been master mechanic of the Texas & Pacific at Gouldsboro, La., for several years, has been promoted to be superintendent of motive power of the same road. He succeeds Mr. A. S. Douglas, retired on account of bad health.

### EQUIPMENT NOTES.

The Delaware, Lackawanna & Western are asking bids for box-cars.

The Jersey Central are about to order a large number of freight cars.

The Huntington & Broad Top people are in the market for 500 cars.

The Florida Central & Peninsula people are in the market for locomotives.

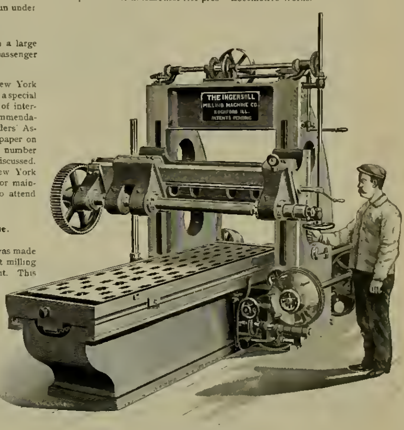
The Kansas City, Fort Scott & Gulf are in the market for new locomotives.

The Pittsburgh, Shenango & Lake Erie are about to order 300 freight cars.

The Noble Car Co., of Buffalo, have ordered 250 freight cars from the Lima Car Works.

The Louisville & Nashville people have placed an order with Rogers for some new engines

The Bangor & Aroostook have ordered seven locomotives from the Manchester Locomotive Works.



NEW HEAVY MILLING MACHINE

The Wilkesbarre & Eastern have ordered 13 engines from Rogers They are in the market for 18 coaches.

The Boston & Maine are getting thirteen new parlor cars built at Pullman They are badly needed on the road.

The Southern Pacific Co. have placed orders with Schenectady for eleven and with Cooke's for fourteen locomotives

The New York Central have specified the Fox pressed steel truck for 1,200 new freight cars contracted for within the last month.

Baldwin's people have lately received orders for eight moguls from the Ohio Southern, and a large order from the Missouri Pacific.

The New York, New Haven & Hartford are getting 14 new passenger cars built at Dayton. Part of them will be sleepers and part chair cars

The Safety Car Heating & Lighting Co., of New York, will have new gas plants in operation April 1 at Chattanooga, Portland, Ore., and North Chicago.

The Missouri Kansas & Texas soon expect to get into St Louis on their own line, and they are getting twenty-eight new passenger cars built to be ready for the increase of business

The New York, New Haven & Hartford are about to enlarge their shops at New Haven to give sufficient capacity to do all the repair work on cars and locomotives for the consolidated roads.

Pullman's people are reported to be turning out about three sleepers a day to meet the extra business of the World's Fair. Part of the sleepers are built so that they may readily be changed into day cars.

The Boston & Albany are about to build 6 combination cars and 100 flats in their own shops at Allston Mr. Adams has been getting out a sample box-car and it is now ready The company will order 500 cars of the same kind soon.

The Schenectady people are about to build some high-speed passenger engines for the New York Central with cylinders 19 x 26 inches, driving wheels 7 feet 3 inches in diameter A peculiarity about the engines is that they will have Buchanan's water table in a firebox set above the frame.

We understand that Mr E P. Watson, proprietor of the *Engineer*, has sold a half interest to Mr. Herbert W Harris, formerly business manager of the *Electrical World*. The *Engineer* is a remarkably bright paper and deserves the success that is likely to come to it by closer attention to the business side than Mr. Watson was able to give

The North Chicago Street Car Company are putting in a Pintsch gas plant which will be used for a novel purpose. Cars operated by small gas engines will be put on the lines to handle the business during the hours of light travel, when it does not pay to run the cables. Motors with gas engines will also be used on the feeder lines.

The Erie have ordered fifty new engines of Baldwins They will be their well-known "Class O" 10-wheeled passenger engines, with 20 x 24-inch cylinders and fire-box above the frame Those for the N Y, P. & O. will have a shorter firebox for soft coal and those for the Chicago & Erie will have a boiler four inches smaller in diameter. Part of them will be compounded.

Work is quite active in the Richmond Locomotive Works, and they are about to increase their capacity by the purchase of about $75,000 worth of new shop tools. They are still working on their large order for the Big Four, and have lately got an order for five switchers for the Chesapeake & Ohio They will exhibit at the World's Fair a passenger engine the same as the Chesapeake & Ohio standard.

## Improving the Reading System.

Mr. Theodore Voorhees appears to be making a decided success in reorganizing the operative departments of the Philadelphia & Reading. The organization has been somewhat similar to that of the Pennsylvania Railroad, but it was defective in many details, and these defects will be remedied by the changes introduced by the new first vice-president, who has a high reputation as an organizer. The intimate knowledge which Mr. Voorhees has of all practical details of railroad work promises to be of great value to the Reading system.

A striking weakness about the Reading, and on other railroads that have adopted the Pennsylvania system of management, is in the superintendents of divisions not being properly trained for the duties they have to perform They are in charge of rolling stock and of track, yet they have not received the proper training to be above mere meddlers with details they do not understand.

The system that makes the superintendent of a division responsible for everything on it, works admirably when the men in charge have been properly trained, but when men of limited experience are in charge it is expensive, confusing and dangerous.

## Wagon Top for Wootten Boilers.

"Thinking over the matter of steam room in boilers," said Mr. Charles Stryker, at the New York Railroad Club meeting, "has induced me to try to make an improvement on the Wootten boiler. The experience we have had on the Central of New Jersey has demonstrated that if we get dry steam the boilers are very economical. An ordinary Wootten boiler has very little steam room. I asked myself the question why a wagon top could not be put on this boiler to overcome the difficulty of having wet steam. Another point that I found on the Wootten boiler and in other straight boilers is, that for the sake of the construction the water space is sacrificed. The general construction of the Wootten boiler gives only 2¾ inches as the lowest water level above the crown sheet. When you come to consider that the Wootten boiler is 9 feet long and has a 3-foot combustion chamber it looks to me that the shallow water space is a source of danger, especially on a grade.

"I asked myself, cannot we put a wagon top on a Wootten boiler and raise the steam space from 16 to 22 inches? The boiler is not weakened by any means by putting this wagon top on it. It looks a considerable item to have 22 inches for steam space instead of 16. That, I think, will overcome the difficulty of having wet steam, besides, by doing it you can raise the main water level from 2¾ to 3¾ inches."

## Tempering Tools—Some Experience.

BY W. G LOTIFS.

I have tried to explain to the best of my ability how to heat and quench steel. It may seem strange, but it is true there are nearly as many tools spoiled in taking them out of the water at an improper heat as there is in putting them in at an improper heat. To convince yourself of this, take a reamer, such as shown in Fig 1, or a milling cutter as shown in Figs. 2 or 3, or a gripper jaw for lathe, as shown in Fig 4 After heating them to the proper refining heat, being careful that your water is clear, so that you can see at least 36 inches down from the surface, plunge your cutter down about 12 or 14 inches and you will see the teeth—just to where they are broken off as shown in Figs. 1, 2 and 3—cool very suddenly before the water can overcome the heat of the body. Now, the colder the water is the quicker it will overcome the heat of the body, and the better for the cutter.

But there is a large percentoge of our tool steel that won't stand to be left in until it is of the same temperature as the water, especially the cheaper grades, because the strain nearly all comes just to where the water couldn't overcome the heat of the body for a second or two, but it does not crack until it gets to about the same temperature as the water. The cause of this is that, when cooling, the cutting parts carry the hot body with them, because they cool so much quicker than the body, and the body being hot and soft it does not require a great deal of power for the cutting parts to draw it with them, but while the body is cooling it is going to have its natural shrinkage, and when it does, it must shrink away from the cutting parts, and this brings nearly all the strain just to that line where the water could not overcome the heat of the body. You will find that this is where your steel generally cracks in hardening.

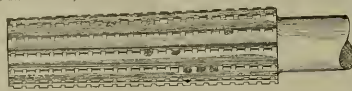


FIG. 1.

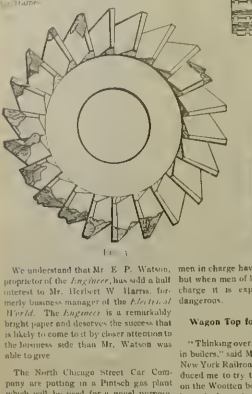

FIG. 3

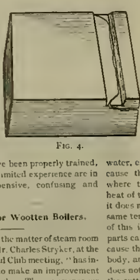

FIG. 4.

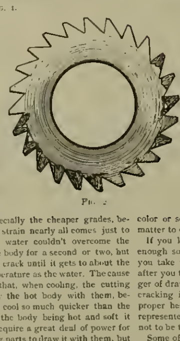

FIG. 2

Now, to prevent them from cracking, leave them in the water long enough so that they will be nearly hot enough to boil the water, which you can plainly see if your water is clear, then take piece out and drop it into lard oil, being careful not to lose time in getting it to the oil after taking it out of the water. If this is not done quickly you are liable to crack your cutter, because the cutting parts are very near the same temperature as the water, and when you take it out the water will stay on your cutting parts; yet there is heat enough in the body of it to dry it very suddenly, and it expands as quickly as it dries Now if your cutting parts are wet the heat will not run out into them quickly enough to expand them as fast as the body is expanding.

A great many toolsmiths hold their cutter over a keen fire after taking out of the water. I believe this practice is the greatest folly that has ever been practiced among toolsmiths, for this reason. If your cutters are of any size, you cannot prevent heating them more in one place than another, which causes unequal expansion, and very often the result is quite expensive. But you take your cutter out of the water as already explained; the body of your cutter will heat the oil and it will run out towards your cutting edges and heat them as quickly as the body heats the oil, and keep them the same temperature as the oil; and when you take it out the oil will form a coat on the outside of the steel that prevents the air from having the same effect it has on a cutter that was taken out of water.

Another bad habit, and one that is practiced a great deal, is taking hold of a fine edge cutter with warm hands after taking them out of the cold water. Fig 1 is a fair sample of such a case, it was quenched in water of a temperature of 34 degrees and left there until it was the same temperature as the water; there was not a crack in it when I took it out.

I took some waste and dried it, and then took hold of it with warm hands, and every tooth that was covered with my hand cracked—and they were the only ones that did.

Now the question may be asked, in what way does your warm hands affect a cutter of this kind enough to crack it? I am satisfied that it is the expansion that is caused by the heat of the hand, the steel being of a temperature of 34 degrees and the hands 100, and the steel being strained to about all it will stand, a very little unequal expansion will cause it to give away just at that line where nearly all the strain comes.

By heating slowly in drawing the temper, even if you don't heat it hot enough to color it any, you are doing away with a great deal of that strain. But I think the safest and quickest way is to take your cutter out of the oil with heat enough in it so it will not color or soften it any, which is an easy matter to overcome.

If you leave your cutter in the oil long enough so that it won't burn the oil when you take it out, or within a minute or so after you take it out, there will be no danger of drawing the temper and less of its cracking if it has been quenched at the proper heat and the steel is what it was represented to be, which I find very often not to be the case

Some of our salesmen make all sorts of claims for the steel they represent, and their knowledge of steel is very often limited, and the working of it more so.

*Madison, Wis.*

Spon & Chamberlain of this city have gotten out a neat little sketch book, for use in drawing offices, etc., with the pages accurately ruled in squares of one-eighth of an inch. Ruled sketching paper has been comparatively expensive, yet this firm are selling their handy book at 25 cents.

It is reported that the Ohio Southern have purchased 2,000 gondola cars of 60,000 pounds capacity of the Peninsula Car Co., of Detroit, also 500 gondolas and 1,500 box cars of the same capacity, and ten coaches and one mail car of the Ohio Falls Car Works, of Jeffersonville, Ind. They received two 18x24 switchers from Baldwins on March 1st, and have ordered eight 19x24 passenger engines to be delivered in May. The cause of this large order is the new 64-mile extension from Springfield to Lima, O, which they expect to open for business May 15th.

## Heat and Combustion.

BY ANGUS SINCLAIR.

The well-known phenomenon of combustion, or the burning of fuel, is due to the rapid union of the elements forming the fuel with the element oxygen, which is drawn from the atmospheric air. The composition and origin of the various fuels have already been discussed. It will now be in order to say something about the element oxygen, which performs extraordinarily important functions in the physical operations of the world.

### OXYGEN.

Oxygen is the most abundant substance in the globe Every atom of this element is like a dagger, always ready to pierce every other element in nature except one. This prevents it from being found in nature in a pure or isolated condition. But in combination with other elements it constitutes at least one-third part of the solid crust of the globe, eight-ninths by weight of all the water upon its surface, more than one-fifth of the atmosphere and eight-ninths of the vapor contained in the atmosphere. When separated from the other elements with which it is always mixed or combined, oxygen is a colorless, invisible gas possessing neither taste nor smell.

Any student of combustion can obtain a specimen of pure oxygen by placing a small quantity of red oxide of mercury in a test tube and heating it over a spirit lamp. When the compound gets hot enough, the oxygen which is combined with the mercury will rise in the gaseous form. If a glowing chip of wood be inserted in the test tube it will burst into flame, the pure oxygen inducing combustion more readily than the diluted oxygen in the air.

This experiment will teach two useful lessons. It will impress upon the beholder the active combustion-stimulating properties of pure oxygen and also show how loosely the gas may be bound into solid form along with another element for which it has affinity. Oxygen is bound very loosely into solid form with compounds of potassium and of manganese, and they are used for the distillation of this gas when large quantities are required. In silica, on the other hand, oxygen is bound up so tenaciously with the element silicon that the hottest furnace hardly suffices to separate them. In some of its solid combinations oxygen exists in greater relative proportion than it does in the air, but from the atmosphere alone can it be successfully drawn for respiratory and combustion purposes.

### THE ATMOSPHERE.

The atmosphere surrounding the earth from which the oxygen that supports combustion is derived is calculated to be about 45 miles in height. We hear a great deal in these days of rapid steam making about forced draught and artificial air pressure for urging combustion, but there are few amongst us who realize the unfailing storage of forced draught we have in the height of the atmosphere. The pressure at sea level caused by the height of the atmosphere is about 14.7 pounds per square inch. This pressure is always active to push the air gases into the furnace. The pressure of the atmosphere is calculated to balance 32 feet of water or 30 inches of mercury.

The atmospheric air is formed principally of the gases, oxygen and nitrogen. The composition is a mechanical mixture and not a chemical combination. Taken by volume there is 79 per cent. of nitrogen and 21 per cent. of oxygen in the air, or one cubic foot of oxygen to 3.76 cubic feet of nitrogen. By weight the proportion is 8 pounds of oxygen to 26.8 pounds of nitrogen, or one to 3.35 pounds.

Besides oxygen and nitrogen the atmosphere contains some aqueous vapor and from 3 to 1 volume of carbon dioxide in every thousand volumes. This carbon dioxide, although a very minute mixture in the atmosphere, is sufficient to perform highly important functions in the operations of nature. It supplies the principal element from which all vegetable and woody growth is built up.

### NITROGEN.

Nitrogen acts entirely as a dilutant to the oxygen with which it is associated, and in this performs admirably conservative functions.

Professor Faraday, writing about nitrogen, says: "It is remarkably curious. If I test it with a taper as I do oxygen or hydrogen, it does not burn like hydrogen and it does not make the taper burn like oxygen. It will not take fire, it will not let the taper burn, it puts out the combustion of everything. It has no smell, it is not sour, it does not dissolve in water, it is neither an acid nor an alkali. You might say, 'It is nothing.' What does it do in the air?

"Ah! then come our beautiful and fine results shown by an observant philosopher. Suppose, in place of having nitrogen or nitrogen and oxygen, we had pure oxygen as our atmosphere; what would become of us? You know very well that a piece of iron lit in a jar of oxygen goes on burning to the end. When you see a fire on an iron grate, imagine where the grate would go if the whole of the atmosphere were oxygen. The grate would burn up more powerfully than the coals; for the grate itself is even more combustible than the coals which we burn on it. A fire put into the middle of a locomotive would be a fire in a magazine of fuel, if the atmosphere were oxygen. The nitrogen lowers it down and makes it moderate and useful for us. It takes away the fumes produced by combustion and dispenses them throughout the whole atmosphere and performs a great and glorious purpose for man in the sustenance of vegetation."

With all its good qualities as a diluent, there are some drawbacks, so far as furnace combustion is concerned, to the large proportion of nitrogen in the atmosphere. It impedes the economical combustion of fuel in various ways. The large volume of this neutral gas accompanying the vital oxygen has to be heated to the highest furnace temperature, which represents considerable expenditure of fuel. Its presence obstructs the direct contact of the oxygen and carbon, and leads part of the gases to pass away uncombined. The increase of volume due to the presence of so much diluent requires also a much greater velocity of the gases than what would be necessary if the volume was smaller.

Having examined the elements, carbon, hydrogen, oxygen and nitrogen, which perform the principal functions in combustion, the next thing in order is to watch the lighting of a fire and note the scientific phrases of the events connected with this operation.

### IGNITING TEMPERATURE.

As has been several times mentioned, the phenomenon of burning is caused by the atoms of carbon or hydrogen entering into combination with each other, an act which is accompanied by the generation of heat and light. Carbon or hydrogen may be mixed or kept in contact for years at ordinary temperatures and no combination will ensue, but raise them to what is known as the igniting temperature and burning at once takes place. The temperature of ignition is the point at which the elements concerned open out sufficiently to come into intimate contact.

Everybody meets daily with illustrations of the fact that fuel will not burn till it has been raised to a certain heat. If you put a piece of wood or coal on the fire it remains unchanged for a time till the temperature at which it combines with oxygen is reached, when it begins to burn. Different kinds of fuel have different igniting points. Coal gas does not burn below a red heat of iron, and carbon has a still higher igniting point. If you take a piece of iron heated to a dim red and try to light an illuminating gas jet with it you will not succeed. Increase the heat till the iron approaches orange color and it will then light the gas. From this it will be learned that the igniting temperature of hydrocarbon gas is about the cherry heat of iron. As the igniting temperature of carbon is still higher, it will be understood that the coke or non-volatile part of the coal must be kept at a higher temperature still to make it burn.

### HOW A FIRE BURNS.

As a preliminary to lighting the fire we cover the grates of the furnace with a coating of wood. Then we strike a match and with its flame ignite some greasy cotton waste and scattering the burning material over the wood, start a fire. The phosphorus at the end of the match ignites at such a low temperature that the heat generated by the light friction of rubbing over a rough surface raises it to the burning point. The sulphur or other inflammable substance at the end of the match is ignited by the phosphorus, and the heat evolved is sufficient to set free the hydro-carbons in the wood, which combine with the oxygen taken from the air, making a bright flame. This keeps the carbon or solid part of the match at the high temperature necessary for combustion.

The flame of the match would not be sufficient to raise a large piece of firewood to the igniting temperature, because the extended surface would carry off the heat as fast as it was generated without raising any part to the temperature at which combustion is maintained. To overcame this, cotton waste saturated with oil, which consists of hydro-carbons, is employed. The waste being in a state of fine subdivision, permits the flame to communicate its heat to small particles which readily ignite and spread the fire through the mass. This being thrown on the wood in the furnace ignites the separate pieces, and raises the temperature to the point at which the elements forming the match burned.

### DISTILLING GASES FROM THE FUEL.

The fire being lighted, we will note the different phrases in the combustion of coal in a locomotive firebox. The principles that regulate the combustion of coal in fireboxes are little varied in their action when the fire is found in any other kind of furnace.

Suppose we have a bright fire burning on the grate and the fireman proceeds to throw in a charge of bituminous coal. The immediate effect of throwing in fresh coal is to reduce the temperature of the firebox, but the heat quickly raises the temperature of the fuel and drives out the volatile gas. If this gas is properly cared for, it is burned, producing intense heat that has about three times the steam-generating power of the solid part of the coal from which the gas was distilled. To burn the hydro-carbons a high furnace temperature is necessary, because the combustion of the volatile gases is performed on the space between the surface of the solid fuel and the mouth of the tubes. Between the heat-absorbing walls of the heating surface, which in this case might more aptly be called cooling surface, and the flow of air intended to provide the oxygen used in combustion, there is great danger of the hydro-carbons passing away uncombined.

### BURNING HYDROGEN COMPOUNDS.

When hydrogen belonging to the volatile gases meets with favorable conditions for combustion, 2 parts by weight combines with 16 parts by weight of oxygen (1 to 8), and the product is water. This process which Dame Nature has of making water generates intense heat. The water formed is not perceptible as it passes off in the form of vapor, but it is the only tangible product of this combustion. If it were condensed and collected, which can be done by special apparatus, the weight of the water formed would be found to equal the weight of the hydrogen and oxygen which entered into combination.

The presence of water as a product of combustion can be perceived when a lamp is newly lighted as the steam condenses on the cold chimney.

When a locomotive fire is first lighted, drops of water can be seen running out of the joints about the smoke-box. This is the steam made by the act of combustion of hydrogen condensing on the cold iron of the smoke-box and stack.

The favorable conditions required for the combustion of hydrogen are a high furnace temperature and the presence of oxygen. If the temperature is not sufficiently high or the supply of oxygen is limited, the whole or part of the hydrogen liberated from the coal passes away unconsumed. This loss is serious. In the first place, a large proportion of heat has been taken away from the coal fire to gasify the hydrogen. In the second place, the hydrogen in separating from the coal has the power of forming a gaseous compound which chemists call ethylene, similar to ordinary illuminating gas ($C_2H_4$), which contains 6 pounds of carbon to 1 of hydrogen. If this mixture is permitted to pass through the tubes unconsumed, it carries away valuable fuel.

In furnace combustion the hydrogen in the volatile gases may be said never to burn as pure hydrogen and oxygen. The engineer anxious to obtain the greatest amount of useful heat from the coal is interested merely in the combustion of carbon and hydrogen. Among the complex gases formed by these elements and oxygen are carburetted hydrogen, bi-carburetted hydrogen, carbon monoxide, and small quantities of other elements. With good firing and properly constructed furnaces the greater part of these gases are burned. When inferior firemen are employed and the furnaces are not properly adapted for the work to be done, the greater part of the hydro-carbons in the coal are wasted. When we hear it said that coke or anthracite coal can be used as economically as good bituminous coal we may be certain that the light gases of the latter coal are not converted into heat.

### BURNING THE SOLID CARBON.

When the volatile gases have been expelled from the fuel the solid part remaining is coke, whose principal constituent is pure carbon. There is very little difference in the composition of coke and anthracite coal.

When the carbon has been raised to the temperature of ignition and a plentiful supply of oxygen is present, 12 parts by weight or one atom of carbon unites with 32 parts by weight or two atoms of oxygen forming carbon-dioxide, commonly called carbonic acid. This is the most valuable combination of carbon and oxygen in combustion because it generates the greatest amount of heat possible by the union of these elements.

### EFFECT OF TOO LITTLE AIR.

In case that the supply of air is restricted in the furnace, one atom of carbon will unite with one atom of oxygen forming carbon-monoxide, a product whose heat is much lower than the heat of carbon-dioxide. The second atom of oxygen in carbon-dioxide appears to be in loose combination with the carbon atom, for should the carbon dioxide encounter any of the compounds of carbon on its way to the tubes, the second atom will leave its partner and form carbon-monoxide with some other atom of carbon. This converts both into the gas of low-heating property.

The atoms of carbon, on being raised to the necessary temperature, appear to start off in search of two oxygen wives, and their highest affinities cannot be satisfied short of this number. If the two atoms of oxygen are found in an atmosphere hot enough for combustion, the union takes place and much heat results. When the supply of oxygen is so restricted that only one atom can be obtained by the carbon atom, the dual union is made and the two march towards the tubes doing small work in the heating of water

Some of the carbon atoms have failed, like many mortals, to find a partner and are lingering about the furnace occupying space for no worthy purpose. A carbon dioxide molecule that has reached its highest destiny comes along with its two wives and one deserts it to embrace the stray carbon atom The result is a general chilliness. From this it will be understood that the oxygen wives ought to be liberally supplied if a hot fire is wanted The air supplies the oxygen

Furnaces and fireboxes have been designed with great ingenuity for the purposes of smoke prevention which systematically robbed the carbon dioxide of its second oxygen partner at a certain part of the journey towards the flues More particulars of this will be given when we are considering smoke preventers

During a recent visit to the Michigan Railway Supply Co.'s works at Detroit, we found them running a full force of men in the manufacture of their steel car-door and steel brake-beam The works are equipped with ingeniously designed special machinery for the construction of these articles and the work is done very expeditiously and with more exactness than by hand

"A Modern Boiler Plant" is the title of a very attractive illustrated circular issued by Westinghouse, Church, Kerr & Co., Boston. The pamphlet illustrates the outside and inside of an ideal boiler house and all the internal arrangements of boilers, bunkers and the plant necessary for running boilers to advantage. The publishers of the circular say that they have organized a department to design, build or remodel boiler plants and to furnish complete architect's drawings with dimensioned details for the construction of first-class boiler plants

The Emergency Train Signal Co., Liberty street, New York, have made arrangements to put in an equipment of their signalling plant upon the South Side Elevated Railroad of Chicago. The system comprises a block system for controlling the movement of trains and a tripping arrangement secured on the track for applying the air-brakes in case the engineer fails to stop when a signal is at danger

The Canadian Pacific Railway Company have sent to the World's Fair a vestibuled train of their well-known palace cars finished inside and out in solid mahogany. The cars look very fine when they are new, but they soon turn black outside. The train is, however, certain to attract much attention.

We have received from the Locomotive Superintendent of the New Zealand Railways a neat calendar for 1893 which has a double-ended suburban engine for a heading, and contains particulars about the expense of operating the motive-power and rolling-stock departments. From this we note that there are 1,869 miles of road in operation, and 1,370 employes in the locomotive department. There are 266 locomotives in service and 8,727 cars of all kinds. The coal consumed is 32.08 per mile; oil, 1.85 quarts per 100 miles; waste, 96 pounds per 100 miles. The total running expenses are 18.4 cents per mile. The car repairs per mile amount to 7.14 cents.

The Legislature of New York State have under consideration a bill making it a crime for newspaper publishers to misrepresent their circulation for the purposes of securing advertising. If this bill should pass it would be a little hard on some of the railroad papers whose subscription lists exist principally in the mendacity of the publishers.

A circular has been issued by Mr. C. A. Hammond, secretary of the American Society of Railroad Superintendents, giving particulars of the business to be transacted at a special meeting to be held at the Grand Pacific Hotel, Chicago, on April 10. An urgent appeal is made to the members to be present, as a large attendance is very much desired

The State of Maine has been exceedingly fortunate in having few serious railroad accidents There has not been a single person killed in a train wreck in that State since 1889.

The Chicago & Grand Trunk have equipped some of their locomotives with electric headlights.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates They are made by BRADLEY & POATES, 251 William Street, New York City.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

WE CAN FURNISH BINDERS FOR PRESERVING A YEAR'S FILE OF THIS PAPER at $1.00. Postage paid any address.

### Tests of Simple and Compound Locomotives.

At a meeting of the Western Railway Club, Mr William Forsyth read a paper on "Tests of Locomotives in Heavy Express Service," in which interesting data were given about the comparative economy of compound and simple locomotives in the pulling of heavy fast passenger trains. Five engines were employed: First, a Baldwin 4-cylinder compound ten-wheeler with cylinders equivalent to a 19 x 24-inch simple engine, 2.135 square feet of heating surface, grate area, 28.3 square feet; weight on drivers, 103,000 pounds; diameter of drivers, 72 inches. Second, a C. B. & Q. mogul compound, with cylinders 20 and 29 x 24 inches, 1,506 square feet of heating surface, 27 1 square feet grate and 94.500 pounds on drivers, the latter being 62 inches diameter. Third, a simple mogul in every respect the same as the compound except that the cylinders are 19 x 24 inches. Fourth, a simple mogul similar to the last except that the driving wheels are 68 inches diameter. Fifth, a simple eight-wheel engine, with cylinders 18 x 24 inches, 1,412 square feet of heating surface, 24 4 square feet grate and 66,000 pounds on drivers that are 68¾ inches diameter.

Tests were made on passenger trains of 11 cars, averaging close on 400 tons exclusive of engine and tender and run at an average speed of about 42 miles an hour.

The author says that the tests cannot be regarded as a measure of the comparative value of simple and compound locomotives, but rather as an indication of the value the Baldwin compound engine with the standard C B. & Q. locomotives for heavy and express passenger service.

The C. B. & Q. compound was built for fast freight service, and has never shown an improved economy over simple engines of the same class when used in passenger service.

The Baldwin compound would not steam freely when it first arrived on the road, and the grates and draft appliances were changed to suit Streator coal. Although the average boiler pressure was 177 pounds, the pressure was not at all regular, and the engine's performance must have suffered on this account.

With a train of twelve cars the simple moguls displayed power to force the train into speed superior to the compounds. With a train of eleven cars the Baldwin compound worked into speed more rapidly than the others.

The general conclusions of the tests given in the paper are as follows

1. The coal measurements show 22 per cent. more tons of cars hauled per pound of coal by the simple engines than by the Baldwin compound.

2 The average rate of evaporation was 5 per cent more with the simple engines than with the Baldwin compound.

3 The cylinder performance measured by the indicator cards taken at average running speed, 45 miles per hour, shows 18 per cent more foot-pounds of work done per heat unit in the steam used by the simple engine than by the Baldwin compound.

4 At 30 miles per hour the cards show the Baldwin engine to have the best economy, developing 14 per cent. more work per heat unit than the simple engine.

5. The poor showing made by the Baldwin compound was largely due to the heavy train and high speed. With a lighter train or the same train on a slower schedule it would have shown a much better economy. The cards taken at 30 miles an hour show this.

6. The Baldwin compound as operated on fast trains weighing 350 to 400 tons was not as economical in the use of fuel as the simple engine by about 25 per cent.

7. When working on heavy express service the Baldwin compound lost the principal advantages of compounding, viz. high initial pressure in the cylinders, increased number of expansions, softer blast on the fire.

As a result its boiler performance and cylinder performance were not as good as simple engines of proper capacity.

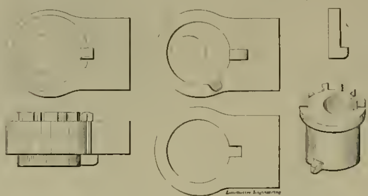
The record of tests shows that the smaller the amount of coal burned per square foot of grate per hour, the greater the evaporation, and at slower speeds the evaporation should increase. The average evaporation was 6.5, the same as that obtained from the same coal burned in a cylindrical tubular stationary boiler at a rate of 25 pounds per square foot of grate per hour. This shows that the locomotive boiler with properly proportioned grate and good draft appliances will burn five times as much coal per square foot of grate per hour with as good economy as the average stationary boiler.

The author of the paper does not say so, but it appears to us that the principal lesson of these tests is, that train service which requires high piston speed is not adapted for compound locomotives.

### A Draw-Bar Shortening Device.

The accompanying sketch shows a little device for shortening the draw-bar between engine and tender, the invention of Engineer H. W. Lounsberry, of the Fall Brook Railway.

Mr. W. A. Foster, superintendent of machinery, writes that they have a number of them in use giving no trouble at all, and that "it's a good thing."

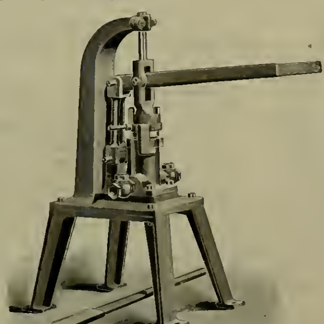


As can be seen, the eccentric block can be revolved enough to take up the slack and held from going back by a key.

A lug on the lower side of the bush goes through the keyway, and, when turned, prevents the bush from coming out of the bar.

### Portable Testing Pump.

This pump was designed for low-pressure work not exceeding 800 lbs per square inch, and is fitted with a double piston, the larger having a diameter of 3 inches, and a stroke of 4 inches, and is capable of giving a pressure of 200 lbs. to the square inch, while the smaller one (1¼ inches) can give the maximum pressure—800 lbs.



The pump is fitted for ordinary steam-pipe connections, 1 inch in diameter, and is mounted on a platform having four legs or wheels of good size as desired, making it convenient in moving and staple while pumping. The change from large to small piston is made by throwing a latching clutch.

It is made by Watson & Stillman, of this city.

### Arbitration Committee Decisions.

A case which ought not to require appeal to the Arbitration Committee of the Master Car Builders' Association, was decided again at last meeting of this committee. The D. L. & W. refused to accept one of its own cars from the Nickel Plate on the grounds that wrong material had been employed in repairing the car. The Nickel Plate protested that no repairs had been done on the car while on that road, and tried to push the responsibility upon the C C. C & St. L., which had delivered the car to the Nickel Plate. That road in turn was ready to place the responsibility back to the C. H. & D., over whose road the car had passed to the C. C. C & St. L. It is not clear how many roads might have been asked to take the responsibility of the wrong material, but the superintendent of machinery of the N. Y. C. & St. L. submits copies of telegrams sent by the P & W., asking for material to repair the car in dispute, and this is offered as proof that the P. & W. is the real delinquent The P. & W. refused to become responsible, and the case went to arbitration. The Arbitration Committee, of course, held the N. Y. C. & St L. road, that attempted to return the car to the owners, responsible, as has been done in numerous other analogous cases. There is no article in the rules of the interchange of cars more distinctly stated than that which holds a road delivering a car responsible for defects which cause the car to be refused. All attempts to trace back the road which caused the defects are futile. The proper time to throw back the responsibility is when the car is received. Then it may be refused, unless carded, which makes the delivering road responsible. It takes a long time to make all concerned understand this rule.

The next arbitration case is another with many previous decisions. The L. E & St L. delivered a Wabash car to a private siding, where it was burned, and the road that handled the car refused to be responsible because it was moved merely on a switching charge. Rule 30 plainly holds the road responsible, nevertheless, and a decision was rendered accordingly.

The Cold Blast Transportation Co. made a claim against the N. Y C. & St. L. for three broken center-plate bolts for which the road put on a defect cord when delivering the car to the West Shore. Two of the bolts were broken when the car was received from another road. The carding road held that the defects were broken by fair usage, and that railroad companies not being responsible for defects of this character on private cars, the charge was not just. The Arbitration Committee took the same view.

A rather novel case was raised by Nelson Morris & Co. against the New York Central. A car belonging to the former company came home with a wrong drawbar, the car being carded for this defect by the N. Y. C.; according to the rules of interchange the carding road was entitled to a credit of two cents per pound for the wrong drawbar, but this the owners of the car refused to grant on the grounds that they could not use a wrong drawbar to put on other cars, as is practiced by railroad companies, and that the drawbar was useful to them only as scrap iron. The Arbitration Committee decided that Nelson Morris & Co. were required to give the credit of two cents per pound according to the rules, but acknowledgement was made that the rule is unjust to private car owners and intimation was given that an effort will be made to change it.

A curious dispute arose between the Mobile & Ohio and C. B. & Q. The former road carded a C. B. & Q. car for one air hose and the owners sent in a bill of $2.55. The carding road held that the market price of an air-hose was $2 12½ and that t l rules specify this as the basis of charge. The C. B. & Q held that $2.45 was the actual cost of a hose applied in their shops and that there was no fixed market price. The Arbitration Committee decided that if the hose could be bought from the manufacturers at the lower price, that was a market price, and the charge made by the owners of the car was too high.

### A New Name.

We have received notice that the name of the Congdon Brake Shoe Company, of Chicago, has been changed to The Sargent Company. This is a proper change, for the company is doing a general business in iron and steel castings, and making brake-shoes is a small part of the work done. Mr. Geo. M. Sargent, president of the company, is so well and favorably known among railroad men that his name is much more potent than the name of any article which the company manufactures. The steel castings made by the company are said to be giving unusually good results.

Write on one side of the paper, state your point plainly and briefly, and then quit. We supply the generalities. No letters noticed unless name and address accompany.

## Hard Times on the Chicago Elevated.

*Editors:*

The notice which you published some ... ago about the pay for engineers and ... men on the Alley Elevated Railroad of Chicago has made many engineers ambi... to find their names on the pay-roll of ... railroad. If any of your readers think ... going there, I would like to give the ... advice given by one of your ... story-tellers who said "Don't." That is enough. I have been through the mill and can talk from experience.

I went there on the invitation of the ... mechanic, whom I found a decent ... and left a good job, thinking to better ... It was the worst mistake I ever made. I began running extra, and soon found out that all the trainmen are suffering from the oppression of rules. They are constantly expected to do things that cannot be done, and when they are not done there are about ten men ready to report it and they never forget the reporting for they have nothing else to do.

The last work I did on the road was on a wild stormy night, with showers of snow flying. The time to be made is fast. It is all a man can do to make the time, and yet they compel you to stop at stations on a margin of 15 inches. If you go in too slow you lose time. If you have to give the engine steam again you are reported for jerking the train, and if you fail to stop within the 15 inches you are reported. If you apply emergency to make the stop you break a seal and get censured for violating an important rule. Just imagine a man working a train into a station with the snow blowing in his face, and perhaps steam blowing across his vision from the cars of a passing train, and see what chance he has to stop opposite a post that he cannot see until he is on it. If he fails there is certain to be a locomotive supervisor, inspector or road foreman of engines ready to make the report, which also goes in from train masters, conductors and platform men. Then he gets ten days.

If an engineer shows that he can run on that road without violating a rule at every turn he is taken in for examination. * * On railroads run by sensible railroad men, examinations are given to find out if the men know enough of their duties to do their work properly. The Alley Elevated management conduct the examinations for the purpose of puzzling men and tripping them up. A brother unfortunate of mine, on being asked some absurd question, answered that he would stop and ask the second man he found on the structure.

"Why would you do that?" asked the examiner.

"Because I would be sure that every second man I met would be an official."

Of course that closed his career on the road.

The management of that road has given infamous treatment to the enginemen and others who performed the hard work of getting the road into running order. The men did their work satisfactorily for months, and had become proficient in performing the hard duties put upon them. All at once they were ordered to attend the office for examination, and because they could not answer a long catechism of senseless questions they were discharged.

* * * * * * *

The truth hurts no man, and it is good for the engineers and firemen all over to understand just what kind of treatment they may expect if they go to the Chicago Elevated.

ENGINEER.

*Brooklyn, N. Y.*

## New Wheel Defect and Tire Gauge.

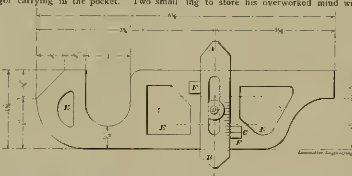
*Editors:*

The sketch below shows a combined wheel defect and tire gauge, which is more light, compact and handy than any other gauge that I have seen for the use of those having supervision over car and locomotive wheels.

A glance at the sketch will show that it covers all the points of the M. C. B. wheel-defect gauge, which need not be pointed out in detail.

The sliding scale *A B* is so made and graduated that the end *B* is used for measuring the wear of flange-tires and the end *A* for plain or "blind" tires, taking the reading in each case from the line *C*, but using different ends of the graduation on the scale.

The gauge and scale are both made of steel about 18 or 20 w. g., and the scale is fastened to the gauge by a stud *D* and small milled nut so that it can be revolved about the stud till it is parallel with the gauge. This makes it more compact, and it is cut out at *E E E* to make it lighter for carrying in the pocket. Two small



pieces of steel, *F F*, are riveted to the gauge so as to form guides for the scale and to keep it at right angles to the gauge when in use.

A gauge similar to this has been patented, but the idea was taken from this gauge when in an imperfect state, and it lacks many of the best points of the gauge here shown.

I have used one of these gauges for the past six years and find it the most useful tool I possess.

## A Good Word for the Chain Gang System.

*Editors:*

I would like to get the views of your correspondents on the method of running engineers and firemen on the rounds.

On this road we do not have any regular engine or engineer—it is "first in, first out," and I think that it is a very good plan.

It affords no lost time for any one, and a fireman picks up a good deal from the different men he fires for. He can soon tell who is the best engineer, as there are hardly any two engines run alike.

A fireman can learn a good deal by keeping good watch of an engineer, and if he will ask once in a while something in regard to his work he will draw out things that he does not know.

It is not quite so pleasant as it is to have a good engineer steady, but in case you are mated with a cross one it is a thousand times better.

I will say for myself I have learned more in three years of running this way than in the previous three years, and since I have taken LOCOMOTIVE ENGINEERING I have been able to stick some good engineers on some of the problems given.

O. W. LA CREQUE.

*Elmira, N. Y.*

## For Examinations and Licenses of Locomotive Engineers.

*Editors:*

We hear every day, and as often as we turn our attention to practical questions, the remark, "We want better engineers, better conductors, and, in fact, better posted men in all departments of railroad life." Let us consider for a little while how we are to obtain better men in all the branches connected with running and operating railroads, and especially in the locomotive and train service. Are we at present on the highway to success or not? I say we are not. The future presents to our distant view a sadder state of affairs than the present, and why? The question is an easy one to answer. Seniority is the stumbling block over which we are to fall. The present and future present to every man of an imaginative turn of mind the fact that to make railroading a success we must keep abreast of the times. Under the present state of affairs it is not necessary for young men entering the various branches in railroading, especially in the locomotive and train service, to bother his weary brain with scientific questions or in reading books, papers, or in any way trying to store his overworked mind with things necessary to success. Seniority will overcome all these difficulties as the inevitable hand of time marks the years as they go by, until the time comes for him to be pushed upward and onward to a position of trust.

Seniority is a word that tickles the ears of a lazy man and at the same time it is the forerunner of three great evils in railroad life.

First, it creates discord among the rank and file of the men in the various callings of life on a railroad. Buried deep in the heart of almost every man is a hatred and an ill-will toward his fellow man, and as time rolls on he is longing for a misfortune to befall some one whereby he will be pushed onward one, two or three steps as the case may be.

Second, it is contrary to nature's laws, for it encourages sloth and idleness, because for a man to reach a responsible position it is not necessary for him to study or employ the leisure hours allotted to him in improving his store of knowledge. Seniority is helping him, and when his turn comes, whether he is competent or not, the company must give him an engine to run, or a train, as the case may be.

Third, we can look around us on every side and see the evil results of seniority in its present state of progress. We see men running engines and trains who are a burden to themselves, a detriment to the company and a danger to their fellow workmen and to the traveling public.

When a man's ambition reaches no farther than the pay car, it matters not what he is, whether a wiper, fireman, brakeman or train dispatcher, you soon set that man down as one who will never prove a success, and the time will come to his sorrow that he did not improve his knowledge when he had an opportunity to do so, instead of perhaps gambling or spending his time and money in saloons, or other places that lead to the ruin and destruction of many men.

There is only one way to overcome these evils, and that is to examine men who are in line of promotion at least once a year, and when the time comes for a fireman to take charge of a locomotive or a brakeman a train, subject him to a severe examination, and when he has passed it give him a license as an engineer or conductor. There is no reason why a locomotive engineer should not be required to hold a license as well as a marine engineer, both positions should be filled with trustworthy, competent and reliable men.

## Approves of De Sanno's Box—Large Exhaust Pipes.

*Editors:*

I want to say, "Bully for De Sanno." I have been at work about fifteen years trying to get rid of the wedge in connection with driving-boxes, and had gotten up an idea almost like his, they are so near alike that I would not change; I hope some road or locomotive works will try them.

I want to say my little say—just a few words about compound engines. I am sure that if a division of any road was equipped with an equal number of compounds and single-expansion engines, each to carry the same boiler pressure, all to be used in same class of service, run first in first out, the single-expansion to have exhaust pipes as large as is possible to get in the saddle, say 4 inches deep by 20 inches wide up to the nozzles—size of nozzle does not matter—that the single-expansion, after all had been rebuilt, would prove much the cheapest.

We have two engines on this (Rocky Mountain) division of the N. P., of same class, 17 x 24-inch cylinders, and one is at least 20 per cent. cheaper than the other, all owing to size of the exhaust pipes as cast in saddle. I believe that there never has yet been an engine built that was large enough in these pipes.

NORTHERN PACIFIC.

*Garrison, Mont.*

## Lining Guides.

*Editors:*

Having read with interest articles on lining guides and wear on same, by L. C. Hitchcock and C. F. Willson, I consider both articles ably written but lacking some proof that the cross-head wears the most on the bottom guide. Having to do with setting up guides for the past eighteen years, I inclose you a sketch showing how

I have found out how or where the cross-head wears the most, so that when guides need reducing I would be able to tell how to proceed so as to keep the cross-head central with piston at all times.

When engine is in shop, overhauled and cross-head planed, a circle should be described on cross-head at both ends, as shown in sketch at *A B*. When guides need reducing a compass should be used in center *A B*, which will indicate which way guides need lining, up or down.

When engine is running forward or backward, as in suburban work, this kink will show where the wear has been the most.

*Colon, Colombia.* Panama Ry.

## Getting Dead Centers by Crossheads.

*Editors:*

Have read in the ENGINEERING about a number of ways to get centers and set valves quickly, but none of them use the cross-head for that purpose. Why not use the cross-heads, taking the one on half

stroke for center of the opposite side, etc., you only have to get two centers and pinch engine one turn of drivers, you also save the time pinching engine to take up last motion; you mark valve-stems in the usual way. Have done this work several ways, but think this the best, doing the work quicker and giving just as good results, if not better. G. E. B.

### Talk About Air-Hose—Some Records of Failures—How to Save Hose.

*Editors:*

As nearly all of the cars that are now being built at the various manufactories throughout the United States are being equipped with air-brakes, a person can easily see that it takes an enormous amount of air-hose to supply these new cars, also to keep up the repairs of those cars which are already equipped.

Now, I think that a discussion as to the relative merits of the various kinds of hose now on the market would be of general interest, as well as beneficial to all air-brake men, also to the railroad companies, as it is to their interest to buy the hose that will give the best service.

This company (A., T. & S. F. R. R.) are using quite a number of different brands of hose, and I cannot help but notice the difference in the construction of the hose and the period of time that elapses from the time of placing in service and taking out.

In giving a description of a hose which I have found to give the best satisfaction, I will say that the rubber should not be too hard, nor the duck too firm, as the hose will undoubtedly be expanded in inserting the fitting to such an extent that it will break the inner ply, thus making a weak place as the other ply are stretched so that the air will soon find its way through and form a bubble on the outside of the hose.

If the rubber be too hard, the hose will not be flexible enough to bend easily and place in the dummy hose-hook without breaking the hose.

By-the-way, I regard that same hook as being a very poor device for the use required of it, and think it plays a very important part in the ruination of a large number of air hose, for when a hose is the least bit hard, it is very liable to be broken or be cramped in such a position that it makes a weak place in it, generally just below the hose-nipple.

Another thing that I have found a great deal of trouble with is the inside seam or lap.

When filled with a pressure of air, this seam is held open and allows any oil or moisture that may be passing through to find lodgment therein; then the mischief is done, for we know that oil is an emeny to rubber, and the hose is soon eaten through.

I will say that I have come across one brand of hose that is made seamless in the manufacture of the inner tube before the duck is wound, and so far they have given entire satisfaction. They are The Boston Belting Co.'s "Imperial."

I would like to know why air-hose with the "patent-ends," or those that have a rubber covering over the ends, are superior to those that have not. I could never quite understand the philosophy of covering the ends if the right kind of duck be used and the hose properly clamped after the fitting has been inserted.

It has been a question in my mind for some time as to what is the average life of air-hose under favorable circumstances, but under the conditions now existing it is almost incalculable.

Perhaps a few statistics which I compiled recently (stating the cause of removal), after receiving a consignment of worn-out hose, will be of general interest.

Out of a total of 250 hose, I found that 88 or 35⅕% were removed for chafing against drawheads, bolts, straps, etc., 42 or 16⅘% were torn apart by breaking in two, switching, etc., and 25 or 10% bad been maliciously destroyed by cutting.

Thus you will see that only 155, or 38%, had seen a lifetime of actual service, and even a large portion of these were ruined by the injudicious use of oil and other causes.

In fitting up hose with machines the operator should be very careful and allow plenty of space for expansion of the hose, the full length of that portion of the fitting to be inserted, and should file off any unnecessary particle of metal that may be projecting from the fitting, as many hose are ruined by allowing these particles to tear the inside lining.

In order to be economical, they have a rule in vogue on this road requiring trainmen to save all worn out hose after removal and exchange them for new.

By this means they save an enormous number of fittings, thereby reducing the expenses in the air-brake department.

From the foregoing it is plainly seen that there are various ways by which we may get good service and a long life from air-hose if properly taken care of. In the first place, good hose should be selected by a person familiar with their construction and manufacture, and one who knows all the good and bad points of the principal brands now on the market.

The air-inspectors should be on the alert, "and with a little work with his wrench may save the life of a hose that may be chafing against some obstruction," or, if possible, remove the obstruction entirely.

The train crews should also be taught that it is considered "bad form" to pour a couple of gallons of car oil in the air-hose in order to oil the "triples," and if they take heed they will be doing their share toward saving expenses and diminishing delays caused by bad hose.

### Testing Air Before Starting—Engineers Held Responsible for Neglected Brakes.

*Editors:*

In the March number of your valuable paper I read a communication regarding train-pipe connection to brake-valve on second engine in double heading. Why will it not do to put brake-valve handle on lap to shut off all connection to main reservoir, and put a small stop-cock in port for the emission of air from train-pipe? Take the one off drip-cup on exhaust-pipe from pump; you can get to end of run by doing this, yet a brake-valve is not complete without a stop-cock on train-pipe, and engine should not be sent out on the road without one.

I also notice a communication from M., K. & T. as regards engineers using air-brakes only in case of emergency, on account of trains breaking in two. He says the management claims it to be the fault of air-brakes; the sooner the manipulators of the M., K. & T. R. R. learn that this is a grand mistake the better it will be for employees, motive power and rolling stock of that system. Why, we will take their claim as to trains parting. This accident is liable to occur at any time, and is as likely to occur to a train that has no cars equipped with air as to the one that has.

Not long ago I was running down a grade of 50 feet to the mile, with engine working steam, when all at once every brake I had in the train went on with a bang. The knuckle of an automatic coupler had unlatched, leaving one car of air with the train and five with engine.

You see no one was to blame for this break-in-two, neither could it be charged to air-cars.

In nearly every instance the cause of trains parting is defective links, pins or draw bars, and not owing to rough handling by engineers.

M., K. & T. says: "When we want to stop at a water crane we apply the emergency," and what is the consequence? Those quick-action fellows back of engine get in their work before that slow triple on engine, the automatic couplers and old style draw bars back of air are strained and cracked, and when engineer gets to division station reports lost motion taken up between engine and tank on account of those quick-action brakes doing their work before that slow triple on engine. There is nothing in the general usage of motive power and rolling-stock that will do as much damage as this emergency every time you stop, so I think the men that handle trains should be allowed to use their own judgment in handling air-brakes, and I have an argument to make for the engineer that sometimes fails to make a stop with a freight train that has, we will say, nine cars of air. The law compels railroad companies to equip freight cars with air-brakes, but does not compel them to keep air-brakes in good working condition.

Not long ago I was pulling a freight train in which were thirteen cars of air, these air-cars handled the train all right on the level, but when I went to head in down a sixty-four foot grade, "I got left." I went by three or four car lengths. When I got in on the side track I set air and went back and looked over these brakes myself, and I found that five out of thirteen brakes I could move with my foot against the brake shoe (the brakeman told me these brakes were all right after trying air at division), and as these air-cars were all empty and loads behind, the remaining brakes would not hold the train.

Sometimes we will get five or six cars of air that will handle a train anywhere, so we will say we will start out with enough brakes to handle a train and one-half of these brakes are not in good working condition, brakeman says every brake set, that is every piston went out, "you see the man that is handling them is the one that is responsible if anything happens."

Suppose Mr. M. K & T. was coupled onto twenty cars of air with a train of thirty loads behind him. After leaving division station the first station was a bad place to go into, and he had a good opportunity of trying air to see whether it would hold or not, and did not try it, and suppose he got by this station and was going down a fifty foot grade and "strikes a short flag," to use a railway phrase, and he goes after the emergency and finds that it will not work, for some one has turned the stop-cock behind the second car. I think Mr. M. K & T would rather have run the risk of breaking in two and tested that air a little at the first station.

*Creston, Iowa.* D. B. HUTCHINS.

### Unsatisfactory Experience with Hollow Stay-Bolts.

*Editors:*

I see in the March number that James Heron approves of the hollow stay-bolt. I have had quite an experience with them and cannot report so favorably.

The road on which I am employed use hollow bolts exclusively, and a short time since we put an entire set in a boiler. After the bolts were cut off and we commenced to head them down, we found some of them split on the end. Ten of them were taken out and found to be split from end to end.

When hydraulic pressure was applied, six more showed leaks at the center hole and were taken out, they too, were split.

We have taken out as high as seventy-five broken bolts in an engine in one month, we always increase the size when renewing—take out a ⅞-inch bolt and put in a 1⅛; we have used some as large as 1¼-inch, these also break. How large will we need to use to insure against breakage.

It is claimed that hollow bolts are more pliable or flexible than solid bolts. We have put solid bolts beside hollow ones and the hollow bolt broke first.

Now, don't say we can't tell a broken solid bolt—we can. I have an inspector that can not only tell when a bolt is broken but when *half* broken.

T. A. JAMESON.

*Knoxville, Tenn.*

[Perhaps the hollow bolts used are of the kind made by welding one piece of pipe inside another, or the "worse yet" kind consisting of two pieces of half-round iron, with a groove in the flat surface of each, welded up, and not the mandril roll bolt. We should like to publish the method of that boiler inspector—so far as we know, stay-bolt inspection is a very uncertain business.]

### Some Common Things You Ought to Know. Do You?

*Editors:*

1. Why is it that the quick-action freight triple has a threaded exhaust port on each side of triple-valve casing while that of passenger has only one?

2. Why is it that W. A. B. Co. forbid the use of freight triples in passenger service and *vice versa*, while at the same time freight train-pipe is larger than that of passenger; under such conditions, why is the freight train-pipe larger?

3. Why is it that, when making an emergency application with empty engine, or train of one or two cars, using the equalizing discharge-valve, that the black hand on the gauge will drop back until the handle spring passes the service notch and opens emergency port, when black hand will rise and indicate a pressure of from 45 to 50 pounds (from original pressure of 70 pounds) when train-pipe should be empty? W. T. HAMAR, R. F. E.

### Some Remarks on the Care of Air Pumps, Swabs, Metallic Packing, Pounding, etc.

*Editors:*

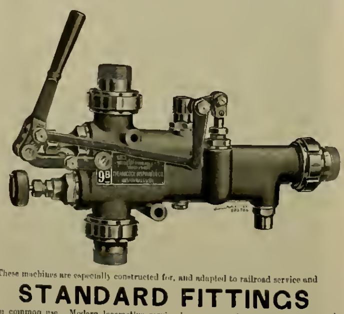
There is one thing about the air cylinder of a pump that is seldom spoken of or taken into consideration, and that is the fact that they wear larger at the ends. This causes the packing rings to contract and expand at every stroke. When you find an air pump in this condition it requires more oil than one that has a good true cylinder. So I find air pumps are just like sick people. They require different kinds of medicine and methods, and also at the right time, for if an air-pump is not treated right it will get worse all the time.

Now about swabs. Nearly all air-brakemen say to put a swab on the piston-rod, but the way most engineers put them on it does not touch the piston-rod but very little, and the swab just lies on the edge of the lower packing nut, and, of course, does the piston-rod very little good. But if instructors would caution air men to make it a close fit to the piston-rod, it would then do some good when it is oiled, and especially is this the case with air-pumps having metallic packing. I find metallic packing is one of the best things connected with air-pumps when properly taken care of; but it has one great disadvantage, and that is it makes a great many engineers very careless about their air-pumps, and they seem to think because a pump has metallic packing it does not need any care, and they will run it without oil until something gives way, which is an every-day occurrence on most roads.

Now about pump-pounding. Of course we all know there is different reasons for it, but there is one point that is very little said about and that is very badly constructed frames, or when the frame gets loose or the pump loose on the frame. This will cause an air-pump to pound in a great many cases, when by making everything fast it will run smoothly.

Another thing which some would-be smart men do, and that is putting in a common check-valve in the discharge-pipe. This is one of the worst things that can be done, and it should not be allowed on any road.

There seems to be a great deal of trouble



with the check-valve in the W. A. B. quick action triple on account of the seat getting very rusty, which is cast-iron. Why could it not be made of brass so as to avoid a great deal of this trouble?

Another thing, how would the air-brakemen expect engineers to handle the improved equalizing discharge-valve in the release position when it has the excess pressure valve attached. If it was left in full release all the time there would be a constant blow from exhaust port from the small detect hole in the rotary-valve. I mean men that do not know how to handle the brake-valve in running.

### Making Irish Mileage.

*Editors:*

An inspector had to speak to a driver of a shunting engine in one of the colonies about the mileage being too small on his daily report sheet, and that he would have to show more. "Faith, sor, I can't do that, for, begorra, every mile I travel goes down on the sheet."

*Inspector.*—"Well, if you can't show more mileage I will put some one on her that will, so let me have more mileage on your sheet to-morrow."

After the inspector departed, the driver of the shunting engine got to racking his brains how to do it. After thinking a long time, said, "Be jabers, mate, I have it. Whin we are done shunting for the traffic, you get down and oil the rails and I'll make plenty of mileage for that blankety blank inspector, sure." And he did make plenty of mileage that day; he showed so much that the superintendent had him up on the carpet before him and wanted to know how he had made 200 miles on a shunting engine in 8 hours. He told him how he made it.

"Well," says the superintendent, "you can now go and act as driver of a wheelbarrow at the ash-pits, and see what mileage you can get out of the barrow."

### Government Inspection of Locomotive Boilers.

*Editors:*

Another one of those inevitable accidents has happened on the K. & G. road. Engineer Ben Wheeler's boiler is sailing up among the clouds, and his fireman has gone to the happy hunting grounds, the hostler is laid up in the hospital for repairs, while Mr. Wheeler is at his home in the care of the doctor, caused by the sudden demise of this particular engine boiler. I often wonder if all the M. M.'s realize how much responsibility rests on them, and them alone, in the eyes of the public.

And then again I wonder does the public realize how the M. M. is held down by his superior officers, and then I wonder how long our great and glorious country will allow things to be thus on railroads.

I just imagine I hear people, and especially our Congressmen, say, "What has the government to do with this question?" I say they have all to do with it, and I will explain how and why in my humble opinion this is so.

I need not go any further than the Marine laws, they are strong and will cover the management of railroads as well as they do steam vessels. A vessel can not run without a licensed crew and they must be licensed by the United States Government, so I say that on a railroad no train should be moved without a licensed crew and management.

I claim that the general government should appoint inspectors of the boiler and car and bridge and track departments for each State. Those inspectors should be paid out of the money that each State takes in from taxes—do not make the railroad companies pay this, as they have enough to pay running expenses and if they are forced to pay for motive power and car and track and bridge inspectors they will find some trouble to get a dividend.

I claim that each State should be forced to take care of the traveling public, even if it does cost them a little money, for what is money compared to life and limb. All these appointments should be made in the same manner as Marine Law appointments are made.

Do not understand me that I want the government to take charge of the roads, for I claim they have not the right to do that, but they have a right to see that they are properly managed, and that the rail road company uses the proper material and keeps the road in proper condition for the safety of the public.

The public includes everybody, not only the traveling public but people living close to a railroad are always in danger, also the people along the track and at the depots.

I think all this danger could be lessened at least one-half by good inspectors. The inspectors could cause the companies to keep their engines in good order also their cars, track and bridges, the same as vessels are kept. If I should live to see this made a law and enforced I think I could cross the dark river happily, but all our Legislatures and Congress think about concerning railroads is rates and a commission to enforce them, and life and limb seem to be an after consideration.

The government does not own the steamboats, but they do own the streams they run on, so they own the land the railroads run on, and thus they have a right to act in this matter as a great protection to the traveling public and the public in general.

As regards these blow-ups, do not understand me that there was anything wrong with the boiler, but I do say that the general government of the United States does not know any more about it than I do, but perhaps if they had inspectors it would not have happened—and yet it might. It is getting so of late years that it is about as much as a machinery officer's position is worth to condemn a boiler; it matters not how old it may be, he must patch it up and keep it going regardless of the danger.

I would bet you anything, if locomotive boilers were inspected as closely as steamboat boilers are by the government inspectors, one-third of the boilers would go out of service, one-tenth of them would not be received from the building works.

If this ever becomes a law, God help the sawmill man with his tram roads to haul logs. Nine-tenths of them would have to hunt up and feed their old oxen and haul logs as they used to do.

State laws are no good for this. It must be by the General Government, so that it will cover each State.

Furthermore, this would break up the blacklisting of employés. General managers, superintendents of transportation, superintendents of motive power and machinery, superintendents of cars, train dispatchers, engineers, conductors, brakemen, roadmasters, track bosses and superintendents of bridges should all be licensed.

Now, will somebody take this up and tell me why it should not be done, and show me where I am wrong, as I am open to conviction and will be pleased to have this discussion pro and con.

YE OLDE RAILROADER.

### Another Plan for Locating Eccentrics Before Wheels are Under the Engine.

*Editors:*

I see inquiries made concerning the keying on of eccentric sheaves or cams before the wheels were placed under the engine.

I never worked in but one shop where that was done, and then only occasionally for the instruction of the apprentices.

After the wheels were on the axle and the pins in, they were placed on a pair of trestles that were perfectly level every way.

Then, with a pair of dividers, scribe a circle on each end of the axle the size of the shoulder collar of the corresponding pin

Now bring one of the pins to a nearly horizontal position with the axle and place a straight edge on the collar of the pin, and the edge of the circle on the axle (Fig 1) and then with a spirit level bring the straight edge level, which will bring the pin to the center on that side.

Now, be sure and clamp the wheel firmly in this position, and then put the eccentrics on the shaft

Then get a sheet of heavy wrapping paper or tin and tack it on the floor immediately under the eccentrics. Now, with a pair of plumb bobs, mark off the extreme travel of the eccentric (*a* and *b*, Fig. 2), and then with a pair of dividers find the center of the travel (*c*, Fig 2) on the side *next to the pin*.

Now set the dividers to the amount of lap that the valve has and the lead that you want and mark it out from the center (*c*).

Then bring the eccentric around until the forward plumb bob (No. 1, Fig. 2) comes to the last or lead mark and mark the eccentric ready to cut the key seats; the same operation will set any of the eccentrics with the exception that strict attention must be paid as to which side of the horizontal center the throw of the eccentric is.

I always set the pin so as to represent the forward center if the wheels were under the engine, and then the forward motion eccentric would be above the horizontal center and the back motion below it.

*Ft. Howard, Wis.* MECHANIC.

### Making Small Tools in Railroad Shops.

*Editors:*

I cannot see why it is that people who have a hobby cannot ride it without ridiculing or blackguarding other folks. Before this, as you know, I have felt called upon to censure writers in the LOCOMOTIVE ENGINEERING for their tendency in this direction I do not care to pose as the great and only champion of the machinists of the United States, but the writer of your first article in the March issue has aroused my ire by his superfluous and entirely unnecessary strictures on the tool-making machinists of the railway shops. Why "ostentatious inspection," and why assert that "then they are threaded with no particular degree of accuracy." Does your contract tool-maker think that his brother is a fool? It is useless to quote from this article. Every sentence almost is a slander on machinists who dare to make a tap, or die, instead of buying it ready made. Now while I am ready to admit that you may buy a ready-made article cheaper than you can make it, it by no means follows that it is better, or even as good. Some of the worst taps and reamers I ever saw were the product of a specialty concern, and I have seen some twist drills that might have been originally designed for taper reamers; and as a rule I believe railroad tool-rooms do not attempt to evolve the twist drill. But then I am charitable enough to allow that this sad state of affairs in the product of the specialists was due to the "stupidity of workmen," or something got wrong with the "most approved furnace," or mayhap the cheap man running four machines, making four small taps at one time, failed to thread them with the "proper degree of accuracy," or it might be the "reliever" had a jag on, and gave one too much relief, the other possibly not enough. Men are but human, whether they make tools for a manufacturing firm or a railroad company

There is another great drawback about buying your tools ready-made, and that is the purchasing agent. After this functionary has interpolated his fine Italian hand the master mechanic wishes he had stuck to his own "deliberate" tool-maker.

I remember a requisition I once sent in for a set of taps and dies, and, shade of Whitworth, I wish you could have feasted your optics on those tools when they came. The die plate was nicely wired to a nice board with rounded corners and covered with nice green paper (the board I mean), then the taps were wired to the board at one end, and the dies ditto at the other end. There wasn't a plug tap in the outfit. It was just the kind of a layout to make the heart of a country blacksmith burst with pride. But why a railroad should be

VERTICAL RADIAL BORING MACHINE.

called on to pay for that class of tools I am unable to say, except that the purchasing agent thought he was getting them cheaper than the incompetents employed by the railroad could make them.

Now I have no objection to the men who make tools to sell holding their business up in every legitimate way, but it is manifestly unjust and unfair, to charge that anybody outside of specialty shops cannot make a good tap or die.

*Nashville, Tenn.* W. H. Wesley.

[There is doubtless two sides to this question, and, on the machine shop side the interference of the purchasing agent is the largest and most important item to be dealt with. When the man in charge can get what he orders, in the way of small tools, we believe it better and cheaper to buy, and that by so doing more uniform work will be done. The specialist shop is much better fitted than the railroad shop for making taps, dies, etc., as the railroad shop is better fitted than the tool shop for repairing locomotives.]

### Curious Performance of a Cylinder Bushing.

*Editors:*

Some two years or more ago, when I was connected with the D. & R. G. road at Denver, Col., we had a peculiar thing happen to an engine that just came out of the shop.

The Rio Grande company have no foundry of their own, and when a cylinder gets worn too large we bushed them, as I find a great many other roads are doing.

The engine I have reference to is a narrow gauge consolidated with cylinders, when new, 15 x 20 inches; we let them run without bushing until they are worn out to 15⅝, then we bore them out to 15¾ and put in a bushing and bore that out to 14½, this makes the bush ⅝ thick when finished.

Before we put the bushings in we cut out the port holes and leave the bush ½ longer than the cylinder; this we face off when we bore out the bushing.

The bushings on this engine went in tight, and was what we called a first-class fit, it was bored out and counter-bored, and counter-bored for the cylinder heads, so that the heads had $\frac{3}{16}$ of an inch bearing on bushing and ⅛ on the cylinder. These joints were scraped and ground in.

The engine went out and was broken in all right, as far as we could see. She left our shop, however, and went down the road and made only one trip, I believe. The engineer that run her on this trip, when he returned he reported cylinder cocks on left hand side to be fixed; then he went to the roundhouse foreman and told him there was something wrong with that engine, and he wished he would come out and have a look at her. He said her valves were out terrible, and were getting worse all the time.

The foreman got on her and hossed her up and down the tracks a few times and sent for a machinist to come out and take off left-hand front cylinder-head. The foreman knew there was something wrong, for every other exhaust was very faint. When cylinder-head was taken off they found that the bushing had turned in the cylinder far enough to almost shut the ports off. Of course they sent the engine back to the shop, and we had a time to get that bushing out, we could not press it out with a common screw-jack, and had to break it in several pieces to get it out.

Now, what I want to know is, what was the cause of the bushing turning?

Some say, how could it turn with the cylinder-heads bolted against it with a $\frac{3}{16}$ bearing on each end? It is very easy to see why the heads will not hold it, for in screwing up the nuts on cylinder-head studs it is natural for a man to screw them just about as tight as they will stand, and this will throw your bearing all on the outside edge of joint, which is all wrong. With a good joint a man can pull it up plenty tight enough with a 12-inch monkey-wrench. After this happened we put a ½-inch plug in each end of cylinder and have had no trouble since. Fred. S. Hill.

*New York.*

### Tools for Blacksmith Work—Labor and Machines—Material and Its Uses.

*Editors:*

It requires experience and close observation to become acquainted as to what kind of iron or steel is best adapted to the condition of things, or the requirements of the work it has to perform.

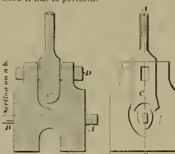

Fig 1 Fig. 2

Iron and steel is often subjected or under the influence of causes not always taken into account.

Now, there are times that the best experiments are those in actual performance in distinction from theory. Of course all mechanical writers, especially those of a scientific turn of mind, tell us that there is no opposition between theory and practice, which I take for granted.

Therefore, in selecting iron or steel for any specific purpose, there are considerations that should be taken into account as regards the relations that the different parts bear to each other, co-ordinate in a measure.

For example we will take the brake appliance of a passenger car, top rod, bottom rod, brake lever and fulcrum; now, the "lastingness" as well as the performance of the brake appliances, are dependent or subject to the support of the fulcrum, which must keep the top rod, and more particularly the bottom rod and brake-lever, from falling, as well as co-operating to secure a result as an auxiliary force.

As the brake appliance is subject to a force that is transmissive, communicating force from one part to another, and all depending or each individual piece, the question arises, What kind of iron is suitable for this particular case? In my opinion, iron that will bear a tensile strength of 45,000 pounds per square inch is sufficient for the top rod, brake-rod and brake-lever, on account of the force exerted being in a great measure direct, but would recommend that the material used in the fulcrum, on account of sudden variations, shocks, and its indirect operation, should be selected from the best grade of iron, iron that will bear a tensile strength of 76,000 pounds to the square inch. Swedish iron, I think, has an advantage over other iron in this particular case, on account of its possessing enough flexure to withstand any transverse stress it is liable to be subject to.

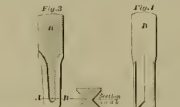
Now I expect some of my critics will ask why not increase the dimension of fulcrum or change the mode of construction. In one case it will impair the strength of a wooden brake-beam and in the other it may necessitate too much labor. I have in view a fulcrum that weighs six pounds and can be forged at one heat and will endure the application of the brakes in any way without breaking or yielding. I merely bring this subject under thought as an illustrative case. I might group a series of subjects more vital to the objects in view for there are many of them, and as I do not wish to invade the propriety rights of superiors, those that are "higher up," and as these are questions rather abstruse I will leave them to those possessed of a more refined mathematical or mechanical investigation.

Of course blacksmiths have no prescribed rules as a guide, consequently they must depend in a degree on experiments from which conclusions may be drawn. When rod brasses wear so as to change the proper distance from center to center of brass bore, it becomes necessary to insert liners in order to take up the lost motion and bring the rod back to its original length. Now, it is a very common practice to cut these liners regardless of the direction of the fiber or grain, which should lay in a cross direction, or in other words, the rod key should run in a direction across the grain or fiber of the liner.

By exercising precaution in this respect a great deal of trouble can be overcome in preventing the liner from dividing lengthwise or suffering disruption.

The same principle should be observed in the rod-strap in order to make it serve the highest good. In forging a rod-strap care should be taken to keep the fibers intact, the fibers should not be severed, but should run around the strap.

In forging a rod known as the solid-ended rod, the grain of iron should be so disposed to offer the most resistance to



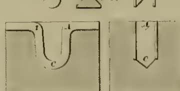


Fig 5 Fig 6

working strains. Although the methods employed in accomplishing these results occupy longer time than the "cutting-out" process, the advantage is well worth all the difference in cost, besides the confidence in knowing that the forging is every way satisfactory.

When we take into consideration the high rate of speed of locomotives on express trains, it behooves us to take into account the material and mode of forging.

Among many men there is a prejudice against labor-saving devices. Some imagine that the increasing use of labor-saving tools operates against the labor market by reducing the demand for hand-labor. How often the remark, "You are killing the business."

Now this is a natural but an erroneous opinion of the subject. Those nations which use the least tools are the most belated and less progressive. Those nations which employ the greatest variety are the most intelligent and progressive, have more of the comforts and good things of life, their hours of labor are shorter, wages are higher, thus signifying a superiority over their less progressive brothers. And so we find compensation wherever hand or manual labor has been supplanted by labor-saving inventions. Tools are evangelizers. "Commerce has done more for man than missionaries," not to undervalue missionaries. It is tools from the simple to the most complicated that makes social life first possible, then feasible and progressive.

The most careless observer cannot fail to note the new methods that are brought into use for the purpose of facilitating the mode of performing work. Even the grim-visaged and smutty-looking disciple of Vulcan is becoming imbued with the inventive spirit, at least so far as lessening the difficulty of his labor.

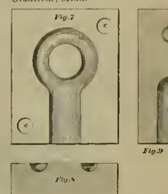
Figs. 1 and 2 represent a device for bending switch rope thimbles, rings, etc. The tool is made in parts in order to get the work off after it is bent or formed. The tool is held together by means of key bolt *a*, and key-bolt *a* is secured by key at *b*. The work is firmly held in place by clamp *C*, which is tightly drawn against the work by key *D*. To relieve the work from tool, drive out key at *B*, then drive out key-bolt *A* and key *D* which separates the tool, and the work can be taken out. Fig. 2 shows top of tool taken off.

Figs. 3 to 6 represents a tool for bending switch chain grab hooks and the like. After the hook is forged up to the bending point it is placed on tool at *A*, with the square on a diagonal vertical position, and the follower *B* is placed on the work in a perpendicular line from *C*, the hammer descending on the follower, thus bending the hook, preserving and keeping the corners intact.

Figs. 7, 8 and 9 represent the lower or bottom tool for forging the eye of a switch-rope hook, the upper or top tool being a counterpart provided with pins for guidance through holes *C C*. In making this tool it is well to provide for the work to be enveloped as much as possible in the bottom die, so as to prevent the work from clinging in both dies. The corners around the impression should be full and sharp with the surface of dies, and the bottom die should be at least ¼-inch deeper than the top, thus possessing two essential features, one is it will relieve the work more readily, and the other is that it will shear the fin by reversing the work. In preparing the work for the switch hook-eye tool, the work is drawn down rudely to the form and a hole punched for the eye under the steam hammer. The next operation is in a preparatory or roughing-out tool similar to Figs. 7, 8 and 9, after which it goes to tool as sketches 7, 8 and 9.

The bending operation of switch-hook is performed in a tool similar to Figs. 3, 4, 5 and 6. Geo F. Hinkens,

*Gladstone, Minn.*



### Excess Pressure and Gauge Tricks—Two Things that Relyea Wants to Know.

*Editors:*

A short time ago an engineer reported to me that he could get no excess pressure, and thought that the rotory valve or engineer's valve wanted facing, so I took out the valve, faced valve and seat, ground in the feed-valve and put the engineer's valve on again and tested it. I found that the rotary-valve was tight and put the handle in running notch to get the excess pressure, but didn't get it; then I thought perhaps the seat of the feed valve might be worn out of center. (To remedy such things I have a reamer with the shank the size of the feed valve, and in order to keep it central, I take a feed-valve cap with the hole drilled through, this I slip over the reamer, and screw it into the engineer's valve and ream the feed-valve seat out. This cap or sleeve fits the shank of the reamer close and keeps it central.) After I reamed the seat and ground in the valve, I could not get the desired excess pressure with handle in running notch, but when by accident I pulled the handle between running notch and lap, I noticed the red pointer kept moving up while the black pointer stood still. Now, I "began to

smell a mice," so I kept the handle in the position above mentioned, and after the red pointer had gained 25 pounds the black pointer began to move up. I stopped the pump and watched the gauge for several minutes, and it retained the 25 pounds all right. I repeated the operation several times with the same results. What was the trouble with this valve?

We can hardly call this a puzzle, it is so simple, but I thought if it bothered me it might bother others of less experience, so I thought it would be well to let the boys study on it for a while.

Here is a conundrum an engineer gave me the other day. He said when the reduced train pressure for a slow-up the black pointer would drop to zero, and then when handle was brought back to lap the pointer would go up very slow to within about 5 or 7 pounds of original pressure, or, in other words, the pressure would be reduced about enough to make an ordinary stop. The gauge was all right. Now, what caused the pointer to drop quick from about 70 pounds to zero, and then move up slow to about 65 pounds?

*Syracuse, N. Y.* W. F. RELYEA.

### Nuts for Machinists to Crack.

*Editors*:

I would like to know why it is that the cylinder next to the saddle under the steam-chest gasket is always worn so much more than the other three sides. Invariably this is the case with all locomotives which I have ever noticed.

Will the tram marks on valve-stem show the same after running engine all day as they did when valves were set previous to breaking-in? MARX.

*Frankfort, N. Y.*

### Who Knows the History of the Cork-Legged Pioneer?

*Editors*:

In 1848–9 there was an engine named the "Pioneer," the first one to run over the Vermont Central from White River to Montpelier. I think it was English built and a venerable looking old scrap—the boys called her the "cork leg." Do you know what she was and where she went?

*Turner, Ill.* JOHN WEST.

### Why Engineer's Valve Should be Kept in Running Position.—Air Brake Kinks.

*Editors*:

In reply to "Nypano's" question, "Is it dangerous to run without excess pressure or without handle in running position?"

With brake handle in release position air has direct passage from main reservoir through supply ports of brake-valve to train-pipe, and pressure in main reservoir and train-pipe will remain same, say 70 lbs. If a hose burst, the brakes are emergency applied by loss of train-pipe pressure, and without doubt, part, if not all, of main reservoir pressure will be lost. The brakes cannot be released without bleeding or enough air has been pumped up to knock them off, making a longer delay; and delays are dangerous to rear ends of trains now-a-days. In emergency application, say train-pipe pressure is used up, the brakes cannot be as readily released with the 70 lb. in main reservoir as if the excess, or 20 lbs. extra, had been added to it by carrying brake-handle in running position.

For ordinary stops, if user desires to make several applications for a stop he has more pressure to release the brake and recharge the pipe with than without.

What would be quickest way to release brake after a hose is burst, or anything occurs where train-pipe pressure with part or whole of main reservoir pressure is lost by having brake-handle in release position and the pump is the only means of releasing? In running position communication is stopped between main-reservoir and train-pipe through supply-port, but is opened through a very small port, called the feed-port, to feed valve held in place by feed-valve spring, having a resistance of about 20 lbs.; this keeps an excess pressure in main reservoir, and when valve opens, port gives communication to train-pipe, supplying what may leak off and equalizing pressure above and below piston 17 in brake-valve.

I see numerous mention of oiling air-pump (both cylinders) with different oils, to prevent their being gummed up and causing other injuries to valves. I do not see where any one has tried kerosene on a refractory pump. Don't mean to use it wholly, but occasionally worked into both cylinders, giving it a chance to go through brake and triple valve will help to keep the parts from being gummed up. Or would you be afraid it would catch fire, as one engineer said it would, when he was finding fault about his pump, and I told him to try that. One pump would not raise over 40 lbs. pressure, either working slow or fast, and would keep catching and jumping. I shut off steam, put perhaps three large spoonfuls of kerosene in top of air cylinder, emptied oil cup and put some in there, letting it into pump; started it lightly so as to give oil a chance to work around it good, then stopped it again. Filled oil cup about a third full of kerosene, balance with valve oil, and put about a teaspoonful of valve oil in top of air cylinder with some kerosene on top, started up pump carefully, and in a short time the pump was working good and had 75 lbs. pressure. When oil cup did not feed good a little kerosene has improved it as well as the rest of attachments, and I do not know of any harm in using it occasionally.

A good many engines here are equipped with Leach's sand-feeding apparatus that works good, but sometimes they work too much. The air to blow the sand is taken from main reservoir pipe inside of cab, before reaching the brake-valve. On some, when air is used to blow sand, the brakes are gently applied, making its use unsatisfactory. Can any light be given on it?

*Troy, N. Y.* INQUIRER.

[Air for the sand jet should be taken from the main reservoir pipe to engineer's valve, then no trouble is experienced.]

### An Association of Air-Brake Inspectors.

*Editors*:

I think that Relyea's proposition in the January number concerning air-brakemen forming an association is a move in the right direction and would receive my ablest support. I would like to hear through the columns of LOCOMOTIVE ENGINEERING what is an air-brake *expert* as referred to in Art. 3, Sec. 2 (c) of the constitution of the Traveling Engineers' Association. W. J. SHREVE.

*Ft. Howard, Wis.*

[The Traveling Engineers' Association consider men who have charge of air-brake equipment as *experts*—men who instruct the men or are in charge of the brakes on a road or for a brake company.]

### Foreman Blacksmiths' Association.

*Editors*:

I note with interest the editorial on traveling blacksmiths, and also the letter from Mr. Thornton, traveling blacksmith of the N. P. R. R.

It was somewhat of a surprise to me to hear that there was such a man employed on any of our railroads—which is certainly necessary, and has been for many years.

If a competent man is appointed he can save the company more than his salary will amount to in material alone.

And it will have a tendency to have our steel manufactors put a better grade of material on the market, which must be done in the near future; and an organization of foreman smiths ought to be a great help in getting a better grade of material in the market.

If the editor will give me room in the May number I will have a letter in on iron and steel, a subject to which I have devoted a good deal of my time for the past two years, and which is something that all smiths ought to devote more time to than what they are doing, and not allow something to come along that is composed of just three things—pants, shirt, collar and cheek—and make him believe that the steel or iron that he represents is the only kind made. W. G. LOTTES.

*Madison, Wis.*

### For the Foreman Blacksmiths' Association.

*Editors*:

Mr. J. J. Thornton, traveling blacksmith N. P. R. R., says: "What is the matter with an organization of the foreman blacksmiths of the different locomotive shops of this great country?" The suggestion is a feasible one.

Organization is in the air. Almost all branches of the railroad departments have an organization. Why should the blacksmith department stand to one side, while others are forging to the front?

Such an organization as Mr. Thornton suggests would be a school wherein members would get new ideas, learn all about new methods and improvements in blacksmithing, to say nothing of the literary part of the work, which would make them better writers and talkers.

I think an organization of blacksmith foremen would perfect the utility of the shop. No one shop excels in all things; each shop can give some useful lessons to all others, and by a mutual interchange of ideas we can gain valuable information.

I know there are some blacksmith foremen who have an idea that they are so far advanced in their calling that they need no lesson from any source. This is a mistake which will be corrected in an organization of this kind.

It is to be hoped that a great many of our wide-awake blacksmith foremen will give this matter their consideration.

I, like my brother craftsman, Mr. Thornton, would like to hear from some of the blacksmith foremen through the channels of LOCOMOTIVE ENGINEERING. I would suggest that some one outline a plan for organization. GEO. F. HINKENS.

*Gladstone, Minn.*

### Why Not Use Something Else than Key for Eccentrics?

*Editors*:

I watched with interest the answer given in March issue of LOCOMOTIVE ENGINEERING in regard to setting eccentrics before wheels were run under engine.

Unless the locomotive department on any road gave an imperative order to have their eccentrics keyed on shaft, it would almost seem like fooling away time to try to set them permanent, for seldom they would be found right when you come to run engine over, especially on repairs.

In shop where I served my apprenticeship and laid out work for new engines, we set our eccentrics on new work before engine was ready for the wheels, and very seldom had to move one afterward.

We got the extreme pitch of eccentrics by drawing line from center of bore to center of eccentric. We drew lines on shaft quartering each way from pin, set pitch line on eccentric ⅛ of an inch, measuring with dividers toward pin.

This would hold good where you have a 7½-inch shaft, 5½-inch throw of eccentric, ¾-inch outside lap of valve, 4-foot 10-inch radius of link, $\frac{3}{16}$-inch off, set to rocker-arm, and $\frac{5}{16}$-inch to link-saddle, and you would want from $\frac{1}{32}$-inch to $\frac{1}{16}$-inch lead.

It takes so little to throw motion out either on lead or cut-off, that I think it almost impossible to get a rule you could swear by, for there is such a wide difference in opinion in regard to motion-work, and any little kink in the motion might cause you to move eccentrics, and if keyed on, would be troublesome and expensive.

In holding eccentrics in place, why not use a feather or flated key, as they are called, if properly fitted up, an eccentric-strap will burn up and break before eccentric would slip. What more would one wish for? Besides they can be adjusted any time and save the expense of cutting key-ways in driving-shafts.

### Puzzling Brake Behavior—Two Questions.

*Editors*:

What causes quick action to take place when a service application is being made? I understand that a weak graduating spring, broken pin in graduating valve, defective slide-valve, or gummy piston (in engineers' valve) are causes of this trouble, but they were all examined and found to be in perfect working order. The trouble, therefore, lies somewhere else, and I trust you will give the readers of your paper an opportunity to solve this and the puzzle below.

While inspecting a train of five cars and engine and after signaling the engineer to apply brakes, 20 lbs. reduction, and seeing that everything was in good condition gave signal to release, at which time I was standing near the tender. I noticed that the brakes on the cars came off immediately, but tender brakes did not. It took about 10 lbs. to release them. What was the trouble with the brakes on that tender? The triple was examined and was found in good condition, in fact, it is a new one lately put on.

### Why that Injector would not Work.

*Editors*:

Please insert the following in answer to injector problem. May refuse to work from one of the following causes

1st. By a small piece of dirt in combining tube.

2d. By supply-pipe being partly frozen, thereby reducing supply below that necessary to condense steam.

3d. By the pinch-clamp that encircles combining-tube having slipped, which is not easily detected. For the reason that the lever pulls the clamp at an angle to the tube, which has a tendency to bind it tight. But by tapping with the hand it manages to get far enough to prevent its working. R. BACHMAN.

*Beaver Meadow, Pa.*

*Editors*:

Replying to C. L. Dennis' Injector Problem, page 133, would like to know if his injectors worked after he examined tank to see if water-supply was sufficient

I have noticed this winter if many delays occured so that tank was not opened or refilled often, the injector would not begin to supply the boiler with water the same as it would on warmer days.

On one of the coldest days we had this winter, sidetracked to meet two trains, the result was, before we could get away, had three more to meet. Water-tank at end of siding we entered on, so tank was filled. Had to saw by these other trains, and when working the injector, it would sound as if strainer was stopped up or tank empty until the tank was refilled again. Before leaving, at 6 P. M., they operated all right for awhile About 8 o'clock refilled tank and made preparations to return, did not get started for nearly three hours (left injector, went on a strike), and then, after about a mile, the right one began to chuckle and finally broke, but started immediately and broke again.

After starting I pried up manhole cover, which was frozen down tight, and found over half tank of water.

The injector now began to work all right and did not bother any more that

trip, for refilled tank three times in fifty-two miles.

Same engine was cut out shortly after for failure of injector on a very cold day, claiming tank was dirty, filling strainers so with dirt they would not work after tank was about half empty. But it was not so, and I think it only by chance I did not have to drop her fire, for was seven miles from water.

Have often wondered at the cause, and last evening, while looking over some of back numbers of LOCOMOTIVE ENGINEERING, I found on page 3, July, 1888, the following, and what I think is a clear solution to the injector problem. "In extremely cold weather injector will often refuse to work, because the manhole cover on tank has frozen down solid and a vacuum is formed above the water in tank." Remedy given "Put on heater for a few minutes and break cover loose." INQUIRER.

*Troy, N. Y.*

*Editors:*

In answer to Mr. C. L. Dennis' question regarding failure of injectors to work, would suggest, he found manhole of tank frozen up, making tank air-tight.

In absence of sufficient atmospheric pressure on water in tank, injector could not get water enough. M. M.

*Dennison, Tex.*

---

THE ANSWER.

*Editors:*

The following is the answer to injector problem I sent you. The lid on tank froze making tank air-tight, therefore injectors could not get any water. Soon as tank lid was opened injectors worked O. K.

C. L. DENNIS.

*Houtzdale, Pa.*

### Why Those Air-Valves Break.

*Editors:*

In answer to the question why valves break, would say they may break from one of the following causes:

1st. By trying to induce pump to make as many revolutions or strokes as the engine while running at a 40-mile gait.

2d. By too much lift.

3d. By not being heavy enough in the wings to withstand the jars to which they are subjected.

4th. By the uneven movement of the pump, which increases the jars. That is, it makes the up-stroke more rapid than the return, and *vise versa*.

ROBERT BACHMAN.

*Beaver Meadow, Pa.*

### Emergency Application.

*Editors:*

In answer to J. S., Moncton, N. B., in February number, you say, "Something kept piston 17 from forcing its valve to a seat, probably gum or dirt." Air-brake men here say the valve is designed in such manner that volume of air discharged in making service application is not sufficient, nor is it intended to cause emergency application. How, then, can the failure of piston 17 to return to its seat cause emergency application? E. T. GRAY.

*Hopewell, Idaho.*

[It is not intended that the sticking up of valve 17 will cause an emergency application, yet it sometimes happens, especially with the first of the new equalizing and discharge valves turned out, more of this kind of trouble is caused trouble in one of the triples.]

### Do Our Side Rods Use Up 800 Horse Power of the Locomotive?

*Editors:*

The March number of *Engineering Magazine* has an article on "Increased Speed in Railway Travel," by Mr. W. Barnet Le Van, which contains many startling statements to say the least.

We have a small number of engineers among us who affect to see good design and merit in the British type of locomotive only, and to this class the writer of the article in question evidently belongs.

A comparison of speed between American and English practice which does not take into consideration all conditions is unfair to Americans. Given a perfect road-bed, double tracked between termini, with grades and curves inappreciable and an absence of grade-crossings, any railway company in this country would schedule quick time, and would make its schedule. If we go farther and have track so thoroughly patrolled that the headlight is dispensed with, we have ideal conditions for fast running. The British roads have these conditions, and in consequence make faster average time, perhaps, than is scheduled by American roads.

It is a mistake, however, to give them credit for the quickest long runs. The fastest trains in Great Britain (regular) run between London and Edinburgh, a distance somewhat less than from New York to Buffalo. Their time is an average of 52 miles per hour. The Empire State Express, between New York and Buffalo, on the New York Central, is 52½ miles per hour.

The writer recently rode from New York to Albany on the Empire State Express when remarkably fast time was made. For some reason there was delay in the block before Yonkers was reached; we passed the station at Yonkers at precisely 9 o'clock, and at 11 15 we were on the Albany bridge, giving a sustained speed of 56 miles per hour for a continuous run of two and one-fouth hours. During this run there were occasional "slows" in anticipation of signals.

So far as the motive power was concerned there seemed to be no reason why this run should not be made daily.

In England people pay for the luxury of fast riding. The Empire State Express, which is the fastest long-distance train in the world, is compelled by law to carry passengers at the rate of two cents per mile. If there were no demand on the N. Y. C. for other than quick travel, it is possible that these fast speeds might be profitable. But the local traffic must be handled, and these fast trains often entail an expense upon the whole system by the right of way.

Mr. Levan seems to think that we have only to adopt the English "single" locomotive to solve the question of speeds.

His reasoning in favor of single drivers will not bear analysis. For instance, he claims that English locomotives will haul an ordinary train at the rate of 53 miles per hour on a consumption of 25 lbs. of coal per train-mile. He places the fuel cost for hauling a similar American train, running 43 miles an hour, at 50 lbs. of coal. If we increase the speed of the American train to that of the English train, 53 miles per hour, it would bring the coal consumption up to about 65 lbs. per mile. The valve gear of American and English locomotives are practically the same, that is, both are operated by the Stephenson link. There is but little difference in the values of American and English coals. It is therefore fair to assume that a pound of coal fairly burned in one firebox will give off the same number of foot-pounds in energy as would be produced by the same combustion in the other firebox.

It will require about 500 horse power to run such trains as Mr. Le Van describes at a sustained speed of 53 miles per hour. In England he claims this is done with 25 pounds of coal per mile. It will require, per his reasoning, 65 pounds of coal to do the same train work in this country, with a coupled locomotive. If the coals are equal, the 65 pounds burned in the American firebox will deliver to the cylinders about 1,300 horse powers, 800 of which—in excess of requirements in the English "single"—get no farther than our side-rods and pins.

If our English friends will consider this question fairly, they will give us credit for a quality of workmanship and material in crank-pins and bearings unsurpassed in the world, even though they do not like our coupled locomotive.

Americans have the reputation of "blowing," but when it comes to the question of steam powers our English and Continental friends occasionally draw a full hand.

It is not long since the technical journals published accounts of M. Normand's torpedo boats, the engines of which furnished a horse power, with 60 lbs. boiler-pressure, at a coal consumption of 1¼ lbs. In this case the total horse power developed was about 120. We also remember the little Perkins steamer, "Anthracite," which came here with an English coal record of 1¼ lbs. of coal per horse power. This same steamer was thoroughly tested by a board of American naval engineers whose best possible result in coal was 2.74 lbs. per horse power.

There is, unquestionably, a loss due to friction in coupled engines. But it is extremely doubtful if that loss is not more than offset by the gains which come from using coupled engines on American roads. It is hardly fair to assume that American railway managers are not as fully alive to the best interests of their roads as outsiders; and as long as such managements as the P. and N. Y. C. continue to use such locomotives, is it not fair to assume they are best suited to their conditions?

*Rahway, N. J.* AMERICAN.

### Practical Questions for Engineers and Firemen.

The Lancashire & Yorkshire Railroad in England issue a small book with the above title for the use of their men. It is divided into chapters as follows: In the shed; on the road, shed day, and engine breakdowns. The book is in the form of questions and answers and is given free to their employés.

One question and answer that interested us is as follows:

Q. Some sorts of coal form a hard and close clinker on the firebox, can anything be done by the fireman to improve matters when working with this sort of coal?

A. Yes; a very good plan is to scatter some broken brick (old arch bricks) over the bars before making up the fire. The bricks should be broken up into pieces rather smaller than a man's fist. Broken limestone is also a good thing to use for this purpose, particularly with some sorts of coal.

Another question and answer reads:

Q. Describe how to set an engine so as to test the valves and pistons with steam to see if they are tight?

A. Set the engine so that the two little ends stand level with each other, either at the front end of the slide-bars or at the end next to the motion plate. When in this position, if the lever be put in middle gear the valves will cover all ports, so that if steam be put on it will test the valves.

Q. Is the same position of the engine right for testing pistons?

A. Yes; then if the lever be put in full forward gear, the steam will be on one piston only, and if put into full back gear, the steam will be on the other piston only.

Q. In the case of a right-crank engine, if the little ends are set level at the motion plate end of the bars, and steam be put on, which piston will it test in forward gear?

A. It will test the right piston from the back. If put into back gear it will test the left piston from the back. If the engine is then shifted a half-turn, so as to bring the two little ends level with each other at the front end of bars, then the right piston will be tested from the front in forward gear, and the left piston from the front in back gear.

Here is a question that would stick most of our boys:

Q. What is the difference between a plug trimming and a tail trimming?

A. A plug trimming is one that only feeds when the engine is running, and is used for those parts that have sufficient motion to shake the oil over the end of syphon pipe, such as big ends and outside rods, etc. A tail trimming is always feeding (so long as there is oil in the cup), and is used for those parts of the engine which are steady, such as slide-bar oil cups, etc. A plug trimming is made by wrapping worsted over a piece of twisted wire in the usual way, and when in use the top of it should be a little below the top of syphon pipe. A tail trimming is made in the same way, but a few strands of worsted are left at the top end, and these turn over and hang in the oil. All trimmings require to be looked at occasionally, as they become clogged by the impurities in the oil.

### An Awful Jump.

The railways on the Island of Jamaica are not exempt from some of the dangers so well known to those who are engaged in train service on this continent. An engineer in Kingston, Jamaica, in a letter sending in some subscriptions to LOCOMOTIVE ENGINEERING, says:

Mr. J. F. Sargent begs to be excused for sending in his subscription so late. The cause is nothing uncommon to railroad men. During the latter part of the month of November, his train of twelve cars and engine entered the Gibraltar tunnel at his usual speed, a white flag having been shown by the tunnelman, but before he made daylight he had to decide between life and death, for thirty feet from the mouth of the tunnel was a huge land slip, and the river Rio Cobre roaring and jumping seventy feet below. He did all he could for the company he served, and waited for the mouth of the tunnel to take his chance. He remembered jumping to clear the coming wreck. How long he laid he could not tell, but he found himself under the body of a freight car, when he crept out he saw his frightened conductor looking down in the river at his engine and two cars on top of her; his fireman went over with the engine and was killed. Since then he has been in the hospital, but I am glad to state he is now out to work again.

### Wash-Room or Tannery?

"I had a green fireman once," said the New England engineer, "and he worked two straight months without having his overclothes washed. I kicked finally and told him if he'd wash 'em I'd furnish the soapine. He put 'em in a pail of water, climbed on the back of the tank and got a can of powder I had there and dumped in a pint or so, and turned steam into the pail through injector-overflow. They didn't 'suds' worth a cent and he dumped in more powder. About here I saw that he had my can of soapstone (for hot boxes) instead of the soapine. After he got all the stuff in and was rubbing, I turned the gang loose on him and went home. Them overclothes looked like a dirty oil-skin 'slicker' or the flesh side of a half-tanned hoss hide—but he wore 'em."

---

---

A reader of LOCOMOTIVE ENGINEERING, writing from Retalhuleu, Guatamala, says that an American firm has built 41 miles of a new railroad there which is doing an excellent business. They have four Baldwin engines. Engineers are paid $180 and firemen $75 a month. Machinists are paid $6 a day. Board costs from $30 to $60 a month. The writer speaks enthusiastically about the delightful climate and pleasant country.

# Car Shops and Car Builders.

## Lining Freight Cars.

A practice of lining box cars from the floor to the top plate, which was introduced by a leading western railroad a year or two ago, is becoming highly popular and promises to be widely followed. The original purpose of this design was to prevent freight which holds moisture from accumulating between the lining and sheathing. This soon rots the wood and shortens the life of the car.

When cars lined to the roof were put in service, it was found that they were much stronger than those built in the usual way, and the practice is now followed because it greatly increases the durability of the car at little first cost. The heavy loads now carried and the shocks due to long trains pulled by powerful locomotives tear cars to pieces very rapidly. Any inexpensive method of increasing the strength of a car is likely, under these circumstances, to receive attention.

## Bird's Metallic Car.

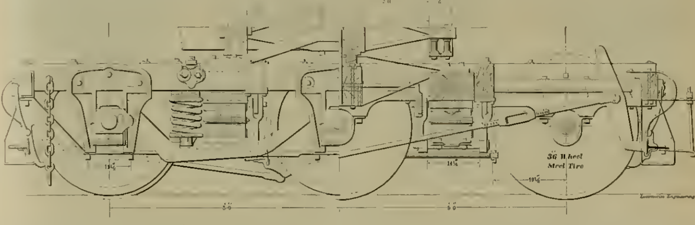
A metallic car for railroads has been patented by G. M. Bird, of Boston, Mass. It consists of sheets of iron or steel forming an outside and inside shell with a space between which may be filled with some heat non-conducting material, such as mineral wool or asbestos. The frame is a semi-circular trough, with the round part resting on the trucks and the rims secured to the body. It is a rather sensible form of construction, and appears to have been designed by a man with sound mechanical ideas.

The objects of the invention are said to be to provide a car of great strength to resist blows, and protect the passengers from injury by fire, or by steam from the heating pipes; second, to connect and hold the car platforms so they cannot telescope or drop to the ground, or be thrown apart away from the road-bed in case of collision or from other causes; third, to secure the trucks to the car frame so they will not be detached by derailment or other causes, and that their weight may add great resistance in checking a train when derailed and prevent the cars from rolling over. Passenger cars are usually made of wood, having the frame and sills under and level with the car floor; to this frame the cross frame and center castings are bolted that the truck is secured to. The platforms are a continuation of the car frame.

I have noticed, says the inventor, in accidents caused by broken wheels, axles, rails and by collision, the bolts that go into the wood-work split it in pieces; the trucks are broken away from the body of the car, the platforms are crushed, the cars fall to the ground and are often forced away from the road-bed, sometimes fire adds terror to the disaster. The weakness of wooden cars is the particular cause of the fatalities attending accidents on railroads. The principal object of the metallic car is to reduce the loss of life and property following accidents on railroads.

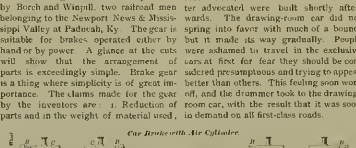
## Southern Pacific Six-Wheel Truck.

The annexed engravings show a very well designed six-wheel truck in use under the passenger cars of the Southern Pacific Co. A feature about the truck which will attract attention is the method of transmitting the power of the brakes to the three pairs of wheels. As six-wheel trucks are on the increase it would be well for those interested to examine the simple way in which the brakes are applied in the Southern Pacific truck. The only criticism we would make is on the turnbuckle used for adjusting the length of tension rod. The turnbuckle has been tried a good deal for this purpose and nearly always fails by running back, moved by the vibration.



## Improved Brake Gear.

The annexed engraving illustrates a form of brake gear that has been patented by Borch and Winpill, two railroad men belonging to the Newport News & Mississippi Valley at Paducah, Ky. The gear is suitable for brakes operated either by hand or by power. A glance at the cuts will show that the arrangement of parts is exceedingly simple. Brake gear is a thing where simplicity is of great importance. The claims made for the gear by the inventors are: 1. Reduction of parts and in the weight of material used, 2. Equalization of power to the several shoes; 3. A direct pull from the air piston and the brake always adjusted.



Brake gear of this kind has been applied to cars on the Newport News & Mississippi Valley, and it is reported to work very satisfactorily.

## Origin of the Drawing-Room Car.

The drawing-room car, which is now regarded as a necessity for the comfort of our luxurious travel, did not come into use till after the war. About 1865 the Old Colony Railroad imported a first-class passenger car, very fancifully upholstered, from England, and it was considered a wonder of comfort, although with the growth of taste for luxuries of travel it would now be considered a very inferior car. The anglomaniac was abroad amongst us even at this early date, and the exclusiveness of the car, which was of the compartment type, commended it to people who disliked to ride in company with mixed classes.

At this time there was a director on the New York Central named Russell who was of highly aristocratic tastes. During a visit to Newport he saw the Old Colony compartment car, and he came back to New York determined to have cars of the same character built for the Central. He was so persistent that Messrs. E. D. Worcester and J. Tillinghast were sent as a deputation to Boston for the purpose of examining the car and making a report. Mr. Worcester made a report advocating the use of a modification of the English car to a design similar to what was afterwards known as the Mann car, with separate compartments reached by an aisle at the side. Mr. Tillinghast recommended the use of an open car, with seats arranged with a special view to comfort, and the putting in of other conveniences then not thought of for day coaches. His views found favor, and some cars of the character advocated were built shortly afterwards. The drawing-room car did not spring into favor with much of a bound, but it made its way gradually. People were ashamed to travel in the exclusive cars at first for fear they should be considered presumptuous and trying to appear better than others. This feeling soon wore off, and the drummer took to the drawing-room car, with the result that it was soon in demand on all first-class roads.

## French Imitation of Wood.

French artisans excel in imitating mahogany, ebony and satin wood. So nearly do they contrive to render any species of wood of close grain like mahogany in texture, density of hue and polish that many expert judges will often mistake the imitation for the natural wood. The following is the mode. The surface having been planed and rendered perfectly smooth, the wood is rubbed with diluted nitrous acid, which prepares it for the materials subsequently applied. Afterward, to a filtered mixture of $1\frac{1}{2}$ ounces of dragon's blood, dissolved in a pint of spirits of wine, is added one-third that quantity of carbonate of soda. The whole constituting a very thin liquid, is brushed with a soft brush over the wood. The process is repeated with very little alteration, and in a short interval of time the wood assumes the external appearance of mahogany. If the composition has been properly made the surface will resemble an artificial mirror, and should this brilliancy ever decline it may be restored by rubbing the surface with a little cold drawn linseed oil.

## Effect of Turpentine Gathering on Longleaf Pine.

We have received from Mr. B. E. Fernow, of the United State Forestry division in Washington a circular saying that longleaf pine is in no way affected by the tapping of turpentine. The circular says

To determine whether any changes in the chemical composition take place, a series of chemical analyses of bled and unbled timber has been made, which indicates that the resinous contents of the heartwood are in no wise affected by the bleeding, the oleoresins of the heartwood being non-fluid, the whole turpentine flow is confined to the sapwood.

Among other interesting facts regarding the distribution of resinous contents through the tree which will be published in a separate bulletin, it appears that trees standing side by side and to all appearances in similar conditions show very varying quantities of resinous contents.

To make sure that experience did not, if sifted down, contradict the results of these investigations, a competent agent, Mr F. Roth, visited turpentine orchards and sawmills in the Longleaf Pine region. He reports that nobody was found—although it was claimed by some—able to discern any difference in the appearance of the bled and unbled timber; that in spite of consumers' specifications for unbled timber, they are almost invariably served with a mixture without finding it out, that experience in the districts where bled timber is cut and used has not sustained the claim of inferiority.

## Chemical Extinguisher for Car-Lamps.

The accompanying illustration shows the details of a fire extinguisher for cars, the invention of W. H. Durant, of Concord, N. H.

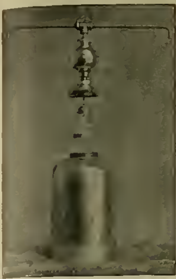
The lower can-like body is a tank containing about one quart of a powerful extinguishing fluid. Attached to the under portion of the cap, which screws on the tank, is a metal loop which carries a hoop on trunions, this hoop holds a small acid bottle; this bottle has a metallic stopper attached to an adjustable chain, and this serves to keep the bottle vertical in the tank. The trunions are always in line with the length of the car to prevent displacement of the stopper from shocks.

The tank is located near the lamps on a bracket fast to the ceiling of the car, and from the cap small pipes lead through the smoke-shades to the tops of the chimneys.

Above the screw-cap is a globe containing an automatic valve that insures the contents of the tank from evaporation and will allow the fluid under pressure to flow out.

The inclination of the car to a certain degree will withdraw the stopper of the

acid bottle, the chemicals mix and a pressure of 45 pounds to the square inch results;



Lamp Extinguisher for Cars.

this sends a jet of extinguishing fluid to every lamp in the car and instantly puts them all out.

## Notes on the Railroads of Northern Italy.

BY WALTER LODIA

During a recent visit to Italy, the writer's third, I took occasion to look up some information about Italian roads. There is a chance for pretty rigid criticism for any of the roads in the land of the Dago.

On one of the principal lines, they have in service 1,280 locomotives, and I found that in one year over 500 of these met with accidents requiring immediate repair, there being 350 accidents to goods trains alone, and 200 accidents happened to their mountain and special engines—of which they use a great many.

There is an engine accident to every 25,000 kilometers; besides this, they had over forty break-downs of air and vacuum brakes—they use the Westinghouse and the Smith-Hardy.

Very careful statistics are kept, and from them I find that the locomotive engineer of Italy has rather an undesirable berth. His average life is 42½ years—just the same as given for an locomotive, by the way—and 18 years, including his time as fireman, the average time spent on a locomotive. This is not a remarkable showing for a man employed in the open air in a climate noted for its salubrity.

Many inquiries were made into the treatment and living of Italian engine-drivers. It was ascertained that locomotive engineers on the chief peninsula road were divided into seven classes. Each class has a fixed salary. They receive a stated sum for their work, and whatever they make by economizing the coal, oil, picking up lost time, etc., is so much extra. About these items, more later on.

As to the established wages for drivers. There are stated to be on the S. F. M. 764 such men under all heads. They are classed according to the number of years they have been in service. There are 26 of the 1st class, receiving 2,400 liri annually, 83 2d class, with 2,100 liri, 79 of the 3d class, having 1,950 liri, 124 of the 4th class, getting 1,800 liri; 87 of class 5, with 1,650 liri, 102 of the 6th class, with 1,500 liri, and 263 of the 7th, obtaining but 1,350 liri. Now, as the liri are equal to so many of the more commonly known francs, and it takes 5 liri to make a dollar, or 25 to the British 20-shilling piece, it can easily be figured out what these amounts represent in American or English money. Thus it transpires that the 1st class passenger express driver only gets $480 per year assured. That is the substance. For the shadow he has to look to uncertain and varying economies.

And even the shadow has been going down as the calendar of years has been going up. The poor engineers, after all their labors at economizing, have been rewarded by the company cutting down the reserve of supplies allotted them. The administration has said to them "Well, you have shown that you can cover so much ground with so much coal, so we propose in future to only allow you that quantity of fuel. If you can realize any on *that* you will get the ordinary percentage." Or words to that effect.

This is something like putting men on piece work to find out what they can do, and then expecting them to do the same amount of work when on time.

What is the percentage earned by the runners on the saving of coal? It is asserted to be (by the shareholders' officers) 7 liri per ton (of 1,000 kilograms). Whether they get this, and whether there is much to be made over economizing nowadays, is another question. Then, as to the profits on oil-saving. They are put down at 12 centesimi per liter (1¾ pints). It is doubtful whether the actual extra remuneration here is any great "shakes" (to use a pat expression among some drivers).

There is a little book of nearly 170 pages issued to the central administration in Milano, entitled, "Raccolta di Disposizioni concernenti il servizio delle locomotive," which is full of matter affecting drivers. Particulars are given therein of premiums accorded drivers for reducing time between stations without exceeding maximum speed of engines; it is usually 3 to 5 centesimi (the centesimi is the hundredth part of a lire) for each minute saved, according to type of locomotive and number of kilometers run. For time made up, under certain conditions, when a train is in retard, 15 centesimi per minute is paid for passenger and 10 centesimi for goods trains, which amounts are reduced respectively to 10 and 5 centesimi for distances of over 150 kilometers.

Drivers are paid overtime at the following percentage in excess of their earnings. If absent with their engine from the depôt for over 15 hours and up to 18 hours, 50 per cent. extra, for from 18 to 24 hours, 100 per cent., 24 to 36 hours, 150 per cent., 36 to 48 hours, 200 per cent. Then there are, of course, a number of other ways in which the driver has an uncertain chance of increasing his small stipend.

Italian railroad reports are interesting, with an effort. The public reports are all figures, with little or no text. The private reports are lithographed. The former, with their network of small and cramped figures, are thus tabulated and statistized to meet the requirements of the national bureau of statistics at Rome. They are all very well for the requirements of that office, but all readers are not statisticians. Then, as to the private reports (for circulation among shareholders). While their contents are reduced and put in more interesting form, their printing is worse than the public memorias, so far as immediate distinctness is concerned. Every line is in lithographed handwriting. At least, this is the case with the Strade Ferrate Mediterraneo publication. Now this report will be intelligent enough to Italians, but even they will admit how much clearer, preciser, better and cheaper would be typographic printing.

Several new types of carriages have been added in recent periods to Italia's chief system. It was time! They are of the three classes—1st, 2d, 3rd. The third-class cars do not seem to have received much attention. And then some of those on the Mediterraneo system, there are perhaps no worse cattle-trucks in Europe. They are cooped-up boxes with no side windows, and only small apertures in the doors. There is no roof ventilation, so that the interior becomes like an oven under the sun's rays.

For fuel, briquettes are used on Italian lines, as on most other continental roads. They give off a fearful amount of grit, as the coal is not dampened.

The total kilometrage of the Strade Ferrate Mediterranean network is some 4,300 kilometres of double and single track. The head offices are in Milano. There the administration has a vast edifice, but are building near by a still larger. The fully subscribed capital is 260 millions of liri (liri is plural of lire, the unit and standard of reckoning.) The other great company in Italia is the Adriatica, with headquarters in Firenze (or, as the name is more commonly and improperly corrupted by foreigners—Florence). They tap all the Adriatic side of the country. Principal of the smaller companies is the Ferrovia Nord-Milano, with headquarters in that capital of Lombardy. Their capital (all paid up) is 13,000,000 of liri. They are fortunate in having the most direct route to the incomparable Italian lake district from the northern metropolis of Italy—to the Lac de Como as well as the Lac Maggiore—and, as scenery is everything to tourists, the road is here again fortunate, for the line between the two lakes climbs up and continues for a long distance among the mountain ridges, from where the views are most extensive, and charmed with all the poetry of distant prospects and vast horizons.

It is this latter and lesser-important company which has been the first to introduce electric lighting into their carriages. The road is supplied by means of accumulators from the principal station in Milano of the local Società di Ellectricità of which the chief engineer is an American, J. Liet, late of New York.

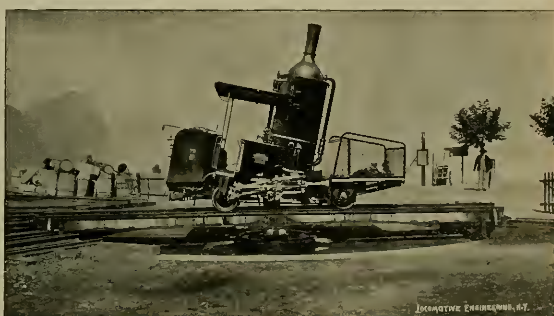
### The Boss.

We all know him and speak of him by this name, yet it is not yet fully recognized as a word legally belonging to the English language. Philologists, the people who interest themselves particularly in the origin of words, are a little divided about the origin of the word boss. Those with Celtic learning trace the word to the Gaelic word *bos*, the hand. The word is, however, doubtless the Dutch word *baas*, meaning master. The pronunciation is almost unchanged. Master, in all the early Dutch settlements, was baas, and boss it became with the English-speaking races, who hated and repudiated the word master, but were willing to endure it under a foreign name. There are many kinds of bitter pills that have their obnoxious taste entirely obliterated by a thin coating of sugar. How many there are who respect bosses and hate masters!

The Butler sand dryer, which was illustrated in the March issue of Locomotive Engineering, has been put on the market and is handled by Mr. G. P. Wilson, 435 North Broad street, Philadelphia. Several railroad companies have already adopted the device, which will dry more sand per pound of coal than any device ever tried for this purpose.

The exhibit for the World's Fair sent by the London & Northwestern Railway formed a special train which went West on the New York Central on March 14. The exhibit consists of one of F. W. Webb's famous compound locomotives, two passenger cars, and a great variety of historical curiosities used on the Liverpool & Manchester Railway when railroading was in its infancy. This exhibit will be highly attractive to railroad men who are interested in the development of railroad machinery.

A new and finely illustrated catalogue has been prepared by the Newton Machine Tool Works of Philadelphia showing their cold saw-cutting machines. Those interested in this class of machinery would do well to send for the catalogue.



An Engine of the Righi Mountain Road—Lake Lucerne in the Background.

## Train Running Under the Confederacy.

BY CARTER S. ANDERSON.

Excuse my delay in fulfilling my promise to tell your readers more about how we managed to so rapidly move the armies of northern Virginia with our very limited motive power and rolling-stock during the campaign of 1862. My apology is that I am at present a supply storekeeper. Between two fires, the trainmen and agents firing their wants at me in front, and our vigilant officers firing back at me, "Decrease expenses," I have been so busy defending my position that it has been out of my power to write sooner.

Allow me space to tell you the golden rule of economy given me as storekeeper by my superintendent, Mr. C. E. Doyle, and then for my part of the story "Issue what is needed, not what is wanted."

While General Lee was keeping one eye on General McClellan on the Bay, and the other on General Pope in Piedmont, we Virginia Central Railroad men were busy rigging our troop trains; bluff old Master Mechanic Wildman was all business—"No time now for foolishness," was his oft-repeated injunction.

Right in the midst of all this the shop struck, and nobody could blame them. Up to this time wages had run on pretty much as they had before the war, while notwithstanding our victories, every kind of living had gone up, so that our men could not support their families, so they determined to take chances of going into the army or of getting more pay. They all came down to the general office, at Seventeenth and Broad streets, two abreast. It was a sad sight, but very soon they broke rank and cheerily went back to the shops, their petition for more pay having been granted by Superintendent H. D. Whitcomb and President Edmund Fontaine.

An illustration of how our wages compared with the cost of living—we had a jolly passenger conductor named Wm. D. Gilkeson, who one pay day, about that time, bet our ticket agent, Wm. F. Adcock, that he could go to a restaurant and eat up at one meal Adcock's month's salary. A big crowd gathered near the old market restaurant, and Gilkeson fairly won the bet, coolly requesting Adcock to send him fifty cents more for a common cigar. Granted.

We soon had ready eighteen trains of about fifteen cars. There were freight cars of all descriptions, with one passenger car at the rear of each train for officers, the conductor riding there also, and acting as rear brakeman generally. I give below a list of engineers and engines, which may remind some of your readers of men and machines that took part in the story of our country, and in adversity played well their part

"Staunton," Martin R Alley; "Albemarle," John M Kraft, "J. H Timberlake," John Harton; "John Timberlake," Robert Murray; "Westward Ho," John Davidson; "E. H. Gill," Geo. W Pelter, "Chas. Ellett," John Dunn, "Greenbrier," Raymond T. Dunn, "Millboro," Seth Mack; "Monticello," Fendall W. Ragland; "Jeff Kinney," Tunis Swatz, "Beauregard," James McCandlish, "Stuart," Wm. Keaton; "W. M. Baldwin," Simon Ailstock; "C. G. Coleman," L. S Alley, "E. Fontaine," R. J. Goodwin, "C R. Mason," Westley P. Huntley.

Some of the army had already been hauled to Gordonsville, and skirmishing had brought the line of battle, with General Pope, near Cedar Mountain. Then it was that General Lee's main army leaned forward in that direction.

It was generally very short notice we would get of army movements. Hearing the drums and seeing the mass of men and muskets moving to the depot was the first positive information we would generally get as to any military move. So it was in this case. Standing at Seventeenth street depot and looking toward the west, as far out in Broad street as the eye could see, we watched the mass of Confederate soldiers bearing down upon us, until, as they got near to the depot, the crowd grew so dense, and it was so hot, that it was almost impossible to keep them in order. However, when we would get the wrong soldiers off a train, and the brigadier-general would call for certain regiments to be loaded on certain trains, they would settle down on it as bees upon a hive, and once down nobody was silly enough to give a soldier any advice as to finding better accommodations here or there. They were "there to stay" We gathered them in for ten miles along the road from Richmond, in the direction of Gordonsville. All trains loaded, we would pull out with about ten minutes' space between trains.

Getting to Gordonsville, the first train would pull up and unload, and pull by until all the trains came in; then we would turn the engines around and start out to Richmond for another load. So we kept going for about ten days, during which time we never undressed, nor saw a bed. We slept some, while waiting for other trains to load or unload—engineers on their boxes, we on the cars. I wish now that I had counted how many soldiers would pile into one train. How tenaciously they would stick! On top of a slanting wood-top car or wherever they could find room enough just to hold on, they would stick. To illustrate: We loaded all the trains one evening and started from Richmond to Gordonsville, just about dark. Going out from Richmond we always had a tough tug to get over a summit about four miles from the city. That night was no exception to the rule. We all got in sight of each other, while going up this grade; but after turning the grade and getting on what our "Uncle" Jimmie McCandlish called "our side of the hill" (down-grade), we endeavored to get our ten minutes' space as soon as it was practicable to do so. We had rolled along down toward the Chickahominy for about two miles, when entering the very heavy curve around Strawberry Hill our engineer called sharply for brakes three times, and reversed his engine. After running back to give the following trains the signal, I ran up to the engine to see what was the cause of his signal. I found our engine, "Albemarle," so near the rear of the preceding train that her head-light cast a ring of light about the size of a hogshead on the rear of the coach ahead.

I saw the men under a freight car. The draw-head had pulled out, dropping one end—the end that was fast prying up the floor of a luggage car that was literally packed with soldiers. The officers were all asleep, and those soldiers were so worn out, and so sound asleep, that we could do nothing with them. We tried to show them the danger they were in, and how narrowly they had escaped being crushed. We begged them to transfer to the other cars, so that we could throw out of the train this broken car and put it into the little side-track near Chickahominy, which the bridge carpenter built there to put the pile-driver on when at work on the trestling. It held about two cars. The few soldiers who did wake sufficiently to make any reply only ridiculed us. I never before heard such nonsense talked as I did that night. They heard us say something about the draw-head.

"Draw-head," one soldier bawled out, "Draw your heads out o' here, or we will draw them for you."

The hole in the floor which had been caused by the draw-head bursting through, they called, "Ventilator," "Head-rest," "Elevator," "Jess let her set," "Jess let her go like she is." "Let her roll," etc. I asked them to move so that I could get room to stand in order to nail down the floor which was torn up. Looking at my brogan shoe, one of them remarked to me

"Stranger, ain't you mighty unhealthy?"

It was very trying to me just at that time, bothered as we were with a dozen trains waiting, but being in his power, I answered politely

"Not particularly so, sir; why do you ask me that?"

"Nothing, Captain, more than I see that most of your body lies on the ground, and I always heard 'twas so unhealthy to lie on the ground. Well, boys, let's move and let the Captain have enough room for one foot"

John Davidson, the engineer of the damaged train, proposed that we quietly put the broken car, soldiers and all, into the little pile-driver track, and leave them there—a very wise solution of the difficult question. We very soon carefully placed them in, cut loose and coupled up to the rear cars and pulled out for Gordonsville. What became of those soldiers, whether or not they went back to Richmond or got on some other soldier train the next day, or deserted, this deponent knoweth not. We were never questioned about it, either by our railroad officials or by army officers. The crowd of soldiers at Gordonsville the next morning was so large and mixed that the car we cut out did not check short. It was "railroad bliss," as the soldiers called it, and they passed by as unnoticed some little irregularities in our management.

On my next trip out from Richmond the regular engineer of the engine "Albemarle," which had been pulling my train, was unable to run her out, and in his place was detailed from the shops a machinist named "Dock" Galloway. I am not afraid to say that a machinist is not necessarily an engine-runner. During that night, with "Dock" Galloway as engineer, we became surrounded by circumstances peculiar and thrilling, and it was by mere chance or good fortune, if you choose to call it, that we escaped a fearful accident, before relating the details of which, it is necessary to show your readers the relationship existing at that time between our military and our railroads, and how it came to be so.

While the Confederate government itself was always very respectful to our railroad officers, and very seldom interfered with their management, our Southern officers would sometimes, especially during the first year or so of the war, attempt to assume command of our trains. To illustrate: It was in 1861, a train load of Southern soldiers came to Charlottesville, from Lynchburg, over the Orange & Alexandria Railroad. It was noticed that two soldiers rode in the cab of the O. & A engine, and it seemed had the engineer under arrest, or rather under their charge. Our Virginia Central Railroad, of course, took charge of the train at Charlottesville. Our engineer, Ragland, running 'Monticello,' asked the engineer of the Orange & Alexandria what those two soldiers were doing in his engine. He replied that the Colonel had put them on at Lynchburg. "And," said he, to Ragland, "they will take charge of you before you leave here."

Ragland replied that he might be arrested, but he swore he would run no engine under arrest. Sure enough, when his engine hooked on to the soldier train, and while Ragland was greasing her up, etc., the soldiers entered the cab and took their position as they had on the Orange & Alexandria engine. Ragland climbed up on his engine and said

"Gentlemen, it is contrary to rules for any one to ride on the engine. You must go back into the train."

They answered him that their Colonel had commanded them to ride there and to take charge of the engineer until he landed them safe at their destination. Mr. Ragland went straight to the telegraph office and got the operator to telegraph Superintendent Whitcomb that he was under arrest and that he positively refused to run an engine under such circumstances. Very soon came orders to the Colonel not to interfere, but to leave the transportation to the railroad officials. The soldiers got off and Ragland got on and pulled out.

One more illustration: It was early in the spring of '62, just before or about the time of the battle of Seven Pines, that there suddenly arose urgent necessity in the Peninsula for some soldiers that were yet in some part of Virginia north of Gordonsville. At any rate, there pulled up at Gordonsville, bound for Richmond, at 8 P. M., a double-headed train full of soldiers, with some refugees among them—women and children. It had been arranged for this O. & A. train to go right through, with O. & A engines and men. We had a train also to come in as a section, either in front or rear of this train. A dispute arose between Fred. A. Kuper, our conductor, and Mr. Jonah Fisher, Assistant-Superintendent of the O. & A. road, as to which train should take precedence. It ended in a fight and every one got into a bad humor, and, of course, while squabbling where there was plenty to drink, they soon got to drinking. Mr. Fisher's O. & A. train took the lead, however, with the engines "Jeff Davis," run by Amos Woodward, and the "Nelson," run by one of the O. & A. engineers

The "Jeff. Davis" was captured from the Loudon & Hampshire in 1861, with two others similar to her in build—the "Beauregard" on our road and the "Johnson" on the R., F & P. road. They were three as nice and as smart engines as I ever knew. The engines were returned to the Loudon & Hampshire road after the war, and may yet live Surely it would be interesting to know what fate befell these noble refugees.

To return to my narrative. The orders received by the conductor of the leading O. & A train were "Come to Richmond—moments are hours." A Louisiana colonel was on the engine. He was about half drunk, and told Amos not to stop anywhere but for wood and water, and to "let her roll." Amos wanted nothing more glorious than such orders from the railroad officials and the military man telling him to go ahead and stop for nothing.

After sending these orders to this train at Gordonsville, necessity arose to start a train out from Richmond to Gordonsville, which left Richmond about 11 P. M., with orders to go to Hanover Junction and report. The train dispatcher considered this perfectly safe, thinking that he, of course, could intersect the fast east-coming train certainly at Beaver Dam, and knowing that all trains were ordered to stop at Hanover Junction—that was a standing order and very strict rule for both roads.

The fast-flying east-bound train came on by the Beaver Dam signal without even slacking up. The operator immediately informed the Richmond officer, whereupon the operator at the Junction was urged to stop the train at all hazards. Anxiously did our faithful train-dispatcher pace the floor waiting to hear the Junction operator call and tell him he had stopped the train. He did soon call, but alas! to tell the sad news that the fast Richmond-bound train had passed and not even slackened, but had crossed the old R., F. & P. R R. as fast as the engineer could run. The dispatcher's heart sank within him, and he calculated where the trains would meet. He predicted that it would be in the curve at "Little River." So it happened. Five minutes after passing Hanover Junction, the "Jeff. Davis," with her ten passenger coaches literally crammed with soldiers with some refugees, amongst whom were some ladies and children, locked horns with old "Millboro" engine, a ten-wheel heavy freight engine run by the oldest engine-runner now living in the United States, Seth Mack. John H. Richardson was the conductor.

Seth was at a great disadvantage, being in a cut, and with a heavy left-hand curve. But he caught a glimpse of "Jeff. Davis'" headlight in time to shut her off, and to roll off into the sand. He knew better than to be found about that time, and he and Conductor Richardson ran off quietly into the pines, made their way to Hanover Junction and reported the accident to Richmond.

This was the worst collision that ever

happened on our road. How any mortal being could come out alive from some of these coaches was the wonder of all who saw the splintered wreck. Coaches were telescoped in every conceivable way, parts of them hanging over the Little River bridge. There were many killed, among them a little child killed in its mother's arms, while the mother was not hurt at all. The "Jeff. Davis" rebounded when she struck the "Millboro," and stood with her front truck off in the ditch and her boiler front all smashed. She looked like some wild beast which had been demolished by old "Millboro," and then dashed aside. The old "Millboro" was standing on the track but stripped back to her cab

It was soon after this that the circulars were issued by the Government forbidding any military officer to interfere with the railroad management unless he had positive instructions from the General commanding the armies. These circulars were posted in every station, engine cab and caboose, and prevented what, as I will try to show you soon, would have been serious accidents.

## Bursting Up a Railroad.

BY DYCE CONVETH.

The boys were sitting around in the club-room one mighty cold night in December. A regular winter storm was raging outside. Occasional gusts, laden with sand-like snow, struck the building and shook it to the ground. A good deal of gust came inside, inviting more than the usual attention to the stove. Each man present had served some time at that job, and as every one fancied himself made for building a fire, the emulation might have caused trouble, but for an interruption. Right in the middle of a gust a thundering knock was heard at the door and in a few minutes a stranger was admitted.

The stranger wanted to see the secretary, but on our statement that that functionary was not present, he allowed that he would remain for a little, anyway.

"The fact is," he said, with easy *bonhomie*, and every syllable and accent betrayed his English education, "I am in town on business, and was told that I could pass an hour or two listening to the interesting and instructive experiences of the members of this club." He was an engineer, himself, he said, and in pursuit of his calling had seen many parts of the globe Was in America as agent for English-made firebricks, and was doing fairly good business. He wouldn't mind, he said, retailing some of his own little experiences, as he didn't believe in entertainment of that kind being all on one side. But of course he did not court the *role* of *raconteur*, not at all, he merely desired to contribute his share of the entertaining.

We thanked him for his visit, and said he was welcome, a remark to which the boys nodded or expressed their assent. We regretted that no amusing anecdotes or experiences would probably be heard that night. Considering the weather, we did not feel in a mood for romancing, and most of us had forgot the way to do anything else Under the circumstances we considered that we were speaking the sentiments of the boys when we suggested that the stranger might favor us with some incident of what must have been an interesting career. This course recommended itself to the boys strongly, and they expressed their agreement loudly. Well, the stranger seemed at first taken aback at his offer being so quickly accepted, but, pulling himself together, he told us the following story

About twenty years ago I was engineer on a road running out of London. I had good wages, a good journey, and should have been contented, but I wasn't. Most men incline to see the world at some part of their lives, and at that period the inclination to rove was strong in me. I watched the advertising columns of the daily papers closely, and when I saw an advertisement for two engine-drivers and two firemen for a railroad in the East, I applied, and after some parleying got one of the places. I got the job with less difficulty than I expected, mainly, I believe, because I had served an apprenticeship as a mechanical engineer, which few engine-drivers in Britain do, and because I was young. Anyway, I got the job, and in three weeks I was at sea on board of the steamer *Ling-Chang* bound for the Flowery Land—for China was our destination.

I learned afterwards that a British-Chinese company, whose headquarters are in Shanghai, had used sufficient influence with the Imperial Wanchow to obtain a charter for the construction of a short railroad on the bank of the Canton river. The road was to be 200 li, or about 72 miles in length, between the towns of Ching-Siang and Ning-Lo. It was expected to be finished by the time we got to Canton, and would be opened for traffic as quickly as possible

I don't know what influenced the Imperial pagan to grant the charter for that particular province, unless he wanted the innovation to be as far distant as possible from the capitol. It is certain that if it had survived on the banks of the Chukiang, it would survive anywhere in the Empire, for a more intolerant race of heathens I haven't met on earth, except the gentle natives of the Corea, who certainly excel the world in antipathy to strangers.

However, to come back to my story. There were four of us on board, engine-drivers, and the same number of firemen, double the number mentioned in the advertisement.

We had a pleasant time enough on the voyage, and arrived all right at Canton.

We were delayed three weeks in Canton for proper transport for our engines, which had come out in the *Ling-Chang* along with us, and were to be conveyed up river in junks. We enjoyed the time like a holiday, and were rather sorry when the word was given to start up-river. The attractions of Canton to an unsophisticated European are many and powerful, especially to anyone with a faculty for the picturesque and ludicrous. Don't imagine, however, that I am going to inflict a description of the sights of that city on you. My story is about the brief history of the Ching-Siang and Ning-Lo railroad, or rather railway, to give it its British name.

We arrived in the junk at Ching-Siang all right after what we considered many hair-breadth escapes. The river swarms with native craft of every kind, and why we were not run down, or why we didn't run into some other junk twenty times in a day, is in my mind an everlasting mystery. Anyway, we got there, and then our troubles began.

Our engines were in the junks, and the railroad was on the land, but no provisions had been made for lifting the engines ashore. It was assumed that being practical engineers we would be able to get over this initial difficulty with ease. We did fairly well under the circumstances.

We rigged up temporary sheer-legs, and by means of some tackle belonging to the junk, got the six engines upon the rails without mishap, except dropping one of the tenders when the tackle broke, but no one was hurt, so it didn't matter much.

We got things into fairly good order during the month which elapsed before the opening of the railroad, and then business was begun with great *eclat*, as the French say.

A gorgeous ceremony inaugurated proceedings. A number of mandarins of high rank—who I heard afterwards had been handsomely subsidized by the company—graced the occasion by their presence. A feast for pretty nearly all comers was provided, and at night Chinese lanterns and fireworks rendered the gim-crack railroad erection at Ching-Siang resplendent.

The heathens did not seem to take kindly to us, however. We ran mixed trains—freight next the engine, passenger cars behind; blamed little there was to fill either kind of cars, however.

It used to afford us no little amusement, at first, to observe, when the road and railroad were running close together, the merchandise being carried swung on bamboos on the shoulders of laborers, or mandarins being carried in palanquins at the rate of six miles an hour, rather than ride with the "foreign devils," as they were pleased to comprehensively describe both us and our engines.

But after a time we got tired of the sight, and from amusement we veered round to annoyance. Our annoyance was, however, of as little importance as our amusement to the placid Celestials. They jogged on their equable gait equally indifferent, apparently, to our presence, and to the facilities which we offered. Rumors were certainly current about the hatred which the people generally bore us; but these we treated with contempt.

We had, however, strict orders to cause no unnecessary alarm in the minds of the superstitious and credulous heathens. Our work was to be performed with as little noise and disturbance as was consistent with carrying out our daily programme.

Well, the work went on for about six months with somewhat increasing results, but the passenger traffic was mighty poor, and the freight portion did not increase much. The company held on, however, but the work must have been carried on at a big loss.

At the end of six months the concern burst up, and some of the Europeans had no little difficulty in escaping with their lives. It came about in this way.

About thirty miles from Ching-Siang the railroad struck inland from the river and upward about ten miles, then level and parallel with the river the rest of the distance to Ning-Lo. At Ning-Lo water was extremely scarce in summer, although in winter it was as plentiful as humanity, of which there was no stint. Our company under these circumstances made arrangements to get a supply of water at an arrack-mill about ten miles the down side of Ning-Lo. Arrack is a sort of whisky made from rice, and the casks in which our water was brought were usually saturated with the spirit. The casks were brought to a platform put up for the purpose, same height as the tender, rolled into position, the bungs taken out, the water then running into the tank.

Well, one dark night in winter we left Ning-Lo with more than the usual number of passengers, mostly Europeans, and a good deal of freight, mostly tea. Jim Lawson, a Yorkshire man, careful and attentive, was the fireman. The engine was of a type now seldom seen. The four-coupled driving-wheels were 40 inches in diameter, inside cranks and low cylinders. A pair of trailing wheels, 36 inches in diameter, behind the firebox. The cylinders cocks could only be opened or closed by moving handles immediately over them, so that in the event of their being open when we started, one had to walk along the foot-plate, closing one on that side, pass in front of the boiler, close that on the other side, then back into the cab. All the outside was yellow painted, beautifully enameled, and on the side of the boiler the name of the engine, "Ning-Chow." in Latin letters, with the Chinese equivalents beneath, were painted in gilt. Jim Lawson was never tired of admiring the glossy aspect of our paint, and whenever opportunity offered he was at work with a handful of oily waste giving a rub-down here, or an extra burnish-up in another place; whenever we stopped, if only for a minute, he had the cylinder-cocks open to prevent any of the condensed water being thrown over the paint on the boiler.

Well, on this particular night we stopped at the arrack-mill as usual to take in water. The casks were waiting, and the attendant heathens had them quickly aboard and empty. They smelt mighty strongly of arrack, we thought, but concluded that our sense of smell must be for some reason exceptionally keen.

The water was pretty low before we filled up the tank, so Jim started the injector at once to keep down steam.

After a bit I noticed a flash of blue-colored flame, amidst the black smoke coming from the smokestack; but as my attention was occupied looking for a signal ahead, the incident did not at first convey any impression to my mind.

After a time, however, I was startled to see that the colored flame was coming continuously, and amidst the black smoke it had certainly a peculiar effect. Well, I was puzzled. While I quite admitted the properties and powers of Chinese coal to raise Cain generally, when it came to steam-raising I'll be hanged (only he didn't say "hanged") if I could see how they could burn blue and black at once. My ideas on combustion were certainly getting into a chaotic state when the cylinder-cocks began spouting fire also. I am not naturally superstitious, but this sight sent the chills down my spine. Fevered with horror and alarm, I jumped up on the tank and drew a dipper full of water to cool my parched lips and throat. I swallowed the contents and found when it was down that I had drunk about a pint of arrack.

It was arrack, as sure as I am a living man. There we were with a boiler chuck-full of whisky, and losing some of it every yard we ran. What could we do? It wouldn't be any good stopping, because we had no casks to hold it. And if we had casks for the arrack we had no water. There was nothing for it, therefore, but to do our best to get to Ching-Siang with the least possible consumption of the liquor.

I was never very partial to arrack. Its effects are too sudden for my taste. I prefer a good comfortable liquor like old malt whisky, which you can drink in reasonable quantities a whole evening without getting much drunker than you will on a couple of rice arrack drinks.

This liquor is as potent as Spanish aquaardiente, but when it comes to racing for a man's upper works the rice article can give the other a long start, and then win each time with ease.

When I returned to the cab, Jim was staring at the smokestack like a blooming imbecile, wondering where on earth all the flame was coming from and where it got its cerulean complexion. By this time the fire had cleared, and instead of the usual clouds of steam, masses of flame were spouting from the chimney. The spirit as it left the cylinder was met by the flame from the tubes, hence the blaze.

I didn't attempt to explain the matter to Jim. The less he knew of the waste going on just then the better for his peace of mind. This thought, however, brought it forcibly to my mind that more arrack was going to waste than the circumstances of the case required. The dose I had swallowed made me think that a little more would clear my mind, so I climbed over the coals and took another pull at the dipper. Coming back over the coals I felt the engine give a kind of a shiver, as if a cold draught had given her a chill; then she seemed to bound forward, landing me in an awkward sitting posture amongst the coals. Recovering an erect position, I was just in time to be violently impelled forward by a sudden slowing of speed on her part.

Grasping the reversing lever in one hand and the throttle handle in the other, I prepared to do all that mere human effort could accomplish to bring to a satisfactory issue what I felt to be a unique task in locomotive engineering.

It had struck me like a blow that the engine was as drunk as Bacchus and only a cool head and steady hand—both of which I rather flattered myself I possessed—would succeed in bringing that train safely into Ching-Siang terminus.

She seemed to go all right for a time, but by-and-by she heeled over and ran along a

but on one set of wheels like a skater doing what is called the outside edge. I should say, as far as I can recollect, that the wheels on the right would at one time all be at least a foot clear of the rails, but of course it would be no good pretending to know to an inch or two, because such a thing would be impossible. I shut off steam whenever she began to heel over, reversed, and turned on steam again.

That brought her to her bearings, I tell you. Then I set her going again, but, Lord! what an awful time I had.

First she would give a jerk forward, as if she intended to boom the coupling-making industry, and no sooner had I turned off steam to steady her than she wanted to stop and rest a bit. Then I would turn on steam and off she went ahead again with a rush. How the couplings stood it has been a mystery to me ever since.

Then Jim Lawson, the blamed fool, thought that I wasn't doing all that was humanly possible, and he wanted to have a hand. But when I proposed to argue the question, with the assistance of the coal-hammer—on my side—he climbed over the coals and left. I didn't see him again for three days.

When we got on the level I fired up a bit to get more steam, and then we seemed to be making it at a frightful rate. Before long that engine was a terror. The flame was pouring from the stack in a stream; the cylinder-cocks were blazing away; the safety-valve began to blow off, and then it took fire. When I blew the whistle for a signal to be hauled down, the handle wouldn't go back, and there we were tearing through the dark night like a flaming, screaming fiend, terrifying the superstitious natives and sending the women and children into fits with fear.

All the time we were making steam at an enormous rate, but I quite recognized my responsibilities, and opened the throttle as wide as it would reach.

As we drew near to Ching-Siang it entered my hazy brain that, as the rails terminated at that place, some difficulty would be experienced in continuing the race. It did not occur to me to close the damper, or draw the fire, or turn off steam, or anything of that sort.

All that was present in my mind was the fact that the steam was being produced, and that it must be used up, or something would burst. But the difficulty of getting beyond Ching-Siang did puzzle me, and to give some stimulus to a wearied brain I took another pull at the dipper. That settled all doubts. I knew that the difficulty would overcome itself in a few minutes, so I lay down among the coals to await events, and have a rest.

I was mentally cursing the sharp corner of a lump of coal which had settled itself in uncomfortable proximity to my left kidney, when I noticed from the lights that we must have reached Ching-Siang. We had.

* * * * * * * * *

Three days afterwards I recovered consciousness on board of the good junk *Fat-Shan*, bound for Canton. Jim Lawson was sitting cross-legged beside the mat on which I was lying. He told me that as we approached Ching-Siang he had succeeded in uncoupling the engine from the train, and the engine alone dashed into a mud-bank, while I was thrown down an embankment without receiving any serious injury. The engine was wrecked, and next day a native horde, thousands strong, came and wrecked the railway buildings. The European officials would also have been immolated in satisfaction of their wrath, but, getting wind of the riot, all hands made for the junks, to which I was carried. Three weeks afterwards I parted from Jim Lawson. He shipped as stoker on board a steamer bound for Europe. I got a job as second engineer on board of an opium smuggler whose headquarters were at Hong Kong.

The Ching-Siang and Ning-Lo Railroad is now a weed-covered monument of the blighting influences of arrack—when used for producing steam.

### Merits of Diamond Stacks and Extension Fronts.

The Union Pacific people have abandoned the extension smoke-box and all the modern forms of spark arresters and returned to the use of the diamond stack. The diamond stack possesses some of the worst features to be found in spark arresters, but most people think it reduces spark throwing just as effectually as any extension front arrangement. To this, however, there are many exceptions. Not a few men think differently. The pros and cons were very fairly stated by Mr. W. Montgomery, of the Central Railroad of New Jersey, at a New York Railroad Club meeting. He said:

As to which is the better spark arrester, the diamond stack or the extension front with a netting, I would say that the extension front, properly constructed, and with a bituminous coal burning engine, with a brick arch, is superior as a spark arrester, and even without the brick arch. With the old diamond stack and a netting with a proper mesh, and cone properly made, we had a fairly good spark arrester when it was in good order. But after a time the sparks began to wear the netting and the engine began to throw fire. This improved her steaming qualities, because the openings were enlarged, and the engineers were careful not to say much about it. When we would get out to look at the netting we would find several of the wires cut. Sometimes they would cut holes through the cone. With that stack we had a great deal of trouble from burning the lagging, and frequently the men's overclothes would get on fire, and it often burned clear back on the cars so that the brakeman could not sit there. The force of the exhaust drove the sparks up and they ground against the netting and the cone until they wore through both.

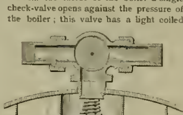
Several years ago we received an order to put on extension fronts. I did not like the idea very well, as I thought the diamond stack was good. But after we had put on the extension front and tried it with bituminous and anthracite coal, there was no question but that, as a spark arrester and as an improvement to the engine, it was a success over the old diamond stack. The tendency of the sparks to stop up the netting was not so great as in the case of the diamond stack, for the reason that the sparks were simply drawn up by the exhaust, whereas, in the other case, they are oftentimes driven in.

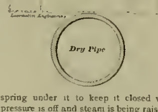
Of course there are disadvantages in connection with the extended front. One of the worst is the tendency of the exhaust pipe to stop up. When we used the diamond stack and had a low pipe with a petticoat pipe or a lifting pipe, we had very little trouble with the exhaust pipes or nozzles choking up. But with the pipe extended on up to the netting line, or in line with the top row of flues, there is a tendency for the pipe to stop up more, and very often the engines are running choked up. A strong back pressure is created by the closing of the exhaust pipe and the engine of course labors very hard. But with the proper construction of front ends and attachments and the nozzles kept clean, I think that the engine with the extension front does not burn any more coal than it did with the old stack. I think the cost of maintaining the extension front is less. Mr. Forney said at the last meeting that on the Baltimore & Ohio they burn 196 pounds of coal per square foot of grate surface per hour. In order to burn that much coal we have got to have a great velocity of draught to produce that rapid combustion, and it seems to me that with an engine running under that pressure of steam and with that force of draught, it would be impossible to prevent sparks from going into the front end—and good-sized sparks, too.

### Foster's Feed-Water Delivery.

The outline cut shown herewith explains the details of a feed-water delivery now in use on the Fall Brook Railroad. The branch pipes from both injectors lead to a T located on top of boiler just ahead of the dome.

From the inside of the boiler a single check-valve opens against the pressure of the boiler; this valve has a light coiled

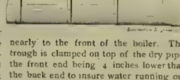




spring under it to keep it closed when pressure is off and steam is being raised.

This plan makes the feed-pipes very short, and gets rid of the dangerous side-checks, the inside valve closing up in case the T is broken off.

Instead of a pipe from the check to front of boiler, Mr. Foster uses a thin steel trough about 16 inches wide and running



nearly to the front of the boiler. This trough is clamped on top of the dry pipe, the front end being 4 inches lower than the back end to insure water running out freely.

Experiments show that the water is delivered at the front of the boiler at about 300° Fahr. There are no pipes to clog up or break off, and all the scale deposited in the trough makes no difference with its efficiency. This device is giving the best of satisfaction on the road.

### Cylinder Proportions of Compound Engines.

Although the engineering fraternity of this country has learned a great deal in the last few years about compound locomotives, there is still considerable diversity of opinion concerning the proper proportions of high and low pressure cylinders. In this connection some remarks made by Mr. F. W. Dean, at the Master Mechanics' Convention, are highly edifying. Mr. Dean said:

"In designing a locomotive, it is desirable to have the cylinder surface as small as possible. The condensation in the cylinders is proportionate, roughly, to the amount of cylinder surface. Therefore, speaking in a general way, the engine which has the least amount of cylinder surface will have the least cylinder condensation, and will be the most economical engine.

"Now, it is perfectly easy in designing a compound engine to so design it that the expansion through the two cylinders will be continuous, and it can be shown mathematically that if the cut-off in the low-pressure cylinder is at that point which is determined by the cylinder ratio, the expansion will be continuous through the tube, that is to say, the low-pressure cylinder will begin its expansion at the pressure at which the high pressure leaves off, and therefore the objection to the two-cylinder type of engine, that you cannot expand your steam continuously, disappears." * * * * * * *

Speaking of a Lehigh Valley compound, which he designed with cylinders 20 and 30 x 24 inches, Mr. Dean said: "It was put to service which I did not expect. It never occurred to me that that engine was to push coal trains up a 96-foot grade at 12 miles an hour. I fancied she was going to be used in a general run on a more level division. The cylinder ratio is 2¼ to 1. I wish it were 2 to 1. Then, although she might have the same total expansion, it would be divided between two cylinders. In pushing thirty coal cars up a hill they cut off at 17 inches, and of course that is too late. She ought to be compelled to do the work with a cut-off not later than 12 inches, and the only way to accomplish anything of that sort when you are limited as to the size of your low-pressure cylinder, is to make your high-pressure cylinder larger. You will then get the total expansion that you expect to get anyway well-divided between the two cylinders, and that gives the minimum condensation with the best results. * * * * * * *

"If any compound engine has a high-pressure cylinder so small that you are obliged to run three-quarters to full stroke in order to get sufficient steam through the engine to make it do the work, the engine is no longer a compound; that is to say, the high-pressure cylinder becomes a sort of steam feeder. It measures off every time so much steam to be expanded in the low-pressure cylinder. Such an engine as that cannot give the best results, and the only way to overcome the trouble is to make the high-pressure cylinder sufficiently large to cut off early.

### New Facts About Train Resistance.

About a year ago tests were made by Mr. Angus Sinclair of the locomotive pulling the Empire State Express, which appeared to indicate that the train resistance was not more than half what the text-books treating on this subject make it out to be. Mr. A. M. Wellington, of the *Engineering News*, took the data found in the run referred to, and comparing it with other reputedly accurate records, plotted out a diagram of train resistances, which makes the resistance at 40 miles an hour 12 pounds per ton, and at 60 miles per hour 16 pounds per ton. This is not more than half the resistance given in the text-books. The correctness of Mr. Wellington's figures appears to be substantiated in a paper read by Mr. William Forsyth, on tests of locomotives. The following is condensed from a paragraph on train resistance, which appears in the paper:

"The dynamometer records show the amount and variation of passenger car resistance for the whole of the trips. The paper traveled one foot per mile. On these diagrams points have been selected where the track was comparatively level and the speed uniform. The average resistance per ton of cars at speeds 39 to 46 miles per hour is 13.5 pounds. At speeds 45 to 52 miles per hour the resistance shows 9.77 pounds per ton. The reason for this being less is doubtless because at the lower speeds, although the speed was apparently uniform, yet the train was being accelerated to higher speed. At 48 to 52 miles an hour the train had attained a velocity where it almost drifted along, and the demand on the engine was very light. This illustrates the difficulty in getting exact figures for train resistance where there is such constant fluctuations in speed and pull. At average speed of 54.6 miles an hour the resistance is 12.2, and at 61 miles an hour the record shows 10.8 pounds pull with 10 to 12 cars."

These figures represent only the resistance of the cars.

The small resistance shown at 61 miles an hour was probably caused by the engine putting less work on the draw-bar than was necessary to maintain the speed.

## THE CHAPMAN JACK.

PATENTED.

THE screw being lubricated and protected, the Jack is always ready for instant service. Railroad men appreciate the importance of having Jacks always in good working condition. Serious delays frequently occur in getting common Jacks so that they can be worked when suddenly required in train service.

Common Jacks are frequently destroyed in efforts to make them work quickly after the screws are set with rust and dirt. This consideration alone makes the **Chapman Jack** the most economical one to purchase.

THE CHAPMAN JACK CO., CLEVELAND, OHIO.

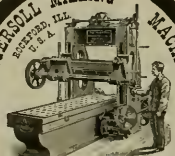
SLAB MILLING MACHINES.
SPECIAL MILLING MACHINES.
HORIZONTAL BORING MACHINES.
CUTTER GRINDERS.

## THE INGERSOLL MILLING MACHINE CO.

ROCKFORD, ILL. U. S. A.

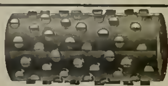


SIZE, 36" x 36" x 96",
New Slab Milling Machine,
Weight, 22,000 lbs.

With our machines we guarantee to mill a specified number of any of the following named pieces in a specified time:

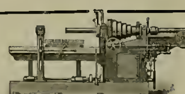
SHOES, WEDGES, DRIVING BOXES, TRUCK BOXES, CROSS-HEADS, SIDE RODS, CONNECTING RODS, VALVES, BRASSES, ETC.

**Write for our time on any of these pieces and compare it with your planers or other Milling Machines.**



PAT. DEC. 24, '89.

MILLING CUTTERS.
Any Diameter or Width for Milling any Shape.



HORIZONTAL BORING AND MILLING MACHINE.
Send for Descriptive Circular of this Machine, it has many improved features.

## SIGNAL OIL WORKS,

LIMITED.
FRANKLIN, PA.
MANUFACTURERS OF
SIBLEY'S Perfection VALVE OIL,
The only perfect Locomotive Valve Lubricant.
J. C. SIBLEY, Prest.

## GALENA OIL WORKS,

LIMITED.

**Galena Engine, Coach and Car Oils, the Standard Lubricating Oils of America.**

SAFETY, SPEED and ECONOMY are the results of the use of Galena Oils. COLD TEST, 10 to 15 BELOW ZERO. These oils do not freeze in the coldest weather, while they are adaptable to the hottest climates.

In the use of Galena Oils there is an entire freedom from hot boxes, except when these are caused by mechanical defects.

The adoption of Galena Oils as standard railway lubricants by a large majority of the leading railways of this country is an evidence of their superiority, while the fact that the same roads use these oils to-day that used them more than 20 years ago, is an evidence of their uniformity from year to year and year in and out.

Galena Oils are in exclusive use upon three continuous lines from Boston and New York to the Pacific coast, and upon one continuous line from the City of Mexico to New York, thus demonstrating their adaptability to all temperatures and climates. Being entirely free from gum, these oils are not affected by dust and sand as other oils are.

We also furnish our customers SIBLEY'S PERFECTION VALVE OIL, which is also used exclusively upon a majority of the leading railways of America.

## ? A. What You Want to Know. ? A.

Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.

(35) J. L., Albany, N. Y., asks

Is there any reason why a locomotive engine should develop a pound in boxes on one side more than other? *A.*—No.

(36) King, Tulare, Cal., asks

Does all the steam used in an injector condense to water in passing through the injector? *A.* Almost all of it condenses, but it raises the temperature of the water in doing so.

(37) J. D. B., Santa Fé, N. Mex., asks

Why will an eight-wheeler slip easier than a ten-wheeler, both same size cylinders? *A.* The ten-wheeler probably has more weight on the drivers and has some more friction, in its extra parts, to overcome.

(38) J. D. R., Wolfboro, N. H., writes

Where does the most strain come on a locomotive boiler under steam? *A.*—At the mud-ring. 2. In a train of twenty cars, which pin does the most strain come on when pulling up hill? *A.*—On the front pin.

(39) L. K., Turo, N. S., asks

What is to be done in case main driver of a mogul should break all to pieces? *A.*—You could probably run in slowly by blocking up the end of shaft, using the opposite cylinder, taking down all side-rods.

(40) F. C. C., Cedar Rapids, Ia., writes:

Please give the number of revolutions a disk 12 inches diameter should be run for cutting off flues, gas pipes, etc.? *A.*—Disks used for cutting rails and bar-iron are run with a peripheral speed of nearly two miles per minute. We think about 5,000 feet per minute would do for cutting off flues.

(41) L. G., Cleveland, O., asks

Will you kindly inform me what is the matter with air pump governor. It will stop the pump at 30 pounds in spite of how much it is screwed down; governor and pipes are perfectly free from dirt or gum and look O. K. every other way? *A.*—We don't know. This is an individual case, the cause probably being local.

(42) G. P., Findlay, O., writes

Will you give me a rule for finding horse-power of boilers and engines, and horse-power to do certain work? *A.*—Depends on the type of boiler and engine; 15 square feet of heating surface is usually allowed to a horse-power, where natural draft is employed. With artificial draft a horse-power is represented by much less heating surface. To find the horse-power of an engine look up any book on the steam engine indicator. The other question is too indefinite.

(43) W. G. B., Ashland, Ky., writes:

We use Ohio river water and Bellfield and Monitor injectors. Why when weather gets warm does water waste through overflow while injector is working a great annoyance? And no one have I found who can remedy or tell me the cause. *A.* When the water gets too warm it does not condense all the steam, which generally causes the injector to break. A heavy fall in steam pressure will cause injector to waste at overflow. Try shutting off part of the water supply on giving the instrument more steam.

(44) W. H., Barring Cross, Ark., asks

Will it make any difference in the weight on the drivers of an engine to raise or lower the front of engine on truck? If it would make any difference, about what amount would it make on a ten-wheel Baldwin engine to raise or lower front end on engine-truck one inch? *A.*—The principal difference would be that raising the front end would throw the water back, take some from the front and put it at the back end of boiler, making some difference with the weight on drivers. The amount for a given engine would have to be determined by actual experiment.

(45) E. E., West Shore writes:

The articles on valve-setting have got up quite an argument here in the shop among valve-setters, some claiming that in running over the cut-off and finding it necessary to change the valve for one motion that both forward and back blade of eccentrics should be changed an equal amount or moved the same distance. Which is the proper method? *A.*—You certainly would not move both eccentric blades to rectify an error in one motion. It often happens that the easiest way to equalize cut-off is to throw the back-up gear "out" a little to help the forward gear. Each are treated separately in valve-setting.

(46) S., Frankfort, N. Y., asks

Suppose we bore the cylinders of a locomotive and leave one ⅛-in. larger than the other, will the power against the piston be more than the power against the piston in the smaller cylinder, both valves being set alike? If so, why so? *A.*—Certainly, the piston in the large cylinder will present the most area to the pressure of steam, and as a result give more power. It is a plain problem in simple arithmetic. A cylinder 18 inches in diameter has an area of exactly 254.47 square inches, while a cylinder 18⅜ inches in diameter has an area of 265.18 inches, a difference of 10.71 square inches. Assuming the pressure to be 100 pounds, there would be over 1,000 pounds more pressure on one piston than on the other. Yet in practical working it would be hard to detect a difference.

(47) E. D. C., Roodhouse, Ill., writes:

I understand the angularity of main-rod, but do not see how the distortion caused by this is overcome by setting link saddle-pin back of center of link. In what way does it affect the travel of valve? *A.*—The angularity of the main-rod causes the piston to travel farther for one-half the revolution of the wheel than for the other half. The placing of the saddle-pin back of the center of link causes the link to swing on the hanger farther back than it does ahead of the perpendicular; this causes the link to slip on the block more for one half of the stroke than for the other half, and this distortion is used to open the valve at nearer the proper point in the travel of the piston. The distortion of the motion offsets the distortion caused by the angularity of the main-rod.

(48) Fireman, Argentine, Kan., asks

1. Is an Allen valve supposed to take steam through supplementory port before valve has opened steam port? 2. Are such valves intended to be set blind or with lead opening? 3. What effect will it have on a freight engine with 58-inch wheel to change side-rods, substituting for old ones a pair lighter by 50 lbs. each? *A.*—1. M. C. Hammett, Troy, N.Y., manufacturer of the Allen-Richardson balanced slide valves, states that the valve-seat for Allen valves should be of such length that the supplemental port will admit steam simultaneously with the opening of steam-port by steam-edge of valve. 2. Allen valves should not have more than ½ the customary lead at steam-edge, as you are having the same amount of lead at supplemental port as at steam-edge. 3. It will change the conditions, and require a lightening of the counter-balance weights.

(49) A. P., Winslow, Ara., writes

I am running an engine that is square when on track curving to the right, but when on opposite is quite lame. She is a ten-wheeler with double-rocker boxes. What is the probable cause of this? *A.*—We don't know—some local cause. 2. When this engine is working full throttle, it is almost impossible to hold reverse lever when taken out of notch in quadrant. Valves, rocker-boxes and eccentrics have been examined, but the trouble has not been located. *A.*—The friction of the eccentric straps on the sheaves causes most of its "pull," and the angle of the links intensifies it at certain points of the revolution. Some engines built with two rockers or with motion-bars are often almost unmanageable from this cause. We should like the experience of some one who has found the cause of the disease—and cured it.

(50) D. O'B., Mancelona, Mich., asks

1. What is to prevent a Nathan light-feed lubricator from cross-feeding? *A.*—The condensing chamber is separate from its cup, and there are two balancing tubes, one for each side; there being no passage for the oil from one sight-feed glass across to the opposite oil pipe. 2. About what candle-power is an ordinary headlight? *A.*—The flame is about 24 candle-power, the reflector intensifies and directs all the light in one direction, making the light many times stronger. 3. How can the steam in an injector overcome the friction in the pipes and still feed water against the same steam pressure? *A.*—This is a question of dynamics; the steam itself could not re-enter the boiler, but it has picked up water, which has weight, and forced it against the pressure within the boiler; it is somewhat in the nature of a blow. 4. About what would be the cost of a 28-ton narrow-gauge mogul locomotive of the common build? *A.*—From $3,500 to $4,000.

(51). G. B. Ashland, Ky., asks

1. Please tell me how to locate knocks or pounds sitting upon the seat-box while engine is running; that is, how shall I know the difference between wedge knock or pound and knock in consequence of loose brasses? 2. How shall I tell whether front-end brass or back brass of main-rod need filing? 3. How can I tell which side is lame without measuring valve-stem? 4. How to know whether it is valve blow or packing in cylinder down and to locate which side blow is on. *A.* 1. There are altogether too many men who want to take care of their engines and inspect them "while sitting on the seat-box." There is a trite old saying, "Naething is got wi'out pains, except dirt and lang nails." Take pains to inspect and examine your engine. The easiest way to find whether a box is pounding on account of a loose wedge or on account of a loose brass, is to block each side of the wheel and let some one give the engine a little steam and throw the reverse lever back and forth while you watch the box. 2. Notice this while testing box, the front end makes a very sharp and distinct pound while passing centers, and once started will wear very fast. 3. All depends on what causes the lameness; you can generally tell if a valve is admitting steam evenly at each end of the stroke by moving very slowly and noting steam at cylinder cocks. 4. If you put your reverse lever in the center and the pin on the suspected side on the quarter (cross-head in center of guides) the valve will cover both ports, leave the cylinder cocks open and admit steam, if any appears at cylinder cocks the valve leaks. If it don't blow test the piston by blocking engine in same position and putting reverse lever in forward corner, this will admit steam to the front side of the piston. If steam appears at the back cylinder cock the packing is down. A valve blows quite steadily, while packing down causes a roaring blow while steam is on; an experienced man can usually tell one blow from the other from the cab, especially if it is bad.

### Compressed Air for Transmitting Power.

At the last meeting of the Northwestern Railway Club, Mr. Wm. McIntosh, master mechanic of the Chicago & Northwestern, read a paper on the "Use of Compressed Air in Railroad Shops." He saw wonderful possibilities in the use of compressed air for cities from places where water power can be obtained. This method of transmitting power is peculiarly suitable for railroads. We have now pneumatic brakes, signals, gates and other apparatus indispensable to the proper running of trains. The time is at hand when an air compressor will be as necessary to a well-conducted shop as the steam engine, and most of the drudgery in and about such an establishment will be performed by this agency. The rapid development of the use of compressed air in railroad shops is astonishing. There is scarcely a shop in this country that does not use it in some form or another, and this speedy evolution is largely due to the technical press publishing each new growth which in turn leads to new applications. In one issue we find illustrations of an apparatus produced in Kansas for cutting off stay-bolts which does more work in one hour than could be performed by hand in twenty hours. From Nebraska comes a description of a pneumatic crane, a grate-shaking device, and an apparatus for opening the furnace door. Then there are numerous air motors, large and small. The portable motor can be attached almost direct to boring bar or flexible shaft, dispensing with complicated counter-shafting, belting and rope-toggles, while the smaller type is used as a breast drill when desirable, or slung up in any convenient manner to reach a desired position.

There are devices for sanding the rails for locomotives, delivering sand in desired quantities directly where wanted, thus saving many a crank-pin and strap from destruction and assisting many a train over a hill that would otherwise stall for want of sand or by reason of a too liberal supply, as often occurs when regulating its delivery by the lever and valves in common use.

There are air bell-ringer motors, neat little devices that are put in operation by a touch from the engineer. Then there are numerous snow flangers and dumping and drop-bottom cars handled by pneumatic cylinders. Drop-pit cylinders are supplied with compressed air, and the heaviest pair of driving wheels or an engine truck can be balanced on the piston as buoyantly as a cork will float on water. There are air-lifts for handling steel rails as easily as fence boards, and innumerable hoists in and about shops, some suspended from cranes, some fixed in a stationary position, and others sunk below floors for lifting driving wheels and other heavy weights. Outside of shops this power is utilized for raising cars and trucks in repair yards and for elevating sand and coal and various other purposes.

The latest application coming under my notice was for tripping and returning the ram of a hydraulic press, giving the operator absolute control of the ram even to $\frac{1}{32}$ of an inch. I might go on specifying indefinitely where this power is already employed and where it can be introduced to advantage. There is practically no limit to its usefulness, which is principally due to the ease and directness with which it can be conveyed to any locality, and the entire absence of complicated machines—all that is necessary is the cylinder with its piston and rod, a common plug-cock, and suitable hose connections for a portable lift and ordinary pipe connections for stationary ones.

The North Adams branch of the Boston & Albany road has been designated as Division No. 4, and the mechanical department has been put under the supervision of Thos. B. Purves, Jr., of the Western Division.

### "Windy" Jackson—Chairman Stove Committee.

"When you're talking about fast running," said "Windy" Jackson to a group of men who sat along the side-rod of the new decapod, "you poor, common railroad liars always spin out some cussed yarn that is so d——d incompatible with scientific principles, and the molecular action of your brains don't reach far enough to discover the incongruities of your statements."

Tom Smith was just telling how Dad Jones pounded the 136 on the back down Maren Hill, and had taken out a plug of tobacco with which to refresh himself, when "Windy" came in—after the manner of a cyclone—and delivered himself of the above opinion. The plug found its way quickly back to its owner's pocket, for the boys all knew "Windy's" predelection for U. P. tobacco, and the size of his mouth assured the rapid disappearance of a neighbor's plug if once he got his fingers on it.

Everybody kept still when "Windy" began to talk; they were all past being insulted by anything he might say of them, and they also knew that he would end his harangue by telling them something from his own store of experience. Standing before them, with his arms revolving like the arms of a Dutch windmill—though without their regularity—he told them this story:

"We were on No. 6, out of Denver, one night, three hours late. Old Sam Burns was on the right side and 222 was as bright and trim as a new dollar. No. 6 is a hummer on the new card, but we kept cutting down that three hours at a pretty steady gait. You know that ten miles of straight track out on the west end? Well, sir, when we struck that, old Sam said he was going to see what the 'Three Deuces' could do. So he pulled her wide open and hooked her in six inches, and say, mister! how that engine did run! I was kept pretty busy attending to the chemical reaction that was taking place in the fire-box, while the old girl kept going faster and faster.

"Allow me, gentlemen, to remark right here, that old Sam's ability to run an engine can only be exceeded by your humble servant's ability to keep one hot.

"We were flying that night, and don't you never doubt it; and I could not refrain from saying, just to myself, that we were a full house—three deuces and a pair of birds. It is not often that I get leary on an engine, but when the drivers commenced to purr like a buzz-saw I began to wonder why Sam didn't ease her off a little. When I looked up at old Sam my heart just naturally dropped into my boots There he sat, spellbound, his eyes fairly leaping from his head and his left hand grasping the throttle. I, too, looked out the gangway at the drivers, and blamed if you could see anything but a circle of fire with a white center, and how they did purr!—they almost put me to sleep. I was feeling a little nervous myself just about that time, so I went over to shake old Sam up a bit; but when I put my hand on his shoulder, dogged if he wasn't as stiff as a piece of statuary.

"I came to the conclusion just then that I'd take a hand in the running and shut her off; but, do you know, I couldn't make him let go nor could I move him. Then I thought I'd dump my fire and stop her in that way, but when I went to do it the fire was out. I have heard a great deal about wind-splitting and wind-splitters, but say, gentlemen, we were the first to practically demonstrate that phenomenon.

"For a few seconds there wasn't enough oxygen on that train to keep a canary bird alive My nose began to bleed and so did Sam's, and my head felt as if it would burst. I heard a noise as of distant thunder, and I thought I'd die for want of breath before we could get stopped. But we were already slowing up, and as we struck that little hill coming into Littmore the train stopped.

"There is usually some sacrifice connected with the demonstration of scientific truths, and this was no exception to the rule. There was a poor consumptive back in the sleeper, who had been out to Denver for the light air, but was compelled to return home because he could not stand the rarified atmosphere of the mountains. The poor man died that night on No. 6, and I've got the papers to prove all I've told you."

Here "Windy" drew a newspaper slip from his vest pocket and read:

"We, the coroner's jury, being duly sworn, and hearing all the testimony in regard to the death of John Kidd, lying here dead, do solemnly affirm that said John Kidd came to his death in the sleeper Patmos, attached to train No. 6 on the X. & Y. R. R., by the rarification of the atmosphere from intensely accelerated velocity."

### Too Complex for Coupling Cars.

He was impressively modest and knocked at our office door. When the boy invited him to enter he dragged in a grip shining of the waterproof canvas variety It appeared to be heavy, but he held a tight hold while he asked for the editor.

On being shown inside the sanctum, he remarked that his friend, Alonzo Dolbeer, had told him that we were fond of examining inventions of a mechanical nature, and that he had come all the way from Central New Jersey to see us.

We were inclined to exclaim superciliously that we were tired looking at car-couplers, but the pathetic look on the old man's face and his simple but earnest manner softened our heart.

He proceeded to relate the history of his invention. Went with elaborate details into certain family reminiscenses to prove that he had inherited inventive faculties of a superior order. The fates had thrown their dice wrongly when they put him down a market gardener instead of a mechanic; but he had done his best to overcome the defects of his training and to rise above circumstances and surroundings adverse to the cultivation of inventive inspirations

"Do you know anything about railroad rolling-stock and the rough service and terrific shocks draw-bar attachments are subjected to?" we inquired.

"Yes," he replied, "I was a brakeman on the Erie for ten days thirty-five years ago," and he proceeded to wind off some reminiscences of railroading as seen in his youth.

On receiving the hint, "This is our busy day," he proceeded to open the grip, and from its depths he drew out an apparatus formed of wood and iron, rough in form but complex in design.

We examined the thing critically, trying to think how it could be secured to the end of a car in a way that it would embrace a similar apparatus on another car We gazed at it for five minutes and imagined it set in all sorts of positions without succeeding in making an intelligible connection.

"Friend," said we at last, "you have made a success in one respect—you have got out the most extraordinary car-coupler we have ever seen!"

"Car-coupler!" he exclaimed, "who said anything about a car-coupler? This invention of mine is a potato-digger."

We bowed down our head and wept for a brief period, then we turned with supreme dignity to the inventor and explained that we knew about car-couplers, grain-doors, compound-engines, and valve-motions just enough to get along, but as to the merits of potato-diggers, we understood as little as the cow of his native state that makes milk-generation a specialty.

One favor we implored that he would grant us. We had seen a shot-gun in a second-hand store to be sold for three dollars. Would he have the kindness to tell his friend Dolbeer that we intended next pay-day to buy that gun and use it on people who send inventors of agricultural machinery to us for consultation.

The old inventor expressed regret at having troubled us, and offered us an interest in the invention on advantageous terms. This we declined with thanks. Two hours afterwards, when we went out to lunch, we happened to see him down the street asking for the office of the *Scientific American Engineer*.

### Misplaced Confidence.

That reminds me, remarked the Northwestern member, of a little story I heard about Mr. Smith. You all know Mr. Smith?

We did not understand what had been the reminder, since profound silence had reigned in the club-room for ten minutes, slightly varied by the creak, creak of the rocking-chair which was aiding McKelvey's meditations. But we all knew Smith, and said so, glad to have the silence broken.

The Smith I mean, continued the N W. M., is William, who is now superintendent of motive power of the Chicago & Northwestern. William is a Scotch country boy, brought up among rural surroundings, and naturally he was innocent and unsophisticated in his youth.

He was for some years an engineer on one of the Cunard steamers, and had not grown hardened by the wiles of wicked men when he came to Chicago to begin making his fortune under the Stars and Stripes.

William made up his mind to stand and fall with the United States, and he took a lively interest in making himself familiar with our political system. As a part of his political education he made up his mind to attend political meetings Hearing from a fellow workman that there was to be a party meeting in a certain hall, one evening Mr. Smith went there.

It was a big meeting called for the purpose of electing delegates for something. William sat down in the body of the hall and he had no sooner found a seat than a small easy-talking chap entered into conversation with him. Mr. Smith explained that he had never been at a political meeting before and wanted information about what was to be done.

"Now," said his new made acquaintance, "you are a big man and could easily make your influence felt."

"How is that, in what way?" asked Smith.

"Well, this way. In a little while they will be naming candidates and you stand up and shout with all your might, 'I propose Charlie Royal of the Tenth Ward.' Don't let them bluff you down. He is the best man in this city."

Mr Smith was good natured and anxious to do his political duty. When the proper time came round he got up and shouted for Charlie Royal. A man who stands six feet and a half and has good lungs is influential in a stormy meeting. Smith's man was duly nominated.

When quiet was restored his new made friend whispered to Smith, shout, "let us hear from Royal" He did so and the call was taken up. At this point Smith's acquaintance left him and went to the platform.

"Well, well, well, shiver my timbers," exclaimed Smith, "if that little cuss who asked me to shout for Charlie Royal isn't Charlie Royal himself."

No one has seen Mr. Smith nominating candidates in a political meeting since that time.

### One Hundred Years in the Steel Business.

The well-known firm of William Jessop & Sons, of Sheffield and New York, makers of the famous "Jessop's steel," celebrate their centennial this year. In 1793 this business was established in a modest way by William Jessop at Sheffield, Yorkshire, England

After the death of the founder the business was continued by the sons, Thomas, Sydney and Henry, who, through careful and judicious management and a thorough acquaintance with the practical part of the steel-making business, amassed great wealth and placed the firm of William Jessop & Sons at the head of all similar concerns in the world, and the management has continued in the hands of the family since its establishment.

About sixty years ago the agency in the United States was established, the firm being represented by one of the sons of the original founder, Henry Jessop, who died in 1849. The present headquarters at 91 John street, New York City, were purchased by the company and have been occupied by them for the past fifty years.

William Jessop & Sons are well represented in the United States and Canada, by a number of agencies controlled by first-class concerns in the principal cities, all under the supervision of Mr. William F. Wagner, who is the general manager of the American agencies. They carry a large stock of cast-steel in bars and sheets and circular plates of all salable sizes. They have acquired a world-wide reputation for making crucible steel for tools, dies, etc Their works at Sheffield are situated on the banks of the river Don and cover no less than thirty acres of ground They have also supplementary works in two other sections of the city in the exact localities where the firm originally started in business.

Several years ago the firm introduced a new branch into their business, that of steel castings. They have now one of the largest plants in existence for this purpose, and have produced the heavy marine castings for many of the largest steamships afloat. The premises are of the most complete character, their equipment including extensive converting and melting furnaces, forges, rolling mills, steel foundry, gas works, engineering shops, and all the necessary appliances for the successful manufacture of steel in its various forms, from the heaviest forgings and castings to the smallest bars, and from the largest plates to the thinnest sheets. The rolling of sheet steel is carried on to great perfection, the company supplying large quantities for the manufacture of circular and other saws, for which the Jessop steel has been found especially valuable Another important branch of the business is the manufacture of sheet steel for making steel pens, for which William Jessop & Sons have almost a monopoly.

---

Queen & Co., of Philadelphia, the instrument makers, have taken hold of the Bachelder indicator. This indicator is a new departure from all other forms, the important feature being the flat adjustable spring by which the change can be made from one scale to another by a simple adjustment of the fulcrum, thus avoiding the extra expense and necessity of carrying a series of spiral springs. This house has also this year put on the market a line of steam and pressure gauges of their own make for which they claim great accuracy.

---

Novelties in the way of car couplers are becoming rare, the ingenuity of many inventors having almost exhausted the possibilities in this direction. Under the circumstances we raise our hat to Frank Bender, Armourdale, Kansas, who has patented a car coupler which he might conscioasly swear is novel and original. It consists of a block which is slotted to take in two links set side by side on edge. Mr. Bender ought to exhibit his coupler at the World's Fair.

---

An improved form of smoke-burning boiler has been patented by Mr. J B Barnes, superintendent of motive power, Wabash Railway, who had already secured several patents for smoke-preventing devices. The principal feature about the latest patent is a chamber placed at the back of the firebox outside, which is used in connection with openings through the firebox and steam jets for inducing a supply of air.

## RADIUS LINK PLANER ATTACHMENT.

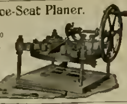
—FOR—

Planing Links, Blocks and Circular Work on ordinary Planer.

Quickly Attached.
Easily Operated.
Does Accurate Work.

## Valve-Seat Planer.

Over 300 in use.



## —DAVIS— Valve Port Milling Machine.

This machine will mill out ports in valve faces of steam cylinders, duplicating work exactly and in the shortest possible time.
It is operated by a rope belt similar to that used for driving drills, etc.
It is much lighter than the cylinder and can be readily placed in position using the stud-holes to attach to for that purpose.

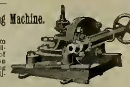
## PATENT PORTABLE Locomotive Cylinder Boring Machine.

Will bore out Locomotive Cylinders **in their places** by removing one or both heads, as desired, and piston. **The end thrust is always in exact line with bar.** It is fed with constant feed of ou' gears.

PEDRICK & AYER, MANUFACTURERS
Special Railway Tools
1001 Hamilton St.
PHILADELPHIA, PA.

## —LEED'S— Horizontal & Radial Drilling Machine.

Designed to work on or from a Drill Press. Is useful in drilling ends and diagonal parts of frames. Can also be mounted on the work and driven by a sliding shaft and universal joints. Drilling in all directions can be done.



## —LEED'S— LINK MILLER & SLOTTER.

For rapidly and accurately Milling out Links to any desired radius. Can be used on Drill Press or as an attachment to our Heavy Universal Milling Machine.

*A link 20 inches long can be finished in four hours.*

## Greenwood's Universal Planer Chuck.

FOR STRAIGHT, CURVED (CONCAVE OR CONVEX) OR ANGLE WORK.

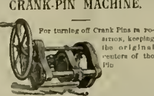
Used on any planer with cross feeds for links, keys, wedges, etc.

*Indispensable for Locomotive Builders and Master Mechanics.*

## —JOINTER— FOR Facing Locomotive Brasses.

Will hold any size brass same as held by strap when in use.
No more time required to place brass than screw up an ordinary vise.
Any desired thickness of cut can be taken, jointing the faces perfectly true.
No files required.

## CRANK-PIN MACHINE.



For turning off Crank Pins in position, keeping the original centers of the Pin.

## PORTABLE DRILLING MACHINE.

**For Fitting New or Old Cylinders to Locomotive Boilers.**

It will drill all the holes in smoke boxes and cylinder flanges necessary to hang one pair of cylinders at one setting of the machine.

Quickly set and operated.
Driven by hand or belt power.

VOL. VI, No. 5. NEW YORK, MAY, 1893. 20 Cts. Monthly. $2.00 Per Year.

## The Heaviest Piece of Freight Ever Transported on a Railroad, and the Car that Carried It.

The two large engravings on the first and second pages will be interesting to our readers. One represents the great Krupp gun being lifted from the hold of the gun suspended, and on the ground to the right can be seen a rack of railroad rails weighing 130 tons, used to test the lifting tackle before the precious 127 tons of rifle was intrusted to it.

This crane consists of two immense legs or shears, made of steel tubes ¾ inch thick, 4 feet in diameter in the center and 3 feet capable of standing over 2,000 pounds to the inch.

When this back leg is at the front and top of its travel, the top of the shears are some 30 feet over the edge of the dock, which will admit of lifting a great weight from any vessel. When the back leg is carried in the weight is brought over the ings being steel castings. It consists, as may be seen by referring to the engraving, of a major bridge, two minor bridges and four eight-wheel cars. The gun rests in the major bridge on two supports, designed to closely fit its perimeter. In addition to these two supports, to avoid any vibration while in transport, the muzzle is

THE HEAVIEST PIECE OF FREIGHT EVER CARRIED ON A RAILROAD, AND THE CAR THAT CARRIED IT.—LIFTING THE GREAT KRUPP GUN FROM THE HOLD OF THE SHIP.

steamer Longueil at Sparrow Point, Md., by the immense crane built for the purpose by the Maryland Steel Co.

This gun weighs 270,000 pounds. This is an immense load when put into the shape of a single cannon.

Krupp's built a car at Essen to carry the gun to the seashore, and the Pennsylvania Company built one on the same general lines to carry it to Chicago, where it arrived safely.

The picture on the first page shows the at each end and 116 feet long, the bottom points being 45 feet apart and joined at the top. The lower ends rest in cast-iron cup-shaped castings.

The tops of these legs are joined to a third leg of the lattice-girder, the lower end of which is 126 feet long, the lower end running on rollers over a curved base or track made immensely heavy. This is moved over the curved track by great hydraulic cylinders carrying a pressure of 1,700 pounds to the square inch and dock, where a railroad track extends along the edge.

The big gun was safely lifted by this arrangement.

The car that carried this load is the largest and strongest ever built. The following description of it was furnished by Mr. Theo. N. Ely, chief of motive power of the Pennsylvania Railroad

The large gun car has a capacity of 285,000 pounds, and is built entirely of boiler steel, the center plates and center bear- secured by wedge-shaped oak blocks set in cast-iron shoes, and drawn up to the muzzle by means of right and left hand screws. The major bridge is 50 feet from center to center of supports, and rests directly on the side bearings, while on the other hand the minor bridges are supported by their respective center plates

The cars have been designed so as to combine strength with flexibility, and are equipped with Janney couplers and draught rigging specially constructed for strength

The journals are 4½ x 9 inches, 37½-inch wheels with wrought-iron centers and steel tires are used

Each car has a Westinghouse air-brake cylinder, with brake on all wheels, and National hollow brake beams with Christie brake heads and shoes.

The load on cars is thoroughly equalized by 32 elliptic springs of 36-inch span each spring having eighteen leaves, 3½ inches wide and ⅜ inch thick

The extreme length of car is 90 feet 9 inches extreme width, 9 feet 10 inches, extreme height to top of bridge, 9 feet 9⅜ inches

The Car that Carried the Krupp Gun to Chicago. Weight of Car and Load, 445,000 Pounds.

### Old Men and Old Machines.

"The modern method of running locomotives takes away all the romance that attached to the business in olden times," remarked an old engineer who was inclined to look upon old machines and old ways with pleasing regret. "A man can no longer talk about 'my engine,' or think that he has got any more interest in a particular machine than dozens of other men The consequence is that he has no special interest in trying to make an engine do better work than she will perform under common treatment

"I have seen many cases of locomotives being kept successfully at work long after they were worn out. This was done by the personal efforts of old engineers who would not see their old favorites sent to the scrap heap as long as care and hard work would keep them on the road. The most striking case of this kind I remember was on the Delaware, Lackawanna & Western. There was an old Winans camel-back that had a famous reputation for pulling trains. Nothing would stall her. This engine in her old age fell into the hands of old Ralph Max. He was proud of her past record, and did his best to keep it green to the last. The master mechanic talked for years of sending the engine to the scrap pile, but Ralph pleaded for delay and kept the engine in repair by his own exertions

"A generation of men came upon the road who knew nothing about camel-back engines, and Ralph's mill was a mystery to them. When he was sick or wanted to lay off for a day the engine remained in the house, for no man would venture to take her out There were very few who would attempt to put her upon the table, after the end of the engine house had been knocked out by men trying to handle the old camel who did not know how to stop her. When any other man than Ralph had her out the old engine was always dropping something or breaking a part that did not seem to have any rational connection with the vitals of the machine, but kept her from working nevertheless Men who were ashamed to have such a thing happen to them would bring the engine in dead, because they did not know how to fix her up to work on one side

"Ralph never had to bring her in on one side. He was always doing something to the 'old girl,' as he called her, not much, either, but she never broke down in his hands. There appeared to be a strong band of union between man and engine and they acted in perfect harmony.

"One day Ralph did not answer the caller and another man and engine had to go out. Other mornings passed and Ralph still remained in bed and the old camel stood cold in the engine house. Both had made their last active trip. One day the engines on the division appeared with white and black bands on their hand rails, and in the afternoon many a sorrowing heart followed Ralph to his final resting-place Some of the boys draped the camel and a week later she was placed upon the bone-yard track."

Quick Way of Loading Consolidation Locomotive on a Flat Car of Steel. Not Recommended.

### Fireboxes that Burn Hard or Soft Coal.

President Blackall, of the New York Railroad Club, having asked Mr Mitchell, of the Erie, if it was true that they were burning anthracite and bituminous coal in the same engine, the following facts were given

We have ten-wheel engines with the fire box entirely above the frames. The engines were originally built for hard coal. We found it necessary to send some of them to western divisions where there was nothing but soft coal. We began using soft coal with them and had no trouble whatever in burning it We afterwards made a series of experiments, and found that we could burn at pleasure either hard or soft coal in the engine without changing the draft or the grates. In fact, it is nothing unusual for these engines to go west burning hard coal and return burning soft coal. Shaking grates are used.

### Motive Power from Explosives.

Daily papers have had a great deal to say during the last few weeks about a wonderful engine which is going to revolutionize ocean travel and dispense with the use of boilers and steam. It is said that the coming engine will use chlorate of potash and sugar to generate a force which will be much more powerful than steam. The inventor has been boasting about what his engine will do, and he expects to drive a 5,000-ton vessel at the rate of 35 miles an hour. This indicates that the man does not belong to the modest class of visionaries. The cylinders of the engine that is to drive the 5,000-ton ship 35 miles an hour are said to be no larger than two flour barrels. That is a little indefinite, but it is near enough to form a basis for something to wonder at.

The mixture of chlorate of potash and sugar forms an explosive. The parties who have been turning the heads of stock-brokers and reporters about what they expect to do with this as motive power force evidently are not aware that explosives have been used a great deal for driving engines and that the engineering world is perfectly familiar with a variety of engines driven by the explosion of gas. The men who are going to drive a big ship with an engine having cylinders about the size of a flour barrel will learn something about the difficulty of controlling explosive forces when they change from the promising to the performing stage. They talk of using cylinder pressures that reach into thousands of pounds to the square inch. It is a pure case of "fools rushing in where angels fear to tread." Machinery has never been made that will control pressures of that kind and keep it going as a working motor

### The D., L. & W. Road's New Ten-Wheeler for Milk Train Service.

Master Mechanic David Brown, of the Scranton shops of the D., L. & W., has recently turned out the handsome ten-wheeler shown herewith.

This road, like the Lehigh Valley, has always been original in designing engines, often departing from the beaten path in detail while still keeping pace with general improvement.

This engine has an immense firebox set above the wheels but without combustion chamber, this gives a grate area of over 83 square feet and an immense heating surface, 2,082 square feet.

The throttle arrangement is, to our way of thinking, the simplest and best that could be devised. Some of the traps recently designed in order to get the throttle stem into the boiler head are as unnecessary as they are trappy.

The arrangement of both injectors on one side of the engine will commend itself.

The extension front is lagged over and covered with a jacket.

This engine has a flange on all her driving-wheels and uses a swing bolster truck. She is said to curve perfectly.

The designers have departed from the rest a little in the design of cylinder-saddles. The steam and exhaust ports are separated by an air space, and the exhaust passages are very large—10 x 5 in., the nozzle is double, each 3½ in. in diameter.

We are glad to note the keeping of the valve travel down to a reasonable distance, and the tendency to using a larger cylinder with a moderately high pressure rather than an excessively high boiler pressure and a small cylinder, although 160 lbs. per square inch is by no means low pressure.

The following general dimensions are given:

Gauge of track, 4 ft. 8 in.
Rigid wheel-base, 11 ft. 8 in.
Total " " 24 ft. 10 in.
Driving journals, 7½ x 9½ in.
Cylinders, 20 x 24 in.
" steam-ports, 1½ x 17¼ in.
" exhaust-ports, 3 x 17¼ in.
" bridges, 1⅛ in.
Slide-valves, Allen-Richardson balance.
" travel, 5¼ in.
" outside lap, ¾ in.
" inside lap, none.
Boiler, diameter of front course, inside, 64 in.
Boiler, 288 flues, 12 ft. 10 in. long.
" heating surface of flues, 1,935 sq. ft.
" center to rail, 8 ft. 7 in.
Firebox, 8 ft. 4 in. wide, 10 ft. long.
" grate area, 83⅓ sq. ft.
Firebox, heating surface, 147 sq. ft.
" fuel, fine anthracite coal.
Total heating surface of boiler, 2,082 sq. ft.
Weight of engine on drivers, 110,000 lbs.
" " truck, 27,000 lbs.
" " total, 137,000 lbs.
Tank, water capacity, 3,700 gals.
" coal capacity, 7 tons.

HEAVY TEN-WHEELER FOR MILK TRAIN SERVICE, D., L. & W. BUILT BY DAVID BROWN, M. M., AT THE COMPANY'S SHOPS, SCRANTON, PA.

### New York to Chicago in Twenty Hours.

About the time this paper appears, a train will begin running between New York and Chicago which passes over the entire distance of 980 miles in twenty hours. The route traversed is the New York Central to Buffalo, thence by the Lake Shore & Michigan Southern to Chicago. The speed is forty-nine miles an hour from starting point to terminus. The route traversed is exceptionally good for the maintenance of high uniform speed, for there are no grades that will reduce the speed of the locomotive, few curves and comparatively few road crossings.

The mechanical difficulties in the way of safely and certainly maintaining a running speed of fifty-five miles an hour have long been overcome. The most difficult part of the problem is to keep the line clear so that the projectile train shall find no obstruction in the way. The Empire State Express, which has been running now for about a year on the New York Central, has been handled with much success, and there is no reason to doubt that the twenty hour train to Chicago will be managed just as well throughout the longer journey. There will be no difficulty whatever experienced in making the time if the right of way is kept clear for the train.

There is some likelihood that the running of this train will supply some interesting data respecting the type of locomotive best adapted for exceptionally high speed. The experience of the New York Central with the Empire State Express has been that a powerful engine with very large driving wheels is necessary to make the time regularly. When the train was first put on engines with driving wheels 5 feet 9 inches in diameter were the best available. They made the running speed with difficulty, the high piston speed militating against them when a velocity above sixty miles an hour was attained. Some engines with drivers 6 feet 6 inches diameter were then tried and they did the work in a manner that was much more satisfactory. Still later an engine was equipped with drivers a little over 7 feet in diameter, and it is said to handle the train with greater ease than the others. All the engines that have been used on this train have cylinders 19 x 24 inches and a boiler capable of supplying them with all the steam required.

Mr. John Newell, president of the Lake Shore, is a civil engineer and takes great pride in having an exceptionally fine track. A tender feeling towards the permanent way prejudices him against heavy locomotives and particularly against locomotives that have excessive weight on any pair of wheels. This influence has led to the stocking of the road with light passenger locomotives, the policy being to employ very high boiler pressure and small cylinders. It will be interesting to note how the small engines will compare with the big ones in pulling the fastest train in the world.

### Making Discord Among Trainmen by Rules.

In the course of a letter on train matters one of our correspondents touches on a delicate point in railroading which nearly all engineers and conductors have suffered from. There is a rule on the road that the head and rear brakemen must be on the tops of the cars when approaching a station or any point where braking is likely to be called for. These men must be out even when the train has enough air-brakes to control the train, and the engineer is held responsible for seeing that the head brakeman attends to his duties, while the conductor has to look after the rear man. If a train passes a station and an official or other person reports that the brakemen were not at their posts, the conductor and engineer get punished. This places these men between the horns of a very annoying dilemma. When a train is equipped with air-brakes it is next to impossible to drive a brakeman to the top of the cars, and the fellow-trainman who does his duty by reporting the delinquent is likely to be very much abused. We do not think that any railroad company acts fairly by making a rule requiring a conductor or engineer subject to punishment for the neglect of duty of a brakeman. The punishment is harder on the man who does the reporting than it is on the man who violates the rules. Officials who have ever been trainmen themselves would not make rules of this character.

### Mr. Leeds Defends the Belpaire Boiler.

The Louisville & Nashville have a great many locomotives in use with Belpaire boilers, and Mr. P. Leeds, superintendent of motive power, is a warm advocate of that type. He writes us:

"I take exception to an article in the March number of LOCOMOTIVE ENGINEERING containing estimates by Mr. Mitchell in regard to Belpaire boilers. He states it as a fact that there is an excessive number of stay-bolts found broken in Belpaire boilers. This is not in accordance with my experience of boilers with the same length of firebox, and their conditions being the same as regards pressures, etc. But what I take particular exceptions to is his explanation why they broke. As I read it, he thinks the long rods extending from side to side of boiler expand to a certain extent, and being so much longer than the stay-bolts, they become loose; or, at least, in lengthening they throw the strain on to the short stays between the firebox and side-sheet. It occurs to me that he has overlooked a very important feature in this case, and that is that the distance from side-sheet to side-sheet, that the outside shell is no longer where the long rods come than it is where the stay-bolts come, and the conditions are such that if any strain is thrown on to the stay-bolts on account of expansion it must be that of compression.

"For instance, we will say that his boiler is 62 inches in diameter, and his longitudinal stays, from side-sheet to side-sheet, the same length. Now the length of his top stay-bolts is the difference between his crown-sheet and these side-sheets, and his crown-sheet makes up the difference as between their length and the long braces. Now, as the crown-sheet is exposed to a greater heat than these long stays, it would look to me as though the expansion would be greater in the combined distance, made up of two short stay-bolts and about 52 inches of crown-sheet, than it would in 62 inches of rod passing through steam or water space; consequently, if expansion has anything to do with it, the tendency would be to press the side-sheets out at the top row of stay-bolts, and that the first row of longitudinal stays would have to resist the difference in expansion between themselves and the crown-sheet, while my understanding of his theory is the reverse.

"I do not write this for the sake of criticising his opinion, nor to air my own, but if there is anything in this statement, I do not understand it and would like to have it explained."

All subscriptions from this on must commence with April or a later date. We are out of papers for January, February and March, though we had lots, but railroad men wanted 'em worse than we did. We don't propose to carry a lot of back numbers.

## An American Express Train.

Nowhere but in America can there be found provision for

people *living on wheels*. All the European railroad does is to transport the body, very few pay any attention to heating their cars, dining cars are curiosities, sleeping cars are very scarce, very uncomfortable, and the rates very high, water-closets are luxuries to be found only in rare cases, and the modern American coach with its closet for each sex, its wash basin and towel rack, its steam heat, careful ventilation and comfortable seat is the peer of many a monarch's private car; while to tell many people in Europe of the bath rooms, barber shops, telegraph offices, etc., to be found on our limited trains is to be put down for a gilted liar.

While this country has but a few Pennsylvania limiteds and Royal Blue Congressionals, and Empire State expresses are not universal, we want to show the comfortable way in which the average American citizen can and does "live on wheels while covering from one to two thousand miles of distance with far less discomfort than an Englishman must endure in going as many hundred miles in his own country.

Our large inset shows a sample American express train. Every trunk line in this country runs trains similar to this.

On this train a traveler can enjoy himself as at a hotel, he has every attention, an electric button at each seat calls an attendant night and day, he dines in a sumptuous car, receiving a five-course meal three times a day, he can smoke at will, every personal comfort is at his command, he can go from one end of the vestibule train to the other bareheaded, without danger of draft, rain or cinders, he can read, write, sleep, or tell stories in the smoking-room.

When night arrives he undresses and goes to bed like a Christian, and all the time a magnificent locomotive is whirling him to his destination. That's solid American comfort. It is unknown except in North America. Every citizen ought to be proud of our passenger service, yet we complain when there's the least bit of a lapse of perfection.

Our inset was made direct from a photograph of the Michigan Central's Pacific Express as the train stopped at Falls View, overlooking the king of waterfalls, Niagara.

The magnificent ten-wheeler looms up grandly, she is one of Schenectady's best, and behind her come eight splendid cars, each over 70 feet long, vestibuled throughout, five of them sleepers.

This is not the Michigan Central's best train by any means. Her North Shore Limited is a marvel of luxury, running between Chicago and New York, 979 miles, in twenty-four hours.

The Pacific Express is one of the regular every-day expresses, stops at all the larger cities on the way, furnishes lots of accommodation—in fact is a fair sample of how the average American can take comfort as he goes.

## Coal Tar as Fuel.

The use of Pintsch gas for the lighting of railroad cars is extending so rapidly that within a few years no other light will be tolerated. In connection with the gas-making plants there is a waste product in the form of coal tar, which some companies find difficulty in disposing of to advantage. Those interested may gain a point by learning how Mr James Holden, locomotive superintendent of the Great Eastern Railway, of England, disposed of this tar.

Not being able to dispose of the tar he tried it as fuel under a Cornish boiler and found that it could be used successfully in steam making. Then he applied the system of tar burning to three stationary locomotive boilers, and the comparative results of a week's working with coal only, and with coal and liquid fuel together, were as follows Staveley coal, 156 cwt. for 63½ hours' steaming, or 275.1 lb per hour, including coal for lighting up. With the coal and oil there was a consumption for 60½ hours' work of 55 cwt. of Staveley coal and 546 gallons of green oil, or an average of 101.8 lb. of coal and 99.3 lb of oil (9 gallons per hour). With coal only the evaporative duty was after the rate of 7.16 lb. of water per pound of fuel, while with the coal and oil it was 8.91 lb. per pound of the combined fuels. Subsequently the system was adapted to a furnace in the steam-hammer shop, to a rivet-furnace in the boiler shop, to a Cornish boiler in the printing department, and to two locomotives. Various descriptions of liquid fuel have been tried. *Engineering* reports a trial run of a locomotive burning a mixture of one-third of green oil with two-thirds of tar, which was completely burnt without smoke or trouble. Roughly speaking, the consumption of fuel in this engine was 1 gallon of liquid and 14 lb. of coal per mile. In Mr. Holden's system the liquid is injected into the furnace (which is not altered in any way) by a steam jet. The steam is supplied to the central jet of the injector, the liquid fuel surrounds it, and an air supply is disposed concentrically outside the whole. A thin coal fire is kept on the grate; and to assist in keeping the grate properly covered with the very thin fire, lumps of chalk are placed on the bars when starting for the day. The locomotives fired in this way with tar valued at 2¼ cents per gallon of 11 lb., show a slight saving as compared with coal.

## American Railway Association.

In the course of a pamphlet on safety appliances, Col. Haynes made a remarkably vigorous defense of the American Railway Association, of which he is president, in reply to disparaging remarks about it in Congress. As this association will perform important duties connected with the enforcement of the new law on safety appliances, information about the organization is seasonable. Col. Haynes said:

"It was stated that the American Railway Association was not a corporation, that it owed no obligation to the public, that no duty could be imposed upon it, and that to recognize its existence would be to recognize a phantom, yet in this very debate it appeared that this association represented more than 122,000 out of the 165,000 miles of railroad in this country. Here is an association whose members are railroad corporations, represented by their managing officials, its reason for existence is avowedly 'the development and solution of problems connected with railroad management in the mutual interest of the railroad companies of America.' It has been in existence for seven years; in that period it has established a uniform standard of time, which enables travelers to pass from the Pacific to the Atlantic slope and across to Europe, and yet follow the schedule of every train without setting their watches; it has promulgated a code of uniform train rules that, once learned by an employé, facilitates his employment on any railroad, and, not to speak of other matters, it has solved this problem of safety couplers, if not prevented by Congressional interference. Surely this is no phantom; it does recognize the duty which it owes to the public and to railroad employés.

"It is not a corporation, but a voluntary association of railroad companies, and its decisions have no binding obligation upon them. Yet within its sphere it expresses the consensus of opinion among those who are looked upon as authority in questions of railroad operations, and its voice is heeded accordingly. Let its work be recognized in the same way by legislators and they can leave to it the solution of these problems relating to railway appliances, not in the interest of any clique nor of any class interest, but dispassionately and intelligently, as representing the impossible management of the whole railway system of this country in a national and not in a corporative sense."

---

While passing through a roundhouse not long since, I stopped to watch a boiler washer, and I learned something. He was removing plugs from a boiler not yet cold. He had with him a little can of cold water, which he slowly poured on the wash-out plug, thus cooling and contracting it. Then a quick, sharp tap on the wrench loosened it, and the plug was easily removed. Since then the ordinary method of pounding a hot plug with a hammer, getting two or three men on the wrench and breaking the wrench or the head of the plug, has seemed to me like making a mountain out of a molehill.

---

The discontented and ugly feeling on many of our Eastern roads among the engine crews could be permanently cured by the companies paying for overtime. The stealing of overtime by the companies is costing them dear and a day of reckoning is coming—better stave it off.

Forty-second Street Station, Third Avenue Line, Manhattan Elevated Road—Looking North.

## New Mogul Passenger Engine for the N. Y., Ontario & Western.

All the operating officers of the N. Y., O. & W. road are very much pleased over the performance of the new moguls for passenger service just put on the road.

Our engraving shows one of these, and from it a good idea of the make up of the machine can be had.

The boiler is a straight-topped one with the dome set well back, coming up through cab far enough back not to interfere with the view of the engineer.

This boiler has shaking grates, which are supported by six separate frames, or carry-irons, and while the firebox is 8 x 10 feet, the grate frames can be passed through the furnace door, which is a very important matter in the item of repairs or renewals.

Another new feature is the use of a steel driving-box with brass gibs; this arrangement is giving less trouble than any kind of box they have heretofore used.

There is another unusual departure from ordinary practice in the design of rod strap. The main rods have spade-handle straps, but they are made in three pieces, the strap-ends being secured to the butt-end of rod by three bolts. This arrangement gives all the advantages of the spade-handle, as the brasses can be taken out by removing one bolt at rear, but it makes a plain rod and avoids the usual trouble from spade-handles, namely, cracking in the corners. The three pieces composing the strap are straight pieces, easily forged and as easily closed sideways on a loose brass.

The general dimensions of engine are as follows

Gauge of track, 4 feet 8½ inches.

Rigid wheel base, 14 feet 6 inches.

Total wheel base, 22 feet 2½ inches.

Driving journals, 8 inches diameter, 11 inches long.

Cylinders, 19 x 24 inches.

Slide-valves, Richardson balanced, ⅞-inch lap.

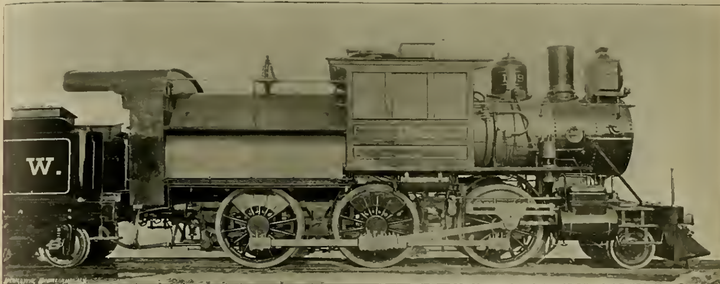
Boiler, 58 inches diamater at smallest ring, shell-plate 9/16 inch thick, longitudinal seams double riveted, with welt strip inside; firebox-sheets ⅜ inch thick, tube-sheet 9/16 inch; hollow radial stays 1 inch diameter, box 10 feet long and 8 feet wide, 236 two-inch tubes, 12 feet 6 inches long, No. 12 wire gauge, set with copper ferrules on each end and safe end a back No. 10 wire gauge; dome 28-inch diameter. Fuel, anthracite pea coal.

Driving-wheels, 62 inches diameter, 3½-inch steel tires on a 56-inch center.

Weight of engine ready for road 130,000 pounds.

The engine is fitted with Westinghouse automatic air-brakes and train signal; American outside equalized driver-brake and steam heating equipment.

The tender has a water capacity of 3,800 gallons.



Slack Coal Burning Mogul Passenger Engine. Designed by Superintendent of Motive Power Geo. W. West, for New York, Ontario & Western. Built by Dickson Locomotive Works.

## A Locomotive Carrying 500 Pounds Pressure.

The stackless and fireless locomotive shown herewith was recently turned out by Baldwin's for the Jefferson Coal Company.

She will use compressed air, taking her supply from storage tanks. The following are her principal dimensions

Gauge, 3 feet.

Cylinders, 8 x 12 inches.

Driving-wheels, 24 inches diameter, with 20-inch centers.

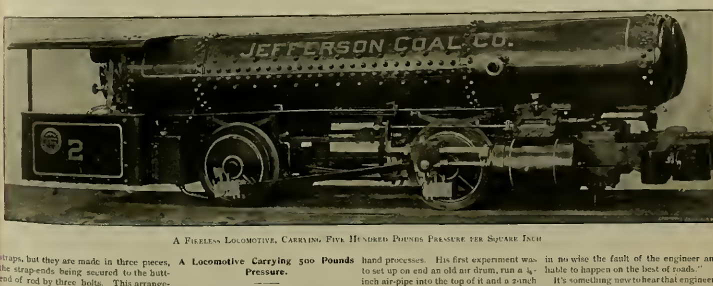
Two air-reservoirs of steel, 7/8 inch thick, of 60,000 pounds tensile strength, right one 13 feet 9½ inches long, left one 16 feet ¼ inch long, both 23¾ inches outside diameter, straight pattern.

Storage pressure 500 pounds, but capable of carrying 600 pounds if desired Tested to a water pressure of 750 pounds. Working pressure in cylinders 100 pounds.

Weight, 15,820 pounds in working order

Wheel base, 5 feet 6 inches.

One tube is made shorter in order to give room for the engineer and the necessary handling gear.



A Fireless Locomotive, Carrying Five Hundred Pounds Pressure per Square Inch

## Filling Locomotive Sand-Boxes by Compressed Air.

Of all the ingenious devices gotten up to use compressed air, none of them have gone quite so far nor helped to lighten so onerous a job as has Mr. E. W Snare, in charge of the Philadelphia roundhouse of the P., W. & B. road. He has made some successful experiments in using air to carry sand to the engines in the roundhouse. This he does without moving mechanism, without lifting an ounce of sand, without getting sand all over the engine, and in far less time and with less help than by hand processes. His first experiment was to set up on end an old air drum, run a ¾-inch air-pipe into the top of it and a 2-inch sand-pipe out of the bottom. This sand-pipe was carried up above the engines and a T connection made at each stall.

The operator has a large hose that he attaches to these T's. The hose has a stop-cock on the end to enable the operator to shut off the supply promptly when the box is filled.

When air pressure is applied above the sand the big pipe commences to deliver sand at once. This flows solidly with no air or dust in it until the sand in the supply tank gets so low that the air blows through it

It seems almost incredible that sand would flow through such a long line of pipe from air pressure in the tank, but it is found that fifteen pounds pressure will start it.

Mr. Snare intends to use a large tank placed where the sand can run from the drier into it.

Just at present his apparatus is out of gear on account of the falling down of a part of the roundhouse roof.

Those figuring on improvement in their sand-handling plant should investigate this system. It has advantages that recommend it very strongly.

## "Falling In" of Crown Sheets.

One of the men who took an engine in the recent strike on the Ann Arbor road dropped the crown sheet of one of their new Mogul engines the other day, and the newspapers report that General Manager H. W. Ashley said of it

"The explosion was caused by the crown sheet of the engine falling in, an accident in no wise the fault of the engineer and liable to happen on the best of roads."

It's something new to hear that engineers can't help the dropping of a crown sheet—they always get fired for it.

But if the Ann Arbor crown sheets are predisposed to this "falling in," we should advise the use of the famous vegetable preparation invented by the late lamented Mrs. Pinkham; or the employment of engineers—real live ones—has been known to stop it.

No more copies of January, February or March of this year. Subscriptions can commence no farther back than April

### Advice to an Invention Promoter.

BY JOHN ALEXANDER.

I have just got a letter from a brother-in-law of mine—who has more money than horse sense—that made me mad. I assume that a fellow has a right to get mad when he comes to think that his own sister is married to a rich man that don't know more than about twice—especially about mechanics.

"American" Passenger Locomotive for Argentine Republic. Built at Glasgow, Scotland.

Bob is a good enough fellow, and knows a whole lot about business, and has had experience in the banking line that I am free to confess I have got along without. He is one of those Connecticut Yankees, however, that are forever dropping some experimental money on chimerical devices that are going to "revolutionize" the world.

He invariably asks my opinion about mechanical questions, but always *after* he has dropped a thousand or so.

Let any man come along with a scheme to do something by machinery that can't be done at all; let him approach Bob Willitts "on the quiet," ask his advice and mention something about a "dead monopoly on the whole business," and "getting in on the ground floor," and Bob is his victim.

Two-Cylinder Worsdell Compound Freight Locomotive for Argentine Republic. Built by Neilson & Co., Glasgow, Scotland.

If Bob asks "I don't just see how your automatic shaving machine can be set so that these revolving razors will fit all kinds of faces and cut beards in all the fancy patterns?" the inventor has only to say, "Why, we do that with electricity," Bob reaches for his check-book at once, goes in "on the ground floor," gets a "dead cinch" on the "controlling interest"—then he writes to me

All an inventor has to do to explain anything that is unexplainable, do something that is undoable or perform any other miracle, to convince Bob Willitts is to say, "Do it by electricity."

Bob owns a controlling interest in a thing to control immigration (by electricity) and to irrigate the Yuma desert (by the same stuff), and a stem-wringing scheme to breed horses with white Angora goat's wool on them—by the use of a pair of dry batteries and thirty feet of No. 13 copper wire—insulated.

Bob goes off the handle on the scheme in hand for about two weeks, and then reluctantly drops the thing, firmly believing that in time some one will take it up and perfect it.

Last week, Thursday, he wrote me about his latest "cinch" I can always tell when he is laying awake nights wondering how he will invest the nine million dollars that he is sure to make out of the new scheme that is going to "revolutionize the whole business."

Bob won't invest in a legitimate mechanical enterprise, he must have a "revolution" or nothing. Yet in the banking business he demands the glitteringest of gilt-edged securities before he lends a sou. He does all his "plunging," "gambling" and "revolutionising" in mechanics, and what Bob don't know about mechanics would make a fifteen volume encyclopedia and have a pamphlet left over

Here is an extract from his letter

"DEAR JNO I write to get a little help from you in the railroad line. I want you to touch the proper button in the general office to get me the loan of an engine (preferably yours) to put on, for a public demonstration, a new oil burning device that I control. You can say to the officials that I will apply this at my own expense, that it will burn 50 per cent. less oil than the engine now burns coal—value for value—that it will prevent fires, ashes, dirt or cinders; being a much fiercer fire, *it will double the power of the engine*, absolutely prevents smoke, automatically extinguished in case of accident, *self-regulating—burns just enough for the work automatically*, thus doing away with the necessity of a fireman and saving the expense of his wages," etc., etc.

This last I knew was to be done by electricity—though Bob had forgotten to mention it.

"I want you," the letter continued, "to write me what you think of the new idea and make any suggestions you care to, as, of course, you know that I am more familiar with the first mortgage bonds of the Old Colony than with the details of the locomotives, though I see the operating expenses are 57 per cent of the gross earnings, this you must acknowledge is an enormous per cent., and if the introduction of oil fuel could cut this down to 25 per cent., as it promises to do—or to even 40 per cent., there is a fortune in it on one road, let alone all the roads in the country. It's a wonder to me some one has not thought of this before."

I had an evening at home last week, and I took and sat down and wrote Bob a letter, and if he falls into any more traps it will be his own fault, for I have certainly pointed out the straight and narrow way.

After mentioning the self-evident fact that I had "sat down with pen in hand," and making a few observations on the health of the Madam Alexander and the young Alexanders, I jumped into Bob something like this—Bob is a Sunday School superintendent, so I thought I would come at him from that side

"DEAR BOB:— * * * 'A fool and his money are soon parted.' * * * 'By their works ye shall know them.' * * * Bob, I think you are the hayseediest bunco-bait I ever heard of. Knowing that Mary and the babies are provided for in their own right, I can't help hoping that the oil-burner man done you up for all the profit you will make in a year. Oil burning on locomotives has been tried 30 times in the past thirty years and always with the same result. It burns, it costs more than coal; it throws more smoke if not regulated with most exacting care; it has caused more shop fires than coal; it is dangerous to handle; it means cremation in a wreck; and there are forty other reasons why it is not good fuel for a locomotive.

"But all that has nothing to do with a man of your alleged sense letting a professional inventor make you believe that by burning oil you could get *more power* out of a locomotive. The fire won't increase the size of the cylinders or add to the adhesion of the wheels—your tea-kettle won't get any hotter and the steam from it won't have any more *power* in it if you should boil it over an oil fire instead of on your gas stove. Haven't I warned you, time and time again, about these automatic, self-regulating things that are going to *learn a trade* and *think*—by electricity?

"You look upon operating expenses as you do on interest—it's different. These schemes that are going to save a certain per cent of the expenses of a road—before they are tried—are good things to let alone until after the trial.

"You ask my advice because you say I am a mechanic. If John Smith sued you for assault and battery I suppose you would hire a lawyer ten days after the case had been tried and you had paid your fine. Why don't you apply your other business methods to mechanical ventures. Mechanics is *business*—just the same as banking.

"If a man earning $40 per month came to your bank and asked for the loan of $1,000 for ninety days, saying he would pay you as fast as he earned it, I am quite sure you would want to know how he expected to pay $1,000 in ninety days from a salary of $40 per month. I suppose (?) he would satisfy you entirely if he explained that he could do that easy enough—by *electricity*.

"Don't you suppose that common sense and machinery will work well together. Do you think that all the wonderful machinery of the world works by some hocus-pocus,—all the difficult problems being solved by a squirt or two of electricity,—or do you suppose they were overcome by the real application of some mechanical device, established and working by some known principle?

"Last year I tried to interest you in the invention of two of our young mechanics, they had a new process for making a well-known household utensil that cheapened the product a few cents and made a better article. A few thousand dollars would have established them in business; but they had nothing new, to you,—you had heard of flour sifters before;—nothing revolutionary in it, they didn't propose to run houses 37 per cent. cheaper with their sifters; you wouldn't put up a cent—the boys couldn't promise to increase the *weight* of flour by the use of their sifter—as the oil man increased the *power* of the engine.

"Moral: They got their capital elsewhere, established a business and paid 11 per cent last year, this year they will pay 15 per cent. on a larger capital. That's legitimate business. You want to gamble on a 'sure thing'—sure for the other fellow.

"It's truly wonderful how some men, supposed to be sane, will go into schemes as ridiculous as an expedition to the moon. I should think you would get tired after awhile.

"Have you ever sold that valve-gear stock?—that wonderful device that was going to save 45 per cent. of the steam, because it *cut off* the steam at one-quarter of the stroke—you explained it to me yourself.

"What will you take for that rotary engine?—the one that was going to have a *constant piston speed* of 1,500 feet per minute and work steam as expansively as a Corliss—without figuring on what the steam would lose catching up to the piston?

"How much money have you got invested in that scheme to propel a ship with a jet of water and a steam-pump—going to 'revolutionize' ocean travel, saving 50 per cent. of the coal and 34 per cent. of the time?

"I believe you are a stockholder in the locomotive tire with flat spots—the one that was going to establish a new law of mechanics and increase adhesion by increasing *surface* instead of *weight*, the one that was going to pull four cars more than a full train (with the spots).

"Why didn't you get rich out of that scheme to double the efficiency of fuel by sprinkling it with a little salt canal water, with a Chinese name?

"I believe you are vice-president of the air-brake company that was going to refill the auxiliary reservoirs while the brake was on—forgetting, if you ever knew—how many eminent mechanics have lain awake nights for years trying to keep the air *out* of the auxiliary reservoirs when *you* want to put it in.

"Yes, Bob, 'get in on the ground floor' and 'control' that oil apparatus—I know from the blueprints it couldn't be controlled on the engine.

"I'll send you a man next week with a car-coupler that, if once adopted, will 'revolutionize' the business—paralyze it, in fact.

"There is a man in our asylum working on a patent hen-food to make pullets lay Easter eggs—sort of a dye-house attachment. You ought to be president and financial backer of that company—it has *bright* prospects.

"I see a South American has patented in the United States a net for catching boa-constrictors. Couldn't you form a syndicate and get control of that patent? We are a little short of constrictors in this country, but you'd have a 'monopoly' on the business, and when you 'got there' things would *squirm!*

"But say, Bob, seriously, look out for those common, everyday mechanics who need capital to push the manufacture or sale of some prosy, everyday tool, device or utensil. Don't put up a cent to help a man with a simple improvement on a lathe or planer, or a locomotive or a wheelbarrow, you reserve all your cash and backing for 'revolutionizing' inventions.

"Edisons, Morses, McCormicks, Stevensons and Westinghouses are as thick as mosquitoes—woods full of 'em.

"If you really want to get a dead cinch on a sure thing I'll sell you the patent on my fodder-can or make you a present of my registering wrench or the grapevine valve motion.

"If you could get a ship load of linen pants up to Greenland I believe you would practically control the whole trade and have a monopoly of the business—or an ice factory in that place where bankers and lawyers and other sinners go, would be a paying investment and make a benefactor of the founder, as it would tend to reduce the 'whippin and whaling and mashing out teeth.'"

Well, sir, that thin-skinned rooster actually got mad at that letter, and wrote me a sarcastic postal card thanking me for my *smartness*.

There's no pleasing people with advice, ingratitude is as catching as the itch—that's the reason I think so many of my friends are jackasses, and keep it to myself—like as not they'd get wuzzy about it if I told 'em so.

### Then and Now.

General Foreman Osborne, of the D., L. & W. shops at Hoboken, N. J., has in his possession an interesting old directory of the city of Newark for 1839. In the back of it we noticed a cut of an old-fashioned locomotive and a common stage coach loaded with passengers, under it an advertisement for the Morris & Essex Railroad—now the D., L. & W. The following passage shows how small were the beginnings of some of our busy lines:

"This road was chartered January 29, 1839, and the company commenced running their cars by horse power from Newark to Orange, November 19, 1836; from Newark to Madison by steam power on Monday the second of October, 1837; and from Newark to Morristown on the first day of January, 1838. The average daily receipts from Newark to Morristown (for passengers) from first of January to first of May, has been $72. An eight-wheel car, capable of carrying from seventy to 100 passengers, was placed on the road the 15th day of February, 1838, and a second engine was put on the road in May, 1838. The cars now leave Newark and Morristown three times a day. The road has also been surveyed from Morristown to Easton, and from thence to Carpenter's Point."

To-day on the same line, there are more than 100 passenger trains, with five to ten times the capacity of the old trains, which stop at Newark daily.

---

On some of the engines of the North-eastern Railroad, of England, the air-pump exhaust pipe leads into the tank, thus heating the water. If the North-eastern runners use as much oil in the steam cylinder of the pump as many American runners do, they could use the boiler as a soda water fountain. On this road a drip-pipe leads from the exhaust-pipe to the back drivers, oiling the flanges.

CARRIAGE YARD OF THE NORTH BRITISH RAILWAY, UNDER CALTON HILL, EDINBURGH, SCOTLAND.

The locomotive engineers and firemen of the St. Louis & San Francisco road have formed, at Springfield, Mo., a reading-room club. The organization intends to furnish rooms with a good library of practical books and have models of rolling stock, machinery and various appliances that can be used for the information and instruction of members. Mr. O. G. Strobach is secretary and treasurer.

Baldwin's have just turned out the latest "largest engine on earth," for exhibition at the World's Fair. The engine is a 4-cylinder compound decapod for the Erie. She has a 76-inch boiler, and cylinders 14 x 27 x 26 inches. Her main rod weighs 850 pounds. The engine weighs 176,000 pounds, empty.

In answer to inquiry we have to say that the photograph of engine 385 was taken by Mr. F. W. Blauvelt, of this city, who does that sort of thing for pleasure and not for profit. The builders of this famous engine, the Baldwin Locomotive Works, would be the proper place to get a photo of her.

LOCOMOTIVE ENGINEERING A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK

Address all communications and make all orders payable to

LOCOMOTIVE ENGINEERING,
5 Beekman Street, New York.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } *Editors and Props*
JOHN A. HILL, }
J. W. CURRAN, *Mgr. Advertising Dept.*
FRED. S. HILL, *Mgr. Subscription Dept.*

**Subscription Price.**

$2.00 per year, $1.00 for six months, postage paid to any part of the world. Single copies, 20 cents.

**Special Notice.**

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary, always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as Second-class mail matter.

### New Subscriptions Must Commence with April.

Although we fortified for the siege, we are obliged to announce that we have run short of the issues of February and March. All subscriptions for 1893 must, from now on, commence not earlier than April. We shall try and keep enough to supply all back numbers from April. Those who want to add copies of issues of 1892 and this year can order now and we will try and get copies for them. All back numbers closed out early—no year-before-last business for us. SINCLAIR & HILL.

### Self Help for Ambitious Workmen.

A month seldom passes but we receive information about educational clubs and forms of mutual improvement societies being formed by railroad trainmen and workmen seeking to secure the means of improving their education. All this is very gratifying and displays a manly spirit of self help, but in these days when so many public men are interesting themselves in providing easy means of self-education to all classes we think that a little more public encouragement ought to be given to railroad men. In a great many manufacturing cities, night schools are becoming a thoroughly recognized portion of the educational arrangements, but most of railroad towns are still very backward in providing night schools where ambitious youths could continue the limited education received before they had to begin to work for a living.

Railroading is a very different thing today from what it was twenty years ago and every year introduces so much new mechanism and refinement of operating appliances that better educated men are required for doing the work successfully. It is the duty of the communities where railroad men or citizens bear the burdens of taxation, to provide the means of education for those who are growing up to citizenship. Ambitious young men and public spirited individuals have hitherto done the principal work of supplying school facilities for those who could only attend in the evenings, but this is not fair or just. Providing means of education that is to make better and more useful citizens ought not to be left to individual enterprise. Unfortunately our educational equipment has been arranged for the needs of agricultural communities and it is extremely hard to get it modified to suit railroad and manufacturing communities.

Ridiculous mistakes have been made in many places where the local authorities have attempted to provide night schools for workmen. Teachers for such schools have been selected from the list of day school instructors, and the instruction attempted has closely followed the day school exercises. The teachers try to impart purely literary instruction to pupils who are in urgent need of arithmetic, geometry and applied science. Between teachers and students so situated cordial relations are not likely to exist very long. Interest languishes on both sides, the attendance falls off and finally the school is closed with the intimation that the young men of the place do not care to attend evening schools.

If night schools for practical men are to be made useful and attractive, educated, practical men ought to be employed as teachers. They would understand the wants of their pupils, be in sympathy with their shortcomings and understand how best to give the necessary help. Draughtsmen and graduates of technical schools engaged on railroad work generally make very good teachers for an evening school.

The majority of mechanics and trainmen do not desire technical education unless it can be obtained without personal or mental exertion, but in nearly every shop and engine house there is a small group of thoughtful, industrious men who will study if they have the opportunity. This is the class from whom our industrial leaders have been drawn in the past, and the same class of men will furnish the foremen, master mechanics, superintendents and managers of the future. Every year makes it more difficult for an ignorant man to rise above the level of a workman. New influences are constantly arising to force onward the man who studies the principles relating to his business. Study is not so pleasant as play at first, but a little perseverance will make it more enjoyable than most pastimes are. Applying one's mind with determination is half the battle and it is surprising how easily difficulties disappear before steady labor. Self-denial and perseverance are necessary to those who pursue knowledge under difficulties, but the reward is worthy of the exertions made.

### Preserving Antiquities.

We have often wondered when wandering from one railroad shop to another when the time will come that the men in charge will be able to run their business as it must be managed by private manufacturing firms that meet competition and avoid bankruptcy. Manufacturers are constantly selling old tools because it does not pay to use them, but railroad companies seldom or never do this. Tools are never scrapped as long as any work can be got out of them. In some places we find a mild sentiment in favor of dispensing with old tools and buying new ones. The time when this action will be taken is when earnings are unusually high and expenses low. That millennium never comes. The earnings may be quite up to the road's capacity and the expenses may be lower than they ever were before but something else than buying shop tools will be found to be done with the money.

This condition of affairs tends to make patchers of the men in charge of the work. No matter how broad a man may be a decade or two spent scheming to make old things look new will narrow him and pervert his judgment. Having the capability of perceiving the point when it no longer pays to repair machinery is a somewhat rare attribute, but ability in this direction is stunted by railroad employment. The service cultivates the species of men who find it torture to send an unbroken article to the scrap heap till years of repose in some place where it is an obstruction has shown that it could never be used again.

In passing through a car shop some time ago our attention was arrested by a peculiar coil spring and case that were lying under a bench amidst many other odd castings and forgings. On inquiring what the spring was used for we were informed that it was the spring of a Creamer brake. It was a curiosity, and so were several other things in the same vicinity. They had all been carefully laid aside in hopes that they might be useful sometime and twenty-five years had passed and they were still waiting.

How often we can note similar practices in machine shops. An engine gets a new set of axle boxes. Two of the old ones are in pretty fair condition and they are laid away carefully under a vise bench to be handy for some other engine of the same class that may come in with a broken box. A discarded eccentric strap taken off another engine and not more than ¼-inch out of round is laid to repose near the axle boxes, and the adjacent spaces are filled with discarded feed pipes, infirm pumps and their fittings, old stack cones, nozzle tips, an odd rod strap, several half-worn piston rings, a cylinder-head with a crack in it, a few brake-heads of different patterns, a sandbox cover and the inevitable oil-box cellar besides a mass of other miscellaneous litter considered too good for the scrap heap.

A shop run under the influence of this kind of saving sentiment is usually a museum of worn out articles, every recess and corner being filled with material that long ago ought to have passed through the rejuvenating cupola or forge. Good money has been paid for tons of pig and bar-iron whose place ought to have been taken by the scrap reserved as available stock. Stuff of this kind is rarely available when wanted, and its individuality is seen only at the annual resurrection caused by stock taking. Those who try to make repairs with half-worn articles generally spend more on refitting them than new ones would cost, and at the end have inferior attachments.

A predilection for preserving half-worn articles is an inconvenient and expensive habit, but a fondness for keeping articles whose pattern has been changed is infinitely worse. In this case casting-houses and store-rooms are littered with articles kept on hand because they have not been used and never will be. A vague hope is entertained that rough castings and forgings of an obsolete character will come in handy for some purpose; but successive annual stock-takings pass, and they all remain on hand, showing apparent plenty in the presence of real scarcity.

When the pattern-house is critically examined, what a store-house of antiquities it presents to the eye! Cylinder patterns that have not been used for a dozen years, oil boxes that this generation has seldom seen in use, pumps that are never used any more, and hundreds of details, whose purpose the old pattern-maker hardly remembers, are still preserved because the house has never been burned down, and the wood has not rotted out. And all this time the pattern-house is so badly overcrowded that searching for a pattern not in regular use entails hours of diligent labor.

We do not blame the men who are responsible for the practices described. The vicious influences above them develop the taste for clinging to everything that promises to save a cent's outlay. We merely suggest that periodical self-examination is a good practice. When this rouses a spirit of reform an inspecting tour around the shops would be likely to bring forth good fruit.

### Nepotism.

Railroad men generally are not familiar with the word at the head of this article, because railroading in the past has been fairly free from the practice it implies. We are sorry to see that the practice in this respect is rapidly changing, to the great detriment of railroad companies' interests and to the injury of the railroad men whose natural ability and training entitle them to expect promotion. Nepotism means literally a fondness for nephews, but it has been widened to cover favoritism shown to nephews and other relations and the bestowal of patronage in consideration of relationship rather than on merit. From this it will be seen that nepotism stands directly on the opposite side of the social fence from what is known as civil service rules. For the last few years there has been much heard on railroads about promotion according to civil service rules, which means according to merit, combined with length of service. This is the ideal method of raising men from the lower to the higher positions in railroad life; but unfortunately the practice of promoting by merit and seniority is less general than it ought to be, and there is a growing spread of nepotism that is greatly to be deplored.

We know of no line of business where favor will do less to make a man efficient than in railroad positions, yet we are daily seeing men pushed into responsible places with no recommendation whatever except that they have an uncle or a cousin or a wife's relation on some pinnacle of power. This practice is notorious on some railroads, the president or general manager having relatives or on-hangers ready for every position of responsibility that becomes vacant. No others receive any consideration. Where this practice prevails there are two peculiarities very noticeable: the road is poorly managed, and discontentment racks the service from top to bottom. We are not aware of any popular method by which railroad stockholders can lessen the profits of a railroad so effectually as by permitting all places of trust to be filled by incompetent relatives of the managers. If the directors of railroads realized how dearly they were paying for the privilege enjoyed by the management of converting the service into a charity institution, they would be ready to pension the needy relatives so that the benefit of competent officers might be enjoyed.

### A Railroad Hero.

When a man is killed on a railroad in Mexico, those whom the authorities think are at fault are thrown into prison.

On the 11th of March a bad wreck occurred on the Mexican Central. A south-bound freight train was taking water at Encarnacion station, when it was run into by a north-bound freight train.

Engineer J. T. Sweeney of the south-bound was fatally injured, both legs being amputated. His fireman was also fatally injured. Sweeney was dying when taken from the wreck of his engine, but he realized that conductor Frank Hartman and engineer W. G. Beatty of the north-bound were responsible for the wreck, and that under the severe laws of Mexico they would receive harsh punishment if captured.

He called Hartman and Beatty to his side and made his will, telling them where he had money on deposit. He then gave Beatty and Hartman $500 which he had on his person, and told them to use what was necessary to leave the country and to leave at once.

The wounded man died a few minutes afterward, and the two men started out of town on foot. As soon as the authorities were notified, a squad of soldiers were sent in pursuit of the fleeing men, but they have not been captured.

If it was not heroic for Sweeney to think of the safety of his friends when they were in danger—though they were the cause of his own death—then the earth rolls her green fields to the sun without a hero upon her face.

perienced—and the more the valve is "monkeyed" with the more trouble will

## Fatigue of Iron.

A highly practical and successful superintendent of motive power who prides himself on freedom from theoretical nonsense has taken us to task about our theories on metals being susceptible to "fatigue" We do not know that the word properly describes the condition metal gets into preliminary to breaking, but highly practical grounds exist for the belief that metals become weakened by use even when no incipient fractures exist. There is a bending or a lengthening and shortening action going on even when the change is too minute for measurement except with exceedingly exact instruments. The movement of the metal causes molecular changes which reduce the adhesion of the particles and thereby make the metal weaker. Nearly every observing mechanic has noticed breakages where it appeared that iron or steel originally good had become so brittle and roughly crystalline that it was unfit to sustain an ordinary [illegible]

A case occurred some years ago on the Central Railroad of New Jersey which appears to be a good practical illustration of the correctness of our theories concerning the fatigue of metals The company named got six new switching engines that were put into the same hard service in a yard where there was a great deal of running over switches and frogs that subjected the running gear to severe shocks. The engines were all of the same pattern, strongly built with unusually heavy axles, Colonel Ricker the designer, believing in a good margin of strength. After these engines had been in service for several years one of them broke an axle. An inspection of the fracture showed that what was originally a fine, fibrous iron, had become coarsely crystalline, the molecular change no doubt having been induced by the constant jars. Within six months all the six engines failed with broken axles, and the fracture in each instance showed the same condition of the iron.

Mr William Woodcock, who was superintendent of motive power of the Central when these breakages happened, believed that re-working restored the strength to iron that had become weakened through use He determined to put the theory to a practical test so he worked up the broken axles into piston-rods, crank-pins, rod-straps and other parts of locomotives that are subject to severe and complex strains. The metal gave excellent service.

## A Crime.

One of our correspondents makes a timely protest in this issue against one of the worst practices in our railroad shops—the changing of parts of the emergency-valve in the air-brake.

That railroad managers should buy the best and latest brake for its equipment, and then have some ignorant employé change something that renders the quick action of the brake impossible, is too bad—it is worse than that.

The quick-action brake is a grand, good thing, a life and property saver, and an advance in the mechanics of railroading. It is necessary where very long trains are handled, it is simple and reliable once put up correctly, let alone and handled anywhere near right.

Because some thick-skulled shoemaker has it in charge and has trouble with it is no reason on earth why he should be allowed to "remove emergency piston No. 8 and substitute a small brass bush."

This is equivalent to letting a raw recruit take the trigger off his gun because it prevented his getting his hand in the guard to carry the gun—almost any experienced officer would teach him how to carry his gun and still leave this piece ready for use.

No matter how much trouble is experienced—and the more the valve is "monkeyed" with the more trouble will be had—there is no possible excuse for this kind of work. The air-brake companies will gladly put their equipment right at any time and could, if necessary, recommend men to keep it in repair that at least knew enough to *not* plug it up.

It behooves every superintendent of motive power to see to it that none of his men are nullifying the quick action of the brakes by criminal ignorance—and a brass bush. Some sharp lawyer will get a proven case of this into court some of these days, and some one's reputation will get smudged and some railroad company will pay damages that ought to be paid by those who have charge of the power to stop and start trains.

## A Big Mortgage.

A great deal of talk has been excited in financial and railroad circles during the past month by the announcement that the Cleveland, Cincinnati, Chicago & St. Louis management had arranged for the placing on the property a blanket mortgage representing no less than fifty millions of dollars. It is one of the most comprehensive financial transactions in railroad history, and one that is likely to greatly benefit the valuable railroad property concerned as well as those who furnish the capital The so-called Big Four lines form a net-like system of tracks over two thousand miles in extent, radiating from Indianapolis and embracing all the principal towns in Ohio, Indiana and Illinois We believe that this railroad company provides traveling and freight accommodation to a greater aggregation of people than any other railroad in the country. In spite of the natural advantages possessed, the company has not been very prosperous. The way that it was built up has been a great drawback to the company. It is formed from the absorption of a great many small lines, which have proved valuable feeders, but brought with them great diversity of machinery that has been difficult to keep in repair and expensive to operate. Of course, the right policy would have been to scrap old machinery and work all the rolling stock into standards; but immediate needs for earning money and for keeping down avoidable outlay prevented the carrying out of the policy that would pay best in the end. The result was that a year ago, out of 550 locomotives belonging to the company, there were more than one hundred diverse classes.

Great progress has been made lately in reducing the rolling stock towards uniformity, but the work has been hampered for want of the necessary capital. The big mortgage will not only provide the means for putting the machinery in satisfactory condition, but will enable the management to provide much new trackage and siding facilities that are badly wanted to develop the business of the road.

A paragraph which appeared in our columns a month or two ago on "Spark Arresters," has stirred up quite a discussion on the subject, and the indications are that the different appliances used for preventing spark throwing will have their merits and defects pointed out by the men who are best able to judge about them, viz., the engineers. We have every reason to believe that the extension smokebox is far from being a satisfactory spark arrester, but we do not think that returning to the diamond stack is in the line of progress The diamond stack may be as good a spark arrester as the extension front, and yet be a very undesirable appliance for the purpose. Those who have experience with diamond stacks and extension fronts are certain that the latter is more cleanly than the former, which is a good reason for the extension front being adopted, other things being equal. The diamond stack scatters the sparks at low altitude, and trails the smoke, which makes its use very undesirable on passenger trains. The netting and cone are also more troublesome to keep in order than the attachments of the extension front The only real objection to the latter is that it puts extra weight on the engine truck.

There are so many inventors nowadays ready to promise a saving of from 20 to 50 per cent. through the use of their devices that railroad men are slow to look at any reported improvement in connection with motive power that does not promise to save one quarter of the fuel. The greater part of the devices offered as fuel savers are worthless, but others have merit. A conscientious man selling a good thing may not care to exaggerate its merits, and modestly claims 10 per cent. of saving Very often that finishes his prospects with a general manager or master mechanic. They are so much accustomed to the tales of colossal liars that modest men make no impression. Nevertheless, the man who offers to save 10 per cent. of fuel is likely to be more worthy of a hearing than the man who talks of 50 per cent.

A few years ago there was an agitation in favor of chilled cast-iron for a great variety of purposes and those who fanned the agitation made believe that chilled cast-iron was highly superior to the finer brands of steel for a great variety of purposes. Cutting tools were all to be made of chilled iron and it was reported that this material made wonderfully durable files. In our travels we occasionally stumble upon cutting tools made of chilled iron, but there is no enthusiasm about the saving effected. Of the cast-iron file we see and hear nothing.

The car builders and several other manufacturers of railroad rolling stock appliances in the neighborhood of Detroit have been making rather noisy threats of moving to another locality on account of the high taxes assessed on their plants. Chicago is spoken of as a more desirable location. There are no labor troubles in Detroit This cannot be truly said of Chicago. High taxation is bad but there are inflictions sometimes endured by manufacturers that overshadow the heaviest taxes ever imposed.

They have curious ways of attending to engineering matters in China. A case was lately reported by a correspondent of *Engineering* where a river broke through its banks, inundating a large extent of country. The Emperor gave orders to the engineers of the district to close up the gap, and they did their best but failed. They were immediately stripped of their decorations and cast into prison. Another set of engineers were appointed; they succeeded in closing the breach and received great honors.

Almost every European mechanic who leaves a railroad job there to take one here, is at once struck with the apparent recklessness with which American builders puncture locomotive boilers and screw pipes into them Over there most of the roads require that every hole in a boiler shall have a flange riveted to the shell, and many of the pipes are placed inside the boiler. No doubt we overdo the puncturing business.

During the month of March we had the pleasure of mailing 130 sacks, containing in all 9,017 pounds of papers. The receipts of the Postoffice Department are in this office, where they can be seen This is saying nothing of 3,550 copies disposed of by the American News Company. Circulation amounts to something — it amounted to 11,000 pounds of LOCOMOTIVE ENGINEERINGS in March.

A road will have no right to discharge its men if the decision stands that they cannot quit at any time. Sauce for the goose is sauce for the gander.

## PERSONAL.

Mr Dan'l Coxe, Supt M. P of the D., S & S., has returned to business after a winter's sojourn in Florida.

Mr. Chas. W. White has been appointed traffic manager of the Suwannee River Railroad, with headquarters at Ellaville, Fla.

Mr. J. R Leonard, trainmaster of the Mohawk division of the N Y. C R R, has been promoted to be assistant superintendent of that division.

Mr G. H. Brown has been appointed division master mechanic of the Chicago, Milwaukee & St. Paul R R., with headquarters at Dubuque, Ia.

We regret to learn that Mr R F Kredell has resigned his position as master mechanic of the Farmville & Powhatan R R, on account of ill health.

Mr. J B. Kilpatrick has been appointed master mechanic of the Des Moines Valley division of the C., R. I. & P., with headquarters at Valley Junction, Ia.

Mr. D J Jerber has been appointed master mechanic of the Connecticut River division of the Boston & Maine, with headquarters at Springfield, Mass

Mr. M D Monsarratt, vice-president of the Texas, Mexican & Gulf divisions of the Southern Pacific system, has been appointed president of the San Antonio & Aransas Pass R R.

Mr. R O. Cumback has resigned as general foreman of the L E. & St L shops at Huntington, Ind., to accept a similar position on the Illinois Central at their shops at Amboy, Ill

Mr. S. C. Hoge has been appointed superintendent of the Macon & Nor R R, with headquarters at Macon, Ga Mr. Hoge was formerly superintendent of the Georgia Southern & Florida.

Mr. A. E. Manchester, division master mechanic of the Chicago, Milwaukee & St. Paul, at Dubuque, Ia., has been appointed assistant superintendent of the Milwaukee system, with headquarters at Milwaukee, Wis

Mr. A G Hollingshead, general foreman of the Wabash R. R shops at Tilton, Ill has been appointed assistant master mechanic of the company's new shops, located at Ashley, Ind, on the new Detroit & Chicago line

Mr. C. S. Hull, superintendent of the Cumberland Valley Railroad, at Chambersburg, Pa, sends in a very interesting sketch of the life and services of the old engine, "Utility" She ought to belong to the G A R

Mr. G. A. Quinlan has been elected vice-president of the Houston & Texas Central R. R. He was previously chief engineer and general superintendent of that road. He is known as one of the best railroad men in the South

Mr J. W FitzGibbon has been appointed master mechanic of the Chicago division of the C, R I. & P, with charge of the company's shops. He was formerly on an Iowa division, and was selected for the new position owing to his ability as a shop manager.

Mr Robert Hitchcock, master car builder of the Connecticut River Railroad, has resigned, after being in the employ of the company for forty-one years Consolidations are hard on the faithful men who have done valuable work in building up the property

Mr C. E Lytle has been appointed superintendent of the Duluth, South Shore

& Atlantic, with headquarters at Marquette, Mich. Mr. Lytle was formerly chief train dispatcher of the Duluth, South Shore & Atlantic R. R., but has lately been on the Lake Erie & Western R. R.

Mr. J. N. Sanborn has been appointed master mechanic of the Springfield division of the Illinois Central, with headquarters at Clinton, Ill.

Mr. D. McMurray has been appointed master mechanic of the East St. Louis Connecting Railroad, with headquarters at East St. Louis.

Mr. P. Hallenbeck has been appointed superintendent of the Iowa division of the Chicago & Northwestern Railway, with headquarters at Boone, Ia.

Mr. C. M. Babcock is appointed master mechanic of the New Orleans division of the Texas Pacific Railway, with headquarters at Gouldsboro, La.

Mr. John H. Greene, of St. John, N. B., has been made mechanical superintendent of the Nova Scotia Central, with headquarters at Bridgewater, N. S.

Mr. Oscar Antz, a member of the Master Mechanics' Association, has accepted the position of chief draughtsman of the Lake Shore car department, at Cleveland, O.

Mr. J. S. Chambers has been appointed master mechanic of the Amboy district of the Illinois Central. Mr. Chambers has been for several years master mechanic in charge of the St. Joseph's Terminal Company's rolling stock at St. Joseph, Mo.

Mr. Addison Hills, assistant to the president of the Lake Shore Railway, celebrated his eighty-sixth birthday last month. Mr. Hills is one of the oldest men now in railroad service on the Vanderbilt system. He entered railway service in 1837, and has been with the Lake Shore since 1868.

Mr. Charles Dunlap has been promoted to the position of general superintendent of the C., R. I. & P., with headquarters at Chicago, succeeding Mr. Royce, resigned. Mr. Dunlap rose in this company's employ through various grades. He was for some time general superintendent of the Western lines.

Mr. C. O. Wheeler, general manager of the Gulf, Col. & Santa Fé R. R., has resigned. Mr. Wheeler had been closely associated with the late Mr. Allan Manvel. It is generally understood that his withdrawal from the Santa Fé system is on account of the new management adopting a policy which he cannot conscientiously indorse.

Mr. W. W. Thompson, supervisor of locomotives of the South Side Rapid Transit Road (elevated), of Chicago, has been East during the past week hunting up rolling stock for the new elevated. The Fair business is expected to call for the use of many more cars than the road can buy, beg, borrow or steal on such short notice.

One of the most popular citizens of Cleveland, O., is Mr. Robert Blee, who was long general superintendent of the C., C., C. & I. R. R. He retired from active railroad life several years ago, but he maintains his connection with the city where his headquarters were, and last month his popularity was manifested by his election as mayor of the city.

Mr. Joseph Harris, who succeeds Mr. McLeod as president of the Philadelphia & Reading, is a railroad man of mature experience and is a good conservative business man. He is a civil engineer by profession, and did engineering work on different parts of what is now the Reading system, on the Delaware, Lackawanna & Western, and was for a time general manager of the Central of New Jersey. The property is safe in his hands.

Mr. L. C. Brastow, division master mechanic of the Jersey Central at Ashley, Pa., died last month. He was one of the oldest master mechanics with the company, having been in charge of the rolling stock of the Lehigh & Susquehanna road before it was absorbed by the Central of New Jersey. He joined the Master Mechanics' Association in 1871 and took a keen interest in the proceedings, although it was not convenient for him to take an active part after he had ceased to be chief of his department.

Mr. P. C. McNiven, who was for some years superintendent of the Canadian Locomotive Works at Kingston, Ont., is in Africa for the benefit of his health. He is suffering from a throat trouble that threatens to shorten his days. He has been devoting attention to railroad matters in Africa, and finds that lime in the feed-water causes great expense to the companies. He writes asking if those who have had experience with lime-charged water on this side of the globe cannot suggest remedies to the African railroad men.

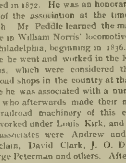
Mr. W. S. Morris, superintendent of motive power and rolling stock of the Chicago & West Mich. R. R., has been appointed superintendent of motive power of the Chesapeake & Ohio R. R., succeeding Mr. Garstang. Before going to the Chicago & West Michigan R. R., Mr. Morris was a master mechanic on the Wabash R. R., having risen to that position through various grades. He is one of the brightest young railroad men in this country and was seriously considered for the position of general superintendent of motive power of the Reading system.

Mr. C. H. Ackert some weeks ago tendered his resignation as general manager of the Iowa Central Railway, and accepted the same day the general management of the Elgin, Joliet & Eastern Railway. Officials of railways, particularly in the Northwest, are favorably impressed with Mr. Ackert's ability as an organizer. He leaves the Iowa Central Railway with the best wishes of both business men and employés, as was shown by the presentation of as fine a Geneva stop-watch as could be procured. We predict a bright future for him. During his management the Iowa Central paid a dividend for the first time.

Mr. D. H. Neale, associate editor of the *Railroad Gazette*, died April 5. Mr. Neale was an Englishman by birth. He received an excellent engineering education and training, and possessed in a high degree the faculty of writing his thoughts in clear, vigorous English. He came to this country in 1883 to make notes of the Exposition of Railway Appliances at Chicago for *The Engineer*, of London. Shortly afterwards he joined the editorial staff of the *Railroad Gazette*. He relinquished the position four years ago and went to be mechanical engineer on the railways of New South Wales, but returned to this country again about six months ago.

Mr. David Preston, mechanical superintendent of the Canadian Pacific, died at Montreal last month of blood poisoning. His death exemplified the serious consequences that sometimes result from a trifle. Mr. Preston was troubled with corns on his feet, and applied one of the patent remedies, which caused blood poisoning. An attempt was made to save his life by cutting off his foot, but that was not sufficient and his leg was amputated. Exhaustion from the last operation caused his death. Mr. Preston began railroad work on the Scottish North Eastern, and rose to an engine driver there. The general manager of that road having come to take an official position on the Grand Trunk, a number of the employés followed him, among them Mr. Preston, who went to work as a fireman on the road. He rose through various grades to be master mechanic on the Grand Trunk. Three years ago he was appointed mechanical superintendent of the Canadian Pacific.

Mr. Charles R. Peddle, purchasing agent of the Vandalia Line, whose portrait is here shown, died at Terre Haute, Ind., on April 19th. Mr. Peddle rose through the mechanical department, and at one time took a very active part in the Railway Master Mechanics' Association, which he joined in 1872. He was an honorary member of the association at the time of his death. Mr. Peddle learned the machinist trade in William Norris' locomotive works in Philadelphia, beginning in 1836. From there he went and worked in the Reading shops, which were considered the best railroad shops in the country at that time. Here he was associated with a number of men who afterwards made their mark on the railroad machinery of this country. He worked under Louis Kirk, and among his associates were Andrew and James Vauclain, David Clark, J. O. D. Lilly, George Peterman and others. After working in these shops for a time he went upon the road as a locomotive engineer. Desiring to learn all there was to be acquired



in the business he went to New England in 1848 and worked in several of the locomotive building shops. He was now what he considered a good all-around man, and seeing superior opportunities in the West he went to Indiana and got a job running an engine on the Madison & Indianapolis road. Three years later he was appointed master mechanic of the Terre Haute & Richmond, which grew and flourished swallowing other lines until it became the Vandalia system. He was made purchasing agent ten or twelve years ago. Mr. Peddle took a great interest in educational matters, and was considered one of the leading citizens of Terre Haute.

The Brooklyn City Short Newtown railroad has placed orders for two more "Kodaks," which has come to be the popular name for direct-coupled generators. The units employed in this station are a 250-horse power generator coupled direct to an 18-30 x 16 Westinghouse compound engine at 250 revolutions. The power station of this road will contain eight of these generators, of which five are already in place. A single one of these Kodaks has handled thirty-eight cars over the considerable grades of this road continuously.

The Manhattan Elevated Railroad of New York has applied a Smith exhaust pipe to one of the engines. The decrease of noise from the exhaust steam is so decidedly apparent with this pipe that we expect it will soon be in demand for every locomotive where the noise of a sharp exhaust is objectionable.

We have received the Transactions of the American Institute of Electrical Engineers, for the year 1892. This is a bound volume of their monthly reports. The volume contains a list of the members and other information in its 850 pages of great interest to electrical engineers.

### Knowledge and Skill.

Our readers frequently request us to publish articles describing operations that turn on manipulative skill. This cannot be done. No article can instruct a man how to push a file level or how to hit the same spot with a hammer twice in succession.

"Chordal," in one of his letters to the *American Machinist* ten years ago, said:

"In handiwork there are two elements—skill and knowledge of skill. Thus in hand turning, the knowledge of skill tells us that a certain kind of chattering proceeds from a certain peculiar handling of the tool. Skill shifts the tool around properly and the chattering stops. Probably the exercise of skill in holding the tool properly cannot be described, and if it could, he who was the most skillful would probably be the most or the least adapted to describe it. You see a man filing something rounding; you take his file and file it flat. He asks you how you did it, you answer that you do it but do not know how you do it. I do not believe that any man knows how he files flat. There are lots of things the skillful do which have no 'how' or 'wherefore' to them that can be got out of them.

"The witness on the stand said, 'I know it to be so,' and the attorney, on cross-examination, said, 'On your oath, how do you know it to be so?' and the witness said, 'On my oath, I do not know how I know it to be so.'

"A man may know lots of things without knowing anything about how he knows them. There are many elements of manual skill, only a portion of which may be stated in descriptive terms.

"When one man wants to learn draughting, the first thing he begins to inquire about is some book out of which to learn draughting. When some other man wants to learn draughting, he goes at it and draughts, and the going at it and the keeping at it constitutes the learning. All the books under heaven will not stuff a man so full of knowledge that he can say that he is a draughtsman before he has commenced to draw. If it was a question of books, all he would need to do would be to acquire all of the knowledge that is in them. I am a sort of a draughtsman myself, and I give it as my honest opinion that books on draughting should be read only by draughtsmen, and not by people who wish to become draughtsmen. These books should be entitled, not 'Information for People Desiring to Learn to Draw,' but 'Information for Draughtsmen.'

"In my opinion, the art of draughting is one of those things which, so far as the art itself is concerned—that is, the skill of it and the practice of it—will force itself upon a person. He will draw in spite of himself, if there is any earthly necessity for his drawing, if the necessity and the honest desire arise, he will draw, and draw, and draw. He becomes a draughtsman—may be a good one, may be a poor one—and the books will do him good in either case. He needs the books to improve himself as a draughtsman, but I hardly think that he needs them to initiate himself as a draughtsman. I draw a broad distinction between the geometry of the art and the art itself—between the perfectly-drawn line and a comprehension of what the line means. He who is up in the science of lines and figures and bodies is a scientific draughtsman, but he is no more a draughtsman than he who knows nothing of them. The skill to delineate the creeping spider or the ugly lathe leg has nothing whatever to do with the laws of natural history, or the laws of the strength of material. A draughtsman may be more useful from a knowledge of the strength of material, precisely the same as he may be more useful by reason of being versed in natural history. When I speak of the art of draughting, I mean the art pure and simple, of delineation, not of design or of mechanical analysis, or of comprehension of the thing delineated."

## The "John Bull" Locomotive and Train.

One of the most novel sights that has been witnessed on an American railroad for many years was the old locomotive "John Bull," shown in the annexed en-

The "John Bull" Locomotive and Train.

graving, hauling a couple of worthy companions in the shape of ancient cars over the great Pennsylvania Railroad, from Jersey City to Chicago, on her way to the World's Fair. The start was made on Monday, April 17, and occupied six days for the 913 miles of the journey. No circus ever attracted more attention. All the way throughout the route vast crowds of people, embracing all classes, lined the side of the track and climbed to every sort of vantage point to look upon the curious cavalcade.

This locomotive "John Bull" is regarded with great interest by Pennsylvania Railroad officials, because she was the first engine used on the Camden & Amboy Railroad, the oldest part of what is now the great Pennsylvania system. The engine is a historical relic for several reasons. It was the first locomotive ever run in the State of New Jersey, it was the third or fourth locomotive that had done work on this continent, and it was the model from which Mathias Baldwin built his first locomotive, the "Old Ironsides."

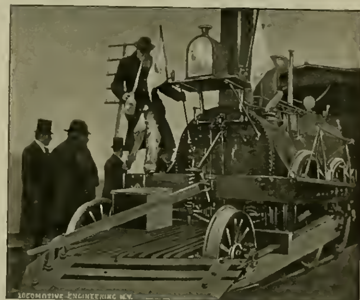
For several years previous to 1830, progressive Americans were watching with keen interest for means of improving the means of inland transportation. Canals had been tried and found wanting. Routes of travel that were frozen up half the year could not satisfy the sons and grandsons of the men who had established a new nation. Oliver Evans, a famous Delaware engineer, had made a success of the high-pressure high-speed engine and preached schemes for applying it to land travel. He ran a scow by steam through the streets of Philadelphia in 1804.

Sundry coal tramways in the North of England had been partly operated by steam locomotives, and the Stockton & Darlington Railway was opened in 1825 and continued to be operated by locomotives. These things were known to all well-informed Americans, and in all directions agitation was going on to give this continent the benefit of the latest inventions in the methods of transportation.

In 1830 the Camden & Amboy Railroad was chartered. Work was begun almost immediately, for Robert L. Stevens, one of the most energetic and far-seeing citizens of this republic, was president of the company. The year before was notable in railroad history by the landing in New York from England of the "Stourbridge Lion," the first locomotive to turn a wheel on an American railroad, and also for the wonderful success of Stephenson's "Rocket" on the Liverpool & Manchester Railway. President Stevens ordered from England one of the most approved style of locomotives, and the engine afterwards called the "John Bull" was delivered in Philadelphia in May, 1831. She was transported by sloop to Bordentown, N. J.

The work of transporting the engine and setting her up was entrusted to a bright young mechanic named Isaac Dripps, who became first superintendent of motive power in this country. He died only last year.

Although the "John Bull" was built only a few months after the "Rocket" made her first famous run, considerable advance in locomotive design were embodied in this engine. She belonged to a form of construction which for years was a model for English locomotive builders. She had horizontal inside cylinders with crank axles, conical firebox, multitubular boiler, blast pipe in the smokebox, drop hook valve motion and slide valves set between



The Old Man Drops a Little Oil.

the cylinders. The latter are 12 x 18 inches. The Pennsylvania Railroad people say that this engine was built by the Stephensons at Newcastle, England, and that she belongs to what is known as the "Planet" class. We doubt the correctness of this statement. The engine is not like the "Planet," which had a plain wagon top firebox with dome on top, a pair of small leading wheels and driving wheels 5 feet diameter. Stephenson's people never built engines with conical topped fireboxes. This was Bury's style of construction, and the "John Bull" has the appearance of belonging to the "Liverpool" class of this famous builder.

The old cars shown in the engraving were Nos. 7 and 9, belonging to the Camden & Amboy Railroad.

The old engineer whom we show talking to the conductor is A. S. Herbert, who ran the engine in the early fifties. W. J. Bailey, the conductor, is one of the oldest veterans in the company's service, and has been a passenger conductor since 1859. Mr. J. N. Sanford, who is now master mechanic of the Meadows shops, acted as fireman, work he had formerly done regularly for the old engine.

THE OLD PASSENGER COACHES.

Hardly less unique than the locomotive itself are the passenger coaches of this historic train. Some twenty-five years ago a farmer near South Amboy bought one of the discarded coaches of the old Camden and Amboy Railroad. He removed it from its trucks, and, planting it on posts in the ground, converted it into a chicken-coop. It served in this capacity until a few months ago, when a representative of the Pennsylvania Railroad, looking for relics, happened upon it, and entered into negotiations for its purchase. The thrifty farmer, realizing that lapse of time had endowed his hennery with increased value, demanded a price which represented compound interest on the original purchase-money, but the matter was adjusted, and the passenger coach of fifty years ago transformed into a chicken-coop is once more fixed upon its trucks and will go to Chicago as a part of the "John Bull" train. After its recovery the coach was refitted and reupholstered, so that it appears now in all the pristine glory of its palmy days. The history of the other coach is not quite so romantic. It was found some years ago in a lumber yard in a New Jersey town among a mass of rubbish, and quietly tucked away in the Meadows shops by a far-sighted official of the company, who foresaw that just such an occasion as this would bring it into requisition some day.

A TRUCK IN THE MARL-PIT.

It is hardly necessary to say that Mr. H. S. Hayward, superintendent of motive power of the United Railroads of New Jersey, who prepared the train for exhibition, was compelled to do a considerable amount of bustling in order to collect all the parts necessary for an exact reproduction of the train as it was in 1836. Not a single one of the relics was complete in all respects, but scrap piles were turned over, repair shops ransacked, and even old blacksmith shops were invaded in the hope of finding some bit of iron which had once been used on the old road. Diligent and persistent search met with reward. When everything else had been secured it was found that one truck was missing. Search was immediately instituted, and some one reported that he had seen an old-fashioned truck in an abandoned marl-pit in New Jersey. It was excavated at once and proved to be the truck of an old Camden & Amboy passenger coach. The wood was worthless, but the iron, though covered with the rust of years, was scraped and cleaned, and with renewed wood-work the truck was placed in position beneath one of the coaches of the present train.

And so it went until every piece of wood and iron that entered into the composition of the old train was duplicated.

Look Out for "Snake-Heads" in Crossing the Meadows Park

## Heat and Combustion.

BY ANGUS SINCLAIR.

HEAT VALUE OF FUEL.

When the design of a furnace is good, when the firing is done with skill and intelligence, and when the rate of combustion is moderate, a small percentage short of the theoretical heat value of the fuel will be obtained in the furnace. This loss will range from 10 to 30 per cent., according to the nature of the fuel.

The text-books on combustion usually tell us that one pound of gaseous hydrogen entering into combination with eight pounds of oxygen produces heat equal to 62,000 units. As the hydrogen dealt with in the combustion of coal is in a solid condition, the liberation of heat is considerably less, and is calculated to be about 40,000 heat units.

One pound of carburetted hydrogen when properly consumed generates about 27,000 heat units. Oxygen combines with the hydrogen of the compound to form water, and with the gaseous carbon to form carbon dioxide. It is in this form that the hydro-carbons of the fuel generally burn.

One pound of solid carbon uniting with

2⅔ pounds of oxygen to form carbon dioxide generates about 14,500 heat units.

One pound of solid carbon uniting with 1⅓ pounds of oxygen to form carbon monoxide generates about 4,500 heat units.

LOW CALORIFIC VALUE OF CARBON MONOXIDE

Every student of this subject is likely to be struck with the difference in the intensity of the heat generated by a pound of carbon under the two conditions of combination Carbon dioxide is worth as a heating medium more than three times the same quantity of carbon monoxide, yet the only difference in their generation is that carbon dioxide obtains a full complement of oxygen (two atoms), while carbon monoxide has been formed with one atom of the heat-producing oxygen This is an eloquent argument in favor of admitting a free supply of oxygen to the fire It explains why the steam gauge pointer frequently moves upward after the fireman has given the grates a gentle shake, or after he has raked the caked crust on top of the fire

Carbon dioxide, with its 14,500 heat units, represents precisely the same quantity of coal as carbon monoxide, which generates 4,500 heat units. The only difference is in the quantity of oxygen taken out of the air, which costs nothing Carbon monoxide may be formed in the combination that takes place on the body of the fire through want of sufficient air and yet be made to perform its proper share of heating if means are taken to supply it with oxygen before it enters the tubes

COST OF HEATING THE MIXED GASES

Although a pound of carburetted hydrogen or a pound of carbon represents the production of intensely high temperature when burned with the full admixture of air, there are several things which materially reduce the heat available for heating or steam generating purposes All the gases of combustion and all the air used to supply oxygen has to be heated, which under unfavorable conditions uses up a large proportion of the fuel's energy.

The amount of heat available for practical purposes depends to some extent upon the volume of gas that has to be heated and on the capacity of the various gases for absorbing heat The specific heat of gases is of as great importance in this as the specific heat of iron and water is in other lines of industry.

SPECIFIC HEAT.

Lest some of our junior readers should not understand the term specific heat, I might mention that different substances require different quantities of heat to raise them in temperature. This is called the specific heat of the substance Water has a higher specific heat than any other substance except hydrogen. A quantity of heat that will raise a pound of water one degree will raise over 30 pounds of mercury and nearly 9 pounds of iron to the same heat. In the scale of specific heat, water is entered as 1, and all other substances represent fractional parts of that number Iron is .115, mercury, .033, hydrogen, 3.405, oxygen, .218; nitrogen, .243, steam gas, .48, and carbon dioxide, .217; air, .238

TO CALCULATE THE TEMPERATURE OF THE GASES.

Now we follow the heat performance of a single pound of good coal, and suppose that by combination with oxygen it generates 14,500 units of heat. The burning of fuel in a locomotive firebox or in any furnace that requires rapid combustion necessitates the saturating of the fire with air in order to supply all the oxygen necessary for combustion. To make certain that there shall be no shortness of oxygen, about 24 pounds of air must be admitted into the furnace for every pound of coal burned. This makes 25 pounds of mixed gases to be heated There is 3⅔ pounds of carbon dioxide with a specific heat of .217, there is 9⅓ pounds of nitrogen with a specific heat of .244, and 12 pounds of air with a specific heat of .238.

The rise of furnace temperature due to the combustion of one pound of coal under the conditions stated is calculated by multiplying the different gases to be heated by the figures representing their capacity for heat. When the products are added together, the sum of them represents the units of heat necessary to raise the temperature of the whole mixture 1 degree Fahr. When the heat units generated from a pound of coal are divided by the sum mentioned in last sentence, the quotient shows the total elevation of furnace temperature The problem is thus stated:

$$(3\tfrac{2}{3} \times .217) + (9\tfrac{1}{3} \times .244) + (12 \times .238) = 5.93 \div 14{,}500 = 2445$$

Calculating the rise of temperature due to the combustion of the hydro-carbons in the fuel is done in the same general way as the calculations given in the foregoing paragraphs, changes being made to suit the combining proportions and the capacity for heat of the different gases involved

These figures, 2445, represent in degrees Fah the net elevation of temperature when all the gases related to the particular pound of coal under consideration have been heated. If it were possible to supply the necessary oxygen by using only 12 pounds of air, the elevation of furnace temperature would be about 4,700 degrees Therefore, the smaller the volume of air used in combustion consistent with giving a full supply of oxygen the greater the heat available for useful purposes. There is no more heat generated with the smaller volume of gases, but it would be spread through a more limited space, which would concentrate the heat and keep the furnace temperature higher As the difference between the water to be heated inside the boiler and that of the heating gases would be greater, a larger proportion of the heat would be abstracted by the water.

WHAT BECOMES OF THE HEAT

All the heat generated by the combustion of one pound of coal is not utilized in steam making. The gases must pass away through the smoke stack at a higher temperature than the water to be heated inside the boiler, and this carries away an important share of the energy of the fuel The nearer the products of combustion come to the temperature of the boiler the less waste of heat there will be. The lesson of this is to keep down the smokebox temperature by taking as much heat as possible out of the gases as they pass through the tubes. The ideal way of using fuel for steam making would be to so arrange furnace and boiler that the waste gases pass away very little hotter than the water to be heated. This is attempted with some forms of boilers where fuel is expensive, but it requires very large boilers A boiler of this kind carrying steam of 100 pounds pressure has an internal temperature of at least 337.5 degrees of Fah. If the gases pass off at 400 degrees Fah. the avoidable waste of heat will be at its lowest.

Suppose the furnace of this boiler was supplied with twenty five pounds of air per pound of coal, as in the example already worked out We found that it took 5.93 heat units to raise the temperature 1 degree. As 400 degrees of heat passes through the chimney we have 400 × 5.93 = 2,372 heat units that are not utilized in steam making. These figures being subtracted from 14,500, the units of heat derived from the coal, we have 12,128 heat units that have been available for heating the water.

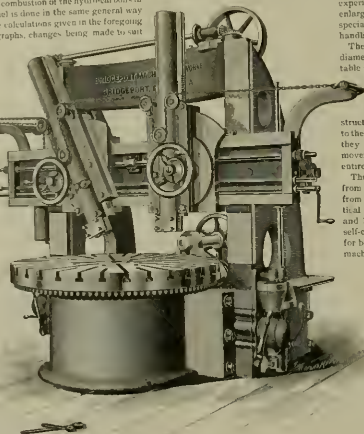
But suppose the combustion takes place in the firebox of a hard-worked locomotive and the smokebox temperature is 900 degrees Fah., a heat intensity common in practice We multiply 900 by 5.93, the heat units required to raise the temperature of the gases 1 degree, and we have 5,337 to deduct from 14,500, leaving only 9,163 heat units for steam making. This is a very serious reduction.

Boilers worked with intensely forced draught necessarily waste much fuel in the exhaust gases It is to restrain this as much as possible that the feed water is admitted near the front of boilers, that being thereby made a cool part and likely to abstract heat from the gases that become cooled in the part of the tubes nearer the fire.

OPPOSITE CONDITIONS THAT WASTE HEAT.

It will be noticed that there are two curious contradictory conditions in the combustion of fuel that militate against economy If a sufficient supply of air is not admitted to the burning fuel combustion will go on by the creating of carbon monoxide, a product of low calorific value If a liberal supply of air is furnished, a large volume of extra gas has to be heated, which lowers the temperature and makes combustion less effective than it would be if the furnace were kept hotter

The theoretical principles relating to combustion having been briefly outlined I shall proceed to give practical illustrations of how fuel is burned in furnaces



New Design of Boring Mill.

## New 62-Inch Boring and Turning Mill.

The machine illustrated is manufactured by the Bridgeport Machine Tool Works, E P Bullard, proprietor, Bridgeport, Conn, and is the result of eight years' experience in the manufacture of tools of this class It embodies all the essential features of their smaller mills and contains many new ideas, which have been suggested by past experience. This company have recently enlarged their works and added many special tools and fixtures for making and handling machines of this character.

The capacity of the mill is 62 inches in diameter and 52 inches in height. The table is 58 inches in diameter, is powerfully geared and has sixteen changes of speed. The teeth on table, as well as on pinion, are accurately planed. The heads are constructed so that either one may be brought to the center, and can be set at any angle they carry the tool bars, which have a movement of 30 inches. Each head has an entirely independent feed in any direction

The feeds are all positive and range from $\frac{1}{64}$ to ¾ of an inch horizontally and from $\frac{1}{64}$ to $\frac{1}{16}$ of an inch in angular and vertical directions. The cross-rail is raised and lowered by power. The machine is self-contained, thus avoiding the necessity for building an expensive foundation The machine weighs 20,500 lbs.

## Seams of Boilers.

With the thick sheets that are now becoming a necessity for the modern locomotive boilers the lap joint that has found so much favor with American boiler designers and boiler makers appears to be a line of weakness. Those who still cling to the lap joint overlook the fact that the proportion of strength of this form of seam rapidly diminishes as the sheets are increased in thickness

In a paper read at the New York Railroad Club by Mr. W. F Dixon, chief draughtsman of the Rogers Locomotive Works, some points worthy of consideration are given about boiler seams. He said

"As soon as the boiler is put in service deterioration begins, and it is the retarding of this as much as possible that should be considered in the design. There is no doubt whatever that when the butt joint is used, corrosion along the seam is much less than with the lap joint. Why this should be is not altogether clear The most plausible hypothesis is that with the butt joint the strain due to the steam pressure is uniformly distributed over the whole circle, while with the lap joint, when the boiler is under steam there is a tendency for the plates to straighten out, the result being that the plate bends to some slight degree each side of the lap; this tendency causes scale that may be deposited there to flake off and leave the surface of the plate exposed to furrowing or corrosion Another theory is that chemical action takes place more rapidly when the plate is subjected to a high tensile strain, and if this is really so, and there is much ground to show that it is, then it is easier to understand why corrosion would be most active where the bending strain is greatest, viz., at the laps, and although a lap joint can be made that will give as high a percentage of strength as the butt joints, yet the established fact that the butt joint lessens corrosion warrants its adoption in most cases, especially with large boilers carrying high pressure.

## EQUIPMENT NOTES.

The Chicago & Great Western is in the market for locomotives.

The Toledo & Ohio Central contract for eight cars has not yet been let

The Chicago Great Western are about to place orders for additional power.

The Soo line has let 15 engines, 8 to Schenectady and 7 to the Rhode Island.

The Boston & Albany have placed orders with Schenectady for ten consolidations.

It is reported that the Santa Fé have let fifty engines to Baldwin and fifty to Brooks.

The Louisville & Nashville have placed an order with the United States Car Co. at Anneston, Ala., for 700 cars.

The Wilkesbarre & Eastern had not yet closed for their eighteen coaches and chair cars on the 1st, but will probably do so very shortly.

Rhode Island Locomotive Works are building two compounds, two-cylinder type, for the South Side Rapid Transit Co of Chicago.

The Chicago & Great Western have ordered 750 box-cars of 60,000 lbs. capacity. They will be equipped with air-brakes and standard couplers.

The Norfolk & Western have placed orders with Billmeyer & Small, York, Pa., for eight vestibuled day coaches and seven second-class passenger cars.

Jackson & Sharp have taken orders for four coaches for the New York, Susquehanna & Western road. This road is in the market for several cabooses.

The Boston & Albany's 700 box cars go to the South Baltimore Car Co., 300 coal gondolas are to be contracted for for this company. Order not yet placed.

The Brooks Locomotive Works are building eight heavy freight engines for the Cleveland, Lorain & Wheeling; ten moguls for the Lake Erie & Western

President Ingalls, of the Cleveland, Cincinnati & St. Louis, has intimated to the stockholders that he needs 50 new locomotives in addition to the 60 ordered lately.

The Seaboard Air Line are buying rolling stock for their new extension to Atlanta They have ordered fifteen coaches from Pullman and fifteen locomotives from Baldwin's.

The Bangor & Aroostook road have placed orders with Jackson & Nordin for six cabooses, 100-box cars and 150 gondolas, also seven engines, with the Manchester Company.

The South Side Rapid Transit Elevated Railway of Chicago are on the market for locomotives and cars. The president of the company has given instructions that simple engines shall be tried.

The order for fourteen new locomotives mentioned in our last issue as being about to be placed by the Kansas City, Fort Scott & Memphis has gone to the Pittsburgh Locomotive Works. They will all have Latrobe tires and Lukens steel boilers.

The Schenectady Locomotive Works are building five locomotives for the Central Vermont and ten consolidations for the Boston & Albany. Among other orders recently received by this firm are compound consolidations for the Minneapolis, St Paul & Ste. Marie.

Immediately on the decision being made to run a train from New York to Chicago in twenty hours over the New York Central and the Lake Shore, the latter company ordered five new locomotives from Brooks' people for the express purpose of handling the train. They have cylinders 17 x 24 inches and driving wheels 6 feet in diameter They have Belpaire boilers, 54 inches diameter, and will carry a working pressure of 180 pounds. The engines weigh 100,000 pounds and are lighter than some of the other passenger engines used for the heavier trains.

## English and American Locomotives in Argentine.

A report was made some time ago to the president of the Western Railway of Argentine concerning the relative efficiency of English and American rolling stock, which contains information of much interest to our locomotive car builders. It appears that the Western Railway obtained control of the Southern Railway of Argentine rolling stock, which had been equipped with English rolling stock. Western Railway had in use principally rolling stock from the United States, which enabled the officers to judge fairly between the relative value of the two kinds. Speaking of the English rolling stock on Southern Railway, the report says that "as regards quality of material and its strength, it is all that could be desired, but the builders did not take into account the character of road-bed and track on which it was to run, and, therefore, made it too heavy and the wheel-base too rigid.

"The locomotive might run well enough on European roads, which are substantially built and well ballasted, but such is not the case in this province, where most of the railways are built on loose soil. The result is a large increase in the maintenance of way and repairs to rolling stock, and, consequently, a heavier burden on the income of the road."

One class of engine used is the Crampton type, with cylinders $16\frac{1}{2}$ x 24, and a single pair of driving-wheels 77 inches in diameter. The boiler has 1,014 square feet of heating surface. Twenty-nine thousand four hundred and fifty-eight pounds of weight rest on the driving-axle out of a total weight of 86,698 pounds. The engine, delivered at Buenos Ayres, cost $14,238. Of this engine the report says "The unequal distribution of weight is very injurious to the permanent way The high boiler pressure of 160 pounds was necessary to overcome somewhat the lack of traction power. When running at less than usual speed against the moderate kind, there was much trouble with the boiler priming."

Another class of engine of similar dimensions to the other, but having two pair of driving-wheels coupled, is spoken of as being a little more satisfactory. The report says "The weight is imperfectly distributed, there being excessive weight on the engine truck; the system of support is interior, while the absence of equalization has the disadvantage of making it impossible to distribute the shocks due to inequalities of work The excessive pressure at which the boilers are worked necessitates frequent and important repairs, such as the renewal of most of the tires and stacks. The tube-plates and the fireboxes are destroyed in a short time, notwithstanding the good quality of the material, owing to the high pressure of 160 pounds per square inch, although high pressure should be admissible without doing injury. All this was proven by the cost of repairs, which amounted in two years to $1,800 in gold "

There is a class of compound locomotives built by Beyer, Peacock & Co., Manchester, which appear to have given a good deal of trouble They are of about the same general dimensions as the simple engines and are the Worsdell & Borries type of compounds, and in regard to these engines the report says "It is evident that this system of locomotives for passenger trains was adopted without proper consideration of the conditions of service Their greater weight as compared with the high pressure locomotives, the repairs required by them, and the qualifications of the men who were to run them, should have been taken into account. Above all, it should have been borne in mind that the inventors of several systems of compound locomotives have found that an economy of 18 to 20 per cent. at a low rate of speed, was reduced to 2 per cent when the speed exceeds 18 miles an hour. Therefore, if all their economy does not compensate for their greater cost and the cost of repairs to permanent way, no practical advantage can be derived from the adoption of this system for our roads."

The pressure required in the boilers of these locomotives is 175 pounds per square inch, this being necessary to obtain useful work; but this has the inconvenience of necessitating continuous and serious repairs to the boiler. The journal-boxes are repaired and replaced very frequently, owing to the rigidity of the springs, and, as if this were not enough, the cylinders are very easily striated, by the heavy weight of the piston, due in our opinion to a blunder of construction which prevents the stem or rod of the piston from keeping its center in action in relation to the axle of the cylinder. The intercepting-valve with which these locomotives are fitted and which helps them to start with the low-pressure cylinder in case the piston of the high-pressure cylinder is at the dead point, must work automatically, that is to say, it must put the boiler in communication with the low-pressure cylinder when the locomotive stops, by means of a small auxiliary pipe. But it happens that it never works with regularity and we have noticed in many cases that it requires from eight to ten minutes to start the train, having to back or reverse in order to effect this, a circumstance which generally causes the breaking of traction hooks and bars, without taking into account the annoyance to the passengers from the heavy jerks, or the delays occasioned by the time required to take out the damaged vehicles and transfer the passengers.

There is another class of compound locomotives which are principally used on freight service. They cost $16,688 in gold and cost $1,950 in two years for repairs. The report says that "these locomotives have the same defects as the others have; in the consumption of fuel they are worse."

The report says that American rolling stock is much more suitable for their roads. Moreover, it costs less, and necessitates much less expense for keeping it in repair than the European stock

After giving some particulars about the Baldwin locomotives in use, the report says that the construction of this class of engine, notwithstanding its simplicity, is first-class, except in a few details. The locomotives for mixed trains have withstood very severe tests during the period when the railway had not the number necessary for its service, as, notwithstanding the excessive work done, the results were very satisfactory.

There are three kinds of Baldwin engines on the road, whose average cost delivered was about $10,000 in gold. One class with cylinders 15 x 20 inches; another with cylinders 17 x 24, and the third, cylinders 18 x 24 inches These engines are reported to be more economical in the consumption of fuel than the English engines The repairs are light, costing about $250 a year, as compared with about $900 a year for the English engines The engines are reported to be very powerful for their weight and with a good distribution of weight, which makes them easy on the track. After three years' service the boilers are said to be in a marked state of preservation. The report concludes, "It may be concluded, from data furnished in this report, that the Southern Railway locomotives are but iron masses, entirely injurious to the roads and interests of the company, and that a large part of its rolling stock is unnecessary for the service of its lines, as neither the conditions of its roads nor the necessities of its traffic require it. So unfavorable has been the result of the compound locomotives that it was necessary to withdraw them from the Mar del Plata service last summer and to use in their place the freight locomotives, owing to the tractive power of the former being less than was required.

There appears to be some curious practices among the boiler inspectors in New Zealand. The engineers do not appear to be instructed on the pressure that their boilers ought to carry safely. The following occurred in a report recently made by a surveyor "I may mention that engineers of steamships have actually come to me asking what their boiler pressure was. This comes about from the present system, whereby engineers placed in charge for the first time during the intervals between the surveys have no means of accurately ascertaining the authorized boiler pressure, especially if their vessels have been laid up for some time. In the case of a small steamship at Gippsland, which had been laid up for some time, I have reason to believe that the engineer got over the difficulty of ascertaining the pressure at which the safety-valves were set by starting a good fire under the boiler, and then watching the result from a hill on which he sat at a safe distance. Fortunately the valves worked well, and he then looked at the pressure guage for the information sought."

Work was started about the beginning of last month in the fine shops at Depew, near Buffalo, recently erected by the New York Central. When in full working order these shops will have capacity for doing all the repair work belonging to the western part of this great system. The shops are very commodious and have excellent machinery. There is stall room for fifty locomotives. We hear complaints from Buffalo that Mr. John D. Campbell, who has charge of the shops, has been stealing mechanics from shops that did not like to part with their men. We have heard this kind of complaint before.

Depew, where the New York Central shops are located near Buffalo, promises to be a manufacturing center within a few years. The buildings for several factories are in course of erection. Very few dwelling houses are up but the saloon interests are well advanced. There are about fifteen saloons in the place already.

On April 5th the Empire State Express ran 148 miles in 146 minutes and made one stop and slowed down once besides reducing speed twice to take water. A considerable part of the run was made at a speed of 76 miles an hour.

The American Railway Equipment Co. has arranged to handle the Excelsior metallic packing for rods.

The Pittsburgh & Lake Erie is erecting repair shops at Riverton, near McKeesport, Pa.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa.

SINCLAIR & HILL.

### New York Central's World's Fair Locomotive.

The annexed engraving illustrates an extremely handsome locomotive, built by the New York Central Railroad Company in their shops at West Albany, for the World's Fair exhibit. The engine is a splendid specimen of excellent workmanship, and is, we consider, the highest development of a fast and powerful locomotive. As a machine combining power and speed we think the engine ahead of anything ever built. If this engine cannot be pushed with a light train to reach a speed of 100 miles an hour we will conclude that such a velocity is beyond the capacity of steam locomotives. The engine was designed by Mr. William Buchanan, superintendent of motive power, and every detail has been worked out with very great care. The cylinders are 19 x 24 inches, the driving wheels are 7 feet 3 inches outside of tires, and the boiler provides about 2,000 square feet of heating surface, and carries a working pressure of 180 pounds.

THE NEW YORK CENTRAL'S COLUMBIAN FAIR ENGINE. DESIGNED TO RUN ONE HUNDRED MILES PER HOUR.

### The Erie Engineers' Locomotive.

The locomotive "E. B. Thomas," shown in the annexed engraving, will be exhibited at the World's Fair, and we are very much mistaken if she does not excite as much attention among railroad men as anything to be found in the Exposition. Some time ago a company was formed among the engineers belonging to the Erie system for the purpose of building a locomotive after the ideas of the promoters of the enterprise, and exhibiting her at the World's Fair. The money was duly subscribed and an order was given to the Cooke Locomotive Works to build an engine according to dimensions and specifications furnished by the men. Mr. J. W. Johnson, traveling engineer of the New York, Lake Erie & Western, was inspector of the engine during her construction, and she bears the stamp of his ideas of what a good high-speed passenger engine ought to be. The very handsome engine shown was turned out of the Cooke Works, at Paterson, N. J., and is now in the Fair grounds at Chicago. She pulled express trains from Jersey City to Chicago and displayed unusual power and speed.

PASSENGER ENGINE DESIGNED BY THE LOCOMOTIVE ENGINEERS OF THE ERIE RAILROAD NOW AT THE WORLD'S FAIR.

The engine as will be noticed is of the eight-wheel type, with cylinders 19x26 inches, and driving wheels 72 inches outside the tires. The boiler is straight with the dome set on the first course ahead of the firebox. The boiler is 66 inches diameter and has 265 2-inch flues, 12 feet 2 inches long. The firebox is supported by radial stays. It is placed on top of the frames, is 126 inches long and 41¼ inches wide. The total wheel-base is 23 feet 6¾ inches, and the rigid wheel-base 8 feet 6 inches. In working order the engine weighs 134,650 pounds, of which 88,750 pounds are on the drivers and 45,850 on the truck.

The engine has particularly large bearing surfaces. The driving journals are 8½x12 inches, and the truck journals are 6x10 inches. One criticism we would make of the engine, which is that she has an odd size of driving-wheel centers. They are 65 inches, and there seems to be no good reason why they should not have been made to the Master Mechanics' standard of 66 inches. There are, however, few locomotives to be found with fewer flaws in design.

As a compliment to the engineers who entered into this enterprise, the following makers of railroad appliances contributed their goods to the engine: Otis Steel Co., steel for boiler and firebox; National Tube Works, tubes, Midvale Steel Co., tires, driving and engine truck axles, crank pins and rods; Westinghouse Air-Brake Co., air-brakes, American Brake Co., driving and engine truck wheel brakes, Nathan Manufacturing Co., injectors and sight-feed lubricators, Ramapo Wheel and Foundry Co., Snow's boltless wheels for engine and tender trucks, Ashton Valve Co., safety valves; M. C. Hammett, Richardson balanced slide valves; Cooke & Strong, bell ringer, C. C. Jerome, piston and valve stem packing, Fox Pressed Solid Steel Co., pressed cylinder head casings; Star Headlight Co., headlight; Crosby Steam Gauge Co., chime whistle; Railroad Lamp & Signal Co., gauge lamps; American Brake Beam Co., brake beams.

### Broken Stay-Bolts.

Any information that will lead to the prevention of broken stay-bolts in boilers is a direct benefit to railroad men and all others connected with the operation of locomotive boilers. In spite of all the discussion there has been on the subject of broken stay-bolts, there appears still to be lack of reliable information on the subject. In connection with a paper which Mr. W. F. Dixon read about "Locomotive Boiler Construction," the existence of contradictory views among practical boiler makers and boiler designers was made apparent.

Mr. Dixon said: "The most troublesome things about a locomotive boiler are the stay-bolts, broken stay-bolts, after low water and hot crowns, being the most prolific cause of explosion that there is. When fireboxes were small broken stay-bolts were not such a pest as they are at this day of large boilers and high pressures. As is well-known, stay-bolts usually break close to the outer sheet, and may generally be found broken in the two or three upper rows along the sides, except towards the ends of the box, where they extend down as far as the sixth or eighth row from the crown. They are very rarely found broken near the mud ring. The cause of their breaking is generally understood to be due to the constant bending backwards and forwards they undergo, due to the difference in expansion between the firebox and shell sheets. The outer or shell sheet being thicker than the inner is more rigid and consequently the stay-bolt naturally breaks there.

How to remedy this trouble is one of the most perplexing problems that confronts the boiler maker of to-day; indeed, it seems improbable that we shall ever be free from broken stay-bolts while we continue to stay our boilers as we do. Various ball-and-socket joints for the ends of the stay-bolts have been tried, and all have so far either failed in their mission or proved themselves such unmitigated nuisances in the way of leaking that they were discarded. A step in the right direction seems to be increasing the diameter of those bolts which are most liable to fracture. Wide water spaces are also advantageous as they make a long stay-bolt necessary, and the longer the stay-bolt the less will its angle of deflection be as the firebox expands and the longer it will last. The sharp V thread so largely used on stay-bolts is probably the worst possible form that could be adopted, the sharp angles at the bottom of the threads presenting admirable opportunities for a crack to start and for corrosion to begin. The most suitable form of thread would be the Whitworth—rounded off top and bottom—but there are the same objections to be raised to its use in this connection that led to its rejection and to the adoption of the U. S. or Sellers thread for bolts and nuts. A compromise between the two that fills the requirements fairly well is a fine thread having the Sellers contour, *i. e.*, flattened off top and bottom. It is easy to manufacture, and, while not ideal by any means, is yet vastly superior to a sharp thread, while at the same time allowing of equally tight work.

---

There will be a great many highly interesting sights for railroad men at the World's Fair, but one of the cars that proved among the most attractive exhibits at the Exhibition of Railway Appliances in 1883 will be absent. This is the dynamometer car built by Prof. P. H. Dudley. Prof. Dudley's engagements to inspect track with the car this summer will prevent him from exhibiting it at Chicago.

---

The Jos. Dixon Crucible Co., of Jersey City, are sending out, free, a book on lubrication by graphite and a sample of their make of that splendid lubricant. If engineers would use a little of this on gaskets and rubber packing they would not find it burned into the metal so hard as at present.

---

Who has drawings or picture of any kind of the engine "Excelsior," whose boiler was on separate trucks? She was built at Reading, if we remember right.

# Practical Letters from Practical Men.

**Facts Wanted. There's a glut of Opinions.**

Write on one side of the paper, state your point plainly and briefly, and then quit. We supply the generalities. No letters noticed unless name and address accompany.

### What Knocked Out This Cylinder Head?

*Editors:*

We had a case of breakdown here which has caused some discussion. A ten-wheeler Brooks engine broke a link-pin at bottom of rocker arm and knocked out cylinder head on that side. What caused the cylinder head to be knocked out?

### A Chance for Coppersmiths.

*Editors:*

Why is patented planished iron that is used for jackets always dished in the center while common or other thin sheet-iron lays flat?

I have read letters and correspondence from all classes of mechanics in a railroad shop except coppersmiths. Why don't some of them start the ball rolling?

D. D. COLEGROVE,
*Algiers, La.* Coppersmith.

[It is always customary for the chair to appoint the mover for a committee as chairman of that committee. The editors, in this case appoint Mr. Colegrove a committee of one to write an article on coppersmiths' work in railroad shops, choosing his own subject—brazing, bending pipes, fitting, making oil cans or keeping up repairs; it's a splendid field of unworked virgin soil. We have set some inquiry on foot about that planished iron business.]

### Running a Steamboat With a Locomotive.

*Editors:*

In the away back times there used to be a steam ferry at what was known as Clark's Ferry, on the Susquehanna above Harrisburg, Pa. I think there was a dam there, and the steamboat was used to tow canal boats from the west to east side of river. In place of the regulation steamboat engine, one of the old time Baldwin half-crank engines was used. She was placed intact on board the boat, and permanently blocked up—the trucks being removed. It must be remembered that in these old engines the crank-axle did not run in the driving-boxes, they being outside bearing; the journal proper was a short section of axle fitted into center of hub, but in this case the journal extended out beyond the driving-box and the projecting part was made square. The driving-axle being in line with paddle-shaft, a sleeve with a square hole was slipped over the end of the journal and acted as a coupling. The man on the foot-board could use the throttle and reverse lever the same as in railroad practice. It was quite an ingenious affair, and the old mill never stuck on the centers. Whatever became of the boat the writer never knew. Perhaps some of the readers of LOCOMOTIVE ENGINEERING can tell us something about it, for the paper seems to go even to the uttermost parts of the earth.

### Reminiscences of the New Castle and Frenchtown Railroad.

*Editors:*

In looking through your paper, from month to month, I have been very much interested in your cuts and descriptions of the early locomotives, but I have failed to see anything yet published regarding the New Castle & Frenchtown Railroad or the early locomotives on it, and as I have been looking this matter up for my own gratification, I thought possibly it might be of interest to some of the readers of your valuable paper, and I will therefore give you some facts concerning it.

The New Castle & Frenchtown Railroad was finished in the winter of 1831–32 and ran from New Castle, Del., to Frenchtown, Md., connecting the Chesapeake and Delaware Bays, and was for many years the connecting link and great thoroughfare for passenger travel between the North and the South.

It was 16½ miles long, and at that time was the best laid road in the country.

The first locomotive tried on this road was the first one built by Colonel Stephen H. Long, who established the Norris Locomotive Works at Philadelphia.

Colonel Long obtained a charter in March, 1830, incorporating the "American Steam Carriage Co. of Philadelphia," and the first locomotive built at their works was tried on this road on July 4, 1831, at which time about two miles of the road had been finished.

This locomotive weighed 3½ tons and was not a success, the failure being attributed to lack of capacity to furnish a sufficient supply of steam.

The next day the Colonel had better luck, his engine then going to the end of the rails that were laid and back, drawing two passenger cars packed with people (say seventy or eighty) with apparent ease, and it had 50 lbs. of steam at the end of the experiment.

The Colonel, however, was not satisfied with it, and the machine was brought to Philadelphia again, and a new boiler was constructed for it at Rush & Muhlenberg's works at Bush Hill. This engine was again taken to New Castle and tried upon the road, but it again failed. It would go very well for a time, but on the 31st October, 1831, a pipe burst and it became disabled. This being repaired two days thereafter, another trial was made but with equal want of success, which was ascribed to lack of power. Alone this engine went very well and rapidly, say at the rate of 25 miles an hour, but would not draw a satisfactory load.

Soon after the above date Colonel Long removed his engine from the road.

When the road was finished two locomotives, built by Robert Stephenson, Newcastle-on-Tyne, were imported.

When the English locomotives were landed at New Castle, Del., it became necessary to select a skilled mechanic to put them together as speedily as possible.

Through the agency of Mr. Wm. D. Lewis, the most active director of the company, this task was assigned to Matthias W. Baldwin.

These engines were of the most improved English type and greatly superior to any that had been made in this country. In putting these engines together, Mr. Baldwin had all the advantage of handling their parts and studying their proportions and in making drawings therefrom.

This proved of great service to him when he received an order in the spring of 1832 to build a locomotive for the Philadelphia, Germantown & Norristown Railroad. This engine, called the "Ironsides," was placed upon the above road in November, 1832, and proved a decided success.

The "Ironsides," in its general arrangement, was a pretty close copy of the English engines on the New Castle & Frenchtown Railroad, but with changes that were real improvements.

For twenty years this road continued in operation in conjunction with a line of steamboats from Frenchtown to Baltimore.

In 1834 the New Castle Manufacturing Company of New Castle, Del. (which, previous to this time were manufacturers of cotton, woolen and metal goods), built a foundry and shops for the building of locomotives, and those in service on the New Castle & Frenchtown Railroad were made there, and the blue print sent you with this shows the general design of those built in 1852, and which gave good service on the above road and subsequently on the Philadelphia, Wilmington & Baltimore Railroad.

This firm of locomotive builders is no longer in existence, although parts of the old buildings are still standing.

### Treatment of Men on the Interoceanic Railway of America.

*Editors:*

In the February number of your paper I see an article that doesn't speak in any favorable way of the Interoceanic Ry., of Mexico. I will say this much in regard to the subject, that the officials are all first-class men to work for, there is no red tape, and any one who is able to run an engine is able to get along all right, as has been proven by the hiring of some engineers that I know would not make a success in some places. This road at one time worked all native engineers, at a small salary, from $1.50 to $3.00 per day, and worked them just as many hours as was necessary. Now since Mr. W. R. Barclay took charge of the motive power department and hired as many American engineers as the management allows, he raised the wages up to where they are—with a great deal of struggling, which every one who was here at the time knows. I think it is unfair for the men to make any complaints through your columns, as every day there are native engineers applying for jobs, who would willingly work for half what Americans are paid. Hoping this will give every one concerned a clear idea as regards the article mentioned, R. COOK.

*Puebla, Mexico.*

### The Fate of the "Cork Leg" Engine.

*Editors:*

I note that John West inquires in the April LOCOMOTIVE ENGINEERING in regard to the final disposition of the "Pioneer," or as she was commonly called, the "Cork Leg," which was the first locomotive run upon the Vermont Central Railroad. Permit me to say that this engine came to the road named from some road down in Massachusetts, and when received was an old scrap without cab and with a "foot brake." (Think of that, ye worshippers at the Westinghouse shrine!) She did not, however, run farther north than Northfield, and was destroyed and scrapped within a year after she came to the Vermont Central, and was succeeded by the "Flying Dutchman" and "Abigail Adams," both of which locomotives no doubt Mr. West will remember.

My authority for the above is Hon. J. W. Hobart, who began railroading in 1848, as he expresses it, "driving a yoke of oxen hauling material for the railroad fence." Mr. Hobart was very soon installed as agent at the head of the work as the road was building north from Braintree, until it reached Montpelier, where he remained as agent for some time, but eventually graduated successively through the positions of master of transportation, general freight agent and general superintendent to general manager, from which latter position he retired in 1891, after having served the same company through its varying fortunes of forty-three years.

CLARK L. PIERCE.

### An Engineer's Opinion of Brake Handling—Increasing from Service to Emergency Applications.

*Editors:*

While discussing the merits, construction, operation, etc., of the air-brake, we should not lose sight of the all-important question, "How should it be handled?"

It is certainly simple enough to operate, but to do so in a skillful manner requires, first of all, a thorough knowledge of its construction, its operation, and a fair share of good judgment; the latter we usually acquire by practice, but the former requires special application.

I think, if we would become skilled in the handling of air-brakes, that we should never make but one application in making a stop. By practice men will become skilled so that it will be an easy matter to do so. It is the smoothest way and requires the least air, and, what is more important, consumes less time, which means everything in these days when you *must make the time* on fast runs.

I believe that the difference between men's ability to make time with air-brake trains on passenger or freight can be oftener traced to the manner of brake handling than to any other cause; particularly on runs where stops are numerous, as in local service.

Some men seem to think there is no variation of power about the brake, but there is a great range of power if the equipment be in good order. There is considerable room between a partial and a full application for service stop, enough to enable one with a little practice to nearly always make a stop without making two or more applications.

The principal fault in handling air is a lack of confidence in it. The brakes are generally applied too soon, necessitating a complete release before reaching the stopping point, and the result is that after making repeated applications the auxiliary reservoir pressure becomes exhausted, and when the stopping point is reached there is no air left to stop with. Some people are pleased to call a case of this kind a failure of the brakes, when it is only lack of judgment. We can understand how and why the brake fails, after making several applications in quick succession, if we remember that the braking power is measured by the capacity of the auxiliary reservoirs. It is an *easier* way to first reduce the speed and then drift along, making the final application at such a speed as to avoid any possibility of running by; but when you are on a run that taxes the engine to the utmost capacity

President, IRA DIMOCK Treasurer, J. L. OTIS.

…ou will not be able to make up any time and likely not even make the running time if the stops are numerous, even though the time can be easily made if not wasted at stations.

Is it not best to acquire the habit of doing things right? Then there is no special effort required when emergencies present themselves where skill is required, and besides, time can be made with as low running speed, which is something to be desired, for the man who can make the time at the slowest speed is counted the best runner.

There is a good deal of information needed as to how to handle the engineer's valve in a manner to operate the emergency feature of the brake. It is generally understood that the increase of brake power due to the emergency feature, is gained by employing the train-pipe pressure to assist in forcing out the piston in brake cylinder, reducing the amount of air drawn from the auxiliary reservoir, and in that way it increases the power of the brake. It is generally known that if the handle of the brake-valve is suddenly moved to the extreme right, the emergency action takes place, but it is not so clearly understood how to bring it into operation when a service application is on.

Air-brake instructors tell us that when a partial application is on, and the emergency is desired, to move the handle quickly to the extreme left for a moment and then to the extreme right, and its action is assured. When the handle is moved to the extreme left, or release position, it is not supposed to be left there long enough to effect a release but merely long enough to recharge the train pipe, and if any of the brakes should release they would, of course, apply again when the handle was moved to the right; but there would be a loss of power that can generally be avoided by one who understands its manner of action; but it is an uncertain action and there is but little gained by it, and in many cases where it is called upon, while a service application is on, it is better to increase it to the full application rather than depend upon such an unknown quantity as the emergency which requires a nicety of handling to operate it to advantage.

I don't wish to convey the idea that I do not believe it to be all it is represented to be, but I have every reason to think that unless it can be used promptly, and before a service application is made, its action depends too much upon skillful manipulation to be given much credit in summing up the efficiency of the brake in service.

### Pump Governor Causing Emergency Application.

*Editors:*

In the March number of your paper the question is asked whether the pump governor can get into such condition as to cause an emergency application of the brakes after a slight reduction in service-stop. I wish the person who asked this would give a little more fully the particulars of the case he had in mind. What was the length of train, the amount of train-pipe pressure, the style of engineer's valve, etc.? There is no single condition of the governor itself which would cause the difficulty mentioned, as the air-pipe connection from the train-pipe is seldom large enough to exhaust the air with sufficient rapidity to cause an emergency action of the brake, even supposing it should be entirely disconnected.

The brake-valve is kept in running position both for safety and to get excess pressure. An accident might happen through inability to properly release the brakes when the handle had been left in the release position, and no excess had accumulated in the main drum.

It is also true that in setting the brake from the train, either with a conductor's valve or at the rear end, it will not take hold quite as promptly if the engineer's valve-handle is in the release position, as a greater amount of air has to be exhausted to produce the same result, unless the reduction is made suddenly enough to set the emergency immediately.

*Chicago, Ill.* PAUL SYNNESTVEDT.

### Cutting Eccentric Keyways Before Wheels Are Put on Axles.

*Editors:*

The article on cutting eccentric keyways which appeared in the March number of LOCOMOTIVE ENGINEERING, written by Fred. S. Hill, is very good. As I had the pleasure of meeting that pleasant gentleman since the article appeared, and having shown him our method of doing the same thing, he earnestly requested me to write it up for the LOCOMOTIVE ENGINEERING. Modesty at first forbade it, but having treasured up many kinks written by others I concluded that this might be of some use to them.

About four years ago the order came to key the eccentric on all locomotives as they passed through the shops. Our first experience was, after setting the valves, to mark, drill and chip the keyways while the wheels were under the engine. This was found to be a thankless task, for when an engine is so near completion it is wanted in a hurry.

By hard thinking we found a rule which can be relied on. If it does not come right every time it is safe to assume that either the workman was not accurate, or that the eccentric blades do not come in line with the lower rocker arm-pin.

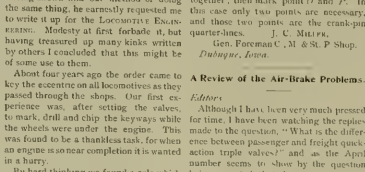

*Fig. 1*

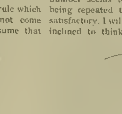

*Fig. 2*

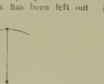

*Fig. 3*

We have keyed the eccentrics on some two hundred locomotives in the past four years, and all were done while the wheels were out from under the engine, and many keyways were put in axle before the wheels were pressed on. In many cases offset keys were required, but this was the reason. Either the workman was inaccurate or the blade did not come in line with lower rocker arm-pin.

The operation is as follows. Take a piece of tin, $U$, Fig. 1, say 12 x 12 inches, and tack it on a bench or board, if convenient. About the center, $A$, draw a circle, $R$, to represent the diameter of driving-axle where the eccentric is located; draw a line, $A$ $B$, to represent the piston-line and equal in length to the distance from center of driving-axle, $A$, to the center of crosshead wrist-pin, $B$, when crosshead is at forward end of guides. At $A$ erect a line, $C$ $D$, at right angles to line $A$ $B$, find the point $E$ and distance below line $A$ $B$ to represent the lower rocker arm-pin when the lower rocker-arm stands at right angles to line $E$ $A$, which represents the center line of motion. At $A$ erect another line, $F$ $G$, at right angles to $A$ $E$, for convenience we will call this the valve-line. Next find how much the top rocker-arm $T$ $T$, Fig. 3, will travel when the lower rocker-arm, 2 2, has traveled the distance equal to the throw of eccentric. This will be equal to the travel of valve; from $A$ as a center scribe a circle $S$ with diameter equal to valve travel. Now find the lap and lead, say ¾-inch lap and $\frac{1}{16}$-inch lead; add these together and you have $\frac{13}{16}$-inch. Now from valve-line $F$ $G$, Fig. 1, draw $I$ $H$, which we will call the lap and lead-line, $\frac{13}{16}$-inch. $M$ and $N$ in front of and parallel to line $F$ $G$. From $A$ draw line $A$ $O$ and line $A$ $P$ through where line $I$ $H$ intersects valve travel, circle $S$ at $J$ and $K$. Point $O$ will represent the center of keyway of forward eccentric and point $P$ will represent the center of keyway of backup eccentric on one side of the engine. Now carry to opposite side for same results. The keyways are supposed to be on center line, drawn through the center of outside of eccentric and the axle center.

If working on one class of engines, make template shown in Fig. 2 and set template so $L$, Fig. 2, and $L$, Fig. 1, come together, then mark point $O$ and $P$. In this case only two points are necessary, and those two points are the crank-pin quarter-lines.

### A Review of the Air-Brake Problems.

*Editors:*

Although I have been very much pressed for time, I have been watching the replies made to the question, "What is the difference between passenger and freight quick-action triple valves?" and as the April number seems to show by the question being repeated that the answers are not satisfactory, I will try to put in what I am inclined to think has been left out. I measured these valves some years ago, and while some slight changes have been made, the figures will illustrate my position.

Quick-action passenger triple valve (Plate D 22). Diameter of piston 3½ inches and piston travels 1¼ inches in emergency, graduating port Z begins to take air at ⅛ inch travel of slide-valve, and this valve travels ¼ inch more before piston stem strikes graduating stem. Size of graduating port in slide valve, $\frac{3}{16}$ inch. In port to brake cylinder, ¼ inch. Emergency port begins to take air at $\frac{11}{16}$ inch travel of slide-valve. Play of slide-valve on piston spindle $\frac{3}{32}$ inch, making piston travel $\frac{11}{16}$ inch before emergency begins to act, and graduating spring is then compressed ¼ inch, and when down on piston seat, ⅜ inch, resistance of new spring at ¼ inch travel of graduating stem is … pounds, at ⅜ inch travel 57 pounds. Now there is no use going over that which has been written, so I will call attention to the fact that the lower edge of graduating port Z, Fig. 9 A, Plate 3, Westinghouse instruction book, on passenger slide-valve, is $\frac{11}{16}$ inch from top edge of valve, and there is $\frac{3}{16}$ inch space from upper edge of the hole to port Z, Fig. 9 A, while on the freight valve this hole Z is $\frac{1}{16}$ inch from top, and there is ¼ inch space between Z and S, and consequently the passenger slide-valve would have less distance to travel from there to produce an emergency application. If I have made this point clear, it is evident there is a larger degree of fluctuation permissible in the freight slide-valve than in the passenger, and to make the action clear and, perhaps, explain why freight train-pipe is largest, as per Brother Hamar, I will copy an extract from *Locomotive Engineers' Monthly Journal*, page 348, April number, by C. P. R.

"The 1-inch train pipe on a 60-foot car, with hose, couplings, crossover pipe and drip cups, would have about the same cubic capacity as a 10-inch brake-cylinder with 8-inch piston travel; therefore, when the emergency application is made by pushing engineer's valve-handle to extreme right, and the train-pipe pressure of 70 pounds reduced quickly to 60 pounds, the quick-action attachment of triple valve is set in operation, and the train pipe pressure of 60 pounds equalizes into the empty brake-cylinder, giving a pressure of about 30 pounds in each; then the pressure of 70 pounds in auxiliary equalizes with the 30 pounds pressure in brake-cylinder to a pressure of 60 pounds, giving about 20 per cent. more power than a full power service application."

If this is examined and compared with the instruction book, it will be seen that the air from auxiliary has to come through ports in slide valve in emergency action, and C. P. R. has not allowed for the fact that it would not quite give 60 pounds, as air would begin coming from reservoir to brake-cylinder at once, and thus lessen the difference in pressure between reservoir and train-pipe; but I do not want to criticise, I wish to make it plain that the size of the port S, as compared to the size of train-pipe auxiliary brake-cylinder is the gauge, or regulator, that allows so much air to pass from auxiliary to cylinder, while another quantity is coming from train-pipe (as piston travel will affect this, don't say slack adjuster). Hence the reason for 1¼-inch train pipe in freight service, as the $\frac{1}{8}$ inch hole S, Fig. 9 A, plate 3, will hold back the air in auxiliary of the size used in freight service till enough air has flowed in from 1¼-inch train pipe to make nearly 60 pounds altogether.

But, says some one, the port S is the same size in the other slide-valve. That is so, but is more sensitive, because it is nearer the emergency, and the size of ports given in the April number modify this, but not altogether, as I have tried a number of passenger coaches and could get but 57 or 58 pounds, and am satisfied that on short travel, at least, the same thing will occur.

I have always understood that both sides of freight triple-exhaust were threaded for convenience in piping as in hopper-bottom cars, for instance.

As for the other question, any one who will take the isinglass card with plate 2, Westinghouse instruction book, will see, by placing brake-valve handle in running position that port G only communicates with space above piston 17, and thus furnishes pressure from train pipe to air-gauge through hole S, and union fitting 15, on gauge-pipe to number 14 and after handle is moved to lap this is cut out. In service stop the preliminary exhaust ports H and C are connected for an instant and as E communicates with chamber D of course train hand will fall. After passing this point, train hand is cut out and air from 10 x 12-inch reservoir equalizes or refills chamber D, raising black hand, but an examination will show train pipe is empty if handle is left in extreme right.

As to our Portsmouth friend, I think a gauge on train pipe, to see how rapidly air is reduced, might help, but if there are no leaks, as probably there are not (else all the brakes would apply), the cause must be local.

I once had such a case in which the piston-spindle was cracked half off at graduating-pin, and it did not show under the solder. It was not found till it broke off although examined. I now put such case between lathe centers and then strain them a little. A 12 x 33-inch reservoir with

an 8-inch brake-cylinder (as is generally found under tenders) will equalize at from 62 to 63 lbs. with 6-inch piston travel, while, with the same travel, an ordinary coach will equalize at from 53 to 54 lbs. and if the coaches would just release by turning air on a 3½-inch piston on coach at 54 lbs., it would be more difficult to release a plate *D* 20 triple with 3-inch diameter piston and 63 lbs pressure, and I generally find this to be the trouble.

Brother Relyea's problem is the same as came near doing injustice to an engineer here once. He would carry his handle between release and running position, and after he was reported and I was called to instruct him, I found the port J in rotary valve was so far to the right it would just open to port F to feed valve enough to feed train pipe a very little, but not enough to work well. "Conundrum's" question is of the same style, and I would look for some obstruction between piston 17, plate 2, and 10 x 12-inch reservoir that would allow air to strain through slowly.

Friend Shallenberger has my sympathy on the hose question. Could there not be made a general kick about it? I don't think it is worked up as it should be.

I wonder if "Inquirer's" engineer did not stand by the old "Durkee" in the Troy & Boston shops below Eighth street one night when I put some kerosene in her pump a good many years ago. Well, I did, and when the pressure got up, I went behind the tender to let out the air and in some way set it afire. I learned a lesson and stirred things up till the air pressure went down.

I think "Texas" in working the new brake-valve, plate D 5, with the figure 5 attachment, went through what we did here. We had some in this condition; when they were in release they would blow in till I took out the rotary valves and plugged the "squizers" with wood, which was taken out when we got reducing valves, and here I will tell you something comparatively new. An engineer came in equipped with new valve and reducing valve and reported brake would not go on in service stop, and then he had to use emergency. On trying the valve, the air man found piston number 47 all right, but the blamed thing went crazy when put up. I found the valve apart on the bench, and in cab, gasket number 61, plate D 5, had opened through, on top of piston valve 47, and as air would go through hole in gasket faster than it would run out of preliminary exhaust, piston number 47 could not rise.

GEORGE HOLMES.

*Roanoke, Va.*

### Diamond vs. Straight Stack.

*Editors:*

In this month's (February) issue of *The National Car and Locomotive Builder* I notice an article from J. Snowden Bell on "Diamond Stack *vs.* Extension Smoke-box," in which he favors the former and is very much opposed to the latter.

It seems strange that that smoky contrivance the diamond stack, after having served its purpose until succeeded by something better, has still got its advocates, who do not seem disposed to allow it to pass quietly out of existence.

If Mr. Bell had seen as frequently as I have the difference between two engines composing a double-header on a heavy passenger train on a long and heavy grade, one with diamond stack, the other with open stack, alike in all respects except their front ends, the former belching out clouds of dense black smoke almost continuously from one firing to another, while from the latter it was comparatively slight and only for a few moments after each firing, I think, if for no other reason than smoke abatement (to say nothing of better combustion), he would have chosen the open stack, even if there happened to be a considerable length of smokebox in front of it. The cause of this was due, not to any difference in the boxes, of course, but to the stacks, for any one observing the puffs of smoke produced from an ordinary lamp-chimney by tapping the top with the flat of a piece of cardboard has a very simple illustration of the draft-obstructing and smoke-producing qualities of the diamond stack principle, the recoil of the exhaust from the netting-shield producing the same result.

It is bad enough to be compelled to obstruct the draft to some extent, but to baffle the exhaust as well is to needlessly increase the obstruction. The open stack is one of the best features of the extension-box combination.

In regard to the steaming qualities of the extended box, I know many good locomotive runners who, to their credit be it said, are not at all backward in letting their superiors know a thing is not worth a tinker's cussing word if such is their belief, but I have yet to hear complaints against the general good steaming qualities of engines properly equipped with the extension-box; on the contrary, I have frequently heard them say engines were improved in steaming after being equipped with extension-box combination.

Yet, superior though it is to the diamond stack, no doubt, in many cases there is room for improvement in the interior arrangement. We know the less the obstruction to the draft the better the combustion, yet, ignoring this, we put up diaphragm plates which are almost perpendicular, and some of them within a very few inches of the flue-sheet; baffles they may well be called. Deflectors should give the draft an easy curve to bottom of box, and no more than is required to drift the cinders to front end. I have seen excellent results obtained by simply changing from the baffle to the deflector. We would not think of pumping water of the same volume and velocity against angles so arranged if it could be avoided, yet we do not seem to give the same consideration to the very important matter of free draft; our long acquaintance with the diamond stack has evidently left us still erring somewhat in the matter of draft obstruction.

It is generally conceded by those who have to do with both combinations, that as a live spark arrester the diamond stack is not to be compared with the extended box, and this for reasons well understood, but in regard to the merits of the long extension as a dead spark arrester, to quote Mr. Bell, the average passenger does not urge them with any great degree of enthusiasm, particularly in summer.

The design of the originator of the long box no doubt was to collect all the sparks of a journey at the forward end, and with some kinds of coal this may perhaps be partially accomplished, but as a general thing we know that an engine has not run many miles of her journey before the cinders have accumulated to the path of the draft current, after which all cinders entering the box are kept in agitation until finally drawn through the netting, and this incapacity of the long box to do the work for which it was originally designed is probably one reason for "the material shortening up of extension," which Mr. Bell notices.

It would certainly add to the comfort of passengers and the cleanliness of the cars in summer if this dead cinder-throwing could be reduced by the use of some device easily operated from the cab, and by its regular use the diaphragm-plate could be kept higher, offering less obstruction to the draft, resulting in freer steaming, less fuel consumption.

One of the hand-rails might be used for working a device of this kind, the steam-valve being placed behind the stack. On trial I find this an easily operated and effective mode of discharging the cinders. Perhaps some of your readers will tell us what they are doing in this direction.

With a good device for discharging cinders as they collect, the utility of the long extension might be questioned, for experience has shown that boxes somewhat shorter afford sufficient netting area to give equally good results in regard to live spark-throwing, and the long box, aside from the "cook-stove on wheels" appearance, has the more important objection from its position as a lever, and with the truck as a fulcrum, of transferring weight from driving-wheels to truck.

Therefore, the question may become, "Full *vs.* medium extension," but the diamond stack is destined to eventually become obsolete.

A. A. MAVER.

*Stratford, Ont.*

### What is a Spark Arrester? Facts Wanted.

*Editors:*

In view of Mr. Sinclair's perfectly reasonable theory, as reported in your April issue, "that an engine having no spark arresting obstructions to the draft could be made to steam with such large nozzles, that no more sparks would be thrown than what pass through the best spark arresters," and of the cold facts known to every one who works or travels on a railroad, as to the failure of extended smoke-boxes to prevent fire throwing, is not the abandonment of the latter by the Union Pacific system, worthy of a somewhat more attentive and favorable consideration than you have given it in your article on "Diamond Stacks and Extension Fronts"? I make the suggestion, not as an advocate of the diamond stack, although my observation has been that it will do better work, both as to spark prevention and free steaming, than the extension, but as a renewal of ineffectual efforts, in the past, to obtain from a technical journal any admission, however limited, of the merit of a short front.

Neither the diamond stack nor the extended smoke box is, in and of itself a spark arrester *at all;* each of them is simply a receptacle in which a spark arresting appliance is placed, and many different designs and constructions of such appliances have been used in each case. It is quite possible that it may be better to locate the spark arrester in the smokebox than in the stack, but this fact (if it be a fact) does not, in the least degree, tend to prove that there is any advantage in, or any justification for, the present fashion, now very noticeably on the wane, of extending the smokebox 100 per cent. more or less. There are many engines now in service, with open stacks and short fronts, which are undeniably giving at least *as good* results as those having extensions, and for this, if for no other reason, it would seem only fair to deal with the *spark arrester* proper, and not start with the assumption that it must be put into an extended smokebox in order to be "modern."

Beyond the statement, which may be accepted as correct, in the "Diamond Stacks and Extension Fronts" article, that the wear of netting is greater in the former than in the latter, I am unable to find any "pros and cons" in the report of Mr. Montgomery's remarks. He says that the extension front, *properly constructed* (a qualification so general as to be meaningless, since we have *all varieties* of them) "is superior as a spark arrester," and again, that "it was a success over the old-fashioned diamond stack," but does not say *what* diamond stack he compares it with. Mere assertions like these are not arguments, neither do they carry with them any reasons on which they are based, yet they are the sum and substance of all that I have heard or found in print in support of the extended smokebox.

A few evenings ago, while waiting for a train at Plainfield, on Mr. Montgomery's road, I saw a Baldwin compound of the 385 class go by with a fast Blue Line train. This engine, burning hard coal, and having an extension whose huge proportions would satisfy the most enthusiastic advocate of that device, was throwing fire at a rate which I never saw exceeded, if indeed equaled, by any diamond stack, and I do not think that any one who knows the facts on that road will maintain that I have overdrawn them, or that this was, by any means, an unusual performance.

If, with the supposed light exhaust of a compound engine and with hard coal fuel, such a result is manifested by the extended smokebox, is there not some reason for the belief that it might be well to get rid of the excess of weight on the truck, and give the engine a chance to steam freely, by cutting off the excrescence, even if we have to follow the example of the Union Pacific, and enlarge our nozzles, as they have been able to do when using a short front and diamond stack?

J. SNOWDEN BELL.

### Answering All the Air-Brake Questions.

*Editors:*

Concerning a number of interesting articles on air-brakes published in your April issue, we should like to say a few words.

Mr. Shallenberger's remarks on the care of air-hose are most timely. More attention should be given to this subject. Any one who has not read the article should turn back and look it over.

What Mr. Hutchins says about the slow-acting triple on the engine calls to my mind a problem o'er which I have often pondered. Why, in nine cases out of ten, do the "powers that be" put a slow brake with little leverage on an engine that is to handle quick-action cars? There is no doubt at all but many break-in-twos result from this condition.

Now that the safety appliance law has become a definite thing, why would it not be a good plan for Congress to legislate that all brakes shall be kept in good order? Are there any suggestions on this?

Mr. Hamer, R. F. E., asks some funny questions. The first, about the single exhaust in passenger triple, he will find answered in a recent issue of your paper. Why the size of the train-pipe should have anything to do with the use of the freight triple in passenger service I cannot comprehend. The freight train-pipe is larger than the passenger because it is *shorter*, and approximately the same amount of air is needed to produce the same equalized pressure after an emergency application. As to question three, the feed port in the rotary of the engineer's valve registers with the equalizing port to the upper cavity when the handle stands about a half inch beyond the service stop in the direction of emergency. The train-pipe in such position may be and in fact is empty in spite of the fact that the gauge does not show it.

Mr. Texan does well to call attention to the need of strong frames for the pumps. Reform in this respect is badly needed on many roads. The remarks about the use of engineer's valve in release position when there is a defect hole in the rotary-valve seem to me rather hazy. The valve is not supposed to be left in the release position.

The trouble with Mr. Relyea's engineer's valve was that there was some discrepancy, in running position, between the relative position of the guide spring on the handle and the feed port through the rotary-valve. This port did not open until the handle had gone too far. Whether the fault was in the location of the port or in the spring, or notch, it is impossible to say without examination. In the case of the engine on which the gauge pointer dropped to zero in service application and slowly rose again to within about 5 or 7 lbs. of the original pressure when the handle was returned to "lap," the trouble was probably caused by some obstruction which closed communication between the upper cavity in the engineer's valve and the small equalizing reservoir. A blind gasket anywhere in the pipe connection between these two would produce a similar result, as any one can prove by simple experiment.

In response to "Inquirer's" inquiry, we should say that the quickest way to release

brakes in any case is to put the brake-valve handle on lap until a heavy pressure has accumulated in the main drum, and then to move it to full release position.

Kerosene is very liable to volatilize and explode if put into a pump under heavy pressure.

The use of air from the main drum, either for sand-feeding apparatus or anything else, is liable to cause a dragging of brakes if the governor be attached to the train-pipe and the train-pipe have but little leakage, for when the pump stops the excess in the drum may reduce slightly below the train-pipe pressure before the governor will permit the pump to go to work again, and in the meantime the back leakage from the train-pipe to the drum may be sufficient to lightly apply the brakes.

Mr. Walker's first question as to emergency in service application I should like to have him answer himself, as the three conditions he mentions are the only ones I ever discovered that would cause such trouble. The tender-brake he mentions as not releasing properly had probably equalized at too high a pressure, either from too short a travel of piston or from the reservoir being too large in proportion to the cylinder.

In conclusion, let us criticise the so-called "Improved" brake-gear illustrated on page 173. It appears to us that, with the ordinary proportions of brake beam-levers, this arrangement gives one truck twice as much power as the other. Will the inventors kindly enlighten us on this point?

*Chicago, Ill.* PAUL SYNNESTVEDT.

### Is there Anything Wrong with this Way of Testing Air Signaling Apparatus?

*Editors:*

Will you kindly allow space in your paper for me to express my views on defects in train signal when caused by reducing valve?

As we all know who are in actual road service, it often occurs that the pressure in the train signal rises to nearly that in the main reservoir, which causes the air whistle to blow while brakes are releasing. This generally occurs as you are nearing the terminal, or after running some distance, and is very annoying, and, in some cases, dangerous, especially where the stops are short, as a man might mistake it as a signal from the conductor and start the train, thereby injuring some passenger.

This is caused by the diaphragm in reducing valve becoming spongy, or by a little dirt, or in cold weather by frost no allowing the diaphragm to work properly. Now, my way to detect this defect has been, after getting engine on ash pit I stop the pump and reduce pressure in main reservoir by setting and releasing the brake until I get a signal from air whistle. That shows me the actual working pressure in train signal. I often find that the air equalizes between main reservoir and train signal as high as sixty pounds, then I report air equalizing at too high pressure between main reservoir and air signal. The air-brake inspector almost always contradicts my report and says the air signal is all right. I ask him if he knows what pressure there was on air-signaling valve. He says that he attached the gauge to air signal and pumped up the pressure and it reduced at thirty pounds. I said that is all right for you, but my gauge shows sixty pounds working pressure. Then I asked him if there was any way to determine the pressure in the train signal other than attaching a gauge to signal pipe, and he answered no. I thought he was mistaken, and I went to the air-brake instructor and asked him the same question and received the same answer. I then explained to him my way of testing by reducing pressure in main reservoir after actual service instead of pumping up pressure, and claimed I got the best results and that this was the only way to get the actual working defect in reducing valve.

As the instructor claims my way is not the scientific or practical way to test any defect in reducing valve and that the same would not be recognized by the Westinghouse air-brake instructors, I submit the foregoing for further comment.

*Meadville, Pa.* NYPANO.

### Changing Steel By Hammering.

*Editors:*

In a letter in the April number I promised to write a letter on iron and steel, but I will have to confine it to steel alone. Railroad companies and a great many of our manufacturers compel blacksmiths to work up, and then hold them responsible for the amount of abuse the tool or forging has to stand, without first inquiring as to what facility he has for doing a good job. They simply tell him that such a shop does it in a certain length of time and so much better. Perhaps the shop that is mentioned has a furnace and steam-hammer and the necessary tools to do the forging with, and also uses a class of steel that is most suitable for the certain tool or forging the smith is asked to make.

As a rule the man that purchases the material only considers the amount it costs per pound, and our steel manufacturers

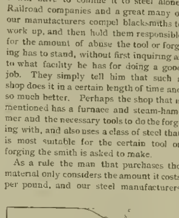

FIG. 1.

are well aware of this, it seems, by the grade of steel some of them put on the market.

Perhaps they are compelled to put an inferior grade on the market in order to compete with those that sell nothing else. Now this inferior grade may give satisfaction for certain classes of work, but the man that has a steam-hammer and furnace at his command has got the advantage of the man that is without them.

You take our steel at present and you can make a wonderful improvement in it by working carefully under a steam-hammer.

To convince yourself of this take a bar, say ¾ x 1¼ inches, and quench it at refining heat, then draw a piece to about ⅝ x 1 inch and quench that at a refining heat in a solution that will cool quick enough to refine your steel.

I have known it to make such a difference in the grain of the two pieces of steel that when sent to the mill where it was made, they were not sure that both pieces were their own make.

Now toolsmiths are very often asked why one tool holds so much a finer and smoother edge than the other. We generally find a tool as shown in Figs. 1 and 2 gives us more trouble than the one shown in Fig. 3. The cause of this is the amount of forging on Figs. 1 and 2 is very little compared with Fig. 3, and again, it makes a difference whether these tools are forged under a hammer or on an anvil. I have been compelled to draw steel under hammer in order to use it for the tools as shown in Figs. 1 and 2.

Now a great many smiths may say that this is all folly, but I have tried nearly all the different makes of steel, both English and American, and find that some will average a good deal better than the other, but I have not found any yet, even the finest grade, but what you can change the grain by working it carefully under a hammer—at least nineteen bars out of every twenty will show a difference. The greatest difference will be in the larger sizes.

What I want to get at is to find out if this refining could not be done at the mill, where they have all the necessary tools to do it with, which a great many railroad shops are without. W. G. LOTTES.

*Madison, Wis.*

### Duty vs. Good Nature and Suspension.

*Editors:*

In your March number I notice a communication from M., K. & T. in regard to handling freight trains with four or five air-brake cars on head end. Now on our road, the C., M. & St. P., the orders are to use the air all the time or in making every stop, or slowing up, or holding train down hills use the air, as air was put on the cars to use. Some time ago our officials here put up an order not to use air only in cases of emergency, but when the officials at the head of the road found it out it was quickly recalled and orders put up to use it all the time, and brakemen have orders to ride on top of trains down all hills and through all stations, and it is the conductor's duty to see that rear brakeman is out on top and the engineer's duty to see that head brakeman rides out on top, conductor and engineer both being held responsible for brakeman not riding on top, as the air-brakes fail sometimes or engineer may let them run too far before using air, and if

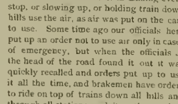

FIG. 2.

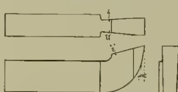

FIG. 3.

brakemen are on top they will be ready to set brakes at the first call.

Almost every day there is trouble between some engineer and brakeman about brakeman not getting out on top, as whenever there is air enough to handle train brakemen do not want to get out on top, and sometimes refuse, then there is trouble, and all the engineer can do is to report brakeman to superintendent, and then all the brakemen on the road get down on him and call him a stinker.

If engineer or conductor does not make brakeman get out on top and it is found out by the train-master, the engineer or conductor gets fifteen or twenty days and brakeman nothing. I think the brakeman should be the one to get laid off or discharged and not the engineer or conductor. A great many of our engineers and conductors are too good-natured to ask brakemen to get on top, and several of them have been suspended for it. There ought to be some remedy for this.

*Ottumwa, Ia.* FRED F. LEE.

### Quick Valve-Setting.

*Editors:*

In reading the remarks of F. C. Charles in regard to Mr. Campbell's valve-setting, I was struck with the vagueness of his criticism, and could not help saying to the apprentice, to whom I was reading his article, "It is too bad he has not given us *his* plan for setting valves."

Several years ago I remember reading an article in our paper from Mr. Campbell, wherein he explained his ten-minute plan. Until then I had been studying a plan to do the job more quickly than was usual, and had about succeeded in my ideas but lacked the opportunity to test the method.

You can imagine my delight when, on opening my LOCOMOTIVE ENGINEERING, I found in it Mr. Campbell's ten-minute scheme, which agreed with my own and gave me the encouragement I needed. I showed the article to my room-mate, saying, "I wanted that badly."

Well, sirs, very soon after that I was successful in getting a position wherein I had the opportunity to try my pet idea, as I called it, at valve-setting.

It did not take me much longer than ten minutes to do the trick, and—will you believe it?—that engine reduced her coal-bill for the month $90.

Of course I do not claim that it could not have been done by any other system of setting. But this I do know, that no other man there could have done it, simply because they were not readers of our paper, LOCOMOTIVE ENGINEERING.

Keep a-shooting with your valve-setting pointers, Mr. Campbell, there may not be much in some of them, but in the main they are all right.

I am able to tell you that I know a score of young men readers of your paper who have obtained better jobs, consequently better pay, through the knowledge gained from reading Mr. Campbell's valve-setting pointers. F. C. Charles says "he *tries*" to tell how to set valves, but don't succeed.

Maybe it would be beneficial to some of us if F. C. Charles would give us his plan to set valves by. I'll bet him a little apple he cannot beat the ten-minute plan.

"YOUNG WHISKERS."

*Fernandina, Fla.*

### Call for Meeting of Air-Brake Men.

*Editors:*

Considerable has been said from time to time in reference to air-brake men organizing and meeting in convention regularly for the purpose of exchanging views and experiences, determining upon some uniform method of instruction for employes, and means for betterment of maintenance of the air-brake equipment now so generally in use on railways in this country, but the little headway which has been made towards organization can be said to be due to the lack of concerted action on the part of the air-brake men themselves.

Numbers of railway officials to whom the subject has been mentioned express themselves highly pleased and in favor of it, and believe much good would be secured to all railways that would send representatives to the convention. Inspectors themselves have long since recognized the need of such organization, and while voicing their sentiments, each one has waited for some one else to take the initiatory step. And now that the Traveling Engineers have organized and generously provided a clause in their constitution whereby air-brake experts are made eligible to membership, a number have availed themselves of the opportunity and have become members, but many others are still holding back, believing that nothing short of a separate and distinct organization of air-brake men will fill the want, and in which belief there seems to be considerable wisdom.

While the air-brake men appreciate the generosity of the Traveling Engineers' invitation to them to become members of their association, yet they believe an amalgamation of the two impossible, and feel they should be separate and distinct, for there would be numbers of subjects brought under discussion that would be almost entirely foreign to many air-brake men, and in which their interest would not exceed curiosity, were the two combined. The air-brake man is usually selfish, and has frequently been called a "crank," and perhaps his devotion to his profession has warranted the "title." Should he go to a convention he would want to talk air-brakes the whole time, nor would he care to be relegated to a back seat until such time as uninteresting (to him) topics were disposed of before he would be given an opportunity for spouting on his pet theme.

Expressions of doubt as to the wisdom of

the air-brake men organizing separate and distinct from the Traveling Engineers have been frequently given; yet the majority of them believe that satisfaction to their interests can only be had from independent organization. While the interests of the occupations are analogous yet they are separate and distinct as are those of the Master Mechanics and Master Car Builders and bear a similar relationship. It is believed that the Traveling Engineers and Air-brake Men's Associations should be separate as are the Master Mechanics and Master Car Builders, and that the plan of meeting followed by the latter associations (one shortly after the other has finished) could be adopted to mutual advantage by the former. This belief is deduced from conversation had with other air-brake men with whom I am frequently brought in contact, and with whom the subject has been thoroughly discussed. This plan would permit those Traveling Engineers whose duties are combined with those of air-brake inspector on their systems to take an active part in both conventions with but one leave of absence from their duties.

Quite an interesting impromptu meeting of air-brake inspectors took place in St. Louis about a month ago, which proved so successful that I have been persuaded to give a starting push to the ball toward permanent organization. F. H. Eddy, of the Fitchburg Ry.; E. D. Desoe, of the Boston & Albany; J. N. Smith, of the Old Colony, J. L. Andrews, of the N. Y., N. H. & H. Ry., and H. S. Kolseth, Westinghouse Air-Brake Company's Boston representative, came to St. Louis to visit the Westinghouse Company's Instruction Car to get "points" to aid them in building proposed instruction cars in the future, and also the system of instruction used by the gentlemen in charge of this car, whose wide experience in this line has led them to adopt. So numerous were the kinks and problems presented for solution, and for which the apparatus in the car was admirably adapted, that it was decided by the gentlemen in charge to abandon the routine work of regular classes for the following day (Saturday), and devote the entire day to experimental work and general discussion of air-brake topics with the visiting inspectors. Telegrams were sent to other inspectors about St. Louis, and the number was increased by the presence of C. C. Farmer, of the M. K. & T. Ry., W. C. Walsh, of the L. & N. Ry., Otto Best, of the N. C. & St. L. Ry.; F. Fisher, of the Mo. Pac. Ry.; Robert Wark, of the St. L. I. M. & S. Ry., and J. B. Cozart, of the Mobile & Ohio Ry. So satisfactory to all of the inspectors present was the discussion that expressions of regret came from all sides that the meeting must so soon adjourn, for the good done in that one day's convention made each man wish, like Oliver Twist, for more; and it was unanimously voted that another meeting be held in the near future in some convenient place, and steps be taken toward permanent organization. It had been settled in the minds of several present (who had hitherto doubted) that air-brake men could convene and intelligently discuss business in a manner that would prove beneficial to themselves as well as the interests of the company which they represented.

Since the meeting in St. Louis a decision has been reached by those present, and I am hereby directed to state that a meeting of air-brake men will be held in Pittsburg, Pa., June 8, 1893, to effect permanent organization. All air-brake men are cordially invited to attend, and it is hoped that all who can will be present and assist this organization of which we all have long felt the need. Railway officials are beginning to recognize the fact that there is hardly another branch in the service which is carried on at a greater waste and needless expense, and which by proper knowledge and attention can, with so little additional expense (if any), be made to serve its intended high purpose, as the air-brake, and as we are working for the good of our companies, it is believed that we will receive the sanction and support of our officials, and the leave of absence required to attend these meetings it is hoped will be promptly given for the asking.

As our object is to better the service and condition of the air-brakes, we believe that any man whose services contribute to that end may become an active member. Hence, air-brake inspectors, air-brake instructors, traveling engineers and air-brake repairmen may become members, and are requested to be on hand in Pittsburg next June to assist in organizing.

ROBERT BURGESS,
Air-Brake Instructor L. & N. R. R.
*Louisville, Ky.*

### Keeping to Runs, Not to Engines.

*Editors*:

I will endeavor to enlighten the writer of the article in the March number of LOCOMOTIVE ENGINEERING whose article is captioned "An Unfair Rule," and signed "A Reader," Huntington, Ind. I must state that there is quite a distinction between our rule and the one he has reference to on the Chicago and Erie. The clause pertaining to that in our schedule is as follows:

"When an engine is assigned to a certain run, and it is necessary to take engine in shop, either for general or local repairs, engineers and firemen will be furnished with another engine." I must say that this clause pertains to all cases. We are assigned to runs here, not engines; and when it is our turn to go out or our time to go out, whether on freight or passenger, the company has to furnish an engine or something in the shape of an engine. We stay with our runs, not with engines. So I hope the reader will see where he was mistaken in that rule. Freight men don't have to lay off, supposing their engine is detailed to go on a first-class run; whether passenger or freight men, they go out on their run with whatever kind of an apology for an engine is furnished them, and oldest men have the preference of runs in freight or passenger. And I must state that it works all O. K. here for the men, though I don't think it is so profitable to the company, as in general men don't keep up their engines as they would if they had regular engines. Hoping this will be all satisfactory to the inquirer,

JAS. W. ANDERSON.
*San Bernardino, Cal.*

### An Engineer's Opinion on the Difference Between Straight and Diamond Stacks.

*Editors*:

I noticed with interest an article in last number of LOCOMOTIVE ENGINEERING on diamond stacks versus straight shots and extensions; I am entirely in sympathy with the latter as regards steaming qualities and "spark arresters," to say nothing of looks and cleanliness. I have run and fired engines during the past ten years and have concluded that without the extension front sparks have got to come out and the greater part of them are good and hot—especially when they drop down the engineer's neck or in the fireman's eye.

The Union Pacific changed straight stacks for diamond to prevent throwing fire, but I fail to see any change in the number of fires set along the road, and I have asked a great number of the men how they liked the change. With the exception of one or two engineers they said they were not as good as the straight shots in any way, as they did not steam as free, threw more fire, were very dirty to ride after on account of cinders flying and trailing smoke and that the second engineers and firemen on double-headers had to keep front windows closed all the time to prevent being burnt up.

Before this change extended over the whole U. P. system I rode from Denver to Cheyenne on a U. P. passenger train and the whole equipment was perfect I thought. The engine was a beauty, clean and in fine shape with an "extension front" and "straight stack" and I noticed no cinders and no smoke and all the passengers including myself were enjoying the ride. I also noticed every time engine was shut off that she *popped*, so she was evidently steaming well. I stayed in Cheyenne a day and then continued my journey west. Everything was fine until we reached Rawlins. Engines were changed here and we got a fine engine but with a diamond stack. Every one noticed the change as soon as we started. The day being warm the windows were opened but the cinders and smoke rolled in so fast that we had to close them and then we nearly suffocated. It seemed as if every passenger on the train was mad, and I did not blame them, as I knew just what the trouble was and they did not. I think engines in passenger service at least should be equipped with straight stack and extension, if only for the comfort they give their patrons. I have always found that no matter what kind of spark arresters are used some kinds of coal make sparks that will fly out. I have also noticed that where diameters of stacks were decreased larger nozzles could be used.

IMPROVEMENT.
*Anaconda, Mont.*

### In Favor of the Seniority Rule.

*Editors*:

In the April number of LOCOMOTIVE ENGINEERING appeared an article from T. J. Henderson, of San Bernardino, California, on the examination and licensing of locomotive engineers. Now, if you can allow me a small space in your valuable instructor, I would like to argue the case with Mr. Henderson. He says, "We want better engineers, better conductors, and in fact better posted men in all departments of railroad life." He has, I presume, forgotten to mention the other side of the question. Better paid men in all branches of railroad life. He speaks of "*we*." The people of the United States, the taxpayers, the railroad men and the voters are "*we*," and "we," as he terms, are the people who vote the funds and give the lands to the railway corporations, and help support them by paying very dear for all favors received. Practical No. 1 railroad men have made railways what they are to-day, and if corporations cannot pay such men fair compensation for their services they should, by law, be compelled to close down.

Mr. Henderson also argues that railroading in America has reached its zenith and is now on the decline. Consider me on the negative of this question also. "Seniority," so says Mr. Henderson, is the stumbling block over which we are to fall. Do you realize, Mr. Henderson, that such an assertion is a burning insult to a first-class blue-blooded railroad man who has a position of honor, and is duly credited with the same by his many years of faithful, unerring and devoted services, rendered strictly in behalf of the corporation by whom he is employed?

A true supporter of seniority expects only what is due him, and what is due a man should be claimed by all, both senior and junior workmen.

Seniority has proved a grand success upon one of the largest trunk lines in the world and that line is the A., T. & S. F. The management (if they give the men their just dues, and I rather guess they do) will admit that they at present have as good a lot of railroad men and obtain as good results as any and better than most of roads.

Upon your non-seniority roads, the nephew, the white-shirt-high-standing-collar and silver-tongued man fall heir to all of the fat positions, and often does ruination and disgrace fall upon all concerned. Many times the offices of train-master, superintendent and master-mechanic are filled by inexperienced men, because of being the relative of some lord. Can such men control men and produce such good results as those who have risen from the ranks, so far as their qualifications permit? I think Mr. Henderson's three rules for condemning seniority are quite strong for supporting it. Ponder them over and reflect a bit and you are bound to admit that true seniority will do away with the backbiting and dragging down.

It has frequently come to my notice that a man who could drink the most liquor and do the most informing and misrepresenting his fellow workman never exchanges a bright bit of knowledge, and was opposed to joining in the march of equalization and progress, was always the man who fell heir to some honorable position; where, on the other hand, had seniority prevailed such a man would never be enrolled on the list.

A railroad man from New York is as good as one from California, so why do you condemn our only elevating medium, "seniority"? And, Mr. Henderson, don't be at all alarmed about the present mode of examinations now in vogue upon our various trunk lines, for many a first-class non-seniority engineer of many years' experience has struck the Santa Fe for a position and then hit some non-seniority road for a job, because he couldn't cut the mustard with the superintendent of machinery and motive power in his examination.

IRA D. MAYHALL.
*La Junta, Colo.*

### Affairs on the Chicago Elevated.

*Editors*:

Quite a few of us here on the "Chicago Elevated" read your paper, and of course saw the communication in the March number from the President of the Ananias Club signed "Engineer." He differs from the *Ghost* in "Hamlet," inasmuch as he unfolds his tale. He thought it too good to keep. Let's see what of truth is in it. The time, as he says, is fast. The engines are able to make it, though, and do make it *to the second nearly every day*. The stops are sharp, but they also are made. No one that I know has been given a single day for any failure to make them. It is also true that you are forbidden the use of the "emergency" except in case of danger. No one here complains that this is a hard rule to comply with, and it is seldom violated. You are expected to stop on a 15-inch margin, but before "Engineer" left they were considering the advisability of making it *fifteen feet*, and issuing an order not to start the rear car first.

No one was called upon for examination without *months* of time for preparation.

The company furnished the books containing a list of the questions and answers. No one was asked any senseless questions and any engineer ought to have passed after ten hours' study. Some stated openly they would not submit to any examination.

It seems that "Engineer" passed the gauntlet of the dreaded examination in safety and it certainly was not a severe one or he wouldn't have mistaken a Pintsch gas tank under each car for a Westinghouse air-brake auxiliary reservoir. Of course he was somewhat rusty on modern railway appliances and thought that the big auxiliary was necessary on account of the sharp stops.

He undertakes even to find fault with our weather in this banana belt. He ought to go up into Dakota about the middle of January next (where they have to hunt for the mercury with a diamond drill) and make a trip or two on a snow plow with three or four healthy moguls behind him, and I can assure him something would "blow across his vision" and meander down his spinal column, too, that would completely eclipse anything he saw here in the blizzard line. If he survived it he would know more about weather than he does now.

To sum up with, no one is oppressed here. The pay is as good as he gets—if not better. The engines are good and well kept up. The entire line is to be

lighted with electricity in a few weeks, and everything that the expenditure of money and the employment of skill and brains can do is being done to make the road a model one of its kind.

*Chicago, Ill.* ALLEY L ENGINEER.

[The letter published last month about matters on the South Side Elevated Railroad of Chicago has brought upon us an avalanche of letters on both sides. We are glad to publish the above letter from one of the men running on the road giving his side of the story. We have not room for any more discussion of the subject as it is not of interest to the great mass of our readers.—EDS.]

### Conger's Three Brake Puzzles.

*Editors:*

Another puzzle for the air-brake men. The brake on a coach with quick-acting triple began sticking as we supposed, and failed to release promptly. After some days it would occasionally not release at all; when it did the air came out of exhaust-port very slow. Triple was taken down and examined at each end of the road, finally given up as a bad one, was taken off car, and I took it all to pieces finding the difficulty at once.

Another one.—A driver brake piston on one side of engine refused to work after it had worked all right for six months. The other side worked O K; the triple and all air pipes clear to driver brake cylinder were taken down and found to be O K, no blind joints. Brake piston did not stick in cylinder; put a lever on top of the cams and it worked down easy. Finally the cylinder head was taken off and trouble located at once; remedied with a cape chisel.

Still another question.—When the pressure retaining valve is cut in so it holds 15 pounds in brake cylinder after triple releases, what pressure is in the brake cylinder on a second emergency application with an auxiliary reservoir pressure of 70 pounds? The first time it is set full on how many pounds does the pressure equalize at? How much more brake cylinder pressure do we get the second time it is set with pressure retaining valve working?

C. B. CONGER.

### Why Would the Tank Triple not Work?

*Editors:*

The tank brake on one of our freight engines would not set from engineer's valve even when valve was placed in emergency position, but would set by opening stop-cock in train-pipe when connecting with train. Of course, the trouble was in the triple-valve, for after triple-valve was oiled and cleaned the brake worked all right. Will some one explain why brake would not work by reducing train-pipe pressure through engineer's valve, when by reducing pressure through stop-cock brake would set all right?

THOS. CRODEN.

*Los Angeles, Cal.*

### Setting Eccentrics on Old-Time Insiders Before Wheels were Put Under Engine.

*Editors:*

I was much pleased with the paper in your March edition by Mr. Fred. S. Hill as to proper methods and sure ways to lay out eccentric keyways on locomotive axles before the wheels are put under the engine, and giving his experience in the matter.

I consider bringing up these matters occasionally a good feature, as instructions for those who have not had experience in such matters, and probably may save them time and trouble.

I agree with Mr. Hill as to his doubts of there being a sure rule, and I also agree with Mr. A. A. Maver's remarks in the April edition, and if in order will, as in a revival meeting, give what experience I have had.

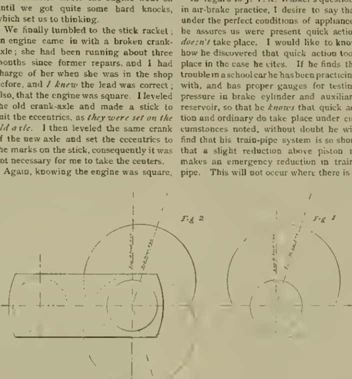
About 1858 the railway I was then working for—and with which I served my time—had principally crank axles, consequently the eccentrics were in two parts and were all keyed on. Of course we thought we were doing first rate if, after we set our valves, we marked the eccentric with a V-chisel, took all down, put our keys in and put the work up again.

Another point we lost in those days with inside connected engines, the two valves were in one steam chest, and we could not get to the back of the valve with the two valves in place. Consequently we had to set one side at a time, which gave double distance to move the engine.

We got out of this rut after a while by marking the stems with a tram and putting both valves in. But the keying of the eccentrics under the engine went on until we got quite some hard knocks, which set us to thinking.

We finally tumbled to the stick racket; an engine came in with a broken crank-axle; she had been running about three months since former repairs, and I had charge of her when she was in the shop before, and *I knew* the lead was correct; also, that the engine was square. I leveled the old crank-axle and made a stick to suit the eccentrics, as *they were set on the old axle*. I then leveled the same crank of the new axle and set the eccentrics to the marks on the stick, consequently it was not necessary for me to take the centers.

Again, knowing the engine was square,



it was not necessary for me to run the valves over. This gave me the points where the eccentrics should be for that class of engine. I did not rest here. I made a stick for every class as they came in the shop and compared notes, and so got this part of it down fine. I finally got onto another racket, something similar to one mentioned by Mr. Hill (understand, though, that I had to get my information from "my sticks" to accomplish this; also, that they were direct-acting engines). When the eccentrics were off the axle, I struck a line showing full throw of eccentric. I then found lap and lead line, as we will call it—see Fig. 1. I would then level the left crank with crank back and put the eccentrics on as shown in Fig. 2, by fastening a straight-edge to lap and lead line and using a plumb level. I then put my sticks under and checked it, and if they corresponded I was done with my stick for that class of engine.

But I soon found out that I could not set them all in this manner where some would be plumb others would have forward eccentric plumb and back ones not quite so, as stated by Mr. Maver. Others would have both forward and back eccentric out of plumb, but having gone so far I was not going to be beaten. I got a level similar to Fig. 3, with an index on the bottom, and I would make a note of where the movable bar had to be placed for those class of engines that needed its being moved.

By using this level I could set all four eccentrics by leaving the axle in the one position, using the side of the level in one case and the bottom in the other.

After I had tested this matter to my satisfaction and had confidence in it, I never took the centers on an engine, merely pinching it around both ways and adjust the rods so that the ports would open all alike, keeping the reverse lever in notch used in running the train.

This saved considerable time. I was afterwards foreman of the shop, and used the same tactics until I left, in 1868. Since then I have not been where the eccentrics are keyed.

This is how I came to the conclusion that there is no sure rule for finding the exact spot to place eccentrics, and this is the way I varied it to get results. D. B.

*Scranton, Pa.*

### Walker's Questions on Brake Behavior.

*Editors:*

In regard to J. V. K. Walker's questions in air-brake practice, I desire to say that under the perfect conditions of appliances he assures us were present quick action *doesn't* take place. I would like to know how he discovered that quick action took place in the case he cites. If he finds the trouble in a school car he has been practicing with, and has proper gauges for testing pressure in brake cylinder and auxiliary reservoir, so that he *knows* that quick action and ordinary do take place under circumstances noted, without doubt he will find that his train-pipe system is so short that a slight reduction above piston 17 makes an emergency reduction in train-pipe. This will not occur where there is a large capacity train-pipe, and his school car can be corrected by connecting a proper reservoir in with train-pipe, which would be equivalent to a long train capacity. Try it and let us know how it works.

Replying to his second question, would say that the proportion between auxiliary and brake cylinders on engine and on the cars was not the same, so that when air equalized between the cylinders mentioned, there was ten pounds higher pressure in engine cylinders than in cars. Of course a higher pressure was required to release. A smaller auxiliary under tender would correct this. Too short a piston travel with similar reservoirs would act as described, but in a small degree.

*St. Albans, Vt.* PHOSPHIC.

*Editors:*

In answer to J. V. K. Walker's question, "What causes quick action to take place in service application of brakes?" my answer is: The preliminary exhaust port in the brake valve seat had been reamed out or enlarged in some way; it is a common complaint among engineers that the brakes work too slow and the reaming out of the exhaust port is resorted to, causing a more rapid discharge of air, which makes the triple valves work quicker. This is one thing that will cause a quick application of the brakes. In answer to the second question, "What made the brakes stick on a tender after they had released on a train of five cars?" I think that pistons on cars had so much more travel than the tender brake piston that the air from auxiliary reservoirs on the cars expanded a great deal more, making it weaker. If this was the case it would take that much less air to raise triple valve pistons on the cars, and the brakes would of course release that much easier. Engineer or some one might have just put new shoes on tender and not adjusted the brakes afterwards. In some places where an old man (or some young man either) is employed to go around and tighten up nuts on tender, put shoes on tender, or wheel out scrap iron or work of that sort, it too often happens that they know nothing about adjusting brakes, and the brakes will be right tight on one tender truck and loose on the other. This is a great mistake, particularly where there is no wedge or floating lever. If the push rod is connected to a cylinder lever that swings on the center, on a bracket, each end swings or travels same distance, and when one pull rod is tight the cylinder lever stops traveling no matter whether the other pull rod is tight or not, causing the wheels of one truck to slide and flatten, while the wheels on the other truck have little or no brake pressure on them.

FRED B. ARMSTRONG.

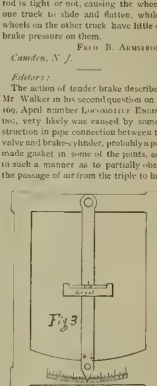
*Editors:*

The action of tender brake described by Mr. Walker in his second question on page 169, April number LOCOMOTIVE ENGINEERING, very likely was caused by some obstruction in pipe connection between triple valve and brake-cylinder, probably a poorly made gasket in some of the joints, acting in such a manner as to partially obstruct the passage of air from the triple to brake-



cylinder, but offering little or no resistance to the air passing from brake-cylinder to the triple valve. MARK PURCELL.

*East Grand Forks, Minn.*

*Editors:*

In answer to J. V. K. Walker's first question, on page 169, April number, would say that the connection between chamber D in engineer's brake and equalizing discharge valve, and small equalizing reservoir was wholly or partially obstructed, thereby greatly reducing the volume of air above piston 17, so that when an attempt was made to make a service application of the brakes the reduction of the pressure in chamber D was so rapid on account of the reduced volume that an emergency application was made instead of a service application, as was intended.

MARK PURCELL.

*East Grand Forks, Minn.*

THE ANSWER.

*Editors:*

The answers are as follows:

1. On close examination a defect was found in the body of the triple; it was a sand-hole that communicated supply part R with emergency part I. It can now be very readily seen that during a service application air expanding from the auxiliary reservoir to brake-cylinder would at the same time pass through the sand-hole on top of emergency piston "8," which would bring in quick action.

2. The reservoir under tender was too large—12 x 30-inch—which, used with an 8-inch brake-cylinder, would equalize much

sooner than with a 10-inch cylinder, such as was under the cars. The tender having the same size reservoir but smaller cylinder would equalize with a much less reduction than 20 pounds, as it took 20 pounds to equalize the pressure under cars to 10 pounds. To equalize it under tender it can plainly be seen why the brakes under cars came off first.

### Those Things that Relyea Wants to Know.

*Editors:*

Replying to Mr. Relyea's question in April LOCOMOTIVE ENGINEERING, permit me to say that the reason he had to carry brake-valve handle past running position in order to secure excess pressure, would appear to me to be on account of the handle not being properly screwed down upon its arbor, lacking almost an entire turn, which brought rotary valve into correct position for securing excess only by carrying handle past position.

Answering the second conundrum, I should say there was an almost entire stoppage of the passage from the chamber D above piston 17 to brake-valve reservoir, so that all pressure was exhausted from that portion of the pipe where gauge took its pressure, until, when placed on lap, pressure leaked through from small reservoir and equalized with gauge.

PHONETIC.

*St. Albans, Vt.*

---

THE ANSWER.

*Editors:*

In answering my article in your April number, I will say in regard to excess pressure, that there was lost motion enough in handle and in slot in rotary valve to prevent opening port to feed valve when the handle was placed in running notch, besides the handle spring was bent by throwing handle in release notch so hard as to bend the end of the spring, which made it strike the running notch before it ought to.

The action of black pointer when making a slight reduction of pressure was caused by a blind rubber gasket having been put in coupling 23 of pipe leading to small reservoir. There was a hole in the gasket which seemed to have been made by pressure, and in such shape as to prevent free passage of air between small reservoir and chamber D of engineer's valve. The hole in the gasket might have been made by simply running the point of a knife blade through it, probably the person who put the gasket in thought that was hole enough.

### Hamar's Questions.

*Editors:*

W. T. Hamar, R. F. E., Atlanta, Ga., asks why quick-action freight triple-valve has a threaded exhaust port on each side of triple valve casing, while that of passenger has only one. By putting a plug in one side and attaching pipe to the other side to run to pressure retaining valve, as is often done, we are enabled to place them under the cars to a better advantage, being able to put them on either side of the car and run the pipe either inside or outside.

His second question, in regard to pipe being larger on freight cars—the branch pipes that connect to triple valves are the same, one inch. But as the freight trains are as a general thing longer than passenger trains, and so many more auxiliary reservoirs to supply, it is only natural that the main train pipe should be larger, to allow more air to pass through the train in the same time.

The third question, the reason that black hand on gauge runs back until the handle spring passes service notch is because while the handle is going over this distance or space air is escaping through preliminary exhaust port out of the valve-chamber above the piston 17, and the black hand is connected to this chamber and equalizing reservoir, and when handle is put at emergency notch exhaust port from chamber is blanked or on lap holding remainder of air in chamber and equalizing reservoir, and letting air out of train pipe through emergency exhaust port, or what is called direct application and exhaust port K, and direct application and supply port L.

### That Governor Trouble.

*Editors:*

In reply to L. G., page 183, I would suggest that the diaphragm valve of the governor is too short to reach the seat, thus admitting air to air-piston at all pressures and shutting off pump as soon as air pressure is sufficient to overcome steam pressure. It may probably be remedied by filing about $\frac{1}{16}$ inch off the top of the nut that holds the diaphragm valve in place and putting a liner of same thickness on top of valve, or by using a slightly longer valve.

In the latest Westinghouse governors the diaphragm is much more flexible, and the adjustment of length of valve is less minute.

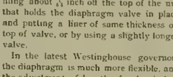
### What is Wrong With This Tester?

*Editors:*

Having to test a number of hydraulic gauges at different times for the system, we have always kept a gauge for test gauge. Having had it in use for some time,



I wanted to see if *it* was correct. I send you a sketch of apparatus we made for the purpose and want to know what is wrong with it. The plunger is exactly ¼ of a square inch in diameter (.565 inch). I put a cap leather on end to keep the glycerine from working out. You see the weight ought to represent twenty-four times on the gauge plus the weight of the frame (which we found by a steam gauge that was correct). By testing the weights with the lever on a platform scales (which was correct) I find I must multiply the weight by 30.

E. S. GRESSEL.

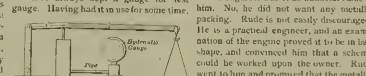
### That Improved (?) Brake Gear.

*Editors:*

In your April number you illustrate an improved brake-gear. In studying the mechanism I infer from the illustration that the live and dead levers *E F G H*



(referring to my pencil sketch) are equal to each other. If so, we will assume that we have a power or strain of 2,000 pounds at the end *A* of cylinder lever. In this case we will also have 2,000 pounds strain on rod *B*. Therefore we will necessarily have a strain of 4,000 pounds on shive *D* or on rod *C*. Hence we will do again as much braking on the truck to the left as we do on the opposite end of the car.

### Metallic Rod Packing Makes a Fine Record.

Metallic rod packing is a great improvement to a locomotive or to any other kind of engine, and the day is not far distant when a builder of engines will no more think of leaving stuffing boxes to be filled with hemp than he would leave off the piston rings and tell the owner to use hemp packing for that part. The day of hemp packing for pistons expired nearly a century ago, the day for fibrous packing for rods passed when the first successful metallic packing was brought into use. The railroads that still cling to hemp pay dear for an inferior material, entail upon their men a vast amount of unnecessary labor, wear out rods prematurely, increasing the cost of repairs, and they incur delays on the road through the fibrous packing giving out between terminals.

These are all points in favor of metallic packing that nearly all practical men will admit to be well founded. When an agent for metallic packing comes along and claims a saving of 10 per cent. in fuel on account of the metallic packing he handles being used, most men who understand much about engines are inclined to sneer, or even use profane protests. Yet there is a man on the road who made this claim and appeared to substantiate it. Not on a locomotive, however.

Our friend, whom we will call Rude, because he is superlatively polished, is agent for metallic rod packing. In the pursuit of his calling he asked the owner of a river steamer to apply the packing to his engines. The owner did not want anything that would cost money, and the saving of labor for his engineer was of no financial value to him. No, he did not want any metallic packing. Rude is not easily discouraged. He is a practical engineer, and an examination of the engine proved it to be in bad shape, and convinced him that a scheme could be worked upon the owner. Rude went to him and promised that the metallic packing would improve the engine so much that she would make ten more turns. If she did not he would ask for no pay for the packing. This was something tangible for the owner, and he agreed, although Rude had put a fabulous price upon his packing, and required the owner to make some repairs that he was willing to overlook. The cylinder was badly out of round and the valve was leaking badly. The cylinder had been in such bad shape that they were in the habit of jamming the piston packing so tight that the engine would not move till the boiler had 25 pounds of steam. After the valve had been faced, the cylinder bored and the new packing put in, Rude was ready for a trial. As soon as the boiler had 10 pounds of steam, Rude called out to start her, and, to the surprise of everybody, the engine went to work. She easily made the ten extra turns. The owner was astonished, but pleased, and he is still talking of the wonderful increase of power and decrease of fuel due to the metallic rod packing.

### Crown Bar Boiler.

"The crown bar boiler," remarked Mr. W. F. Dixon, "has long and deservedly enjoyed a wide popularity, and when a boiler is small, the pressure comparatively low, say 140 lbs. per square inch, and the water tolerably good, there is probably no better method of staying a crown sheet extant.

"When bad water has to be used—water that is rich in impurities that are precipitated freely—then the difficulty experienced in keeping the crown free from sediment is much increased by the obstruction that the crown bars offer. This trouble is appreciated in regions where bad water prevails, and on that account alone many roads have abandoned the crown bar in favor of the radial stay. When we come to large boilers having wide crown sheets and carrying high pressures, then the crown bar is insufficient to carry the load without the assistance of a large number of sling stays. When putting in the slings it is well nigh, or I may even say quite, impossible to so hang them that each individual one shall have its own proper quota of load no more and no less. When the boiler is under steam some will get an excessive strain while others will be almost inoperative, and the trouble of it is that you cannot tell anything definite about it; there is nothing positive except the continual presence of the unpleasant element of uncertainty, and if the crown sheet should ever start to come down, all the sling stays that could be got into a boiler will not hold it—down it will come. For this reason I consider crown staying the most unsafe of any when, as I have just stated, the boiler is large and the pressure high."

The radial stay system has come into quite general use of late, more especially since the advent of the extended wagon top boiler, and it has much to recommend it, at first there was and still is for that matter, considerable apprehension felt as to its security owing to the angle at which many of the stays must necessarily pass through the sheets, some stays being so pitched that but one full thread could be obtained in the sheet, and although on the face of it this certainly looks like a weak point, yet when the work is carefully and honestly done there appears to be no ground for alarm on this score, as many boilers so built have been in successful operation for years, in fact, we have yet to hear of a single instance of this style of staying giving out under ordinarily fair conditions. The general construction of this type of boiler is so well known as to require no special attention, except that the center six or more rows of stays down the length of the firebox should be fitted with button heads under the crown sheet, so that in the event of low water and a hot sheet the stays will prevent the crown from dropping as readily as it would were there nothing but the screw threads and riveted over-heads to hold it.

---

### Water Circulators.

Several railroad companies in New England have applied the Mack water circulators to a number of their locomotives and very favorable reports are made about the effects of the change. The circulator consists of a pipe arrangement which connects the front water leg of the firebox with the front part of the boiler. The cold water that stands without circulation in the water leg of ordinary locomotives is by Mack's device carried upwards to the hotter regions of the boiler and a constant circulation thereby induced.

Attachments for inducing circulation in locomotive boilers have been often tried, and they have always effected a saving of fuel. Some years ago Mr. Lewis James, master mechanic of the Wheeling & Lake Erie, experimented considerably with a water circulator. His device consisted of a water leg which extended from the crown sheet to a point slightly below the lower row of flues. There were two openings through the crown sheet, one at each side. One of the openings had a funnel-shaped pipe extending about a foot over the flues.

The practical effect of applying this circulator was that the engine steamed much more freely, and it broke up the scale that had previously been in the boiler. Why this form of circulator was abandoned we have never learned. There is difficulty in keeping a supplementary water leg tight, and it is a troublesome thing to have in a firebox. These drawbacks may have proved fatal to the use of the water circulator.

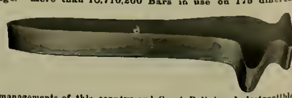
Manufacturers of the new "GREER" Railroad Track Spike and the Celebrated "SAMSON" Bar.

Fourteen years' unexampled success has demonstrated the fact that under all varieties of Railroad Service they will prevent "low joints," battered rail ends, and in a remarkable degree withstand the test of breakage. More than 10,710,200 Bars in use on 175 different Railroads, equivalent to 15,213 miles of track.



The "Greer" Railroad Track Spike is the latest and best spike offered to the Railroad managements of this country and Great Britain. Indestructible. A holding power of from one to two tons more per spike than any 5½ x 9-16 spike. Automatically sharpened to chisel edge, it cuts; does not tear the wood fiber. Hand packed in kegs—every spike perfect. Particularly adapted for use on Bridges, Trestles, and on Switches.

## Freight and Passenger Triple Valves.

BY PAUL SYNNESTVEDT

Permit me to make a few comments in relation to the difference between the freight and passenger triple valves. I confess I was a little surprised, not to say gratified, to find in the replies given, nearly all the points I had found myself after most careful investigation. I say surprised, because I had put the question to a great many different well-instructed air-brake men, and had never before received anything like a satisfactory answer. Many thought and stated positively that the only difference was in the size of the feed groove.

Of Mr. Nypano I would seek further light, as I confess I do not understand his answer at all. I was not aware that the difference would cause any difficulty in getting the check-valve to close properly, nor was I aware that there was any check-valve between the auxiliary reservoir and the brake cylinder. If he will explain himself further I shall be much obliged, as he evidently has something on his mind which is entirely new to me, and my curiosity is always excited when I scent anything novel. I may say, for the information of your readers in general, that at one time I did considerable experimenting on a pretty good quick-action brake, which seemed to set all right without any check-valve at all between the cylinder and train-pipe, though of course it leaked off when the train-pipe pressure was very greatly reduced, as when the train broke in two.

The statement made by one of the writers, that, "On some roads they take out the emergency valve piston No. 8, and put a small brass bushing in its place," verifies some information to the same effect that I had received some time ago, and I guess this is as good a chance as any to lift my voice in protest against a practice not only dangerous but positively criminal, unless ignorance be offered as the excuse.

I am not unaware of the damage that often results from too frequent use of the emergency feature of the air-brake, especially on long freight trains only partially equipped, but I do not agree that to entirely dispense with this valuable improvement is the way to remedy the difficulty.

The exhaustive tests made at Burlington in 1886 and 1887, on a fifty-car train, showed conclusively that no brake except an emergency brake was fit to use on long freight trains, because of the tremendous jar on the rear cars when the slack ran in before the brake was applied.

This shock in some cases was so great as to seriously injure both the cars and their contents, to say nothing of the hardy investigators who were riding in them, and who, I have often thought, deserve much credit for their courage and perseverance.

Besides this, there is of course the all-important fact, that on a long train there is a gain in time of application in cases of emergency of several seconds in favor of the quick-action brake, and this frequently represents the prevention of a serious collision, and the saving of valuable property, as well as lives and limbs.

No one is really capable of fully realizing the importance of a saving of one second, except he who has had the experience of riding on the locomotive of a fast train, or perhaps being slightly shaken up in one or two wrecks.

The emergency brake is a good thing, and I can only say in concluding these remarks, that it is a great pity that there seems to be a number of people still living who do not know a good thing when they see it.

There is one big improvement the Chicago "L" has over the New York and Brooklyn up-stairs routes—the cars are gas-lighted. You can actually read in them on a dark night.

## Something New in Slide-Valves.

Henry R. Fay, an ingenious locomotive engineer on the Boston & Albany road, has recently invented and patented an improvement on slide-valves, and the device has been put on several engines on the above-mentioned road.

Mr. Fay's device consists simply of four drilled holes from the valve-seat, at the ends of the bridges, as shown in Figs. 1, 2 and 4, and four small cavities in the face of the valve, as shown in Fig. 3.

The object of the invention is to reduce the compression, and the inventor claims especial merit for it in an ordinary two-cylinder compound.

The amount of compression gotten rid of by this device is determined by the location of the ports and the design of the valve.

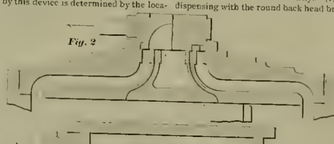

Fig. 2

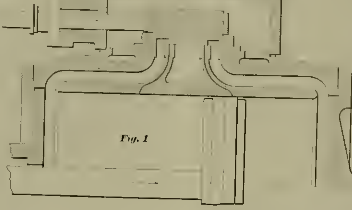

Fig. 1

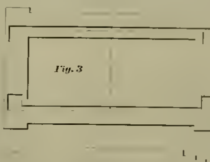

Fig. 3

Fig. 4

The inventor believes that at high speeds, where links are hooked up close and compression is excessive, this device will very materially increase the efficiency of the engine and augment the speed.

As can be seen in Fig. 1, the piston is just passing this auxiliary port and compression is beginning to take place, but once the piston passes this hole in the cylinder the steam confined in the forward end of the cylinder can escape from the port through the extra ports in the valve and the holes to the cylinder back of the piston, as shown in Fig. 2.

As will be discovered by examination of the drawings, steam cannot enter these ports when the engine is at work.

Those in use have not yet had time to demonstrate their value, but it is said that these engines drift down-hill very freely.

## Belpaire Boilers.

In his paper on Locomotive Boiler Construction read at the New York Railroad Club Mr. W. F. Dixon said: "Within the last three or four years the Belpaire type of boiler, first introduced by and taking the name of M. Belpaire, at one time at the head of the motive power department of the Belgian state railways, has come into extended use in this country. I may say here that 68% of the entire output of the Rogers Locomotive Works for the last two years have had boilers of this type. When properly designed and well constructed this style probably presents the best solution of the problem of crown staying yet brought forward. The crown-sheet is comparatively unobstructed, and may readily be kept clear of sediment. The staying is positive, all the stays having good bearings in and on the sheets. All the strains may be accurately calculated and provided for, and all the stays may if desired be made of one length, an advantage that is appreciable.

"The two main objections that have been raised against it are the difficulty of keeping the crown-stays tight in the neighborhood of the ends of the braces running from the back head to the top of the firebox shell owing to the constant downward pull of these braces. This trouble may be overcome in several ways: (1) By dispensing with the round back head braces and substituting in their places gussets or plate-braces attached to the roof-sheet by long angle-irons, thus distributing the strain over a large area and preventing its localization, (2) by running the braces forward to the waist of the boiler, a plan which is in many cases impossible owing to their number, (3) by running the braces clear forward and attaching them to the front flue-sheet, a plan I would not recommend owing to the difficulty in keeping the ends tight, the incessant vibration tending to cause leaks, (4) by riveting heavy angle-irons crosswise of the roof-sheet as close as possible to where the brace ends take hold, thereby stiffening the sheet and preventing it 'giving.'

"The second objection to this type of boiler is the difficulty experienced in some quarters of keeping the top corners of the throat of Belpaire sheet tight where they join the shell. These corners have been a thorn in the side of the mechanical department of more than one road. The trouble in the majority of cases appears to be caused by not allowing the flue-sheet sufficient room in which to expand vertically. After a boiler is fired up, the fire-box, being at a higher temperature than the shell surrounding it, expands more. The two are rigidly connected together at the bottom by the mud-ring, so that the only direction in which the firebox sheets can expand is upwards, the result being that the crown-sheet is slightly higher above the center line of the boiler when it is hot than when it is cold. As the flue-sheet is more rigid in an up and down direction, owing to its flat shape, than the side sheets, which are more or less arched or curved, it seems plausible to suppose that a greater strain is brought to bear on the crown-stays in closest proximity to it than on those further back.

"If the first row of crown-stays is close up, the flange uniting the flue and crown-sheets say 1½ or 2 inches from the edge of the flange to the center of the stays, the crown is hardly able to give at all, and the stays are carried up the amount the flue-sheet expands. This of course tends to distort the top of the shell at a point close to where it is riveted to the waist of the boiler. The constant moving up and down which takes place every time the boiler is cooled off, and, indeed, whenever the fire-door is opened, permitting a current of cold air to strike the flue-sheet, causes the seam to work or loosen and allow more or less serious leakage to occur. If, however, the first row of crown-stays is kept well back from the flue-sheet, say five inches from the edge of the flange to the center of the stays, the intervening portion of the crown, while amply strong to withstand the steam pressure, has a chance to bend or give slightly, with the result that the upward thrust on the stays and the consequent distortion of the shell are lessened. If, in addition to throwing the centers of the stays back, a heavy bar-iron brace running crosswise of the shell-top and well down the sides is riveted on just back of the throat or Belpaire sheet seam, the trouble with leaky top corners can be reduced to practically nothing. There is another advantage in throwing the first row of crown stays back from the flue-sheet as far as is consistent with absolute safety, which is that the expansion strains in the flue-sheet itself are lessened, and the chance of cracking the sheet between the flue holes is reduced. On some of the English roads I saw radial boilers in which the two first rows of crown-stays did not go through the top of the sheet at all, but were connected to wrought-iron or possibly cast-steel crossheads, which were in turn pinned to a piece of T-iron riveted to the shell. This arrangement apparently worked well and gave satisfaction, but has the disadvantage of being pretty expensive."

The cars on the elevated road in Chicago are the same size as those on the New York "L," but they have double sliding doors. These affairs stick, won't lock, and require constant tinkering, they have caused more annoyance than all the other ills the cars have been afflicted with. These double doors were going to cause a quick handling of the crowds, but the platforms and gates being the old size there was found to be a congestion just at the gates. It was an improvement (?) of that kind that puts a 24-inch port in a steam chest and 3-inch nozzle at the end of the passage.

Last summer the junior philosopher asked a Scotch engine driver if the company employed any "body-snatchers." He did not just know what "body-snatchers" were until it was explained that they were extra men who were sent to engines ordered out, to take them in case the regular man did not show up the required number of minutes before leaving time. "We dinna ha' the like," said he, "but we ha' the excise man." Then the j. p. was stuck. "Breath testers, mon," he explained, "them as see wha has gang adrift wi' John Barleycorn and lost the abeelity to gang awa' wi' their trains."

## Laying Out Shoes and Wedges.

BY C. K. W.

In laying out the shoes and wedges on a locomotive engine, the principle to be kept in view is, to have the centers of the driving-axles equal distances from each other, the centers on each axle at right angles to the rails, so the flanges will not "cut" or wear sharp, and the face of each shoe and wedge parallel with each other, and also parallel with the other shoes and wedges on that side.

Before laying out the shoes and wedges, the pedestal jaws and inside of each shoe and wedge should be filed true, so when the shoes and wedges are put in place they will be solid, no "rock" in them. The pedestal-braces or binders should be fitted to pedestals so there will be no lost motion when up to place.

When the shoes and wedges are put up, the shoe should be of such a length that it cannot move up or down, or be held to pedestal jaw by a bolt through pedestal, and the head of bolt should be on outside of pedestal, so if at any time after the wheels are put under the engine the shoe can be taken down to put a liner behind it by taking the bolt out. The wedges should be down about ¼-inch from top of binder. Block the shoes and wedges in this position by putting a bolt between them, as shown in Fig. 1.

Get the center of the frames on back cylinder-saddle as shown at *A*, Fig. 1, then with a tram that has one end pointed and on the other end a sliding point, put the straight point at *A*, and with the sliding point make a line at *B* and *C*, Fig. 1, the centers between the pedestals; make a line lengthwise of the frames, and the same distance from the top on both sides make a small center punch-mark where these two lines bisect; these points are on inside of frames, and should be carried to outside of frames by putting a "square" on top of frame and extending points *B* and *C* to top and over the top and down on outside, make another line lengthwise on the outside of frame equal distance from the top; make a small center punch-mark where these two lines bisect.

To make this one drawing answer our purpose, we will suppose the points *B* and *C* are now on outside of frames. Mark off the width of the driving-boxes between shoe and wedge from the points *B* and *C*, then put liners between shoes and wedges and pedestals until the distance between the shoe and wedge on each side is enough less than the width of driving-box so they can be planed. It is best to use as few liners as possible; make them as thick as can be used. From the points *B* and *C* make the lines *D E* on left side and *F K* on right side, the distance between these lines on each side to be 2 inches larger than the width of the driving-boxes. Put a surface-plate or two parallel blocks on top of frames, and with a "square" placed against surface-plate, draw the lines *D I* and *E H* on left side and *F J* and *K G* on right side; make a small center punch-mark on these lines near the top and bottom on each shoe and wedge.

Put a straight-edge across the frames between the shoes and wedges, let it rest on the bolts that are holding shoes and wedges in place, set it so the edge will be the same distance from lines *E H* and *K G*, then make a line on inside of each shoe as shown at *M* and *L*, this line to be same distance from straight-edge on inside as the lines *E H* and *K G* are on outside; mark the inside of each wedge the same way, having the points *O* and *P* same distance from straight-edge as the lines *D I* and *F J* are; make a small center punch-mark at each one of these points, *L M* and *O P*. These points are to be on inside of each shoe and wedge.

Before laying out the back-shoes and wedges, get the length of the side-rods. If solid side-rods are used, great care must be exercised in laying out the back-shoes and wedges, so the distance between centers of driving boxes on each side will be the same as length of side-rods.

With a tram set to the length of side-rods from the points *B* and *C*, make the lines *B1* and *C1*, make a line lengthwise of the frame on each side, and same distance from the top; make a small center-punch mark where these lines bisect same as at front end; from these points mark off the width of driving-boxes and put liners between shoe and wedge and pedestal, until the distance between the shoe and wedge is enough less than the width of driving-boxes so they can be planed. With the tram set to the length of side-rods, put one point at *D* and make the mark *N*, and from *E* to *R*, from *I* to *U*, and *H* to *V* on left side; and from *F* to *W*, from *K* to *X*, from *J* to *S*, and from *G* to *T* on right side. It is a good idea to try these points to see if they are correct by measuring from *N* to *R* and *V* to *U* on left side, and from *W* to *X* and *S* to *T* on right side; if they are the same as on front shoes and wedges, they are correct. The points for inside shoe and wedge can be gotten the same as in front by putting a straight edge across the frames between shoes and wedges.

Make a small center punch-mark same as done on the front shoes and wedges. If a ten-wheeler or consolidation engine, lay out all the shoes and wedges, measuring from the front or main shoes and wedges to the others.

In case the back driving-boxes are different width than front ones, lay out the points *B1* and *C1*; then from these points lay out width of driving-boxes, and 2 inches more, as shown at *N1* and *R1* on left side, and *W1* and *X1* on right side, then set tram from *D* to *N1*, using this length, carry the points from front shoes and wedges back to back shoes and wedges, same as when driving-boxes were same width as front ones.

The shoes and wedges are now ready to be planed and can be set to the center punch-marks on the sides. In planing take off enough, so it will measure 1 inch from the center punch-mark to the face of the shoe or wedge. The reason that each shoe and wedge is laid out 1 inch from face is, after they are planed, they should be put up to place and tried; if out, the points are there to tell if they were planed wrong or laid out wrong.

A handy gauge for measuring from face of shoe or wedge, is made out of a piece of ¾-inch square steel, planed true, and with a sliding steel point, held by a thumb-screw in end, as shown in Fig. 2. As all sizes are given it can be easily made, and be found useful in a great many cases.

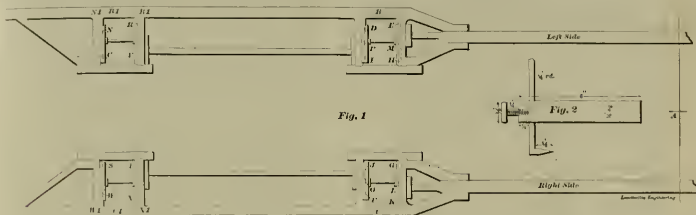

Fig. 1
Fig. 2

## Weight on Engine-Truck Due to Form of Boiler.

There is one objection to the Belpaire boiler, and indeed any straight boiler, apart from any question of boiler-making, to be found more especially in the case of eight and ten-wheeled engines, and that is the unduly large percentage of the total weight of the whole machine that is thrown on the leading truck.

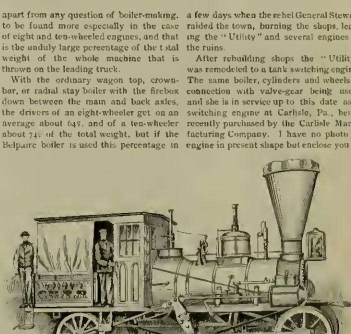
With the ordinary wagon top, crown-bar, or radial stay boiler with the firebox down between the main and back axles, the drivers of an eight-wheeler get on an average about 64%, and of a ten-wheeler about 74% of the total weight, but if the Belpaire boiler is used this percentage in the case of the former sinks to about 61 and in the latter about 68. The reason of this is that with the wagon top boiler a sufficiently large space can be obtained for steam room over the crown-sheet, while keeping the waist of the boiler tolerably small in diameter, but the Belpaire, being straight on top in the great majority of cases, that is to say, without any rise at the back end, the waist must be increased at least four inches in diameter in order to obtain the necessary steam room. The larger the waist the larger the smoke-box and front must be, the branch and exhaust pipes must be longer and heavier and altogether the weight of the front part of the boiler, which comes directly on the truck, is materially increased.

## History of the "Utility."

BY C. S. HULL.

The locomotive "Utility" you refer to in LOCOMOTIVE ENGINEERING of March, 1893, was built by Seth Wilmarth, Boston, Mass., for Cumberland Valley R. R., in the year 1854, and was in use at Harrisburg and Bridgeport, Pa., as a switching engine until 1862 when in a collision she was wrecked. At the time of collision engine was drawing a train of wounded soldiers from battlefield of Antietam on their way to hospitals, when she collided with a Northern Central R. R. engine, badly breaking frame and front end. Engine was taken to company's shops at Chambersburg, Pa., and was only in shops a few days when the rebel General Stewart raided the town, burning the shops, leaving the "Utility" and several engines in the ruins.

After rebuilding shops the "Utility" was remodeled to a tank switching engine. The same boiler, cylinders and wheels in connection with valve-gear being used, and she is in service up to this date as a switching engine at Carlisle, Pa., being recently purchased by the Carlisle Manufacturing Company. I have no photo of engine in present shape but enclose you an old photo of the engine as she was from 1852 to 1862.



THE "UTILITY," AS SHE APPEARED IN 1862.

Those men who worship at the shrine of the "good old times" in railroading, who think the world would be better off and engineers twice as happy as now if we had the old engines of the 40's, will have a chance to compare the ancient mills with the modern ones at the Fair. There will be found a vast difference between the average locomotive of thirty years ago and that of to-day—mostly in size and attachments.

Has any of our readers got a picture of the famous old-time engine "Carroll of Carrollton"?

# Car Shops and Car Builders.

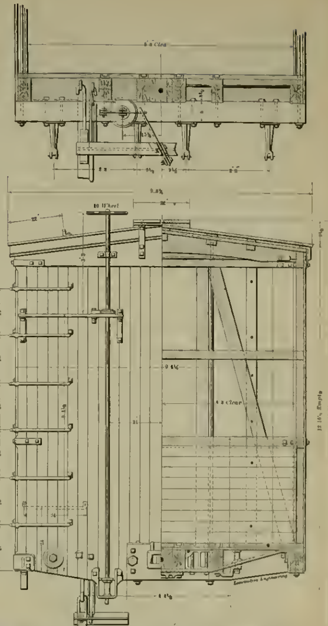
### Southern Pacific Furniture Car.

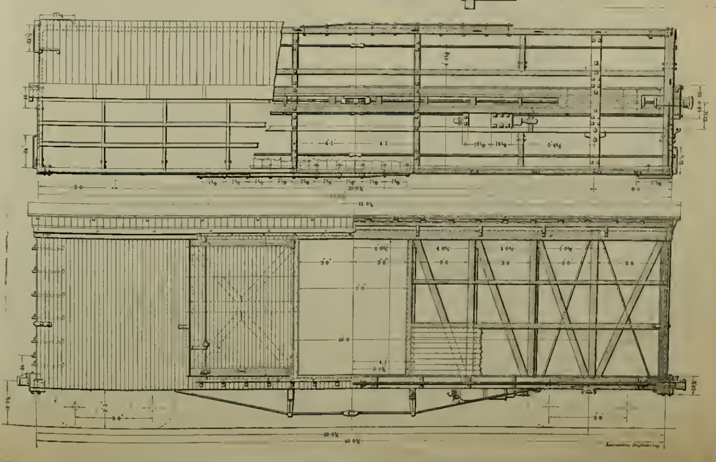
The annexed engravings illustrate a very fine form of furniture car designed and built by the Southern Pacific people at the company's shops at Sacramento, Cal. The cars are very commodious, and the design and wormanship are so good that they stand up remarkably well and bear the heavy shocks of mountain roads without signs of distress, notwithstanding their great length. The framing, as may be seen from an inspection of the cuts, is unusually strong, the plates, posts, braces, etc., being heavier than usual. The distance between posts is 42 inches, they are 2½ x 5 inches, and the diagonals are of the same size. This is stiffened by two heavy girths and rods. The end posts are 5 x 5 inches. Native timber has been used throughout for the building of the cars, California red-wood entering largely in the material. A few of the principal dimensions are: Length, clear inside, 40 feet, outside length, 40 feet 6¾ inches; height from sill to plate, 8 feet 11 inches; width inside, 8 feet 4¾ inches, and over sills, 9 feet 2¾ inches. The cars are equipped with the Westinghouse quick acting brake, steel brake beams, continuous drawbar and iron transoms. The capacity of these cars is 60,000 pounds.

### Dead-Blocks for Cars.

At a meeting of one of the Railroad Clubs a curious statement was made by one of the members to the effect that his company have two lawsuits against them, one for an accident that happened to a car that had no dead-blocks, the other for an accident alleged to have been due to dead-blocks at the end of the car. This is not by any means a rare case. There is so much diversity of opinion between railroad men and others, respecting the utility of dead-blocks, that it is not surprising that lawsuits should arise, alleging danger both from the use and from the absence of this attachment. When all sorts of light draw-bars were employed that were inadequate to sustain the blow of cars coming together violently, there was good excuse for using dead-blocks that would maintain an opening between the cars for the protection of life and limb. Although protection to life and limb was the ostensible object of dead-blocks, in many instances they proved a greater source of injury than of safety. In fact, the vertical form of double dead-block, used so much on Eastern lines, was known popularly in the West as man-killers. This grim term described exactly the action of this form of dead-block upon switchmen who were not skillful in escaping the dangers of the arrangement which seems designed to prevent coupling by hand.

When the M. C. B standard draw-bar was adopted an important advantage expected from the employment of the vertical plane type was that it would dispense with the necessity for dead-blocks. Certain superintendents of machinery appear to have changed their minds on this subject, for the discussions in railroad men's meetings seemed to indicate an attempt to establish some new form of dead-block adapted to the new form of coupling. It appears to us that this proposal is calling for an expensive superfluity. The form of the coupler is such that dead-blocks cannot be employed that will protect it from a severe blow without being dangerous in rounding sharp curves. The use of the Standard coupler obviates the necessity of switchmen going between the cars when coupling, so that dead-blocks are not a necessity for their protection or safety. It is argued that dead-blocks are a necessity during the transition period. If railroad men would agree to apply uniform style of dead-block there might be increased safety from their use when a common draw-head comes against a Standard coupler and fails; but with diverse forms of dead-blocks the danger to men coupling would be even greater than it is without any. Very few practical men will question the truth of this. It would then, we think, be very unwise for the railroad men of the country to go to the expense of applying diverse forms





a dead-blocks for a temporary purpose The subject is likely to come up at the next M. C. B. convention There are indications that some of the members will make a struggle to introduce dead-blocks as a connection of the Standard coupler. Men who have given this subject a great deal of thought, consider that nothing will be lost by letting the subject stand for another year

## A Sensible Continuous Draft-Gear.

The engravings shown herewith represent an improvement in draft-gear, the invention of Mr Geo Dole Wadley, general superintendent of the Central Railroad and Banking Co. of Georgia.

This form of continuous bar prevents the falling of the draw-bar on track when bolt breaks—the accidents from this cause have been worse since the introduction of vertical plane couplers; they are larger than the link-and-pin draw-bar

The greatest improvement consists in putting a taper section six inches long from the head to rod. This prevents the draw-bar from coming off, even should the head break off.

The two sections of the continuous bar meet in the center of the car, and are adjusted by a turn-buckle, a cotter prevents the turn-buckle from slacking off, while by removing it the slack can be taken up and the bar kept close up to the buffing plate.

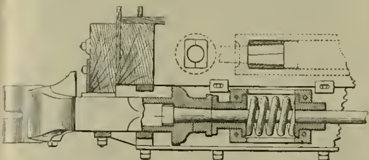
This does away with keys and nuts and the trouble from their maintenance.

Where applied to old draw-bars a sleeve with a taper hole is dropped into the draw-bar to take the taper fit of the bolt.

The illustration shows it with the Butler attachment, but it can be applied to any car with any attachment.

More than 2,000 cars with this draw-bar have been running for the past eight months without a single failure, this has encouraged the designer to form acompany and put themon the market.

The Wadley Continuous Draw-bar Co., with an office at 912 Havemeyer building, New York, and headquarters at Savannah, Ga., will push the sale of this device



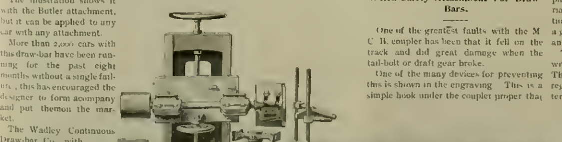
## The M. C. B. Car Coupler.

In the course of a pamphlet on "Safety Appliances," President Haynes of the American Railroad Association has this to say about the Master Car Builders' standard car coupler.

The coupler patentee, whose name is legion, opposes the standard automatic coupler because it is not a patented device, but only a type of which there are different kinds already patented; so many, in fact, that there is no hope of drawing a single capital prize in a lottery where all the others would draw blanks. What a prospect of a glorious monopoly was thereby destroyed! The only kind of automatic couplers that to-day can be bought on the market are of the standard type, and where else except in open market are the 800,000 couplers for cars to be obtained

Link-and-pin couplers cannot be successfully used in freight trains equipped with air-brakes, and there is no other coupler known as a commercial article except the standard type which can meet this requirement.

The distinguishing feature of this latter is that it is a type of which there are many different patents, yet all of them will couple interchangeably with each other, and the field for improvement and for variability is free for all, conforming only to those restrictions embodied in the type, that enable them to be uniform as to this feature of being interchangeable This is the fundamental requisite; in this direction alone lies the way out of danger to employés and toward their protection.



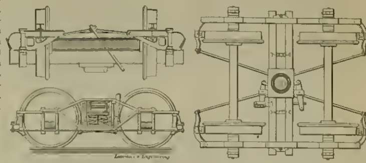
LARGE CAR TENONING MACHINE.

The *American Machinist* has heard about a man out West who has invented an osculating engine. We suspect Utah must be the only region where a labor-saving apparatus of this character would be tolerated.

## Something New in Brake Gear—A Beamless Truck.

The Bloomsburg Car Co., of Bloomsburg, Pa., have recently built a car for exhibition at Chicago with what they call the "Star" brake This is simply a device for doing away with the brake beam. And the plan is plainly shown in the two drawings of the truck shown herewith.

As can be seen, the brake shoes are hung on short levers hinged at the outer end to extensions of the arch bars and connected at the inner ends to its brake rods. These bars are of a very strong form and made of malleable iron. The manner of connecting to levers is shown in the plan.



What this device will do in service, of course, remains to be seen, and its use will be watched with interest.

WELCH SAFETY HOOK FOR M. C. B. COUPLER.

## Welch Safety Attachment For Draw-Bars.

One of the greatest faults with the M. C. B. coupler has been that it fell on the track and did great damage when the tail-bolt or draft gear broke.

One of the many devices for preventing this is shown in the engraving This is a simple hook under the coupler proper that prevents one knuckle from dropping down and out of the other.

This hook is a malleable casting that is put on to the coupler with a bolt and key The photo shows just how it works in pratice. It is the invention of C. L. Welch, of Birmingham, Ala., and has been adopted by the L. & N., Queen & Crescent and Illinois Central.

Fairbanks & Co., of this city, recently made some exhaustive tests of the Smillie coupler The knuckles showed a tensile strength of over 146,000 pounds.

## Large Car Tenoning Machine.

This machine will cut tenons up to 12 inches long on 14-inch timber. The frame upon which the carriage-ways are placed is cast in one piece and bolted to the sole-plate of the column, forming a rigid carriage support This form of construction permits of a low height for the table, a great convenience in handling timbers and material to be worked.

The cutter-heads are of large diameter, with serrated spurs and 6-inch knives They have a simultaneous adjustment for regulating the length of shoulder to the tenons by the hand-wheel and screw at the top of the column, also an independent adjustment to determine the thickness of the tenon by the center hand-wheel The heads are provided with an adjustment to make the shoulders perfectly square, or out of square if desired.

The vertical spindle is $1\frac{11}{16}$ inches diameter, fitted with a vertical head 12 inches diameter, for cutting double tenons up to 4 inches in length, regularly fitted with a pair of 2-inch cutters It has a separate, independent vertical adjustment by which it can be raised to any height or lowered sufficiently to permit the passage of large timbers over it The horizontal arbors are $1\frac{11}{16}$ inches in diameter, the journals lead-ground, and run in long bearings.

The belt is at the end of the machine, away from the operator, and controlled by an automatic, self-acting binding pulley actuated by a sheave, pinion, and weight. This compensates for any motion of the head up and down, and always maintains a uniform tension of the belt. The carriage is broad and of good length, and fitted with friction rollers, which run on planed

ways arranged to retain the table and keep it at a constant right line with the line of the heads. It is supplied with adjustable stops and gauges, a long fence, and a wrought-iron clamp for holding the timbers in position.

The countershaft is placed at the base, with a heavy floor-hanger support for the outer bearing. The vertical head is driven from an independent countershaft placed in the rear, which takes its power from the counter in the machine.

The machine is made by the J. A. Fay & Egan Co., Cincinnati, O.

---

### English and American Cars in Argentine.

It is generally supposed that English passenger cars have less dead weight for the paying load than American cars, but a report made about the passenger car equipment on the Southern Railway of Argentine complains that the reverse is the case. Complaint is made that the cars are unnecessarily heavy, very expensive in first cost and that they need a great deal of repairs.

The point is made that the American cars in use are lighter, stronger, cost less and require little repairs. The cars are said to be in perfect order after four years' service. The dead weight per passenger is one-half less than that of the English cars excepting the sleeping cars, which are only a little lighter than those of English make. The system of carrying the cars on trucks is highly commended. They are said to have very little lateral motion compared with the others, and curve much easier.

---

The chairman of the committee appointed by the Master Car Builders' Association to investigate the subject of metal for brake-shoes having declined to serve, the secretary of the association is calling for information. He has sent out a tabular circular calling for data about the wear of brake-shoes of different kinds. Exact information on this subject is badly needed, and it is to be hoped that railroad men having reliable records about brake-shoe wear will answer the circular.

---

A committee of the Master Car Builders' Association having the subject of draw-bars and brake-beams under investigation have sent out a circular in which they ask the different railroads to intimate the height of draw-bars on their cars. This subject is of peculiar interest at present since Congress has provided a certain means of putting an end to the reluctance displayed by many railroad companies in adopting the standard height, which is 33 inches from top of rail to center of draw-bar.

---

Mr. Robert M. Dixon, who is one of the officers of the New York Safety Car Heating and Lighting Co., has obtained a patent on a hot water heater for cars. It consists of a furnace with a vertically set water cylinder in the middle, connecting with which are coils of pipes. The apparatus looks as if it would make a very good heater.

---

Two pages of the *Patent Office Gazette* were filled recently with descriptions of an automatic train arrester invented by Jesse Frysinger, Hanover, Pa. The purpose of the invention is to stop trains when block signals are at danger, no matter whether the engineer sees the necessity for stopping or not. Four different patents are required to cover the details of this invention, which are exceedingly elaborate, and are evidently well worked out.

---

The J. A. Fay & Egan Co., of Cincinnati, have sent out a general invitation to all machine users to visit their exhibit in Machinery Hall at the World's Fair.

## ?A. What You Want to Know. ?A.

**Don't ask questions that simply require a little figuring to determine, make each question separate. No notice taken of anonymous questions.**

(52) W. R., Washington, D. C., asks

Will you kindly tell me, through the columns of your paper, what causes the peculiar groaning noise the air-pump makes when first started, and a remedy? *A.*—Groaning is usually caused by water in the cylinder; dry or cut seats or cylinder walls. Drain the cylinder before starting, start slowly, lubricate carefully; if cutting has taken place to any extent it can only be cured in the shop.

(53) E. S., Brookline, Mass., asks

I want to know whether in England or on the Continent there is in use any brake that will apply its power to every wheel in the train, or, if there is not, please explain the kind of brake in common use? *A.*—Passenger trains in Europe are generally equipped with automatic air-brakes or automatic vacuum-brakes, there being much more of the latter than the former in use. Freight trains are not so equipped.

(54) H. L. H., Boston, Mass., asks

Can you tell when the steam whistle was first used on locomotives, or when it was first invented? *A.*—A steam whistle made in the form of a letter-carrier's whistle was in use about the beginning of this century, but the cup whistle was not invented till about 1830. It was first used at the Dowlais Iron Works in Wales, and is supposed to have been invented by a workman named William Stephens. It was first applied to a locomotive in 1835 by Bury, an English builder.

(55) C. A. H., Brainerd, Minn., writes:

In a recent number of LOCOMOTIVE ENGINEERING mention is made of a "Hudson" locomotive. Please let several interested readers know what kind of an engine it is. *A.*—The Hudson engine is a double-ender with a pony truck in front, two pairs of driving-wheels coupled and a four-wheeled truck carrying the tender, which rests on an extension of the engine frames. The Illinois Central use this engine largely for suburban service. It was originally designed by William S. Hudson, superintendent of the Rogers Locomotive Works.

(56) I. A. M., Des Moines, Ia., says

1. I have been reading books about the steam engine, and have met with the expression "coal per horse-power." I am puzzled to know how long the horse-power is to be used. Is it a minute, an hour, or a day? *A.*—An hour. 2. What is considered the amount of coal required to produce a horse-power? *A.*—It varies from 2 pounds in good engines to 10 pounds in poor ones. Some Corliss compound engines are reported to be producing a horse-power on as low as 1¼ pounds of coal.

(57) A subscriber, Collinwood, O., asks

1. Why is the pin of the link not put in the center of the block? *A.*—Because putting it back of the center helps to provide the means of equalizing the cut-off of the valve. This question has been answered a great many times and more particulars given. 2.—Why will a lubricator sometimes nearly empty itself when left standing? *A.*—A common mistake is made in asking this question. Sufficient information is not given to enable us to judge what the defect might be. In the first place, the kind of lubricator ought to be mentioned, and then particulars as to how the instrument acts.

(58) H. E. S., Alexandria, Va., writes

1. If the valves of an engine are set properly and the reverse-lever is placed in the center "out of gear-notch," will the engine move if the throttle is open? If so, how far? *A.*—The engine will have an amount of valve opening equal to the extent of lead which increases as the reverse-lever is drawn toward the center. Most of the locomotives will pull a light train with the reverse-lever in the center notch. 2. Give a rule for finding the proper length of the link. *A.*—There is no rule. The link in locomotive practice, where its use was developed, was made so that it would be short enough to clear the boiler and keep away from the ground. A very common size is 14 inches between eccentric rod pins.

(59) S. A. U., Ashland, Mo., writes

1. Will you please state what is meant by decapod, consolidation and bogie locomotive? *A.*—A decapod has five pairs of drivers coupled and a pony truck; a consolidation has one pair of drivers less; a bogie is the English name for a truck. Mason bogie engines, for instance, have the drivers secured in a truck. 2. Is it good practice to build 8-wheel locomotives with one-third of the weight on the truck? *A.*—Yes. 3. I have seen a statement to the effect that a train could be stopped quicker when the wheels were not slid than it could be when the wheels were sliding. Why is that? *A.*—Because the friction is greater between the brake-shoe surface and the wheel than it is between the small point of the wheel that comes in contact with the rail in sliding.

(60) L. on J., New Windsor, Col., asks

1. What sized exhaust nozzles should a 22 x 26 soft coal burning decapod locomotive have; what sized nozzles should a 9 x 14 locomotive have? *A.*—The size of cylinder has very little to do with the size of the nozzle. They should be designed to make the boiler steam freely and as economically as possible. 2. If an accident happened to a shifting engine that it would have to be towed in and only had one-half or three-fourths of a mile to go to get to the shops, would it be necessary to disconnect? *A.*—Not unless the moving of engine without disconnecting would break something or risk breaking something. 3. What is the difference between first, second and third class certificates for engineers, and how large an engine is a third-class engineer allowed to have charge of? *A.*—The first-class man is the more experienced and educated than the third class. In marine work where classification is used the license specifies the tonnage of the boat the engineer is authorized to have charge of. No such classification is used on railroads.

---

Even the children know a good thing when they see it. In one home where LOCOMOTIVE ENGINEERING is eagerly read and much enjoyed by the parents, the little ones are quite as interested in the pictures as anybody, and must see them as soon as the paper arrives. The observations made and the questions asked are sometimes amusing. A six-year-old girl was looking at the picture of one of the English engines recently shown in LOCOMOTIVE ENGINEERING, and was telling wherein it differed from our own engines. Soon she looked up and asked "Mumma, don't they have cows in England?" Her mother answered "Yes, certainly, why do you ask such a question?" And the six-year-old said "I thought they didn't, 'cause the engine has no cow-catcher on it."

---

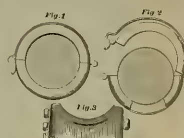
Part of the fireproof (?) building (Temple Court) in which we are located was burned on April 2, but the elect of earth are always cared for—more or less—and we were not smoked or wet down. For all of which we are truly thankful, and, in the language of the *Podunk Podanger*, this is the time to subscribe.

### A Piston Swab Holder.

The engraving will show at a glance the details of a metallic swab holder for air-pump and other pistons, recently patented by a railroad machinist, James N. Elliott, of Battle Creek, Mich.

The hinged shell is hollowed out and contains a strip of thick felt that is pressed against the rod when the two halves of the holder are snapped together.

A swab of this kind not only lubricates



the piston rod of an air-pump, but it prevents a great deal of water from being drawn down into the air cylinder when the gland on the steam cylinder is leaking.

---

The Baltimore & Ohio Railroad company require that specimen bars shall be furnished of all the principal castings that are made in contract shops for use in rolling stock. This company has promulgated a good many foolish rules at one time or another, but requiring cast-iron specimens is as foolish as anything we have heard of, and certainly was not approved by a man familiar with foundry work. A good foreman molder can by selecting the period of pouring provide a specimen that will give any kind of test desired.

---

"Globe Special Castings" is the title of an illustrated catalogue published by the Builders' Iron Foundry, of Providence, R. I. The specials handled are unusually numerous, more than 250 varieties being listed, while more common sizes are kept in stock. The Builders' Iron Foundry has a motto which is a good one. It says "We make specials as compact as we can, as light as we can; we utilize every pound of metal. Our business is to sell Globe specials."

---

A correspondent in Fargo, N. D., sends us the following scientific explanation (?) of the air-brakes: "The air-brakes of railroad cars work by air pressure. Pipes connected with the brakes are carried to an air-pump fitted on the side of the engine and keep up a vacuum in the brakes; when the brakes are to be applied, the air-pump is thrown out of gear, air is admitted to the pipes, and the springs of the brakes immediately press on them and bring them in contact with the wheels."

---

One of the most attractive and interesting machinery catalogues we have ever seen has lately been published by J. A. Fay & Co., Cincinnati. Besides giving admirable engravings and descriptions of the wood-working machinery, the catalogue gives a great deal of useful information about wood-working machinery.

---

We are informed by Howe, Brown & Co., Pittsburgh, that in addition to their offices and warehouse in North Jefferson street, Chicago, they have decided to open a branch office in the Monadnock building, where Mr. Jackman will have his headquarters. Customers and friends are invited to call.

---

A patent has recently been granted to H. H. Westinghouse, Pittsburgh, Pa., for improvements on an air-pump. It covers the new style of pump, which has the reversing mechanism entirely in the top head.

# Railway Liars' Association

Dr. MUNCHAUSEN, Sec'y.

References as to experience and ability required of all candidates.

### The Best Thief of the Two.

"When I werer running a 'yard-wide' on the Rio Grande," said the old-timer reflectively, "we had a cool sorter cuss runnin' freight train by the name of Gunnip—Bob Gunnip.

"Well, the art of car-robbin' never blossoms and gits ripe any place quite so good as it does out to the front.

"Almost every crew had a car-tapper that would get behind a seal, somehow or other, and tap kegs and barrels and touch candy-pails and fruit-cases, to say nothin' of shirt and sock boxes.

"The detectives were everywhere on the lookout, a half-dozen clerks were kept busy startin' out tracers, and readin' 'em as they got back.

"They mostly all told the same story namely, to wit. 'Car 4,944, on train 21, January 14th, received in good condit. all seals intact and turned over in same shape, Seals L. S., 1921.'

"Everything and nothin'.

"Well, one of these tracers dropped into Division Superintendent Bancroft's office at Pueblo one day, and he took and set down and put an appendix to it hisself.

"He went on to say that there was twenty ways to 'touch' a car without defacing the seal, an' 'en he detailed just how to do it. He explained how to take the cast door-clip off the back corner of the side door with a wrench and then spring the door up far enough for a man to slip in.

"How to cut open a lead seal without destroying the sealing letters, then take out the wire.

"How to put it back and scrape its edge to cover up the cut.

"How to cut the wire inside the seal.

"How to re-eyelet tin seals.

"How to pick locks.

"How to 'fish' oranges through fruit car ventilators.

"How to open a barrel of bottled beer, remove three bottle and replace the head.

"And forty other schemes to get at the contents of a car—no doubt the old man was mad and trying to jack up and give the detectives pointers at the same time—and 'en the tracer was sent to Gunnip; there bein' a strongish suspicion in the old man's mind that Bob and his two brakemen knew suthin' about car-touchin'.

"Bob writ a leaf for their tracer that prevented any more from ever goin' out. He said: 'My train-book shows this car taken from 120 to 217 with seals intact. But I should like to call attention to the astonishing revelations made in the confession of the man making the last report. No one but an expert could describe with such detail a score of sharp tricks in car burglary that I have never even heard of in ten years' experience. I don't know much about stealin', but if I were a detective I'd have the yard where this man lives watched at night.

"They put Bob on passenger shortly after that, the old man went to the Western division about the same time, and the car stealin' suddenly dropped off about 50 per cent., so the boys never could tell which was which."

### A Variable Exhaust Experience.

"Talking of variable exhausts," said Hank Collins, "reminds me of a little trick on the D., L. & W. way back in the fifties.

"We got some new Cooke engines with a variable exhaust; these things had a taper plug, not unlike many now in use and yearly 'invented' over again, exceptin' that the plug in these was as big as the nozzle, and went up into the exhaust stand from underneath the saddle. It was raised and lowered by a bell-crank and rod

"Well, Mike Flynn had one of 'em and had a certain place to run it—but the pesky things would get lots of lost motion in 'em—well, one night when everything was clear, Mike told his fireman to come over and run a few miles while he took a snooze.

"Well, you know how a new fireman will experiment when he gets his fingers onto the keys; this one wasn't any exception.

"He changed the lazy-cock just a hair, hooked her up a notch, gave her a thirty-second more throttle, tried her water forty times, and then went for the variable nozzle—it worked with a lever held on a sector with a set screw—he moved it a little and in setting up the thumbscrew did not get it very tight, it worked loose directly and the steam shut it up kerslam!

"Of course she commenced to choke right down and stopped. The fireman shook Mike and said she was broke down. Mike told him to take the torch and look her over just as if he was alone—so as he could learn to run and take care of an engine.

"The fireman got down and looked her over from end to end, and Mike, who hadn't been asleep at all, reached over and put the 'variable' where she belonged."

"'I can't find nothin' the mather wid her, Moike,' reported the fireman.

"'Did you look her all over?'

"'From ind to ind.'

"'And nothin' the matter?'

"'Divel the thing can Oi see.'

"'Well, an engine with nothin' the matter of her will go—try her.'

"But, man, she broke and stopped hersel'.'

"'Try her, my boy, try her.'

"Fireman tried her, and she went off just as if she never had had a fainting fit in her life.

"That fireman's pullin' passenger there now, but I don't believe to this day he knows what did ail that engine; he was one of them superstitious cusses as believes engines has 'queer spells' anyhow."

### Presumably from Boston.

"We had a feller named Bean come out to the front onct," said the old-timer, resting his foot in the spittoon, "one of them edicated, 'cientific engineers, and I'm here to tell you fellers that the way he could sling the king's English would jest make old Dan Webster sick o' the dickshunary bizness.

"If he wanted the fireman to douse the front glim (railroad for putting out a headlight), why, he'd bow, perlitely like, and say

"'Horace, preambulate your jaded anatomy along the by-way of the locomotive and extinguish the nocturnal illuminator.'

"We was burnin' wood at the front then, and when this 'cientific cuss wanted the firesey to drop in a few more chunks of tie, he'd bow again and say

"'Horace, deposit in the furnace of the locomotive a diminutive number of the curtailed excrescencies of the defunct tree!'

"Well, he went 'cientifically to sleep one night, with the injector layin' off, and the crown-sheet wilted, he reported on the book

"'Owing to a temporary deficiency of dampness on the roof of the furnace of engine 76, the active combustion of carbon produced caloric intensity sufficient to permanently derange the contour of the sheet, suspend active participation of this locomotive in the transportation department, and require the employment of skilled artisans and mechanical appliances, unattainable at the time and place of such unsolicited and unexpected derangement of crown-sheet and schedule, caused by procrastination in the application of appliances for the introduction of water to the interior of the boiler.'"

### "Couldn't Pass the Examination."

The man from the Missouri Pacific lit his pipe after Rogers' lie put it out, stretched himself in true Missouri style, and said

"Our old man—Frank Reardon, you all know Frank—has recently had a severe stroke of rigid economy in oil. The Galena Oil Co. are furnishing the oils—good stuff, too—but the old man is putting the nippers on the boys. Valve oil is at a premium.

"Since we commenced using the Galena company's oils on this the Arkansas division of the Iron Mountain, we have double the oil mileage. The oil company have a man here to keep cases on us.

"Not long since he was present when the old man was examining a fireman for promotion. The boy got through with about all the questions put to him, and finally the old man gave him this

"'What would you do if you were out on the road with an engine and train and you saw another train coming against you with no possible show for you to avoid colliding with it?'

"The boy said he would reverse his engine, whistle down brakes, *grab the valve oil can* and jump off.

"The old man was just saying 'all right, you will pass,' when the oil man interrupted and said

"'No, no, Mr. Reardon, that man ain't safe; he never ought to be let run. Why, sir, he should never jump in this world till he had *shut off his lubricator*.'"

### Slow to Get Under Way.

Col. T. H. Long, one of our most famous civil engineers at the beginning of the railroad era, was the man who induced William Norris to engage in the business of locomotive building. Col. Long, like all the civil engineers of early days, took a hand in designing the machinery for railroads, and he made drawings for the first locomotive built by Norris. The engine was not a success. It was tried first on the Columbia Railroad. Col. Long, describing the events of the trial trip years afterwards in a public speech, said "Gentlemen, I can on my honor assure you that we ran four miles and a half in seven hours and a quarter, running all the time at that.'

This was something like the evidence given by Napier, a famous Scotch civil engineer, about a trial of one of the pioneer locomotives experimented with in Scotland. All sorts of odd engines were tried as locomotives at first, many of them being utter failures. This engineer was present at the trial of one of these, and he was questioned about the engine's performance, with the expectation that he would say something favorable. But he was carefully non-committal. When a man having stock in the invention had tried his best to get Napier to commend the engine, and got nothing but grunts, he exclaimed impatiently "You saw the engine running, at any rate." "Well," said Napier, "you may call it running. I saw you fellows shoving the engine."

### A Handy Accident.

"You know Hank Small, don't you?" asked the Jersey Central engineer: "Well, Small had a queer accident a few years ago that for slick good luck takes the cake. He was coming down from Easton with a coal train and didn't notice anything wrong—'cause he was drifting along, the boys holding him with the train, all he had to do was help 'em out on the sags here and there.

"Well, sir, they stopped for water and Small got down to oil around and found that his engine was disconnected and on one side

"The key had come out of the valve-stem and dropped the valve just in the center of the seat; this caused the piston to break and it took the front head out. The crosshead was riding back and forth all right.

"Small was considerably worried and looked her all over but it was no use to do anything—she was disconnected just right—he brought her in that way.

"That's the kind of an accident to have I always have to jack the engine up if anything happens to me."

### The Cowboy's Story.

Speaking of excitement, I tell you nothing so stirs up all the latent depths of one's imagination as the prospect of seeing yourself a millionaire in a week's time, and you can't stay long in a gold country before the fire gets into your brains and you watch the ground at your feet and the rock cliffs at your side, expecting any minute to pick up the nugget that will be the foundation of your fortune. I was up in the Black Hills not long ago and ran across a little incident in this line. The railroads hadn't been there very long and some of the boys were just in the state of mind I've been speaking about—watching to "strike it rich." Abe Bowers was roundhouse foreman and he had listened to the mining talk till he was sure there was luck for anybody who kept his eyes open, and so one of his machinists laid for him. He saved up his brass filings till he had about a quart and one day when the coast was clear, he raked them well into the sand on the bank of the creek out behind the shop, and then watched for developments. He didn't have long to wait, for Abe's prying eyes soon caught the glitter of the yellow particles, and he picked up a handful of the dirt to examine it. His eyes opened! The sand was full of minute grains of free gold! The find was fabulous, for old miners had said free gold never showed to the naked eye unless it was immensely rich. His wildest imaginings were to be realized! He trembled in his eagerness to store away his glittering find, but not till dusk could he begin his willing task; and then just as he was beginning to sack up his fortune, along sauntered the passenger conductor, who asked him what he was doing. It was hard, but he must share his secret, so he told the conductor of his find, and by the light of a match showed him the glistening dirt. The conductor was electrified, and offered to help him sack and hide it for half. Abe was compelled to acquiesce, and together they filled half a dozen sacks, which they carried across the creek to a deserted log cabin for safe keeping. This was no light task and they were two pretty tired men when it was finished, but nevertheless they sat up late planning and making arrangements to be relieved of their railroad duties, so as to give all their time to the development of their fortune, and not until they had washed out a quantity of the filings and taken them to a bank for sale, did they fully realize what "tenderfeet" they were.

---

During an examination of engineers and firemen on a Western road, one of those ultra-practical engineers who scorns "book larnin'" to the extent that the book of rules is to him a delusion and a snare, was asked by the examining committee "When the train is running, what do three taps of the signal-bell signify?" The man colored, squirmed, scratched his head and answered "If I was on my engine I'd know!"

---

"Say, Rogers, wheredidger git the black eye?" asked Pomeroy

"Why, that's a birthmark!"

"Birthmark birthmark? Well, it's funny I never noticed it—funny-looking birthmark. What-de-ee think caused it?"

"I got into the wrong berth on the B. & O. last week."

# Cast Steel Works of FRIED. KRUPP, ESSEN, Germany.

**Represented by THOMAS PROSSER & SON, 15 GOLD ST., NEW YORK.**

These works cover an area of 1,200 acres, employ about 18,000 men, have the most improved plant, and stand unique, from the fact that they have their own Ore and Coal Mines, Blast Furnaces, etc., and that *every* stage of manufacture is under their own supervision, and are not (like others) dependent on the open market for a miscellaneous assortment of crude material; which, in connection with 75 years' experience, enables them to turn out a product of a very superior quality, second to none, and at the same time the different grades of Steel are always of the *same uniform* quality.

**Locomotive Tires, Crank Pins, Piston Rods, Spring Steel, Steel-Tired Wheels, Etc.**

After a test of over 25 years the "KRUPP TIRE" has proved itself the best in the market. If a reliable article is wanted, which will give satisfaction, get KRUPP'S.

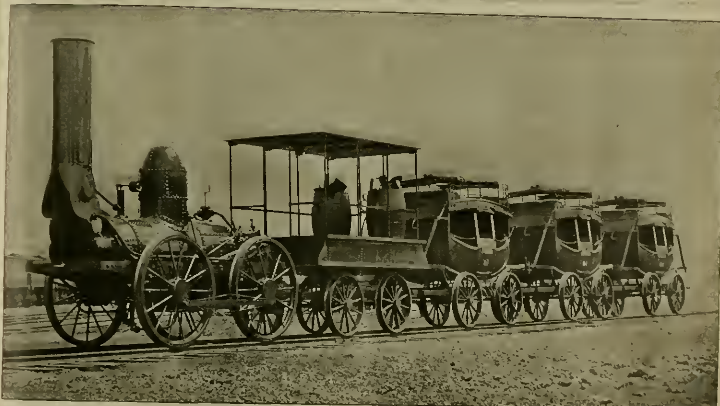
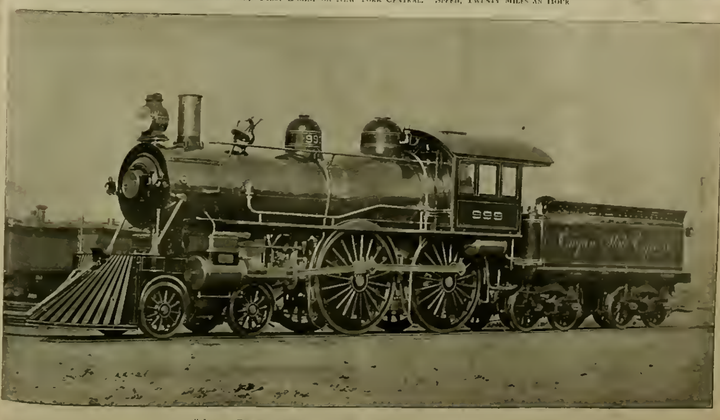
## A Practical Journal of Railway Motive Power and Rolling Stock

VOL. VI, No. 6. NEW YORK, JUNE, 1893. 20 Cts. Monthly $2.00 Per Year.



"De Witt Clinton," First Engine on New York Central. Speed, Twenty Miles an Hour



"999," Latest Engine on New York Central. Speed, One Hundred Miles an Hour

### The Fastest Locomotive in the World.

In our last issue we gave an illustration of the New York Central's engine "999," built for exhibition at the Columbian World's Fair. In presenting the picture of the engine we spoke of her as a splendid specimen of excellent workmanship that we consider the highest development of a fast and powerful locomotive; a machine combining power and speed that could be pushed to a velocity of 100 miles an hour, if such velocity was not beyond the capacity of a steam locomotive. We illustrate the engine again in larger form, so that our readers may form an idea of how the locomotive looks that has made the highest speed of any engine that there is a record of, and did it pulling a regular train.

For a week or two before being sent to the Fair, engine "999" was run on various trains to demonstrate her power and speed. On May 9th she took the Empire State Express clear through from New York to Buffalo, a distance of 440 miles, on time. The train was 28 minutes late on leaving Rochester and it is claimed the run of 69 miles from there to Buffalo was made in 68 minutes, and one mile was made in 35 seconds, being at the rate of 102.8 miles per hour. The train consisted of four cars, the weight being 362,000 pounds. On another run, passengers in the train claimed that one mile was made in 32 seconds, which is over 112 miles an hour. These claims of terrific speed are not official and we do not believe that the engine ran 100 miles an hour, but has probably made the highest speed of any locomotive in the world.

Engine "999," as will be seen by the engraving, is an eight-wheel engine, standing remarkably high on her wheels, and of plain, though extremely handsome, appearance. The cylinders are 19 x 24 inches, the valves are Richardson balanced, and the driving-wheels 86 inches diameter, the tires being 3½ inches thick and 5½ inches wide, secured to cast-iron centers by Mansell retaining rings. The rigid wheel base is 8 feet 6 inches, the total wheel base being 23 feet 11 inches. The engine truck wheels are 40 inches diameter, with cast-iron spoke centers, and tires also secured by the Mansell retaining rings. The weight on the four driving-wheels loaded is 84,000 pounds, and on engine truck 40,000 pounds. The boiler is of the wagon top style, 58 inches diameter at the smallest ring, and has 268 two-inch flues 12 feet long. The firebox is 108 inches long by 40⅛ inches wide, set above the frames, and has the Buchanan water-arch. The grate area is 30.7 square feet and the total heating surface of the boiler is 1,930 square feet, 232.92 square feet of that being in the firebox. The boiler has an extended smokebox, and is fitted up with a deflector and perforated steel plate spark arrester. The exhaust nozzles are double 1½ inches diameter. Steel is used throughout for boiler and firebox, and a pressure of 190 pounds per square inch is carried. Remarkably large bearing surfaces are used throughout, the driving-boxes being 9 x 12½ inches, the engine truck-boxes 6¼ x 10 inches, and the tender-boxes 4½ x 8 inches. Ajax metal is employed for all bearings and has given remarkably good satisfaction, the engine having started and run cool from the beginning. After making the unparalleled run of 440 miles without a break, the bearings were all perfectly cool, no water having been used upon them.

The tender has a coal capacity of 6⅞ tons and carries 3,587 gallons of water and is fitted with a water scoop. It is carried on two four-wheeled trucks, each with 4 feet 5 inches wheel base and cast-iron wheel centers, and steel tires secured by Mansell retaining rings. The weight loaded is 80,000 pounds, making the total weight of engine and tender 204,000 pounds. The engine and tender are fitted with the Westinghouse quick-action automatic air-brake and signal. Monitor injectors are employed and Nathan sight-feed lubricators. The engine rides like a drawing-room coach and steams remarkably well.

### Southern Relics at the World's Fair.

The Illinois Central Railroad Co. exhibit at the World's Fair a curious old locomotive called the "Mississippi." The engine was built in 1834, and looks like a class built by the Stephensons at that time, many of which were sent to this country. After a careful study of the engine, we came to the conclusion that she was like the boy's knife which had several times got new blades and new handles. The boiler looks modern, the cylinders were certainly made in this country and she has a link motion. The cylinders are 9½ x 16, and the wheels about 40 inches diameter. She was for three years on the Natchez & Hamburg Railway, from 1836–38. The last service she did was on the Meridian, Brookhaven & Natchez, which is now controlled by the Illinois Central. Some time in the year 1868, the engine was carried away by a flood and was buried in the debris, where she lay for ten years, and was then resurrected to go into service. She is a curious looking relic and well worthy of inspection.

Some other kindred relics are shown beside the engine in the form of strap rails, that were used on the road where the "Mississippi" first ran. They were rolled in England and were of the usual form of rail used at that time.

The Western & Atlantic Railway of Georgia have sent their famous historical engine "General" to the Fair. She looks quite modern beside many of the antiquities to be found in her neighborhood.

In our last issue the types made us say that C. S. Hull was superintendent of the Cumberland Valley road, when we knew perfectly well that Mr. Hull was the draughtsman, and not the superintendent.

John Hickey,
President American Railway Master Mechanics Association. Supt. M. P., No. Pacific Ry.

E. W. Grieves,
President Master Car Builders' Association.
M. C. B., B. & O. Ry.

### More Anent the "Utility."

The sight of the old war engine "Utility" in the pages of LOCOMOTIVE ENGINEERING brought up memories of the days of his youth to Mr. George W. Cushing, well known for years as the chief of the motive power departments of one or another of our largest railroads.

Mr. Cushing was an apprentice boy at Seth Wilmarth's shop in Boston before the "Utility" was built; he was then nineteen years old, and far enough along with his trade at the time she came out to be entrusted with the job of setting her up.

When she was ready for service Mr. Cushing was sent out to run her at her trial trips. It was the first time he had ever run an engine, but those were the days when "machinist runners" were about all the kind there were.

Mr. Cushing afterwards earned his bread by running a locomotive, and slowly, step by step, went up to the top of his profession.

He supposed the "Utility" long ago dead, but seeing her picture and being assured of her present healthy and useful old age, was like finding an old schoolmate in a soldiers' home.

### A Griggs Engine.

The New York, New Haven & Hartford Railway Co. exhibit at the World's Fair one of the best of the Old Colony locomotives and a handsome day coach, both designed and built by the superintendent of machinery, J. N. Lauder. They have also an historical engine built by G. S. Griggs, in 1858. This engine was as much noted in her time for the progressive ideas embraced and for the remarkable work done as the New York Central's "999" is to-day. Beside her, there is one of the first form of coaches used on the road, the body being the same as the old style stage coach.

We have received from the Standard Steel Works of Philadelphia, a very handsome illustrated catalogue giving various views of the works and showing specimens of the steel tires, wrought iron wheel centers and other castings made by the company. The views are mostly half-tone engravings and are as fine specimens of this art as we have ever seen. Persons interested in wheels and tires will find valuable information in this catalogue and the artistic work to be found in the book will make it an attractive addition to the desks of railroad men.

### Some Frauds in the Watch Business—How Railroad Men are often Imposed upon.

BY JOHN J. MCGRANE.

When a man is sick he usually sends for another man who is said to be a physician, and puts his liver, or his lungs or his larynx into his hands—in fact, leaves it to the other fellow to take his choice and to try and get his disarranged anatomy into working order again. The sick man does this because he knows more about something else than he does about livers, lights or gizzards and their ailments. Man at this age is a specialist; he knows considerable about one or two things, and a little about other things. He leaves law to the lawyer, physic to the doctor, sewers to the plumber and hash to the boarding-house. He makes a specialty of, well, say firing and running locomotives.

When the road wants engineers it don't hunt for shoemakers and cotton pickers (except in case of a strike). There is no doubt that an unscrupulous lawyer, doctor or shoemaker can and does deceive his customers—he knows how to do it. When an engineer who, maybe knows ever so much about locomotives, takes his hundred-dollar watch to the jeweler, he puts himself and the watch at the mercy of that jeweler. If the watch has stopped and the watchmaker (?) screws a magnifying glass into his eye, looks into the bowels of the movement, shakes his head seriously, and says "You must have given this watch a hard jar—the staff is broken."

There is nothing for the owner to do but say:

"Is that so? Well, you put it in running order and give me something to carry and, mind, I want a good one, for my life depends on its being right."

Oh, yes, there *is* something else to do. There is $3.50 to pay for a *new staff*—made by cleaning the watch.

Two railroad engineers known to the writer once took a new watch to four different jewelers to examine. The watch was all right except that the hands crossed and caught, and it was run down, and they knew it. The three first men were the jewelers who did the largest railroad trade in town. The first one pronounced the staff broken. The second one said a jewel was cracked. The third said the watch was simply so dirty that it couldn't run. The fourth was an old man, a Hebrew, very much distrusted by "the boys." He was a splendid watch repairer, but there had been stories told about his taking jewels out of watches and substituting glass, the boys took the watch to him. He screwed his glass in his eye, looked in the works, shook the watch, wound it up, shut the case, looked at the face, opened it and bent one of the hands up, set them right, and said: "Poys, maypee she vould co badder if you wind him oupp." He was an honest man—the others were rogues.

All this is small potatoes, however, it's when the engineer goes to *buy* a watch that they lay for him and do him up. The average engineer and fireman knows nothing about watches, but he knows that the Compound or Express Train or some other movement has given the very best of satisfaction to some friend of his, so he says he guesses maybe he'll take one of them. Perhaps he has seen the advertisement of some watch firm's pet movement and determines to have one. The jeweler may not have the one he wants in stock, or may not make so much on one of these as he would on another make, so he says

"I should think you'd want a better watch than that, you know things have improved. What was a first-class watch ten years ago, is no good now; why, ten years ago I got $40 for that movement, it's worth $18 now. Now, here is something fine, there ain't no finer. That's full jeweled; patent regulator, dust proof; safety pinion, adjusted to heat, cold and position, etc., etc." He goes on to point out alleged points of superiority and ends by selling the watch. If he can't soak the victim on the movement he gets even on the case.

"Full jeweled," may mean several things, there must be at least 15 jewels to come under the head. Some full jeweled watches (so called) have 15 jewels, some 16, 17. The three general grades are 7 jewel, 11 jewel and full jeweled. The 7 jewel movements are of the cheapest class. The most important points are jeweled. Generally but one jewel is visible, and that is on the bridge—the one over the balance. Any movement of this class should never retail at more than $7. The 11 jewel movements are a better grade and all the essential points are jeweled; it is hard for a novice to tell this movement from a better one. Most of them have jewels on top while the other end of the shafts run in brass holes—even a watchmaker has to take a movement down to be sure of this. In an 11-jewel movement there are generally four jewels in sight; these are in a row around and under the balance and one on bridge. No 11-jewel movement is worth more than $9 at retail. Full jeweled movements all have five jewels in sight on the back or top plate, four on plate and one on bridge.

There are two kinds of jewel settings; one where the jewel is set in the plate, and one where a separate setting holds the jewel while itself is held in the plate by two screws.

While on this subject I might add that the idea that a watchmaker would have any incentive to rob a watch movement of its jewels is folly. Jewels are usually garnets and each one costs less than the cost of setting it.

There are very few watches of any grade worth considering that do not have the safety pinion, a simple device to prevent the ruin of the movement incident to the breaking of the main spring.

The word "adjusted" as applied to most watches nowadays means very little. Any watch that is regulated may be called adjusted. When the balance is poised by adjusting screws it may be called adjusted. A watch adjusted to heat and cold generally means a balance wheel cut open at two points; one-half of it composed of steel, the other half of brass, so put together that the contraction and expansion from the changes in temperature do not change the size of the wheel—one of the metals expands more than the other; one offsets the error the other would make. The position of the screws in the rim of balance also plays an important part in the adjustment. Adjusted to position means considerable. It means the regulation of the watch in several different positions for days and weeks at a time; great care and close regulation. Adjusted to heat, cold and position, means considerable, and if properly done is expensive. Adjusted for isochronism means a great deal and is a subject that even the makers of fine watches let alone as much as possible. Isochronism means that the long and short arcs of vibration made by the balance wheel are of the same duration of time so that a watch runs the same when wound up or nearly run down.

Perhaps the intricate looking patent regulator has cost the boys more than any other one thing. There are dozens of these of all kinds and shapes. The argument that in jumping off an engine, etc., you can't move the regulator accidentally, generally clinches the sale of a watch with one on. They are a good thing, but add nothing to the time keeping qualities of a watch. The highest priced watch in the world—the *Jurgensen*, has a plain regulator and it is a good one.

The magnetism of watches was thought very little of and caused very little trouble until the advent of the modern dynamo and introduction of heavily charged currents of electricity. Many thousands of dollars have been paid by railroad men for non-magnetic shields, guards, charms and liver-pads; and, as far as real protection from magnetizing a watch by a strong current of electricity is concerned, the owner might as well have said a charm or put a drop of witch-hazel on the back case. A practical demonstration can easily be made with any of these things. Ninety per cent. of our best watches can be stopped dead with a three-inch magnet outside the case. There is only one really non-magnetic watch and that is one having in it the Paillard spring and balance. These are made of a metal entirely non-magnetic, and, strangely enough, the inventor was not hunting for that when he experimented with the different metals.

Paillard was a watchmaker at Rio Janeiro, Brazil, who made a specialty of marine chronometers. In the damp and hot climate of the tropics, steel springs will rust in a week so as to be useless. Paillard was hunting for a metal that he could use in place of steel for springs, balances and other parts of chronometers and when he had found the alloy desired, it was discovered accidentally that it was also non magnetic. Watches and clocks made by him seventeen years ago are still running and giving satisfaction. Many a watch with Paillard's balance and spring have been condemned by ignorant jewelers, because they did not understand what they were—didn't want to make an effort to find out, and didn't want to have anything new around, anyway—just as some old-timers want a pump instead of an injector. When anything is wrong with a Paillard watch, it is more liable to be in the works than in the metal the spring and balance are made of. A watch with this improvement is as cheap as any other, grade for grade, with the added advantage of absolute protection from magnetic influence.

Good watches should be kept away from dynamos or heavy currents of electricity, yet it is hard to tell when and what caused a watch to get magnetized. The usual symptoms of a light case is the gaining of time. The fine hairspring becoming magnetized, the coils stick together, thus shortening the spring, causing the watch to run faster.

Watches can be de-magnetized—but it's like inflammatory rheumatism—you're always afraid it will come back.

Don't let anybody take the gold cap, or inside case, out of your watch and put an iron "preventer" in its place, keep the cap, and charge you $5 beside. It will be just as liable to prevent small-pox or catarrh and no more so.

Another catchpenny improvement (?) is the stem-set. This scheme is handy, as it admits of the setting of the hands without opening the case, but it is a dangerous thing for railroad men, as one is very liable to get hold of the crown of the stem in taking the watch out of the pocket and pull out the "set," letting the hands stand still or fall out of place. The lever set, where you have to pull out a stop and replace it before you can close the case, is simple, safe and sure. Don't take any other, or if you do, watch it close, it's a loop-hole for a calamity.

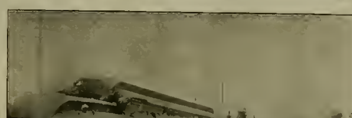
A man running a locomotive cannot afford to be without a first-class watch. A fifty-dollar movement is cheap enough. Require that any watch you buy must run within three-quarters of a minute per month of correct time. Most roads require a less variation than half a minute per week. Get a guarantee for this service. Don't attempt to regulate the watch at all, don't even open the case. Wind it regularly and let the jeweler do the regulating, and once right don't change it for a slight lapse—maybe you forgot to wind it for some hours, and be sure what you set your watch by.

Have your watch cleaned and oiled once every year-and-a-half or oftener. Think of the thousands of thousands of revolutions the shafts make at one oiling. If you could do as well with your engine the road would pay a dividend next Thursday.

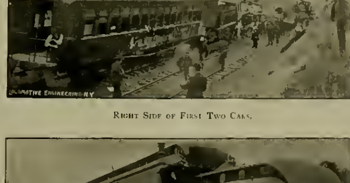
One of the latest improvements in fine watches is the double roller escapement. This is a safety device to save the fraction of a second—just as the emergency valve in the air-brake is for saving a fraction of time in an emergency case. The fork of the lever goes over a very fine ruby pin on a flange under the balance wheel, this moves the lever back and forth as the balance oscillates and regulates the running down of the main spring. Should a very quick jar be given the watch just at the right time and in just the right direction, the balance may be made to momentarily stop or move a little too far. Here is where the double roller comes in, counteracting the effect and keeping the watch to its regular rate.

The above is not written for the eyes of watchmakers, if it was I should have had to go more carefully into details and address my readers in technical terms. This is written with a view to giving the railroad men of the country a few straight pointers, and perhaps put them right when buying a watch. If it shall save one from being imposed upon, or imposing on himself, its object will have been attained.

THE SILVER CREEK WRECK AND ITS LESSON IN CAR CONSTRUCTION. THE HEAD END.



RIGHT SIDE OF FIRST TWO CARS.



LEFT SIDE. TWENTY-THREE KILLED.

Those attending the World's Fair will do well to examine the exhibit of the Ashcroft Manufacturing Co., which will be found in the Machinery Building, section 25, column K, 24-25, main center aisle. It is the largest and most complete exhibit in this line to be seen in the Columbian exhibition. It contains a great variety of pressure and vacuum gauges, beautiful specimens of the Tabor indicator, pipe and gas fitters' tools and other specialties well worthy of examination.

We are under obligations to Eugene V. Debs for a bound volume of the *Locomotive Fireman's Magazine* for 1892. This publication stands at the head of all the "official organs." The new dress for 1893 puts the *Magazine* on a level, typographically, with the best of the magazines.

### Locomotive "Director-General."

The annexed illustration shows the locomotive "Director-General," built by the Baldwin Locomotive Works for the Baltimore & Ohio, and exhibited in the World's Fair at the head of the "Royal Blue" train. The engine is painted to harmonize with the train and has a very handsome appearance. She is compound, with two high-pressure cylinders, 13½ inches, and two low-pressure cylinders, 23 inches diameter and 24 inches stroke. The driving wheels are 78 inches diameter. The boiler is straight, 60⅝ inches diameter at smallest ring and has a firebox 107 x 34 inches. The grate area is 24¾ square feet and there is a total heating surface of 1,693 square feet.

BALDWIN COMPOUND FOR B. & O. RAILWAY. NOW AT WORLD'S FAIR.

### Brazilian Compound Locomotive.

The locomotive shown is a narrow-gauge compound built by the Baldwin Locomotive Works for a railway in Brazil and exhibited at the World's Fair. The principal dimensions are: Cylinders—H. P. 9 inches, L. P. 15 inches diameter, stroke 20 inches. Driving wheels, 49¾ inches outside diameter. Boiler, 45½ inches diameter, with a total heating surface of 861 square feet. The total weight of the engine is 58,320 pounds.

BRAZILIAN GOVERNMENT METER-GAUGE PASSENGER ENGINE. NOW AT WORLD'S FAIR.

The Pennsylvania R. R. Co. appear to be in an unusually fortunate condition this spring as far as the track is concerned, for the management have issued orders reducing the expense of track work. Nearly all other railroads are increasing their force to repair the ravages of a peculiarly hard winter. The heavy locomotives and cars that are becoming the rule make sad havoc of the soft railroad beds that most of our railroads have. How the trains are run safely over some roads is a mystery. There is a growing demand for stone ballast, and it is becoming apparent that nothing else will keep the track out of the mud.

Mr. Frank Hedley, for several years master mechanic of the Kings County Elevated Railroad of Brooklyn, has been appointed superintendent of machinery of the Lake Street Elevated Railroad of Chicago. Mr. Hedley rose to be general foreman of the Manhattan Elevated Railroad shops and is an excellent mechanic and executive officer.

### Wanted—A Jag Cure for Chronic Inventors.

BY JOHN ALEXANDER.

I once asked my friend Hank Colvin if he had ever drank whisky or used opium to excess.

"No," said he, "but I've invented a balanced valve."

Sitting last night, as I am prone to do, on the very masthead of fame (Selah), and dropping the sounding-line of remembrance in the wake of my long voyage of experience, I evolved a scheme for making myself famous. I'm going to ask the government to establish life-saving stations to prevent inventors (?) from imposing upon themselves—and others.

I am going to ask my Uncle Samuel to do something *for* the real inventor and do something *to* the imitator—the man who makes something *different* and then puts on a medal, calling himself an inventor.

Now, I am not a pure, white soul, standing on a virgin cloud, pointing out the straight and narrow way. Like the widow, "I've been there, many times before"—I'm an awful example myself.

I used to think I was an inventor, but, bless you, my children, that was ever so long ago.

I'm cured now, and, like the man who had the catarrh, I am willing to publish my picture just to show what a really *awful* example I am.

But, talking seriously now, this inventing (?) fever has got to be isolated—it's as catching as fleas.

Railroads suffer a great deal from the disease. Many a man—engineer, machinist, fireman, or master mechanic—has cost his company thousands of dollars in experimenting on a patent. If, say, the man is an engineer, and don't use an ounce of the company's material, he takes from the company his intelligent services, which they pay for and he should deliver. A man can't think about his orders when his head is so full of his own valve motion that the wimble-rods and gill-cranks are sticking out of his hair.

Some roads breed this kind of inventor—imitator—by encouraging their master mechanic or superintendent of motive power to make something that will "get around" some patent of merit that they want to use—and ought to pay for.

Most of us go at it of ourselves. It's like prospecting—some one digs a hole in the ground (because he has studied the locality and the indications) and strikes pay-dirt; then every mother's son in sight or hearing goes out and imitates the digger—they make a hole in the ground, and, as a rule, that's all.

The piston-valve craze is the small-pox of inventive diseases. It's as common as dirt and always pits the pocketbook If the ark had motive power controlled by a piston-valve she would have hit bottom long before she did. Just as quick as a fireman is told what a load the slide valve carries, he commences to scheme up a contraption to carry it. All at once the piston idea suggests itself, and he goes off by himself and plans it out—there's been 900 invented, all just alike. Piston valves come, work awhile, then crawl into their holes and die, while the wasteful slide keeps sawing wood at the old stand. It may not be balanced or have a port longer than the moral law, but, at the same time, it didn't inherit scrofula and quick consumption.

The balanced-valve fever—putting hats, caps, or overcoats on plain valves—is in the nature of chicken-pox; the rash breaks out early, sees that it is nothing more than a second-hand, common sort of rash, anyway—and sneaks back.

The gauge-cock fever is local, severe, but not dangerous.

Spark-arrester invention is usually accompanied by chills—to the boiler.

Air-brake inventors are always sanguine, even in the worst cases. Their mania is to get something *different*—and they always get it During convalescence patient has fits of generosity—usually wants to become a benefactor to mankind in general and the Westinghouse Company in particular. Only want a mere pittance of a few hundred thousand for their particular deformity—want the world to have the rest. Usually leaves patient morose, and may lead to settled melancholy or hallucination, cases have been known where patient imagined himself a saviour out of a job Nobody wanted him to save life and limb with a brake-gear that could "stop a train instantly." It's funny how the mechanical world, after years of experience, have become conservative and want to stop slow.

I won't dwell on the car-coupler man seeking for a new device. He is a poor unfortunate for whom nothing can be done He should be placed in the incurable ward, treated kindly, but firmly, bathed frequently, and allowed to exhibit a model of his device and explain its merits —to some other inmate of the ward.

Valve motion is the cholera of inventive diseases. It strikes quick, and a large per cent. of the cases are fatal. Little or nothing can be done, except to dispose of the remains. In this disease prevention is everything—there is no cure. The very best preventative is knowledge of the merits and demerits of the very efficient valve motion that is condemned.

A few kindergarten lessons illustrating in some simple way the fact that a desirable Corliss engine card is not a desirable locomotive card; that the link motion admits of the use of large cylinders necessary to the starting of trains, and then, in effect, makes them smaller when the links are hooked up. Explain that this is done by compression, which takes the heel off the card at the expense of power, but gives this back again in filling clearance spaces, keeping up heat in the walls of the cylinder and in a higher initial pressure. Thoroughly impress upon the patient's mind that all of this is a good thing, and that a substitute for the link *that won't do just what the link does* will be a bad thing for the locomotive.

If railroad companies would chip in and pay for the making of good engravings of all the still-born thing-im-bobs ever designed to take the place of the link and post up a copy in each roundhouse in the land, with a line of large, plain, red letters reading, "Is yours like any of these?" it might save the company money and would certainly let some inventors (?) sleep

Doing something with the heat in the front end is a favorite disease. It has several stages. one of them is where they are going to heat the feed water; in another they are going to heat cars, and in both they are sure to give the boiler the ague.

The independent water arch and circulator is a Baptist invention—it does more than sprinkle.

The diseases are legion and the cures simple, but hard for the patient to take.

One of the evils of the invention mania is the ease with which one may get a patent. A patent means nothing—I will bet my reputation against the pension roll that I can get a patent on the complexion of a hot pin—if they won't grant it on the color of the pin they will on the combination of the pin with the complexion or application to this form or that "herein as substantially set forth, etc., etc." There are patent agencies that will get *some kind* of a patent on anything If this is not stealing from the poor I wouldn't know a charity if I found one dead in the street. Between the shark who gets a patent for a fee in advance and the one who proposes to sell one on the same terms, the inventor is held up and robbed to a queen's taste.

There are one or two fundamental principles—I wish they were laws—in inventing, that once understood and heeded keep a man from committing homicide, parricide, suicide or foolicide in this particular way.

One of these is the difference between invention and imitation. A man who first thinks of a thing and makes one is an inventor, a man who sees that thing and at once makes one a little different is not—he may be an improver, but he is not the inventor. Gutenberg wouldn't know the font of type this article is set in from a peck of shoe-pegs, but he is the inventor of movable types just the same. He's the old, original inventor; all others come after.

Babbit was the inventor of the anti-friction alloy that bears his name. "Smith's" babbit metal, and the "Original," the "Eureka" and "Genuine" babbits are not inventions.

If Jones invents an injector that throws water by using smoke, and Smith changes the pattern and design so as to cheapen the cost of producing the injector, it don't change the fact that it's Jones' injector, and all Smith can claim is improvements. Yet both may have done good.

When Timpkins invents a tire fastener that holds the tire on with glue and four bolts it's an invention, perhaps, and Timpkins deserves the credit, but when the general manager of the G. R. A. & B. road sees it and fastens his tire with mucilage and four rivets there is mighty little invention to it. If it isn't Timpkin's fastener it's nobody's—preferably the latter.

I don't believe that 10 per cent. of the men who are wracking their brains to-day trying to invent something to sell to railroads, know what has already been done in the same line or can tell the *advantages* as well as the disadvantages of the device they want to supplant.

A good many of these railroad inventions are made at the wrong end to be real improvements. I suppose that the amputation of the old, plain slide feet of the Esquimaux and the substitution of wooden shanks would prevent cold feet—but the Esquimaux aforesaid would rather wear fur boots any day.

When you think you have thought of something new and useful *don't* write to a patent agency. Write to some newspaper in that line, get reports of societies, consult railroad men and hunt up all the *facts*; see what has been done, what is wanted and what not wanted—you will probably find your invention (?) properly labeled in the Patent Office as of the vintage of '57. Invent something before you patent it.

If I can only get an institute established where they will give unfortunates addicted to the patenting habit a few jabs of bichloride of information, I think that posterity would give me credit for making one blade of inventor grass grow where formerly there were two—to say nothing of sprouts and suckers

Taking Indicator Diagrams on a Swedish Locomotive.

### Exhibit of the London & Northwestern Railway.

[EDITORIAL CORRESPONDENCE.]

The London & Northwestern Railway's exhibit at the World's Fair attracts extraordinary attention, not only on account of the novelty in appearance of engine and cars, but on account of the elaborate finish put upon every part. Nothing in the Fair compares in finish with the compound locomotive "Queen Empress." All the iron and steel parts exposed are highly polished and the painted parts are polished in a style equal to the finest cabinet work to be seen anywhere, even the inside of smokebox has the pipes painted and varnished, and the tube-plate and the sides of the box are a snowy whiteness. The engine is by no means ornate, being painted a dark blue, with very few red stripings, and edgings of light green.

The engine has two pairs of driving-wheels, the front pair being driven by the low-pressure cylinder through a crank-axle, the hind pair being driven by high-pressure cylinders In this engine there is a novelty of construction, as regards other compounds, in the fact that the high-pressure cylinders are set ahead of the front pair of drivers, the reach to the hind drivers being made by means of unusually long piston-rods. Another novelty about the engine is that a link motion is used for the high-pressure cylinders, the low-pressure cylinder having the steam distributed by a shifting eccentric. The high-pressure cylinders are 15 inches in diameter with a 24-inch stroke, while the low-pressure cylinder is 30 inches in diameter with the same stroke. Both pairs of driving-wheels are seven (7) feet and one (1) inch in diameter. Fixed wheel base of engine is eight (8) feet and three (3) inches. Total wheel-base, 23 feet and 8 inches, total weight in working order, 52 tons and 200 pounds.

LONDON AND NORTHWESTERN CARS.

The sleeping car is 42 feet long, carried on two four-wheeled trucks, the wheels having wooden centers and steel tires. The composite day carriage is of the well-known English type, with running boards on the outside, but has only two entrance doors. The upper part of the cars is painted white relieved with gold and brown moldings, the lower part is painted white relieved in gold, the whole being beautifully polished. The under frame is of iron.

The sleeping car consists of four staterooms, two containing two, and the other two containing four berths each Each compartment is provided with its own lavatory accommodations, and each compartment is also fitted up with electric communication. The panels are finished in walnut with sycamore centers and satin wood, and the lavatory compartments are finished in bird's-eye maple. Underneath the berths there is a long wardrobe adapted for holding the clothes of the occupants. The upholstering is dark-figured plush, and the carriage is heated by gas. In the center of the carriage is a smoking compartment, fitted with folding tables and easy chairs, this room is finished in walnut and satin wood, and presents a very striking appearance. Connection between the two ends of the car is obtained by means of a side aisle.

The composite carriage, in exterior, finish and build, is very much the same as the sleeping car, only less elaborate. It contains two third, one second and one first-class compartment, with lavatory accommodations to each. The difference in the different compartments is entirely in the finish, all being cushioned and well upholstered. This car represents the ordinary day coach of the London & Northwestern. It has one compartment for the storage of baggage. The coaches are fitted up with the vacuum and Westinghouse brake. The other parts of this interesting exhibit we will describe elsewhere in the paper. A. S.

### Good and Bad Views of the World's Fair.

A great many people have gone to visit the World's Fair with the idea of scoffing at what they saw, and returned to give unstinted praise. No person with common sense can walk around the magnificent "White City," as the people of Chicago delight to call the Fair buildings, without being impressed with the wonderful character of the exhibit. After spending ten days in the place, which was shorn of many of its attractions owing to its unfinished condition, we have nothing to say but words of unqualified commendation for the Exposition in itself. It is a place that every intelligent man, woman and child in the country ought to see, for they will have small likelihood of ever being able to witness such a spectacle again, and it is certain that no one has ever seen such an affair before.

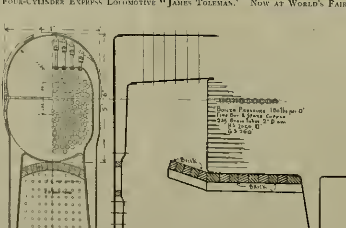
While feeling enthusiastic over the wonderful exhibition, we found many things about the place and about the city of Chicago to dampen our ardor. The exhibition would be likely to give a greater amount of pleasure to a greater number if it were not for the drawback that so many people in the Fair and in Chicago look upon it as an opportunity for making their fortune. We have never been in a city where special attraction drew great crowds of people without finding more or less extortion going on; but Chicago people and privileged persons in the Fair are showing examples of unscrupulous dealings such as the world has never seen before, not even at a political convention. Chicago and the Fair appear to have a great deal of human genius of a certain order—of the order that excels in inventing new and original methods for taking advantage of visitors under the guise of legal exactions. The people of Chicago display much sensitiveness to criticisms of the charges going on inside and outside the Fair, yet their own journals make the evil a continual object of denunciation. Unfortunately this does not seem to mend matters any.

It would take too much space for us to enumerate the large and small exactions that visitors will encounter in the Fair and the city of Chicago, but we would like to say a word about the hotel and restaurant charges. We should advise railroad men visiting the Fair to follow the practice which was so common in the Paris Exposition, of taking their lunches with them. Those who are able to do this will be likely to save themselves from annoyance. Not that there is any deficiency of eating places in the Fair grounds. We were in the Fair nine days and went to a different restaurant every time. This gave us considerable experience. When railroading in frontier regions we have often had worse meals than we found in the Fair, but then we did not look for places to be run like Delmonico's out on the plains. One can get a very satisfactory meal in most of the Fair restaurants, but the charges cannot be called moderate when they are considered in the light of the victuals eaten. Travelers do not generally object to paying seventy-five cents for a lunch; but when a lunch which can be bought ordinarily for twenty cents, is charged at the higher sum, there is cause for complaint, not to say protest, in more or less picturesque language.

The hotels and boarding-houses of Chicago appear to be following a very near-sighted policy in their charges. It was natural that the prices should be a little high, because there was the opportunity for exaction. There is no fairness or justice in raising prices because there is an unusual rush of business. It would be just as fair for railroads to raise their rates at this time as it is for hotel people to do so. There are howlings already to be heard because railroad companies are not cutting the rates in two, while everybody else is increasing charges. We will cite an instance to show how hotel charges have been raised. We have been in the habit of staying at the Great Northern Hotel, and have a right to be considered a regular customer. That hotel had been for months becoming a resort for railroad men. When we went to secure a room there during our last visit we found that the rates were just doubled. The effect of this was the driving away of all the railroad men who were in the habit of going to that hotel, and we heard a great deal of indignation expressed at what was justly considered unfair treatment. If this does not cease to be a resort of railroad men we greatly mistake the temper of those concerned. We understand that the Grand Pacific did not alter their rates for old customers, and that several of the more respectable hotels adopted the same policy, although there were exceptions, the Auditorium being one that ignored all past connections.

There are two things that we would advise our readers to do when going to Chicago. They should take a well-filled purse along, and ascertain carefully the charges at the hotel or boarding house where they propose to stay. The supply of accommodations for visitors appears to be beyond what the demand will be likely to reach, and we are greatly mistaken if the natural law of supply and demand does not cause a bad break in prices before the season is far advanced. Then people a little short of being millionaires will be able to go to Chicago and return without being utterly fleeced.

Four-Cylinder Express Locomotive "James Toleman." Now at World's Fair.



Details of Boiler, "James Toleman."

### A Curious Accident.

One of the great decapods on the Erie met with a curious accident the other night. She went out to push a train up the hill from Port Jervis. One of her forward sand-boxes was filled and the other neglected. This caused her to catch on sand on one side only, and broke the side-rod between the two front pairs of wheels; one side letting go broke the other, and the first revolution the stub end of one rod flopped over against the saddle and chest and blocked that pair of wheels. The engineer could see or hear nothing wrong after the first noise, and went on pushing the train some ten or fifteen miles. When he let go the train and started to back up she made racket enough to call for an emergency stop—she had flat spots 14 inches long on her forward tires.

---

Business is so active with L. S. Starrett, of Athol, Mass., that he is building an addition of 160 x 40 feet for the manufacturing of milling cutters.

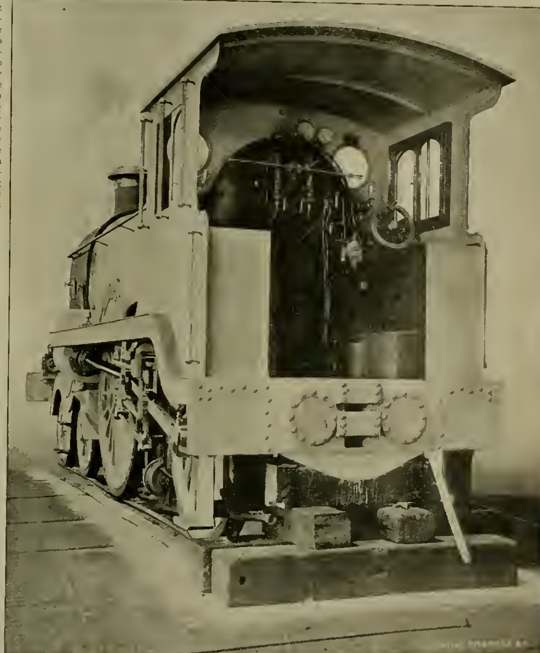
### The Locomotive "James Toleman."

The annexed illustrations show the locomotive "James Toleman," exhibited in the English section of the World's Fair. The engine is a very great novelty and attracts as much attention as anything found in the Transportation Building. The engine represents the ideas of an English mechanical engineer as to the best form of locomotive for handling fast heavy trains. She was designed by Mr. Winby, of London, and was built by Messrs. Hawthorn, Leslie & Co., the well-known locomotive builders of Newcastle, England. That the engine is very much different from ordinary locomotives is apparent to the most casual observer; but there are many novelties about the machine which can only be seen after a laborious examination. To obtain high speed and great power combined, two pairs of driving-wheels 90 inches diameter are employed, and they are each driven by two pairs of separate cylinders, the front drivers being driven by inside cylinders set under the smoke-box, and the back drivers by outside cylinders set back of the leading truck. The inside cylinders are 17 x 22 inches, and the outside cylinders 12½ x 24 inches. The valve gear for the inside cylinder is a shafting link motion, and that for the outside cylinders is Joy's motion. A striking point about the outside connection is the very long piston-rod employed to transmit the power from the cylinder to the main rod. The arrangement of cylinders and their connection obviates the use of parallel rods, which, in our opinion, is the principal real merit possessed by the engine.

To supply steam for four cylinders of the size used by this engine, a very large boiler was required and a peculiar plan was adopted to make the boiler narrow enough to go between the driving wheels and yet give room for a large number of the tubes. The boiler, as may be seen by the engraving, is narrowed at the middle of the horizontal diameter, and crossed stays are employed to bind the shell into this shape. The firebox is also of a peculiar shape, to provide a large grate area and not to unduly lengthen the boiler. The tube plate is extended back into the firebox, the lower part of the boiler shell being protected from the direct action of the fire gases by a lining of brick. The total grate area obtained by this means is 28 square feet. There are 235 two-inch tubes 14 feet 9¼ inches long, which provide 1,817.4 square feet of heating surface, while the firebox provides 182.6 square feet. This gives a total heating surface of 2,000 feet.

The engine is admirably equipped with apparatus for handling. She has a very simple form of steam reversing gear, which works simultaneously with a hand wheel. The Westinghouse quick-action brake is employed, and brake shoes are applied to all the driving wheels. These have also steam sanding devices.

The designer and English engineers generally agree that the engine has unparalleled tractive force, having 143.2 pounds per pound of steam pressure. This is high for an engine with 90-inch driving-wheels, but we have plenty of ten-wheel passenger engines with cylinders 20 x 24 inches and drivers 66 inches in diameter that have the same tractive force as the "John Toleman." The engine has about the same heating surface as Buchanan's large passenger engines, and we feel satisfied would be beaten by any of them in a race with a heavy train. The two pairs of cylinders represent a single pair of about 20½ x 24 inches, while the Buchanan engine has cylinders 19 x 24 inches. We believe that the extra friction due to the additional cylinders and their connections will take away the advantage that might be obtained from the greater cylinder capacity. After all, the measure of the capacity of a locomotive is the boiler, and Buchanan's boiler will be likely to make steam more freely than the odd arrangement of the "Toleman" boiler. The most fatal objection to the engine, however, is the complication of ports, and the difficulty is certain to be encountered in keeping the machine in good working order. The designer appears to have had no consideration whatever of the fact that repairs would have to be done very frequently to a locomotive pulling fast heavy trains. The engine is very handsome and displays admirable workmanship. She has large bearings and strong connections, and is a curiosity to examine; but we wouldn't like to have the duty of keeping a number of them in working order.



Looking into the Cab of the Locomotive "James Toleman."

### Curious Cause for Thinning of Firebox Sheets.

At the last meeting of the New York Railroad Club, Mr. Sampson Fox, the celebrated steel-maker, of Leeds, England, related a curious incident in the talk which he gave on steel plates.

He said that in the furnaces of some torpedo boats, where a very strong force draft was used, considerable trouble was experienced with the sheets failing by becoming thinned at local points. At first it was supposed that the intensely hot flame impinging on the plate, burned out the surface. On careful inspection being made, it was found, however, that the thinning took place on the water side of the sheet. Careful observation led to the knowledge that the damaged spots were at points where free access of air at the sides of the grates caused intensely hot jets of flame to strike. It was at first a mystery why the unusually hot flame should cause thinning to the inside of the plate instead of the outside. A careful investigation was made, and the conclusion arrived at that the flame was sufficiently hot to drive the water away from the sheet, and dissociate the steam into its original gases, which, of course, are hydrogen and oxygen. The hydrogen mixed with the steam, but the oxygen found a better affinity, and combined with the hot sheet, forming oxide of iron, and, of course, wearing away the material.

It would be interesting to find if failures of locomotive fireboxes have not been due to a similar cause. Some of our fireboxes certainly produce as energetic combustion as anything that can be found with forced upward draft. It may be, however, that the pull of the exhaust in the locomotive has not such a tendency to cause jets of flame to strike the side sheets. The remedy found for the trouble with the torpedo boat furnaces, was to put a bar around the grate, with a joint made air-tight inside, which prevented jets of air from passing up close to the side sheets.

### A Matter of Justice.

The Supreme Court of the United States has rendered a decision to the effect that a railroad employé cannot collect damages for an accident due to the carelessness of a fellow servant. This is a far-reaching decision, and is based on one of the most unjust laws in the statute book. The law originated at a time when every workman was familiar with the habits of his fellow workman, and could guard against careless and reckless habits. It is no more adapted to modern conditions of industry than any of the laws relating to obsolete institutions. Railroad men and everyone else engaged in dangerous occupations ought to combine to have the law changed. It was very much to the credit of one member of the Supreme Court that he not only differed from the judgment given, but wrote a very strong opinion on the other side.

The Tryon Investment Co., of this city, are putting out a sight-feed device for introducing kerosene oil into the feed-water of a locomotive, for the purpose of preventing scale. Their device is well known in stationary practice, where its success is unquestioned. Kerosene is absolutely safe and will not produce foaming.

## The New York Central Brake Trials.

The report of the tests made last September of freight train brakes at Karner, on the New York Central road, by P. H. Dudley, C. E., has been published.

This work is composed of sixty-seven large pages containing many tables and diagrams and overflows with details, that, to the ordinary railroad reader, covers up all the essential points that he wants to get at the worst.

We do not believe the report contains a single misstatement, but there are so many entirely superfluous ones, and they are so general—no comparisons drawn, no difference pointed out and no general summing up done—that, to say the least, the report is vague, unsatisfactory and disappointing. Still, it's a report "that will be liked by people who like that sort of thing."

The main object of the test was to determine the relative merits of the Westinghouse and the New York automatic brakes. Two trains of fifty cars each, all alike, all of one make and all of one age, were equipped with the two brake apparatus. The foundation brake, the main air-pipe, hose and fitting were alike on each train, and the engines were just alike except the numbers.

In emergency stopping tests the trains were run side by side at one speed, the brakes applied by a tripping device on the track and results noted. The engineers got their fifty cars each into good control, in all instances running at the same speed and in one instance passing the signal at exactly the speed asked for (thirty miles per hour) and this without instruments on engines to record speed.

Each train made four emergency stops, and among the mass of information we find that the average length traveled by the Westinghouse train before stopping was 360 feet and the average stops of the New York Brake train was 418¼ feet. This is in favor of the Westinghouse train of 58¼ feet or over 16 per cent. It is only fair to say, however, that there were break-in-twos in two of these tests, and that there was a difference in train-pipe pressure in one test, if corrections were made for these differences a still better showing would be made for the Westinghouse brake.

The shock at the rear end of a fifty-car train is a matter of great importance, and all railroad men who know anything about brakes, are aware that shocks are caused by slow application of brakes, the one next to engine going on first, then the next and so on, allowing the rear cars to strike those ahead.

In these emergency stops, the average shock recorded by the slideometer on the Westinghouse train was 2¾ inches, that of New York 28¼ inches. The reason of this was told by record of the standing tests.

In this test each train was divided in half and the two halves placed side by side, on parallel tracks, a pipe connected the 25th and 26th cars, thus bringing the 50th car beside the engine, and this last car was attached to Mr. Dudley's dynagraph car where delicate instruments recorded results.

From the time the brake went on to the first car on the Westinghouse train until it applied on the 50th car was 2.58 seconds, while on the New York train it was 3.07 seconds in doing the same work. This is a difference of but half a second, which seems awfully small, yet it is 20 per cent. of the time required, and enough, so brake experts say, to account for the difference in shock.

Another interesting and important test was made. It was the same as the above except that three consecutive brakes were cut out on each train. Under these conditions the fiftieth car on the Westinghouse train applied in 2.47 seconds, average time for three trials. The New York brake had five trials in this test; in the first and last the brakes behind those cut out did not apply at all, and in the other three trials the brake went on the fiftieth car in 3.75 seconds.

Trains where the two brakes were mixed up showed that slower stops and heavier shocks were had than when a full train of either brake was used.

The service stop tests were as exhaustive as the report, but they showed something of importance—especially to mountain roads.

In one of these tests a moderate reduction was made through the service application port and repeated until full application was had. In this test some of the New York brakes did not go on, and in a second test others stayed off and the old offenders worked.

In one test the brakes were fully applied by emergency and left on. In thirty minutes none of the Westinghouse brakes had leaked off except one that had a ruptured jacket. On the New York train fifteen had leaked off in thirty minutes.

Tests were made to determine leakage; this was done by admitting air to release the brakes through a $\frac{1}{16}$-inch hole in a diaphragm, all conditions being the same. It was found that in five minutes the pressure in the train-pipe of the Westinghouse train was 10.50 pounds, and in the train-pipe of the New York train it was 22 pounds. In 15 minutes the first-named train line had a pressure of 53.55 pounds, while the second train had a pressure of but 47 pounds, showing that there was a heavy leak at first.

There were quite a number of other trials running and standing, and there is something to be learned in each of them, but space forbids our summarizing them here. Mr. Dudley makes some interesting statements, as, for instance, the following:

"* * * A loaded grain train, of a total gross weight of 3,000,000 pounds, running at 25 miles per hour—not uncommon on your line—(N. Y. Central) would require and have stored in the train an amount of energy greater than can be imparted to a projectile by the largest of modern guns, 3,000,000 pounds multiplied by 20,896, velocity head, equals 62,688,000 foot-pounds, the same amount which would be required to lift the entire train 20,896 feet above the track. This vast amount of energy must be supplied by the locomotive besides overcoming all other train resistance of friction, air, grades and curves, and requires a long run to do it, and it then requires distance and very efficient brakes to destroy the energy in a harmless way and stop the train."

Again: "The present time of application from the first to the fiftieth car is so near the velocity of sound waves, that it is more difficult to shorten the time one-tenth of a second now than it was to shorten it ten seconds in 1886 or two in 1887."

To the average observer watching these tests there was little difference in the stops; the two trains running neck-and-neck when the brakes went on and stopping about an engine length from even *seemed* pretty evenly handled by their brakes. The average observer was comparing the difference between the engines' pilots with the great length of train. The brake sharps were comparing it with the length of the stop—it was about 2 per cent of the first, but 16 per cent. or more of the latter.

A report of a comparative test, that does not compare, is in the nature of a certain good book—contains many true things but furnishes such a variety of good, bad and indifferent, leaving each to pick out what suits him best, that the lay reader needs a pilot to steer him aright.

The Westinghouse people have every reason to be satisfied with the report, their brake having done the best on the vital points—why should it not? They have been through this all before, and have years the start of all competitors in experience—many a new brake concern are spending their good money to-day experimenting with something that Westinghouse took up and abandoned years ago. If a new brake concern had put on the market, on the very start, a better brake than the Westinghouse, it would have been more than a wonder—it would have been a miracle.

## Reduce Delay at Stations.

One of our correspondents, who has watched with interested attention the numerous improvements effected on rolling stock and railroad machinery generally for the purpose of making train running time on reduced expense, suggests a novel improvement.

He appears to think that compounding locomotives is in the line of progress, but he thinks that considerable saving could be effected if a little more attention was given to the conductor of the train. We believe the position taken to be perfectly sound, and have no doubt whatever that the practice of neglecting to see that the men on the hind part of the train perform their duties properly is responsible for a great deal of waste and annoying delays. A conductor who is of a social disposition and likes to make brief visits to his friends at stations, is likely to be very expensive to his company.

We can give an illustration of how this thing worked on a Western road that we are familiar with. The locomotives in use pulling a particularly fast train were considered unequal to the work, and larger engines were bought for the purpose of hauling that train. After the engines had been in service for a few weeks it was found that they did not make the time any better than the other engines, and the traveling engineer was instructed to ride on the new engines and find out the source of trouble. He did so, and the experience of a trip or two convinced him that the engines did very rapid running, and he could not make out why the trains were not taken through on time. To supply a graphic record for the use of the manager, he applied a speed recorder to the engine without saying anything to the train men, and took a record of several trips. This showed that the engines ran at a speed over sixty miles an hour part of the time, when the average speed was about thirty-five miles an hour.

It was seen that the loss of time was at stations. The conductors would go into the telegraph office and have a few minutes' social talk with the operator; at other places a few minutes would be spent talking to other trainmen, and dependence was put on the engines for making up the lost time. After the manager examined the record of two or three runs, he entirely exonerated the mechanical department from all blame for the loss of time in running the trains, but he gave the conductors talk of a very impressive and picturesque character. There has been a great decrease of sociality on that road since then, but the trains go through on time. Not a few railroad managers might with advantage get a useful hint from this experience.

## The Mechanical Conventions.

The conventions of the two railroad mechanical associations will be held in the middle of next month, and the business laid out for the meetings indicates that very interesting and profitable sessions will be held. There appears to be considerable apprehension that these conventions will be thinly attended this year on account of the counter attractions of the World's Fair being likely to keep many of the members absent. It seems to us that there ought to be as many present as there usually are, for the World's Fair will offer an inducement to members at a distance to go to Chicago, and the journey from there to Lakewood is so short that few would hesitate to undertake it. We understand that in the immediate neighborhood of Chicago some of the members of both associations are likely to be kept at home, owing to the large extra business that will be performed by their roads in the middle of June. The decrease of numbers due to this cause promises to be made up by a larger attendance from the distant States. We have heard some fears expressed that the accommodations furnished by the hotels are likely to be too limited for the comfort of the visitors. We have made careful inquiries into this matter, and have been assured that nothing will be spared to make the conventions as comfortable as possible. There are two good hotels that will furnish about five hundred rooms, and twenty cottages that will furnish over a hundred more. Besides this there are a number of other good hotels and boarding-houses in the place, and Jamestown, a city of twenty thousand inhabitants, is only five miles away, and is connected with Lakewood by an electric railroad that has an excellent service of cars.

Complaints have been heard because the hotel keepers propose to put two men in a room, when the applicant has no one with him. This is nothing new, and has been done at all places where the conventions have been held of late years. The difficulty is that the conventions have become so large that it is almost impossible to find a place with hotel accommodations sufficient to provide a room for each person. We know of no place where this can be accomplished except at Saratoga. If the members and their friends are not satisfied with the limited accommodations of the ordinary watering-places, they ought to establish a regular meeting place in some town where the accommodation will be equal to the demand.

In other respects Lakewood is a splendid location, and is certain to be popular with most of the visitors. It is a beautiful place with fine shady drives and a beautiful lake that has excellent fishing and the best of boating accommodations. We feel certain that those who go to the place of meeting without prejudice will come to conclude that the Joint Committee did not make any mistake in deciding on Lakewood. They had a very difficult task to perform in making a selection, for there was no place in the neighborhood of Chicago where reasonable rates could be obtained.

## Merits of Different Engines for Passenger Trains.

Since six-coupled types of locomotives are coming so largely into service for hauling fast heavy passenger trains, great diversity of opinion has been manifested respecting the real value of this kind of engine for the service named. Renewed interest has been thrown on the subject by the decision of the Chicago, Burlington & Quincy to abandon six-coupled engines and return to those of the eight-wheel type. The Mogul type of engine has been in use on the C. B. & Q. for several years for passenger trains. Talking at a Western railway club meeting on the reason why this kind of engine was tried, Mr. G. W Rhodes says "We were having our passenger trains and our heavy freight trains run with double-headers, and every now and then we would have something fail or break down on the engines." He explained that the use of double-headers doubled the chances of breakage and the chances of axles running hot, so his company decided on using Mogul engines, which were fairly satisfactory; but they undertook a series of tests to obtain accurate records of different forms of locomotives pulling the fast train. These tests indicated that at very high speed the pull on the draw-bar is much less than at low speed. This fact led them to the conclusion that on long continuous runs it was not necessary to have the heavy adhesion obtained by six-coupled engines. This being the case, four-coupled engines would be more satisfactory on long runs than six-coupled, since there would be one pair of journals less to heat and fewer connections to give trouble. They had decided to continue using six-wheel connected engines for service where stoppages were frequent.

Mr. Barr, of the Chicago, Milwaukee & St. Paul, said that his company had come to a similar decision to that outlined by Mr. Rhodes in regard to engines for through passenger service.

This seems to be an important movement. In the course of a protracted tour the writer made a great many inquiries respecting this question of eight-wheel against six-wheel connected engines, and was surprised to find how conflicting the views are of men who ought to be thoroughly informed respecting the merits of the two types of engines. One set of men hold that the eight-wheel engine is preferable to the other, because it is easier on the track, while other men who ought to be equally well informed on the subject say that it is quite the reverse, and that a ten-wheel or Mogul engine is much easier on joints, curves and bridges than the heavy eight-wheel engines employed for fast passenger train service. They say that the ponderous weight on the engine truck strikes joints, curves and bridges with blows in proportion to the weight carried, and that the types of engine carrying less weight in front are much easier on the structure. It appears to us that this phase of the question ought to be thoroughly investigated by the engineering department. An engine may be very satisfactory to the mechanical department and yet be very expensive for the service of the company. Before a final decision can be reached respecting the merits of these two types of engines the effects of the different forms on the permanent way ought to be properly understood.

The railroad men who are most in favor of the use of eight-wheel engines assert that the others are more expensive for repairs. On this question there is also diversity of opinion, and we are inclined to think that there is very little difference. Of course, six-wheel connected engines have extra journals, extra tires, and extra rod connections to keep in order, but they do not slip so much as the others, and the lighter weight per journal makes them less liable to suffer from hot boxes

During a discussion at one of the Master Mechanics' Conventions, objections were raised to ten-wheel engines on the ground that the tires of the hind pair of drivers were very liable to wear faster than those of the other drivers. If this fault were inherent to this form of engine it would greatly depreciate its usefulness, and would be liable to cause broken rods, bent pins and excessive wear of journals. The engines that displayed this peculiarity must have been defectively designed, with too much weight on the rear drivers, for our inquiries fail to find any case where there was a decided tendency of the tires of ten-wheel engines to wear irregularly. All the evidence collected pointed to the fact that the tires wear as uniformly as the tires of eight-wheel engines.

### To Abolish Passes for Employes.

There is a report current that the Pennsylvania Railroad Company intend to stop giving passes to its own employés. As this company has always been noted for its generosity towards its employés, especially in the small favors that cost little and generate good feeling, we are inclined to doubt the truth of the report. There is no railroad in the country where the *esprit du corps* and pride in the system is so prevalent as on the Pennsylvania proper, and this spirit is not cultivated by refusing to grant favors that do not belong to the letter of the bond. Any change of policy which would reduce the cordial relations between the company and its employés would be a calamity to the road and a very costly experiment. There are officers high in power on some of the Western Pennsylvania lines who strive to be so intensely just with all classes of workmen that they would not let any person below the dignity of a section boss ride on a handcar if they could help it. This class of officer says that a railroad man has no more right than any other person to ride on a train without paying. This is no doubt abstractly correct, but it is a policy which no railroad company has ever followed, and it will be a sad day for the Pennsylvania Railroad Company should such narrow-minded practices be inaugurated. Any employer who displays solicitude lest an employé should receive anything more than he is entitled to by the agreement between the two is not likely to be very well served. Zeal and personal interest in the way duties are performed are not paid for in money, but it is highly important to a railroad company that the majority of the men should display these attributes. The best way to obliterate the noblest qualities of workers is to give them to understand that no favors will be given.

### Old Inventions Made New.

There is something curious about the persistence with which some old inventions are given new life by the inspiring influence of the Patent Office. There are several patents in active force to-day giving protection to furnaces with downward draft, yet this invention dates back into dim vistas of centuries. We rather suspect it was a favorite plan of burning fuel with the ancient Greeks, yet an ingenious French physician named Papin, in 1680, claimed the invention of the downward draft furnace. It has had a great many admirers since that time, and not a few inventors who could not find any other part about an engine on which to hang a spark-arresting patent have boldly invented downward draft for that purpose. We frequently read over the fascinating pages of the *Patent Office Gazette* and sigh half-forgotten prayers to keep us from being drawn from the paths of truth and rectitude by its romancing and impudent distortions of truth in the interests of inventors who never had an original idea. When claims of novelty are made for devices that are nearly as old as Noah's ark, we wonder if there really is anything new under the sun.

### Cranks' Products Excluded.

Those who visited the Chicago Exposition of Railway Appliances in 1883 will remember how much valuable space was wasted by being occupied by a collection of impracticable car-couplers and other inventions that no sane railroad man would think of applying to railroad machinery. Those who go to the Columbian Exposition will find that the products of the crank are conspicuous by their absence. We understand that Mr. W A. Smith, chief of the Transportation Department, had to display Spartan qualities in refusing absurd car-couplers and impracticable devices, but he has succeeded wonderfully well. In spite of his watchful care a few crank notions have been admitted, but they are scarcely noticeable. There are two or three car-couplers that will excite merely fun and ridicule from railroad men, who are the most vigorous of critics. But the exhibit which will excite most ridicule is the H. B. & L. elevated and electric train, which consists of a model of one immense car carried on a single pair of wheels at each end, which are supposed to be about 15 feet in diameter. There is supposed to be an electric motor for propulsion on each end, and the ends are pointed to cut through the wind. These funny exhibits are not without good uses, for they give visitors a little relaxation and offer good material for small jokes.

---

The American Railway Union, the new, non-secret association of railroad employés, of which Eugene V. Debs is president, have issued a pamphlet setting forth their principles and calling for a mass meeting of railroad men in Chicago on June 20th, to perfect the organization and commence the work. The promoters of the new order have made-over nothing. They have built on entirely new foundations, placed on new ground. They propose to afford protection of rights to employés and to employers as well, to keep the cost of membership down to a dollar per year, or less; to do away with secret meetings, conventions, grievance committees, strikes and boycotts. The engineers-in-chief have surveyed off a very large and stony field for operations, but the directors are energetic, able and sanguine of success. It goes without saying that the success of such an order means the eclipsing of the present forms of railway labor orders. An interested public, as well as railroad officers and employés, will watch the progress of this new democratic fraternity with interest. They offer to send their pamphlet free to interested parties who ask for it. The headquarters of the order will be at the Ashland block, in Chicago.

### BOOK REVIEW.

THE RAILWAY PROBLEM By A. B. Stickney. D. D. Merrill Co., St. Paul, Minn. Paper binding. Price, 50 cents.

This book will be a surprise to the reader. The author is president of the Chicago, St Paul & Kansas City road, and one expects from the start to find a defense of railway management against the so-called granger laws, the discussion of which called this work out. But Mr. Stickney shows up some of the iniquities practiced by the railroads and rather takes the side of the granger if anything. He brings to his use inside facts and all the time impresses the reader as one who is arguing for justice for the whole people and not for a class. He exposes the bones of the idol of discrimination and shows why people worship it—because it is called competition. Mr. Stickney believes in a rate made and maintained by Government

---

Pedrick & Ayer, of Philadelphia, are very busy on the larger sizes of Richard's open side planers and their milling machines. The open side planer is a whole repair shop on one foundation, and is destined to become a popular railroad shop tool.

---

LOCOMOTIVE ENGINEERING may be depended upon to publish more engravings of engines at the World's Fair than all the other papers combined.

### PERSONAL.

Mr. J H. Hamilton has been appointed general manager of the Northern Adirondack Railroad.

Mr. John Bonner has been appointed master mechanic of the San Francisco & Northern Pacific, with headquarters at Tiburon, Cal.

The jurisdiction of Mr. J. J. Ryan, general master mechanic of the Eastern lines of the Southern Pacific, has been extended to Algiers, La.

Mr. E. T. Burnett, assistant purchasing agent of the Norfolk & Western, has been appointed purchasing agent of that road, with headquarters at Philadelphia, Pa.

Mr H. L. Gault has been appointed superintendent of the American Steel Wheel Co.'s Works at Garwood, N J He was formerly with the Midvale Steel Co.

Mr. M J. Drury, formerly gang foreman on the Atchison, Topeka & Santa Fé, at Topeka, Kan., has been appointed general foreman on the same road at La Junta, Col.

Mr Geo. Bailey has been promoted to be master mechanic of the Great Northern, with headquarters at Breckenridge, Minn He was formerly an engineer on the road

The many friends of Mr H. B. La Rue, the well-known railroad supply man, will be sorry to hear that he has lost the law-suit which he brought against some parties for slander

Mr. A J McBlair has been made superintendent of the Chicago South Side Rapid Transit. Mr. Blair has been on the road as assistant to the president since it began operating.

Mr. G. D. Hutchinson has been appointed superintendent of the Chicago, Fort Madison & Des Moines Railroad in place of Mr E. F. Potter, resigned. His headquarters are in Fort Madison, Ia.

Mr. E. H. B. Kopperman, formerly foreman of locomotive repairs at the Buffalo Creek shops of the Buffalo, Rochester & Pittsburgh, has been made master mechanic in charge of the shops at that point

We regret to hear that Mr R B Sutherland, master mechanic of the Boston, Revere Beach & Lynn Railroad, has suffered from a severe attack of pneumonia We are glad to hear that he is able to be about again.

Mr S. R. Tuggle, formerly with the Kentucky Central, has been appointed master mechanic of the Newport News & Mississippi Valley, with headquarters at Paducah, Ky., in place of Mr. Wm. Hassman, resigned.

Mr. Jas. A. Graham has been appointed master mechanic of the Cleveland, Lorain & Wheeling R R, with headquarters at Lorain, O. He was formerly a passenger engineer on the Canada Southern, part of the Michigan Central

We have to acknowledge a pleasant call from Mr Herman Johansson, mechanical engineer in charge of the Swedish State Railways at Stockholm. Of course Mr Johansson came here for the purpose of visiting the World's Fair.

Mr. Charles B. Peck, assistant general manager of the San Antonio & Aransas Pass Railroad, has accepted the position of general manager and chairman of the Texas Car Service Association, with headquarters at Houston, Tex

Mr. James Morrison has been promoted to be train master of the Chicago South Side Rapid Transit. He was trained on the Manhattan Elevated and was considered by Colonel Hain one of the smartest train dispatchers on the system.

Mr. William McPhail, master mechanic of the Ohio Southern, was killed at Springfield, O., last month by the breaking of a pulley which he was using to pull a derailed engine upon the track. He went to that road from the Chicago & Eastern Illinois.

Mr. Charles Froberg has been promoted from roundhouse foreman at Albert Lea, Minn., to a similar position on the M. & St. L. R. R., succeeding Mr. B. Reiley, who has taken charge of the M. P. department of the Des Moines Northern & Western R. R. of Iowa.

Mr. W. H. Truesdale, receiver of the Minneapolis & St. Louis Railway, has been elected president of the company. Mr. Truesdale has been with this company a great many years, rising from a subordinate position, and no one is better acquainted with the needs of the company.

Our correspondent, Mr. L. C. Hitchcock, has been compelled for his health to move away from the harsh climate of Minnesota, and he has found a location in Los Angeles, Cal., where he has linked his fortunes with the Southern Pacific Co. We heartily commend Mr. Hitchcock to the good-will of Master Mechanic Gregg.

Mr. James Farrell, master mechanic of the San Luis division of the Mexican National, has been appointed master mechanic of the Northern and Texas divisions of the same road, with headquarters at Laredo, Tex. Mr. M. J. Schneider has been appointed to succeed Mr. Farrell as master mechanic of the San Luis division, with headquarters at San Luis, Potosi.

Mr. C. E. Nichols, who for the past ten years has been a machinist and shop foreman for the Northern Pacific road, has been appointed master mechanic of the Spanish-American Iron Company's road and shops at Santiago de Cuba, in the West Indies, sailing for the scene of his future labors from this city on May 11th. From a Dakota blizzard to a Cubian box fry is quite a change.

A variety of personal changes have been made by the new management of the Santa Fé. The road has been divided into two parts, with Mr. H. R. Nickerson as general superintendent of the eastern and Mr. H. U. Mudge as general superintendent of the western portion. The jurisdiction of Mr. John Player, superintendent of machinery, has been extended over the Colorado Midland division.

The Order of Railway Conductors, in session during the past week at Toledo, re-elected Grand Chief Conductor Clark, of Cedar Rapids, Iowa, by acclamation. Others elected were: C. H. Wilkins, Chicago, assistant chief; A. B. Garretson, Osceola, Iowa, grand senior conductor; E. W. Purrett, Toledo, grand junior conductor; W. P. Daniels, Cedar Rapids, Iowa, secretary and treasurer.

On May 2d, Mr. M. D. Monserrate, vice-president and general superintendent of the Gulf, Western Texas & Pacific and New York, Texas & Mexican Railways, tendered to the Southern Pacific Company his resignation. He had been in this office for nineteen years. As soon as relieved he went to San Antonio to take the position of vice-president and general manager of the San Antonio & Aransas Pass.

Mr. John C. Mackinnon has been appointed general manager of the Chicago, Fort Madison & Des Moines, with headquarters at Port Madison, Iowa, to succeed Mr. J. P. Tucker, resigned. Mr. Mackinnon has been general freight and passenger agent of the road since February last, and it is understood that he will continue to perform the duties of that position in addition to those of general manager.

Those who were at the last Master Mechanics' Convention will remember the smartness displayed by Mr. E. S. Jackman in advocating the merits of Park Brothers & Co.'s steel. Mr. Jackman appears to have prospered since that time, for a company has just been formed bearing his name, with offices in the Rookery Building, Chicago. We have no doubt that Mr. Jackman is prepared to talk steel to any caller.

Mr. B. M. Brown, one of our club raisers at Covington, Ky., and a remarkably warm friend of the paper, was killed at London, Ind., by a collision with cars blown out of a siding. He was crushed in attempting to get off his engine, which was one of those lately designed for the company with the boiler head coming to back end of frames. There is a feeling among the men that to the awkward style of engine was due the death of Mr. Brown.

Mr. Joseph York, whose portrait appeared in LOCOMOTIVE ENGINEERING last July, has gone to Chicago to be employed in connection with the Baltimore & Ohio's exhibit at the World's Fair. Mr. York now resides in Meadville, Pa., where he is living retired after being long employed, first as an engineer, then as a conductor, on the N. Y. P. & O. His first railroading was done on the B. & O. in 1837, when he went to work firing a grasshopper locomotive. Within a year he was an engineer, and ran grasshopper engines for three or four years. Then he went taking out engines for the Norris Works and from that took a turn as engineer on nearly all the leading roads in the North before the war. He is still a hale and hearty gentleman, seventy-four years old. We expect to fill our note book with reminiscences of old time railroading when we meet him at the Fair.

One of the most regular visitors to this office since it was opened has been Mr. H. L. Leach, of Boston, who could lure the editor from his desk on his busiest day to listen to well-told reminiscences of locomotive building and railroading extending over fifty years. It seems only a few days since Mr. Leach was dilating to us about locomotive construction of the olden time, yet it is sad to reflect that we will listen to his voice no more. He was attacked by pneumonia last month and succumbed within a week. Mr. Henry L. Leach made his mark in the mechanical world as superintendent of the Hinckley Locomotive Works of Boston, and he lost the savings of a life-time when the concern failed. We say it to the credit of Mr. Leach that twenty years ago, when interchangeability of parts had not come into fashion, that he built engines that were the most absolutely interchangeable locomotives we have ever found. How he did the work with the ancient tools the chief proprietors of the works insisted on maintaining in use is a mystery. Of late years Mr. Leach has been in the railway supply business, and devoted his principal attention to pushing a rail-sanding device invented by his son. He was one of the oldest members of the Railway Master Mechanics' Association.

One of the best engineers in the East, Morris Clapp, of the Central R. R. of N. J., has been appointed foreman of the Communipaw shops of that company—the New York terminals. There are very few runners better known than Clapp; he has always taken a deep interest in the Brotherhood, has represented his division for years, has made piece and got an agreement between the road and the men many a time. Morris will now find out what it means to have 400 jobs on 100 engines, with force enough to do about 13. This will call for his best judgment in choosing what 13 jobs shall be done and what 387 shall go undone. He will also find how much kicking is justifiable and how much comes as a matter of course. If there is any one man that the boys ought to help make a record it's Morris, he deserves help at their hands—and we believe he will get it. If "the boys" would only take an interest in the success of one of their own number when a position of responsibility is given him there would be more engineers become master mechanics and superintendents of motive power; but the tendency of the majority seems to be to "rattle" the new incumbent and make him give up. This fact and the other one that the roads pay less for general foremanship (and often master's position) than they do for the best runs, makes many good men tired of the raw-hiding and they go back to the throttle, just as John Ericsson, whom Clapp succeeded, did.

In the death of Mr. John Black, which happened at his home in Lima, O., the Master Mechanics' Association loses one of its oldest honorary members and many railroad men lose a friend. Mr. Black came to this country from Scotland in 1850, and went to work as a machinist with a firm building locomotives. After gaining some experience in Eastern shops, and in running

locomotives, he went West and rapidly rose to be master mechanic of the Dayton & Michigan Railroad. When this road was absorbed by the Cincinnati, Hamilton & Dayton, Mr. Black became superintendent of motive power, and remained there till within a few years. By judicious investment of his savings Mr. Black accumulated considerable property.

A host of railroad men and people connected with the supply interests are touched with sorrow at the sudden death of Mr. George B. Ewing, agent for the Ashcroft Mfg. Co., who was killed last month on the Illinois Central Railroad, near the Fair grounds at Chicago. One of the firm which he represented, writing about Mr. Ewing, says: "He was in our employ ten years and was very highly esteemed by every one connected with us, old and young. Aside from his value to us as a representative, he became greatly endeared to us by his personal qualities. As you know, he was a Scotchman, born in Aberdeen, and was a man of that sturdy character, intelligence and integrity that always makes itself felt among men. The letters we are receiving from the largest houses in the country, written by the principals, are a very touching tribute to his qualities as a man and a business man. He leaves a widow, son and a married daughter at Wilkinsburg, Pa., one of the suburbs of Pittsburgh. He was in charge of our Ashcroft and Consolidated Safety-Valve Co.'s exhibits at the World's Fair, and was very much pleased with the fine location we had and the magnificent exhibit that we sent him, and he anticipated great pleasure in meeting his many friends during the summer while in charge of the exhibit. His loss to us is almost irreparable in the sense of anyone valuable to us in a business point of view and also as a friend. It is one of the severest losses we have ever met in our business family."

Intimation has been given by Park Bros. & Co., of Pittsburg, that Edwin S. Jackman Co., Rookery Building, Chicago, will act as exclusive agents for the sale of their steel and copper.

## Examining Firemen.

The Traveling Engineers' Association, the new educational association recently formed, are getting down to business. At their September meeting in Chicago they will discuss several important questions. One of these, and a very important one it is, as it means the determination of the standard of intelligence of future locomotive engineers, will be the report of the Committee on the Examination of Firemen for Promotion and New Men for Employment. The committee have sent out a circular asking replies to the following questions:

1. Do you examine your firemen on machinery and ability to handle same before promoting them to engineers?

2. Do you use any progressive form of examination?

3. Do you examine them on various kinds of "break downs," and how to get an engine to the shop?

4. Have you any educational test, except ability to read and write English fairly?

5. Do you examine engineers hired from other roads: if so, do you do it as thoroughly as when examining firemen for promotion, or more so?

6. Do you have any set form of questions, or do you ask questions as you see fit?

7. Do you examine applicants for position as fireman; if so, what does it consist of?

8. Do you examine on air-brake practice and how is it done?

9. Do you examine them on colors and vision?

10. Who examines them on time card and rules?

11. Do you have any age limits for new men—youngest and oldest?

12. How are the examinations conducted? Are answers written or verbal?

13. In promoting men, do you consider ability paramount of seniority?

14. How do you determine the comparative standing of men examined?

15. Is the examination conducted by a board, or by yourself only?

16. Do you consider the ability of men to economize in the use of supplies when promoting firemen?

17. Are engineers for whom firemen have fired consulted regarding candidate's ability? If so, has their opinion any weight in the matter?

18. Do you issue any form of certificate to candidate passing a mechanical examination?

19. If a man does not pass his first examination, do you give him one or more trials?

## President Lincoln's Private Car.

Information has been wired over the land that a car built at Alexandria, Va., thirty-five years ago, for the use of President Lincoln, has been taken into the Union Pacific shops to be rebuilt, put in its original condition and sent to the World's Fair. The call for historical appliances to be sent to the World's Fair has been the means of the cleaning and polishing many an old relic that otherwise had fallen upon evil days. Few cars of high degree have ever gone through such ignoble uses as that car built for President Lincoln. By the time the war closed she was already out of date, was sold among other government property and was sent West to decay with the rising country. By degrees the old car descended in the social grade until she reached what railroad men regard as the bottom of the ladder, having been converted into a boarding-house car for a construction gang. The next move was naturally the scrap heap, but it has escaped that place, and will appear in gay array at Chicago, and no doubt after that will go to some museum.

## Canadian Pacific Exhibit.

[EDITORIAL CORRESPONDENCE.]

At the front of the Canadian Pacific's exhibit, at the World's Fair, is a ten-wheeled locomotive, weighing 106½ tons, [illegible],000 pounds being on the drivers. The cylinders are 19 x 24, and the driving-wheels 69 inches in diameter. The valves are balanced with ⅞-inch lap and $\frac{3}{32}$ lead. The front pair of driving-wheels has bald tires. The boiler is of the wagon-top variety, made of steel throughout, and carries a steam pressure of 180 pounds. The wheels of engine and tender truck have wrought-iron centers, with steel tires; the engine is equipped with the Westinghouse driver-brake. It is very plainly finished with Russia iron jacket, black painted wheels and polished rods. The tender is black with a single gold-bordered panel, having red facing. The engine supplies steam for heating the train, which is done on the consolidated system, and engine and train is equipped with the air signal.

The cars are all finished in mahogany outside and have a most striking appearance that attracts much attention.

The baggage car is the standard type of the road, of soft wood, finished in oak graining. Next car is a second-class sleeping car, the only kind of this class used for through travel. It has a very handsome interior, with leather-covered seats and mahogany finish. The seats can be made up into sleeping berths, very similar to the Pullman first-class cars, the upper berths being made in the same manner. The car has sixteen sections. There is a ladies' lavatory in one end and a gentlemen's lavatory in the other. In every respect it seems equal to an ordinary first-class coach, except in the upholstering of the seats.

Next is a first-class day coach, which is one of the most striking triumphs of the car builders' art we have ever seen. It is finished throughout in white Honduras mahogany, elaborately carved, with parcel racks made in the form of extended shelves, supported by beautifully carved brackets of the same wood as the car. It is divided into four parts by small casements supported on double columns that extend half way along the seats, forming a semi-partition; these are open and do not obstruct the view of the car, but they give it a novel and massive appearance. The head-lining is made of the solid wood, beautiful panels being selected for this purpose. There is a smoking-room at each end, with three seats on each side of the main aisle, the seats being upholstered in corded plush. The finish of the smoking-room is oak, beautifully carved like the rest of the car. The arrangement is that the smoking-room towards the rear end of the train is used when train is running. There is a ladies' lavatory in one end, the gentlemen's in the other. The main body of the car is upholstered in wine-colored plush, and the body of the seats are of wood, the same as the rest of the inside.

Next comes the dining-car, containing five tables on one side that hold four persons and five on the other that seat two persons each. This car is also finished in white Honduras mahogany and presents a most striking appearance although less ornate than the day coach. All the train is lighted by electricity, but this dining-car seems to have an unusually large share of light, there being ten incandescent lights in body of car. The seats of this car are very massive in appearance, covered with morocco leather of terra cotta color. The floor of dining-car is very heavily carpeted. At the end of each table there is an elaborately carved bronze alcove, with a smaller recess beneath that looks like a miniature balcony. At the back and end of each seat there is a rounded pillar, terminating in a carved scroll, which seems to support the plate beneath the rounding panel. The head-lining of this car is also of solid mahogany and has a very striking appearance. The sideboard, which in this case faces those looking through the car, is a very elaborate article, rounded at the base, with two massive rounded pillars forming the front support for the top, which is a section of an octagon, beautifully carved, with plate-glass in each panel. The part which leads to the kitchen is finished in dark oak. The kitchen is finished in oak and has tables and wash-sinks covered with copper. There is also a very large hot-water boiler of copper, and very complete arrangements are made for the holding of dishes and cooking utensils.

The last car is a sleeper, finished like the others in white Honduras mahogany. The style of finish has a modest look, yet on close examination is extremely ornate—a great deal of carving being done on the wood work. The seats are covered with yellow raw silk, beautifully flowered. The main body of the car consists of eight sections, and at each end there is a very elaborately carved bulkhead, with an arched door, closed by a silken curtain. There is a tasteful grating of bronze above each door. The head lining consists in this case of four panels with an oblong gilded center. The car bears the traces of high artistic design and exceedingly skillful workmanship. At one end there are two staterooms, with three berths each, a sliding door intervening, which makes each entirely separate. These rooms have raw silk lining, richly flowered, and the seats are finished in dark green plush with raw silk hangings; the window curtains are also of beautiful flowered silk. In connection with these staterooms there is a very large toilet room, which is finished in oak, with handsome plate glass mirrors. The gentlemen's wash-room is square, finished in oak below and white mahogany above. At one end it has a lounge of corded plush, extending across the room, and the other has very finely finished wash basins and mirrors. Beyond the wash-room is a bath-room, and beyond that the water-closet, both being plainly finished in oak. The cars as well as the engine tender are equipped with the Trojan coupler, and the cars with the Barr vestibule. The last two cars are carried on 6-wheeled trucks. The cars are supplied with Pintsch gas for lighting, as well as electricity, heating being done on the consolidated system.

A. S.

## Schenectady Compound.

The consolidation compound locomotive shown belongs to the Schenectady Locomotive Works exhibit at the World's Fair and was built for the Mohawk & Malone Railroad. The engine weighs 149,000 pounds, of which 132,000 are on the drivers. She is of the two-cylinder type of compound, the high-pressure cylinder being 22, the low-pressure 32 inches diameter, the stroke being 26 inches. She has Richardson balanced valves, with 5½ inches travel and ¼-inch outside lap. The engine is notable for the large bearings of all journals and connections, the driving-wheel journals being 8½ x 9 inches. The pony truck has a swing-bolster and Krupp wheels. The boiler is the wagon-top style, 62 inches diameter in front.

SCHENECTADY COMPOUND CONSOLIDATION. NOW AT WORLD'S FAIR.

Engineer E. Beans, better known along the line of the N. Y., O. & W. as "Bootjack," has a mogul all to his lone self on the Ellenville branch. The water could be better, and there was considerable trouble with checks. Grinding them in became a regular Sunday job, and, as they leaked at once, "Bootjack" lived in a perpetual Turkish bath. After all else failed, he writes us he took four big dollars of his own money and bought a 2-inch Jenkins check-valve for straight pipe and put it into the branch pipe between the check and injector and then took comfort for eighteen months. "Bootjack" fails to see why this simple check is not the thing for all engines, and points out the ease with which he put in a new seat instead of grinding in the valve.

The New York offices of the Westinghouse Air-Brake, of the American Brake and of the Union Switch and Signal Companies have been moved to the Havemeyer Building.

The New York offices of the Rhode Island Locomotive Works have been moved to 31-33 Pine street.

Don't miss our July number.

### Many Men, Many Minds.

"It is surprising," remarked the President, "the diversity of opinion that exists among men about things that one would suppose nearly everybody would agree about. It is not altogether surprising that men in the West should have experience with appliances different from men on Eastern roads; but why men on the same road should differ so much as some of them do is hard to understand.

"I remember a case which gives a very good illustration of this at the time when corrugated firebox sheets were popular. At a railroad meeting I came across several of the D. L. & W. master mechanics, and, of course, the subject of corrugated side-sheets naturally came up.

"To Mr. Dawson I remarked 'Well, are you people doing anything about corrugated side-sheets?'

"'Why, yes,' he replied, 'putting them into everything. Best thing ever come out. No more cracked side-sheets since corrugations are used.'

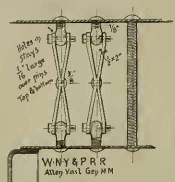
"A few minutes afterwards I happened to meet Jas. Buchanan, who was on the same road but another division. 'Well, Jim,' I inquired, 'are you doing anything with corrugated fireboxes?'

"'Yes,' was the reply, 'we are throwing them all out, they are not worth a *damn*.'"

### Cracked Flue-Sheets in Radial-Stayed Boilers.

The writer, in his various travels about the country, has noticed that not a few roads have experienced trouble from cracking in or about the flange at the top of flue-sheet of radial-stayed boilers, owing, it is thought, to the fact of the crown adjacent being too rigidly stayed. Various expedients have been resorted to, but among the best we have seen is a plan in use by Mr. Allen Vail, Gen. M. M. of the W. N. Y. & P. Railway. (Fig. 1.)

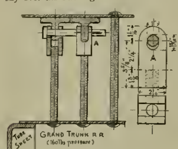
In Mr. Vail's plan the first two rows of stay-bolts are replaced by a flexible sling-stay. Eye-bolts are screwed into the roof and crown-sheets and then riveted over. These are connected by slings ½ x 2 inches, the holes of which, both top and bottom, are 1/16 inch large over pins, admitting of a total movement of ⅛ of an inch, sufficient



to relieve the strain on this part of the boiler, and hence cure the evil. (All of the stay-bolts in Mr. Vail's boilers are drilled.)

Another plan, in use by the Grand Trunk Railway, is shown in Fig. 2. The stay-bolts are screwed into the crown-sheet and headed over the usual way, the upper ends are screwed into a knuckle or clevis, which in turn is pinned to angle irons riveted on to the roof-sheet. The hole in the top of clevis is slotted, being 1 3/16 inches long, permitting a movement of 3/16 inch over the 1-inch pin, or 1/16 inch more than in Mr. Vail's plan.

We do not wish to publish any more articles signed by a *nom de plume*. Articles in a first-class engineering paper ought to be signed by the writer, unless he be the editor. Every correspondent to this paper should be proud of his article; if he is not, it is not good enough for us. Some have said that a man will often say things over a *nom de plume* that he would not say over his own signature. We do not



want articles for this paper that their own fathers are ashamed of. Any man's honest opinion is entitled to respect, and the man who is afraid to own up to his honest opinions is, to say the least, cowardly. The *nom de plume* is a fad; it is continued because it is common—like cutting notches in our coat collars. It has no place in mechanics, and should be discontinued. Please write over your own name for publication—it's right.

Randolph & Clowes, Waterbury, Conn., have issued a pocket price-list of brass and copper tubes and sheets and similar goods. It is a very complete work, giving inside and outside diameter, weght and gauge of different sized tubes, weight, thickness and surface per pound of sheet metals, and a great deal of other information needed by any one buying, ordering or using goods of this class. The work is invaluable to master mechanics, purchasing agents and to copper and tin smiths. It is sent free to those interested. This firm are furnishing 125,000 pounds of copper roof sheets for the Broad street station of the P. R. R. at Philadelphia.

In a recent personal letter to ye junior philosopher, Mr. W. D. Holland, M. M. of the Guatemala Northern Railway, located at Puerto Barrios, Guatemala, says "Please say to all those who write you about coming to this country that if they take my advice they will not come. We are flooded with engineers and machinists now. The only way to come is to secure employment beforehand through some locomotive works sending engines; but many are not sending men now, as there are more here than can find employment. Be sure and tell those who *will* come to bring money enough to get back, for they will want to bad enough, even should they get work. A few months' pay in the depreciated currency of the country will impress upon their minds the size and value of the many blessings they have left at home. I am speaking particularly of that territory that lies between the Rio Grande and the Charges Rivers, but I believe it is as true of the territory between the Charges and the Straits of Magellan."

### Some Facts About the Brake Trials at Karner's.

*Editors :*

The editorial comments which have been made by some of the railroad papers regarding the brake tests on the New York Central Railroad at Karner's, utterly ignored the circumstances which occasioned that test, and their conclusions are decidedly erroneous. The occasion which led to the tests was the issue of a circular by the New York Central Railroad Co., instructing their train men to cut out all brakes but the Westinghouse on their fast freight trains. The New York Air-Brake Co. asked that before such an order was promulgated the railroad company would test a train of fifty of their standard brakes in comparison with the Westinghouse standard brake at that time being applied to the cars of the New York Central Co.

The New York Company claimed that their standard brakes would duplicate every action and function of the Westinghouse brakes then in use. An order was placed with the New York Company for fifty sets of brakes in March, 1892, and these were applied to fifty cars from a lot of 1,000 then being built at the Buffalo Car Works. The Westinghouse Company were not willing to permit a test with any of the thousands of cars then equipped with their standard brake, and they therefore prepared fifty special equipments with triple valves adjusted so delicately that there was less than one pound margin between service and emergency action. The Westinghouse standard then in use required three times as much. The New York brakes were made to meet the Westinghouse standard used on the railroad, and would have been condemned without trial if they had been adjusted to such a narrow margin. There was, therefore, an inequality in the conditions of the two trains that made a comparison impossible.

If the deduction that a fraction of a second difference in time was the cause of the shocks, then it condemns the 200,000 Westinghouse brakes now in service, for they would all require the same time as the New York brakes in the test. How does it happen that the Westinghouse train in the Lehigh Valley tests, which was equipped with the same delicate valves that they used at Karner's, had terrific shocks, while the New York train, at the Lehigh Valley tests, with the same valves as used at Karner's, had no shocks? Here were two pairs of trains equipped with duplicate brake apparatus, yet, at the Lehigh Valley tests, the Westinghouse train had all the shocks, and at Karner's the New York train had all the shocks. This does not seem very conclusive of anything. The practical result of the test was the removal of the embargo off the New York brakes, and a series of orders from the New York Central Co. for brakes manufactured by the New York Air-Brake Co.

The sensitiveness of brakes is only a question of adjustment. The margin between service and emergency can be varied to suit the requirements of the Master Car Builders' Association. The brakes of the New York Air-Brake Co. will be found to equal any other in rapidity of emergency as well as in stability of service, in graduation, in release and in the ability to maintain a uniform and unvarying pressure down a long mountain grade. They may be seen and tested at the World's Fair under the most favorable conditions for observation, and in the most critical manner. We invite investigation.

THE NEW YORK AIR-BRAKE CO.
*May 24, 1893.*

[This communication was received too late to print with regular correspondence, and as it is a matter of importance to the New York Brake Co. we publish here.]

### Science Mysteries.

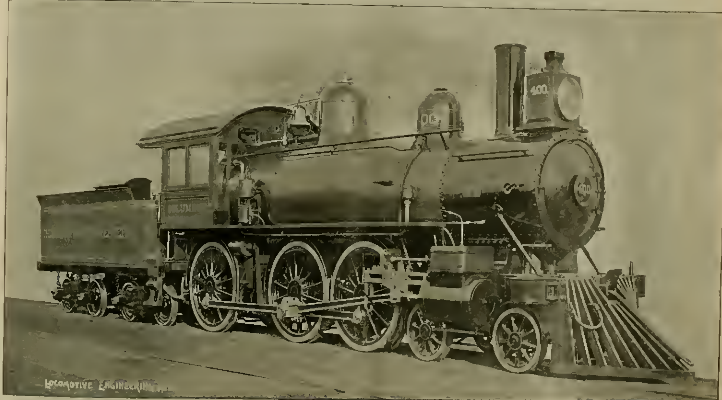
Those who begin to study scientific problems after they are grown up are entitled to as much sympathy in the difficulties they encounter as the heathens who have passed a life in moral darkness and at years of maturity have religious doctrines thrust upon them. When a young man receives scientific instruction as part of his education, the mysteries that are liable to excite heresy and unbelief are gradually made clear and instructors help to explain away obstacles to comprehension. When a grown man, however, becomes a student of science problems he meets at the very portals of the study with unproved statements given as facts, he is in danger of giving up the pursuit of this species of knowledge and saying in his wrath all scientific writers are liars and that Ananias would have had to take a back seat among modern savons.

One of the most trying studies for the faith of a novice is connected with the laws relating to matter. To be informed that all matter is divisible into infinitely small particles called atoms that no human eye will ever be able to see, is to excite the question, How can that be proved? To be told that atoms of different substances are of certain known weight naturally suggests the query, Who was able to weigh an entity so small that no microscope can be made powerful enough to show it? As the student advances in the study these and other difficult problems become more comprehensible, but it would be well for text-books to distinguish a little more clearly between what are established facts and what are theories by what seems good evidence.

There are a great many things believed about matter and forces of nature which never will be conclusively proven; yet those who have studied their phenomena most profoundly are thoroughly convinced of the truth of the theories concerning them. Molecular motion, for instance, as an explanation of heat, is one of the most trying theories to put upon the faith of a novice. Scientists say that heat is caused by the movement of the internal molecules forming the substance. The natural question is How can there be movement in the particles forming a piece of hard steel? Common sense would, at the first blush, call the theory absurd. Yet there are proved facts in connection with metal and other substances that seem equally absurd and can still be proved by experiment to be facts—not theories.

If the objector who considered it absurd that there could be movement in the molecules inside of a piece of dense steel were asked, if he thought it possible that the same steel could absorb any form of gas, he would readily answer that such an idea was as absurd as the other. Yet the power which solids and liquids possess of absorbing many times their own bulk of gases is among the most astonishing phenomena in nature, and is as true as the fact that water becomes steam when heated to a certain temperature. This is spoken of as the occulsion of gases in solids and liquids. Platinum, which is the densest of all solids, absorbs as much as five times its own volume of hydrogen without any increase in bulk, and the metal pallodium absorbs 643 times its own volume of carbonic oxide and remains unchanged in size. Most of our readers are familiar with the operation of converting wrought-iron into steel by the process of cementation. The success of that process is due to the readiness of iron to absorb a foreign substance under favorable conditions. The carbon which converts the iron into steel penetrates to the heart of the metal. Other phenomena of a similar character might be mentioned, but the instances given illustrate how readily one with imperfect knowledge may make a mistake by assuming that things asserted by scientists as facts are contrary to common sense.

In German railway cars there are little iron pockets into which you are requested to deposit your cigar stumps. These are collected by a society, sold to snuff makers and the proceeds used to support some charitable institution.



SCHENECTADY HEAVY PASSENGER TEN-WHEELER. NOW AT WORLD'S FAIR.

### Schenectady, Chicago & Northwestern Engine.

The locomotive shown here is one of the Schenectady exhibit shown at the World's Fair, and is a ten-wheel passenger engine, built for the Chicago & Northwestern. This style of engine has been doing splendid work in hauling the heavy fast passenger trains that are a prominent feature of this Western road. No kind of engine ever tried has done the work sa satisfactorily. The engine is quite heavy for passenger business, weighing 129,000 pounds, 96,000 pounds of this being on the drivers, and 33,000 pounds on the truck. The cylinders are 19 x 24 inches. The slide valves are balanced and have a travel of $5\frac{1}{2}$ inches; the outside lap $\frac{7}{8}$ inch and the inside lap $\frac{1}{16}$ inch. The driving wheels are 67 inches outside diameter; the boiler is of the extended wagon-top style, 60 inches diameter at the front ring, and made of Wellman steel $\frac{9}{16}$ inch thick

## EQUIPMENT NOTES.

The Santa Fé are in the market for a lot of locomotives.

The Beach Creek Railroad is receiving bids for 500 coal cars

The Duluth, South Shore & Atlantic is said to be in the market for 800 box cars.

The Brooks Locomotive Works are building fifteen engines for the Illinois Central.

Jackson & Wooden, of Boswick, Pa., have the B. & O. contract for 300 gondolas.

The Elmira, Cortland & Northern are about placing orders for 100 hopper-bottom gondolas.

The Florida Central & Peninsular have ordered from the Jackson & Sharpe Co. fifteen coaches.

It is reported that the Big Four have let contracts for 50 engines, 30 with Richmond and 20 with Brooks.

The Fall Brook Coal Co. have just received from the Schenectady Locomotive Works two consolidations.

The Pittsburgh Locomotive Works have an order from the Brooklyn & Union Elevated for three compounds.

The Florida Central & Peninsular Railway's order for fifteen engines has gone to Baldwin Locomotive Works.

The Manhattan Elevated Railroad people are in the market for twenty locomotives. They have lately ordered seventy-five passenger cars from the Wason Mfg. Co.

The Cooke Locomotive Works have received orders from the Southern Pacific for fourteen 10-wheel engines, with cylinders 19 x 24 inches and driving wheels 63 inches in diameter.

The Rogers Locomotive Co. have just finished thirteen locomotives for the Wilkesbarre & Eastern, and eight switchers for the government of Chile, these are saddle tank engines with cylinders 13 x 22.

The Wilkesbarre & Eastern Construction Co., which is a portion of the N. Y. S. & W Railway, have placed their order for fifteen coaches with Jackson & Sharpe, two of which are parlor cars.

Within the month the Baldwin Locomotive Works have received orders from the C. N O. & T. P. for eight engines, from the Seaboard & Air Line for eight, and from the Missouri, Kansas & Texas for ten.

---

The Hall system of block signals has been applied by the Illinois Central to the tracks between the Chicago terminals and the World's Fair grounds, and works admirably. Within the last few weeks the Lake Shore & Michigan Southern has decided to adopt the same system. For some time the Chicago, Rock Island & Pacific has been engaged putting in a Hall signal plant between Chicago and Joliet.

---

The Cardenas & Jucaro road in Cuba is having two moguls, 17 x 22, and one eight-wheel switcher with same size cylinder, built by the Rogers Locomotive Company. The mogul will have a 57½-inch wheel and the switcher 42-inch. The odd size wheel is the "standard" of that road and came about in a strange way. Long years ago, when Rogers built the first engine for this road, a lathe hand made a mistake of ⅛ of an inch in turning up the wheels—they were to be 57½-inch—and the road has used that size ever since. This company are busy on twenty-six 19 x 26-inch moguls with a 56¼-inch wheel, and seven 18 x 24-inch eight-wheelers with 69-inch wheels. They also have in the erecting shop five eight-wheelers, 19 x 24, and seven ten-wheelers, same size, for the Florida, Central & Peninsular, and two moguls 19 x 24-inch, and one eight-wheeler, 18 x 24-inch, for the New York, Susquehanna & Western.

---

The Reading Railroad kept up its record of boiler explosions last month, two persons having been killed and five severely injured by a boiler blowing up at Lebanon, Pa We will repeat what we have previously said about occurrences of this kind. A boiler explosion is a crime due to gross carelessness of some person who ought to be readily identified. When these explosions go on week after week and no one is punished, it is plain evidence that the authorities in Pennsylvania, responsible for the suppression and punishment of crime, are grossly neglecting their duties

---

From the appearance of the *Patent Office Record* a great many inventors are devoting their time to the designing of compound locomotives and their attachments. It looks as if the compound locomotive promises to become as fertile a source of revenue for patent lawyers as brakes and car couplers have been. At the beginning of this year there had been fifty-seven patents on compound locomotives taken out in this country. England was a little ahead of us with ninety-four patents, but it looks as if our inventors would be ahead before this year is out. Other countries have been well represented by inventors of compound locomotives, for France has 22 patents on this kind of engine, Germany 14, Italy 2, Switzerland 2, Russia 1, and Norway 1.

---

We have had the best of reasons to be satisfied with the ready response accorded to our numerous club-raisers, but there is occasionally a road or a place where railroad men appear to have no use for engineering literature. A club-raiser at one of these places, which, by the way, is noted for the number of its liquor saloons and for the audacity of the men interested in them, says "We have one set of men who know everything, and they don't need any paper, think it would imply ignorance to be seen reading papers that give information about their business; then there is another class who do not profess to know anything, don't know anything, and wish to continue always in that happy condition. They think their ignorance is bliss and that it would be the worst kind of folly to try and make themselves wise."

### Kindness Rewarded.

When J. Y. Smith was superintendent of machinery of the Government railways during the war time, Sir Edward Watkin, now a famous railway magnate in England, came to this country with a party of military officers, who were anxious to examine the military railways, and particularly the method of building temporary bridges quickly. Great confusion prevailed at Washington at the time, and it appeared as if the military men would not be able to accomplish the object of their mission. After they had besieged the War Office for days and interviewed no end of secretaries and other officials, some one recommended Sir Edward to see Mr. Smith. He did so, and Mr. Smith took the party to the front on a special engine which he had for his own use, showing them everything of interest to be found on the way.

After the war Mr. Smith invented his vacuum brake, and went to England to try to get it introduced. There was strong prejudice at that time against American inventions, especially brakes, because several electric brakes had been tried and found worthless. Mr. Smith had forgotten the name of the gentleman who came with the officers to look at the military railways, but he received from some one a letter of introduction to Sir Edward Watkin. When he presented the letter he was astonished at the cordiality displayed by the great railway king, who knew him at once and was ready to offer every assistance in his power. The success which Mr. Smith met with in applying the vacuum brake to English railways was due in a great measure to the kind offices of Sir Edward Watkin. There is good reason for believing that the popularity of the vacuum brake on English railways and the large proportion in use there originated in the act of kindness displayed by Mr. Smith to a party of strangers.

### Rhode Island Compound at the Fair.

The accompanying cut was made from a photo of the Rhode Island compound engine for fast, heavy passenger service between Chicago and Milwaukee.

She has cylinders 21 and 31 x 26 inches, 78-inch drivers, with a rigid wheel base of 13 feet 6 inches, and a total wheel base of 29 feet 9¼ inches.

The boiler is of the Sample, or extended wagon-top type, the smallest ring being 62 inches in diameter, the back head is a perfect circle, butt-joints throughout, 272 2-inch tubes; firebox, 120 inches long by 33⅜ inches wide.

The back truck or trailing wheels were put in to distribute the load, as the company limit the load per wheel.

The engine weighs, in working order, 143,000 pounds, 88,500 being on the drivers, 36,500 on the forward truck and 18,000 on the trailing wheels.

Rhode Island Compound Express Engine. Now at World's Fair

This is one of three of the same class built for this road, the other two go into fast service June 1st.

---

Breaking the record for fast running can and will be done, but a jump from 91 miles an hour to 112½ is too much of a good thing. The "999" may make 100 miles per hour, but she won't do it with four cars.

### Duty of Injectors.

Exact information about the performance of injectors is not easily found. The *American Machinist* lately applied to all the injector makers in the country to obtain answers to the questions What has been the best performance of the injector in raising or lifting water to any height? What is the greatest volume or weight of water raised relative to height with a given weight of steam?

In reply to this William Sellers & Co. intimated that in one of their tests the injector delivered 25.51 pounds of water into the boiler with 1 pound of steam. The gauge pressure was 65 pounds and the water temperature 64°, flowing to the injector under one foot head.

The Hancock Inspirator Co. said that with one of their instruments R. H. Buell lifted water twenty-seven feet with a steam pressure of 63 pounds, delivering against pressure equal to the steam.

# Practical Letters from Practical Men.

**Facts Wanted. There's a glut of Opinions.**

Write on one side of the paper, state your point plainly and briefly, and then quit. We supply the generalities. No letters noticed unless name and address accompany.

### Cast-Iron Test Pieces.

*Editors:*

Noticing your commentary on B. & O. tests for foundry castings, and having some experience in foundry tests, I wish to make the following suggestions:

You say, "A good foreman molder can, by selecting the period of pouring, provide a specimen that will give any kind of test required."

This is true only within limits. Given a uniform mixture in the cupola for an entire heat and it is true that the forman can get his closest, strongest and hardest iron in the first charge, but so only relatively to the nature of the mixture used.

The B. & O. people should specify that test pieces or specimen castings shall be taken from the cupola (not from the ladle if a large one) at the center of the heat for their cast. That is, if they are getting say 10,000 pounds of castings from a certain stack and it takes 40 minutes to run that amount of iron, their tests should be required taken 20 minutes from the time of first tap for them in the contract shop. The above is provided their work were all poured together — if not, then the test should be taken at the middle of time from first to last in order to secure average iron.

Several different mixtures may be had from the same cupola in one heat if necessary.

Better than any "sample casting" would be to specify certain results by "Keep's Tests," based on good practice, and see these tests properly made.

*Netherwood, N. J.* E. H. M.

### Draft Obstruction.

*Editors:*

At the recent discussion on spark arresters, it was generally admitted that in the matter of fuel economy, even the best of them are objectionable on account of the obstruction which they offer to the draft. To overcome the effect of these obstructions the exhaust nozzle is contracted to sharpen the blast, resulting in a tearing action on the fire, which is pro-

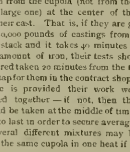


Fig. 1.

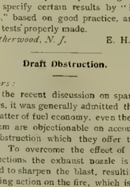

Fig. 2.

ductive of a greater number of cinders being drawn through the flues than with the softer exhaust of a large nozzle, and for this reason some one has said "No spark arrester is the best spark arrester." But it is doubtful whether he would make this "best arrester" his choice were he a participant in the settlement of fire claims due to fire thrown during our dry season. Certainly, the best spark arrester is that which throws least sparks and offers least obstruction to the draft, a point which does not seem to be as clearly borne in mind by some designers as it should.

The diamond stack combination is one of the most objectionable spark arresters, inasmuch as it baffles not only the draft but also the exhaust, thereby increasing the obstruction to the draft and resulting in much black smoke. This form of spark arrester is, however, fast becoming obsolete.

With the open stack combination the diaphragm plate becomes the obstructer, but with this arrangement the obstruction varies according to the location and angle of the plate. The only object of this plate is to deflect the draught to bottom of

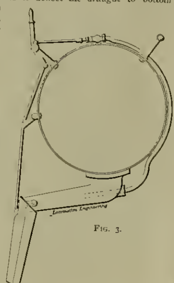

Fig. 3.

smoke-box for the purpose of drifting the sparks to front end, and it should be arranged to do this while impeding the draft as little as possible.

The position which I have found to be most objectionable and in which the plate is least calculated to perform the object for which it is intended, is when it is located within a few inches of the tube sheet, and this is a position still used by some prominent builders.

When engine is working hard and the diaphragm is set as in Fig. 1, the draft recoils from this baffle to an extent that is discernible on the fire, the result being that the cinders are deposited just clear of the plate and there is always a certain amount lying on the netting; to assist this plate to do what it would do alone if properly located, the nozzle is sometimes lowered and a lifting pipe placed above the netting. A plate in this position, therefore, not only fails to do its work, but is a serious obstruction to the draft. I have seen engines which were working unsatisfactorily while handicapped in this manner, converted into good, free-steaming engines by simply changing the plate from the position of a baffle to that of a deflector.

With the plate in the position shown in Fig. 2, there is no trouble whatever in keeping the smoke-box clear of cinders if desired, but they can be collected at the front end by lifting the plate higher, with the advantage of improving the steaming by allowing greater freedom to the draft, and also decreasing the cinder nuisance on passenger trains.

But with the fine dusty coal so commonly used, the cinders soon accumulate, and without some means for rejecting them from time to time as they collect, this advantage is short-lived.

It is a common practice to run with plate low in order to force the draft to front end, thereby keeping the cinders constantly in agitation until they escape through the netting.

Fig 3 is a device the object of which is to permit the plate being kept high by ejecting the cinders at intervals as they collect. This arrangement is operated by a movement of a handle at end of hand-rail in cab, which simultaneously opens the lid of cinder spout and a steam valve placed just behind smokestack, to the lid is fastened a sleeve which comes into position for projecting the cinders clear of engine when the lid is opened.

The important matter of free draft does not seem to receive the close attention to which it is entitled, not only at the smoke-box but also at the fire-grate. Comparisons are now being made between compound and simple engines. Among other information required in order to arrive at correct conclusions, the size of nozzle and grate area is asked for, but the size of the nozzle is regulated to a certain extent by the amount of draft obstruction to be overcome. An engine with deflecting plate in good position will run with a larger nozzle than one with draft throttled at the flue-sheet, therefore the arrangement in smoke-box should be given.

Two engines may have equal grate area, yet one may have 25 per cent. more draft opening than the other; the conditions are not equal, and therefore the percentage of draft opening in grate area should be known.

I have seen the draft opening increased even more than 25 per cent. with beneficial results.

*Stratford, Ont.* A. A. Mayer.

### Mr. Hamer's Brake Questions.

*Editors:*

Referring to the questions submitted by Mr. W. T. Hamer upon the subject of air-brakes in the April number of Locomotive Engineering.

In answer to the third question, permit me to suggest that there should be no difference in the conduct of the black hand, whether the engine is light or working air on a number of cars, although, of course, there would be a marked difference in the action of piston 17. In case of light engine, the reduction of train-pipe pressure *under piston 17* would be quite rapid, and its valve *n* would seat much quicker than would be the case if a number of cars were attached. This, of course, comes about from the difference in quantity of air necessary to escape from the train line in the different cases to equalize pressure above and below piston 17. In making an emergency application, up to a certain point the conditions are the same as in a service application. As the handle is carried around to and beyond service notch, air escapes from above piston 17 until communication between port *h* and preliminary exhaust port *e* is closed, and as it is carried around further, a point is reached about midway between service and emergency notches, where air passes direct from main reservoir to brake-valve reservoir, through port *j* in rotary valve and equalizing port *g* in its seat There being over twenty pounds greater pressure in the main than in the brake-valve reservoir, of course the black hand shows an upward tendency, and if handle is left in this position a few seconds the brake-valve reservoir will be charged to same pressure as main, and black and red hands will register alike That ports *j* and *g* are ever in communication is undoubtedly accidental, as it will be noted that this is avoided in the new model valve. Finally, as the handle is carried around to full emergency position, all escape from brake-valve reservoir is closed and pressure is retained therein, regardless of whether or not all pressure has been exhausted from train line in emergency application. A little confusion in respect of the black hand is introduced by the Westinghouse plates stating that it indicates train line pressure While this is true when the valve is at rest in either running or release position, it is not true while the valve is being manipulated. As a matter of fact, the black hand simply registers the pressure in the brake-valve reservoir, which, as shown above, may be vastly different from train line pressure. Phonetic.

### Improvements That Will Cause Damp Steam.

*Editors.*

The illustration in the April number of a feed-water delivery, used by Mr. Foster on the Fall Brook R. R. is interesting as it shows originality of design.

The plan of combining the two injector tubes on top of boiler is really a good one, but I doubt the propriety of allowing the trough to feed water of 300 degrees on top of a dry pipe containing steam of probably 350 degrees plus the latent heat of evaporation, all of which it is willing and anxious to part with and would deliver this heat over to the cooler feed-water without objection, and what is the result? Cylinders receive wet steam from a boiler which is making a good article.

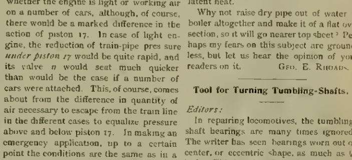
It seems to me that getting steam into dry pipe at a sufficient height above water to insure its dryness does not entail the fact that it will be the same when it reaches the cylinders if pipe is not kept out of the influence of water of a considerably lower temperature, both as regards sensible and latent heat.

Why not raise dry pipe out of water in boiler altogether and make it of a flat oval section, so it will go nearer top sheet? Perhaps my fears on this subject are groundless, but let us hear the opinion of your readers on it. Geo. E. Rhoads.

### Tool for Turning Tumbling-Shafts.

*Editors:*

In repairing locomotives, the tumbling-shaft bearings are many times ignored. The writer has seen bearings worn out of center, or eccentric shape, as much as ⅛ inch. This has the effect of changing the length and position of link-hanger, in which case the valve-setter must of necessity either shorten or lengthen the link-lifter or raise one of the tumbling-shaft boxes in order to equalize the cut-off.



Tool for Turning Tumbling-Shafts.

The accompanying sketch is a tool devised by the late Sylvester Charnley, who for eight years was master mechanic of the C. M. & St. P. shops at Dubuque, Ia.

*A* is an extension with flange and center that screws on to head-stock of a small lathe, *B* is a sleeve with extension that slides on *A*, *C* is a star with six points, fastened on feed-screw *E*, which has a bearing in flange, *D* is a bracket which is fastened on lathe-bed. As the tool revolves with the lathe the star strikes bracket *D*, thereby advancing sleeve *B* to the right. Cutting-tool *E* being set at the

proper depth will carry a cut on tumbling-shaft bearing as shown. The tumbling-shaft being held firmly in lathe-centers, but does not revolve, a small lathe can do the work which otherwise would require a very large lathe in order to swing the long arms on tumbling-shaft. This tool gives excellent satisfaction.

*Dubuque, Ia.* J. C. MILLER.

[This tool is not unlike many others we have seen, but is the simplest of the kind, and a good one to copy.]

### In the Catskills.

*Editors :*

Never having read any items in your magazine about the Catskill Mountains and how to get there, I dropped off one of the New York Central limiteds the other day, crossed over the ferry at Catskill station and found myself at the Alpha of the Catskill Mountain Railway, where I met Mr. John L. Driscoll, the master mechanic and master car builder, whose warm welcome created within me a desire to abide with him forever.

This is one of the daintiest narrow-gauge railroads it was ever my lot to see, and I have seen several. It is 3-foot gauge, sixteen miles, up-grades of 100 and 120 feet to the mile to Palenville, at the foot of the towering mountains, with a branch to Cairo, eighteen miles away, and has a roadbed surpassed only by the New York Central and the Pennsylvania, winding around rocky bluffs, through beautiful hills, over deep gorges with dashing cataracts and deep pools where the finny tribe sport, shaded glens where lovers might murmur the old, old story of bread and butter and an oil-stove, without fear of prying ears, and flitting by sleepy farmhouses suggesting perpetual peace and rest—that is the Catskill Mountain Railway all the way from the mighty Hudson up to the Mountain House station, where the elegant Otis Inclined Plane Railroad with its 3-rail double track, parabolic form and mighty cables winds its safety-grip cars with their passengers a mile high to the mountain's top, above the clouds, and deposits them at the doors of mine host of the Mountain House.

As the Otis Inclined Plane road has been fully described and illustrated before, I need say nothing concerning it unless to state that by it passengers are now elevated from the station to the hotel in ten minutes, whereas by the old hack and stage lines it occupied nearly two hours and about wore the patience of the tourist into shreds. Between the 4th of July and the 15th of August last year it carried over 8,000 passengers. Two cables are used, their speed is about twelve miles per hour, and each car is equipped with an automatic brake-governor somewhat similar to those used on Corliss engines. Should a cable break, the governors instantly apply the powerful rail-grips and stop the car.

But to wander back to the railroad. The motive power consists of three 8-wheeled engines, having cylinders 13 x 18 inches and 48-inch drivers, built by the Dickson Locomotive Works, Scranton, Pa., eleven years ago, and, with the exception of the past two winters, have stood out in the storms and biting frosts with nothing between them and heaven's blue canopy but a coat of slush, and closest examination fails to show a rust or tarnish spot on their bright Russia iron jackets or a patch or other evidence of a calking tool ever having been used on their glossy, black tanks. The cabs have been rebuilt by Mr. Driscoll and made more roomy. I also noted that he had made one large hinged glass window, swinging outward from the top, in the front of them, in place of the usual sliding affairs commonly used. This is the first evidence I have yet seen of the fruits from the missionary efforts of the Rev. John A. Hill, he having described and advocated just such an arrangement in the *American Machinist* a long time ago. It is a good idea, and all cabs should be built that way.

One thing impressed the writer above all others, and that was the absolute cleanliness of those engines. Every night they are thoroughly wiped from pilot point to tender coupler, and their excellent condition can be readily comprehended when I say that their schedule time over the eight een miles up the mountain, around curves of 200 feet radius, with seven coaches and two baggage cars, is only thirty minutes.

Another interesting feature in railroading lies in the fact that this line during its years of existence has been operated by telephone service. In despatching trains and giving orders of all kinds there has never been heard the click of the Morse key. Janney couplers and the vacuum brake are to be found on every coach, baggage, box and flat car, and for the benefit of the Western Railroad Club I will state that the breakages of knuckles are 000 per cent.

The shops where repairs are kept up are at Catskill station and are practically all new buildings, the sand-house and oil-rooms are models of neatness, likewise the storehouse, but the marvel comes when we reach the "shop" proper. A well-constructed building having two tracks and two pits just to fit those engines, and at the extreme end a room fifteen feet wide by twenty-five long, containing a small upright engine and boiler but little larger than a boarding house teapot, a Sebastian twelve-inch engine lathe, a post drill press, two vises and bench and several tool closets and racks—this is the machine shop. Off from this room is a smaller one, probably ten feet square, containing an anvil and small blower—this is the smithy. Over the machine shop is the pattern shop, drawing room and office, while through a door to the attic over the engine stalls is a broad shelf containing patterns for brasses, brake-shoes, nozzles, center-plates and the endless variety of small patterns always required on a well ordered railroad—this is the pattern loft. And I have described the whole plant, but there is one thing I almost forgot, everything was CLEAN. No greasy floors resembling tar pavements, no tools too filthy to be handled, no greasy waste balls being kicked about the floors, but absolute, perfect cleanliness and order existing everywhere. Just think of it ye great big systems with decapods, compounds, testing departments and high-titled officials and go put on clean linen for once in your lives.

Spring switches made by the Pennsylvania Steel Co. are the standard and used everywhere, the points are always thrown to let the trains in sidings, but never opened to main track afterward. I confess to a little nervous feeling coming down to the junction of the Cairo branch at the rate of forty miles an hour and seeing the switch wrong in front of us, and I thought of that old P. R. R. regulation of "ten dollars for running through a switch," next pay day, but we went over it as though it were only a solid rail and that was what it was made for.

While the engine was being turned at Palenville (and here I might remark that every time they turn an engine they have to turn the whole end of the road also), I saw a home-made velocipede car designed and built by the agent of the road here. It was somewhat on the lines of the Sheffield, the wheels under the rider having belonged previously to defunct wheelbarrows. They were flanged with sheet-iron, and the back one was equipped with a 6-inch crank and no gearing, the operating lever being fulcrumed about four to one, thus giving the handles a sweep through the air about equal to the circumference of the wheels. He built it for exercise, I guess, not for speed.

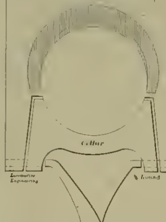
Mr. John L. Driscoll, M. M. and M. C. B., is about fifty years old (although he don't look it), and comes from the solid old New York Central, having been a runner away back in the sixties under the designer of that royal type of American locomotive pulling the Empire State Express. Mr. William Buchanan is superintendent of motive power. His manner, too, is similar, being quiet and unassuming, allowing his work and results to speak his merits and worth. OLD MAN ROGERS.

*Troy, N. Y.*

### A Cellar Remover.

*Editors :*

I send herewith a sketch of a handy pair of cellar tongs that only need to be tried to be appreciated. The chain can be hooked up to any length so as to give the most purchase to a bar, and the harder



you pull the harder the tool takes hold. Any blacksmith can make one from a bar of 1¼-inch iron, and—they are awfully handy. A. J. EDMONDS,

*Mason City, Iowa.* R. H. Foreman.

### No Spark Arresters the Best.

*Editors :*

Reading an article in April's number under the heading, "No Spark Arrester the best Spark Arrester," tempts me to write you on this subject, in the hope that some day spark arresting devices in front ends will be a thing of the past. A fierce exhaust with fire in the smokebox caused by drawing air from below necessitates spark arresters. Remove these causes and the necessity of arresters is gone. A free working engine and economy in fuel follows.

I have run engines six years without any spark arresters in the front end and never to my knowledge have burnt a blade of grass by throwing fire.

I will give you an account from memory of a coal test I was concerned in, in the year 1871, between two six-wheel coupled inside connected engines, 17 x 24, 5-inch single nozzles, no spark arresting devices of any kind in the front end. One engine had a brick cemented arch baffle door, a cast-iron grate frame, 5 x 3-inch, narrow edge bolted to side sheets inside of firebox, level with bottom of mud ring, beveled off next side sheets front and back. The bevel was filled with fireclay to keep out the cold air from coming in contact with side sheets front and back of firebox.

The opposing engine was similarly equipped, with the exception of the air-tight grate frame, the object of which was so well-known to the opposing crew that they imitated it to perfection by forming a cement of fine dross coal, plastering it from time to time around the side sheets back and front. Andrew Young, engineer, ran the opposing engine, with Robert Fairbairn as inspector, and I rode with Mat. Ruddick in the same capacity. It was a fair, sharply contested issue. The coal was weighed on and off the tender at commencement and finish of each trip. The average weight of the train pulled was 310 tons, the test was one way only, from March to Stratford on the Great Eastern Railway, England; distance 86 miles. Some parts of the road the grade was 1 in 100. After weighing coal off tender at end of trip at Stratford the front end was inspected, the cinders, of which there was only one-third of a bushel, averaging the size of pearl barley and so little heat in them that when taken out of front end one could hold them in one's hand, the results of an air-tight front end. The tubes were swept out at end of each trip with a tube-rod and a little hemp.

The test continued for one month, and Mr. S. W. Johnson, locomotive superintendent, now of the Midland, was generally on hand to inspect the contents of the smokebox at end of each trip.

The results of the test were as follows: The engine with the air-tight grate frame consumed thirty pounds of coal to the mile, or sixty-six miles to the ton. The opposing engine consumed thirty-one and a half pounds to the mile, or sixty-three and a half miles to the ton. D. McD.

*Los Angeles, Cal.*

### How a Toolsmith Proposes to Test Steel.

*Editors :*

I see a criticism in the April number of *Sparks* of a letter of mine that was copied from LOCOMOTIVE ENGINEERING, in which the writer says that I take toolsmiths to task when I said, "Test your steel and see that it is pure from phosphorous sulphur, silicon and other impurities of cheap ore."

Now, he says, this would be a job for a Bergmann, Berzelius or Reaumur and would be quite a job for chemists of the present age.

Now, I would like to ask why this is such a great job for toolsmiths. If the writer would go to work and take three or four different makes of steel and also different brands of the same make and harden them at the lowest heat they will harden at, number and break off a piece from each bar, examine them under a microscope and note the difference in color and grain, especially between the high and low price pieces, and then break off another in the same way and have them analyzed, he could, by practicing this, soon be able to tell the steel that contains a large percentage of these impurities from that which contains less.

Again, he says, the next axiom laid down by the writer is "See that your steel will refine."

He asks what steel will not refine. Now we all know, if we know anything about steel, that we very often run across bars of high price tool steel that will not refine.

Again, he says, as regards that sample of drill-rod, if it were to harden in the center it would split. Now, this is a mistake, that drill-rod can very easily be hardened to the center without splitting.

W. G. LOTTIS.

*Madison, Wis.*

### Testing Signal Line.

*Editors :*

Referring to "Nympano's" inquiry in regard to his method of testing for pressure in signal line, I note he states that the pressure frequently runs up to 60 pounds, and that he proves it by reducing pressure in main reservoir to a slightly lower point, and finally asks if there is anything wrong with that method of testing. If he means testing to determine whether or not his reducing valve is defective, I should say it was a very good way, for the conditions he mentions proves that very fact, but if he intends to use his method for determination of pressure in train signal line, when

he has a perfect reducer, then it is fallacious. That the pressure in signal line rises above 25 or 30 pounds, in itself would prove that valve 5 did not seat properly, or when seated allowed air to leak through. The diaphragm being spongy(leaky ?), with no other defect in the valve, would not operate to increase the pressure in signal line, but quite the contrary. The signal sounding when brakes are released would indicate that there was almost a perfect equalization between main reservoir and signal line pressure, and leak enough through reducer to sound the whistle. With a leak of this magnitude, however, I cannot understand why the trouble is not noticed at once, instead of only at the end of a long run. Did "Nympano" ever test more than one valve with same result?

*St. Albans, Vt.* PHONETIC.

### Piston of Triple-Valve Stuck.

*Editors:*

Regarding Thos. Croden's question in May number, permit me to say that if there was no obstruction in the piping, the reason the triple-valve under tender would not work when pressure was reduced at brake-valve, but would when reduced from stop-cock, would appear to be that its piston was so badly "stuck" that it required a severe shock to start it, such as would not be produced by an ordinary application, but would be by the sudden and excessive reduction obtained by opening the stop-cock. Of course, from the very nature of the case the only difference there can be in the methods of reduction named, so far as the triple was concerned, is one of quantity. PHONETIC.

*St. Albans, Vt.*

### Chain Ganging.

*Editors:*

I saw an article in the April number of the LOCOMOTIVE ENGINEERING headed "A Good Word for the Chain Gang System," written by a fireman. He seems to think it is a grand, good thing for the firemen. It may be. But I do not see where there can be a good word spoken for it, and I will venture to say that the majority of the engineers are bitterly opposed to the chain gang system now practiced. It may not be so disagreeable where there is but one class of engines to run; but you take it where we have three classes of them and it is a very disagreeable way of running. I would like to ask some of the readers of the LOCOMOTIVE ENGINEERING where is there any material gain to the company or to the men? The company claim they can get more service out of their power. They may run them steadier for a time, but they are shopped that much sooner, so where is the gain?

The greatest trouble in running engines in the pool is to get the necessary work done on them to keep them in good running order. I will give you a few hints of how we are run and the fruits of pooling. The engines on the West Iowa Division of the C., B. & Q. we run first in and first out. We have three classes of engines to contend with—the class A, and the classes H and D, or Consolidated. We are required to pack a small tool-box of tools, weighing about 40 pounds. This is the fruits of the pool. Not long ago I got an engine out and the gauge-cocks were leaking so we could hardly see anything, and the injector-throttle leaking at the same time, and tank so dirty that we were compelled to take down the hose three or four times and clean out the strainers in getting over the division. At the same time the boiler was so dirty that we could not pull out of a station with more than a gauge of water without throwing it out of the stack. We were mad, to put it mild, and censured the man who had the engine in for not reporting her washed out, but on investigation we found that the man that had her in reported boiler and tank washed out, gauge-cocks and injector-throttle ground in.

Now this was the way the work was done. They filled up the boiler and blew out about two gauges of water, and took down the tank hose and cleaned out the strainers, put up the hose and let her go. This is pool. This last winter and spring we had several engines that did not steam as they should, and after the roundhouse forces exhausted their powers to make them steam properly, the engine foreman had them remove the bottom flues in one of the engines and they found it filled with mud and scales up to the third row of flues. They afterwards removed the flues from four or five others and found them in about the same condition. This is the fruits of blowing off engines instead of washing them out as they should have been. This is another case of expense and trouble that can be attributed to the system of chain ganging engines. Before the chain gang system took effect we ran Consolidated engines from twenty-four to twenty-six months before shopping them. But now if they get eighteen months' service out of them they are doing well. In my way of figuring it is a bigger expense in the long run to the company and a source of trouble and annoyance to the majority of the men.

*Creston, Iowa.* A. W. LONG.

### Running Position—Tender-Brake Rig—Testing Signal Whistle.

*Editors:*

Please note mistakes in my article in May number. Third line, second paragraph, page 211, should read "one and one-sixteenth" instead of "one and one-sixth." Fifth line, same paragraph, "seven-sixteenths" instead of "seven-sixths." In fifth paragraph, ninth line, read "short trains" in place of "short travel."

I wish to raise a question as to running position in brake-valve. There seems to be no question in the discussion lately as to this being at all times the right thing to do. In the Westinghouse Instruction Book, page 23, paragraph 3, it says: "Let the brake-valve handle remain in release position down-hill." I believe on very short passenger trains the Plate D 8 valve will give no trouble if left there, unless the main reservoir on engine was very small. I have tried these trains so when standing still and never had a triple valve stick on an emergency application (unless the valve was out of order or some brakeman had noticed on a passenger train a pressure-retaining valve and closed it), and I have been on these trains up-hill with no reserve pressure, when they broke in two, and I always found engineer had time, after placing brake-valve handle on lap, to get all the pressure needed to release his brakes by the time the train-pipe cock was shut off, and in such cases, where air is in good condition, I fail to see the necessity of making this (in this case) surplus. At any rate, I advocate using weak feed-valve springs, No. 20, Plate D 8, on such trains. We had an experience with the Fig. 5, Plate D 5 brake-valve when it first came on this road. The pumps were of the latest pattern, 9½-inch, and if the brake-valve handle was in running position and an ordinary stop was to be made with from four to six passenger cars, the auxiliary reservoirs would charge to 80 or more pounds in absorbing the air made by this pump, hence the "plugging" business till governor was changed to main reservoir.

Apropos of the tender-brake question, it is my experience that tender-brakes have the worst proportions and are least utilized of anything in the air-brake line. I was once sent out to get measurements of the tender air-brake rigging on all tenders on the roads, and if I had found machinists using corkscrews for straight-edges when I came back I don't think I would have been surprised any. In my opinion there is one defect in the tender-brake that could be easily remedied; on tenders the shoes are usually found setting up to the wheels nicely, but when the top of live lever is pulled back, a man could put his foot between the shoe and wheel. I found it took 18 pounds on a spring scale to pull the top end of lever back, and over 100 pounds to pull back a brake-beam; of course, after the engine starts up, the beams loosen, as the hangers are generally pulling away from the wheel, but is there not some loss of power in starting with over 100 pounds on each brake-beam? I think, for my part, that starting time is the wrong time to have any brakes on at all.

My way to test signal pressure is to put a gauge on signal train-pipe, *and watch it a short time* to see if the reducing-valve leaks up any more pressure after it has cut off; I also instruct engineers to test their signal pressure by stopping pump and opening drain-cock on main reservoir after the trip. Whistle will begin blowing as soon as main reservoir pressure is reduced below that in signal-pipe, and can be seen on air-gauge provided, of course, there are no leaks, but, as there is a likelihood of some fitting coming loose before the trip is ended, this method is not infallible, is only intended for use in absence of test-gauge, and it is to be understood that the whistle blowing at 60 pounds, while signal-pipe only showed 25 or 30 pounds, would indicate leaks or imperfect signal-valve. I once had a signal-valve that would only blow when cut out from train, while on engine it seemed to blow to perfection; when taken down the round portion of spindle in "signal-valve," above three-cornered part, had been filed away till air flowed freely to under side of rubber diaphragm; also should this diaphragm have more tension on one side than the other, or soften only on one side, it is apt to give trouble. GEORGE HOLMES.

*Roanoke, Va.*

### That Gauge-Tester.

*Editors:*

Referring to the hydraulic gauge-tester problem submitted by E. S. Grensel, in May LOCOMOTIVE ENGINEERING, allow me to say that the statement that "the plunger is exactly ¼ of a square inch in diameter" seems to be a little obscure. I assume, however, that Mr. Grensel intended to say that the face of the plunger exposed to pressure had an area equal to one-fourth of a square inch, as the number he gives (.565 inch) is the diameter of a circle having one-fourth the area of a square inch. If I am correct in this, Mr. Grensel's assertion that "the weight ought to represent twenty-four times on the gauge" is erroneous. With the levers shown the ratio between the weight in the balance and the pressure upon the gauge would be 28. Mr. Grensel evidently gets upon the wrong track by figuring from power to load, when he should figure from fulcrum to load, or using 24 inches for the entire length of his lever when it is actually 28 inches. To correct his tester he should either figure the ratio 28 or make the long end of the lever 20 inches and use ratio 24. In either event he should calculate the weight of lever and make proper allowance, or preferably, arrange a counter balance to compensate. CLARK L. PIERCE.

### A Good Suggestion for Distinguishing Brake-Valves.

*Editors:*

In the May number there is an article by Paul Synnestvedt, wherein he says: "The remarks about the use of the engineer's valve in release position when there is a detect hole in rotary valve, seem to me rather hazy. The valve is not supposed to be left in the release position." Now, in fact, a good many engineers are running with their valves in release position; the excuse they usually give is that when carried in running position the brakes creep on. I have run a number of engines that had the "pinhole" plugged up to prevent it blowing. When an engineer runs with valve in release position he is destroying one of the most important features of the valve. Westinghouse and Phelan tell us that the feed port in running position is ample for any ordinary leaks, to all of which I agree; but here is where the trouble comes in. In starting out on your run or picking up empty cars, you turn handle to release. Now, we will say you have 70 pounds in main reservoir and train pipe; you now turn handle to running position to get excess pressure; now, until pressure in main reservoir runs up to 90 pounds (if you are carrying 20 pounds excess) your valve might as well be on lap, for no more air will come to train pipe until then. Whenever I feel the brakes creeping on I go into release just long enough to "kick" brakes off, and no longer. As soon as excess catches up there will be no more trouble.

I see that the last valve out, which was illustrated in a recent number of LOCOMOTIVE ENGINEERING, has remedied this trouble. There are so many valves now in use that it is difficult to understand which one a writer is alluding to. What's the matter with naming the last one out—the '93 valve? ORANGE POUND.

*Bartow, Fla.*

### A Stolen Air-Brake Article.

*Editors:*

The letter from A. W. Long, which you print in the May number, is almost a verbatim copy of the article over the signature of Paul Sords, published in the technical department of the *Engineers' Journal* for February, this year. Such plagiarisms have occurred several times. Ideas have been taken from the writers to the *Journal* without giving credit, but I never saw anything so near a deliberate steal as the mentioned article seems to be. Better keep an eye on that department of the *Journal*. It contains some good ideas, but they don't look so well when reprinted over the signature of another than the author and in another publication. Trusting that you will accept this as an attempt to prevent imposition on LOCOMOTIVE ENGINEERING,

I am, yours truly,

WILL W. WOOD.

*Terre Haute, Ind.*

[We find our correspondent is correct, and regret to have to acknowledge that an engineer would impose upon us a cribbed article over his own name. We only hope that it may be proven that Paul Sords and A. W. Long are one and the same—this would change the charge from "plagiarism" to "repeating," both of them disgusting to all fair-minded men.]

### What Was the Matter with This Valve?

*Editors:*

I had occasion to inspect a ten-wheel engine recently, equipped with Westinghouse automatic air-brake equipment, equalizing discharge valve. Driver brake of latest design outside equalized lever and operated by separate auxiliary reservoir.

Engineer complained that driver brake would not apply in service notch and only in emergency. Tender brake worked perfectly in service notch. I tried the brake, and, noting conditions, quickly formed an opinion, examined the valve and found where the trouble existed.

Now, what was wrong with this valve?

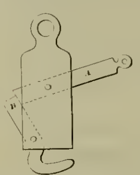
### A Drop-Hammer Trip.

*Editors:*

While in Los Angeles, Cal., May 3d, I spent a couple of hours to good advantage in looking through the Baker Iron Works, situated on Buena Vista street. This is quite an extensive plant, supplying a general contract trade. While strolling through these works, with both eyes open, my attention was drawn to a very simple but neatly working device which was used to trip a heavy weight with which scrap cast-iron car wheels were broken in pieces

to be melted in the foundry. While this subject may not come directly under the head of railroad matters, I thought, perchance, it might come handy to some reader of LOCOMOTIVE ENGINEERING, who might at some time find use for such an appliance. The contrivance consisted of a simple rough fork, or jaw, such as is generally used on the ends of tender-brake rods, and was made of ¾ x 3-inch wrought iron. The top terminated in a strong eye. The bottom was left open. Space between the jaws was about 1 inch near the top, and in the center of the device as it was held in position with the eye up was a ⅝-inch steel pin, upon which worked a lever, *A*, made of ⅞ x 1¼-inch iron, one end of which terminated in an eye, the other end being left square. This lever could be made of any consistent length, the length of this lever would determine the power required to trip the hammer.

Below this lever and to the left of the jaw was another ⅝-inch steel pin, upon which swung another lever, *B*, on the



lower end of which was a hook, left medium straight; the top end of this lever was also straight.

To place this contrivance in position to work, the square end of lever *A* was placed against the edge of lever *B*, near the top end. The hooked end was then placed through the eye in the hammer or weight and the hoisting power applied. When the weight had reached the desired height a slight pull upon a chain or cord attached to the eye of lever *A* caused its square end to slip from the end of lever *B*, whereupon lever *B* instantly flew to a perpendicular position, throwing back the hook, which allowed the weight to slide freely from it and fall.

This device could also be used to advantage, I think, upon a hammer which worked between ways or guides, as a very slight pressure upon the top end of lever *A* against any obstacle which might be placed above it between the guides would cause the hammer to fall, and I believe it would work quicker and surer than the appliance now generally used for this purpose. L. C. HITCHCOCK.

*Los Angeles, Cal.*

### Different Ways of Valve Setting.

*Editors:*

I see that my little dig at Mr. Campbell's pointers has raised a cry from away down in the Cracker State.

If "Young Whiskers" will refer to my article he will see that I asked for information in regard to the method of setting an eccentric with the pin on the quarter; outside of that, my only criticism of Mr. C.'s method was in the amount of time it required. I do not believe that "Whiskers" ever had the pleasure of working on a narrow-gauge engine, for any one who has knows that a machinist cannot get under one of them and loosen the set screws in a back motion—or outside—eccentric in ten minutes.

W—— says that he had an opportunity to try his "pet idea," and he succeeded so well that the engine saved $90 on one month's coal bill. He says, "Will you believe it?" From what I know about the readers of LOCOMOTIVE ENGINEERING, I don't think they will.

I was looking over the fuel expense sheet of a railroad for the year 1892, not long since, and will give a few figures taken from it.

Average miles run per ton of coal, 24½.

Tons of coals used for one month's run of 100 miles per day or 3,000 miles per month, 122.

Cost of coal on engine, $1.65 per ton, $201.30.

Amount saved by "Whiskers" in ten minutes, $90, or nearly 45 per cent.

I have heard of agents who offered to save from 20 to 40 per cent. of the coal bill by putting on their feed-water heater, mud extractor, or some other patent attachment, and I suppose that we may expect to soon hear of an agent going to the general managers and offering to save 45 per cent. of their coal bill if they will only put WHISKERS on their engines.

For the benefit of your readers I will tell how I set valves.

Referring to the January number of LOCOMOTIVE ENGINEERING, will say that I follow the same method as "A Practical Machinist" up to the point of setting the eccentrics, from there I vary a little from his method.

After getting the blades the right length, place reverse lever in front notch of quadrant, move engine forward till right crank-pin is on forward center. *Always get pin on front center when setting eccentrics*, for in that position the throw of the back motion is down and the set-screws can be got at much easier. If forward motion eccentric shows too much lead, move it away from the pin till valve-stem shows BLIND, then move towards the pin till stem shows the required lead and set up the set-screws. Put lever in the back notch and repeat the operation with the back-motion eccentric. It is not necessary to move the engine to take up lost motion in setting eccentrics, when changing from the forward to back motion, as you take up all the lost motion by moving the eccentrics till the stem shows *blind*.

If you have to move the back motion very much it is better to reset the former one, for if you move one eccentric very much it will alter the lead of the other one on same side. Now, go over this and see that it is all right by moving engine off of the center and then back to it with lever in front and back notches. Move the engine forward till left pin is on the forward dead center, and set the eccentrics on that side in the same manner.

Engine is now square at full stroke, but as it is generally worked in about 6 inches, the valves should be squared with the lever in that notch or near there.

Place lever in 6-inch notch, hold tram on valve-stem and move engine till valve just closes the front port on left side. Stop moving engine and measure the distance the cross-head has traveled from the dead-center on the guides, which is 6 inches. Mark it on front end of left guide. Move engine forward and obtain point of cut off for back end of right side, this is 7⅜ inches, mark it on back end of right guide, get point of cut off of back end of left cylinder. This is 7 inches. Get cut off front end of right cylinder 8⅞ inches. Now you have right side front 8⅞ inches, back 7⅜ inches, left front 6 inches, back 7 inches. To make engine cut off equal on both ends of left side, add 6 and 7 inches=13 inches, one-half of 13 inches is 6½ inches, move engine till crosshead travels 6½ inches, the distance on valve-stem from point of tram to point of cut off will be the amount to change the back motion blade. To make right side cut off equal, add 7⅜ and 8⅞ inches=15⅞ inches; one-half is 7¼ inches, move engine till crosshead has traveled 7¼ inches, the distance on valve stem from point of cut off to point of tram will be the amount to change back motion blade on right side.

The engine now cuts off at 7¾ inches on right side and 6½ inches on left side. To make it cut off the same on both sides will lengthen the link hanger on left side or shorten the one on right side. I do not like to raise or lower the tumbling-shaft boxes, for it is apt to cramp the shaft and make the engine handle hard, and besides, if you raise one box, the arm being about 10 inches from the box, you only raise the link about three-quarters what you raise the box and you also raise the other link about one-quarter as much.

With reverse lever still in the 6-inch notch, move engine till the head on left side has touched 7¼ inches. With a scratch awl make a mark on the side of link under plate of link block, then move lever until valve has cut off steam, as shown by tram on valve stem; make another mark on side of link, and the distance between these two marks will be the amount lifter will have to be changed.

By "Practical Machinist's" method find if the reach-rod is the proper length, and if it is not, change it; as a general thing, if it needs changing it will not be enough to affect the lead so as to require the eccentrics to be moved again.

Your engine is now as near square in the forward motion as it can be made without some radical change in the design of the link motion.

The reasons for changing the back motion blades in equalizing the cut-off in the forward motion are: A road engine uses the back motion very little and so it can be sacrificed for the benefit of the forward motion, also, if you change the forward motion blades you affect the motion more the farther from the center the lever is placed, while you want to change it most the closer to the center the lever is placed.

It is impossible for a person to learn to set valves by reading or studying without he has practice, for no two sets of valves will require the same changes, as different engines have differently proportioned valve motions. One point that must be considered in changing the length of blades, is whether the two arms of the rocker-shaft are of the same length, for if the outside arm is the longer the blades will not require quite as much change as the stem shows.

I will venture to say that if "Whiskers" saved 45% in ten minutes by his method, if he had used this method he would have saved the other 65%.

Now for the benefit of "W——" or any one else who wants a quick method of setting valves, and one that will be found more accurate and, I think, quicker than the ten-minute plan—at least it saves part of the pinching.

When taking the port openings at *A* and *C*, also mark them at *D* and *F* with a tram bent on one end, and the straight end in a center punch mark on any convenient dead part of the engine. I like the guide-yoke the best, for when working

from there you will be out of the way of the steam from the cylinder cocks.

Put a center at *E* between *D* and *F*. Now, when engineer reports valves run over, have the hostler handle engine for you, and with the reverse lever in the forward notch have him move the engine slowly one revolution while you walk by the side of guides, and with end of tram in punch mark at *X* mark the full travel of valve at *G* and *H*; one half the difference between *E G* and *E H* will be the amount the forward motion blade will have to be changed. Rub out the marks at *G* and *H*, and with lever in back notch have hostler move the engine slowly one revolution while you mark the stem again at *G* and *H*, one half the difference between *E G* and *E H* will be what the back motion blade will have to be changed.

Mark the amount on the blades with a piece of chalk and repeat the operation on the opposite side. Be careful to commence marking the valve-rod before valve gets quite to end of travel. Now get under engine and change all blades that require changing, after which you will have to get some one to pinch engine and get one dead center on each side and set the eccentrics if they need setting.

In setting valves this way, all parts of the motion are under the same conditions as when the engine is in service, but the fault that it has is that it tells nothing about the cut-off. I am not the discoverer of this method of setting valves and only recommend it for an emergency, when an engine must be got out in a hurry, or for those who are opposed to a machinist taking the time that is necessary to set valves the way they should be set. F. C. CHARLES.

*Cedar Rapids, Iowa.*

### Conger's Puzzles.

*Editors:*

If I were working on Brother Conger's puzzles, on No. 1 I should examine port in brass bush in triple valve body leading to brake cylinder, and the cavity under the bush. If these were clear, which could be ascertained by filling this port with thin oil, and observing how fast it disappeared; if these were all right I would pour oil in exhaust port outside and see if it came out readily in first hole in seat under slide valve No. 3, plate D 22. Thus, assuming exhaust cavity was clear, Piston No. 4 had its proper travel, and bush, Fig. 9 *b*, plate No. 3, was tight. On puzzle No. 2, would disconnect pipe from brake-cylinder, and by applying brakes or giving straight air, see if the air came through properly. Next, if this failed, would, if piston were free, take off head, and if it were a cape chisel job look for it in bottom of ½-inch pipe hole in cylinder head, taking it for granted that when he speaks of pushing down cams he means push down driving-brakes. No. 3 would depend on piston travel very much. There is a range of 10 pounds on that alone. On a passenger car with 12 x 33-inch reservoir and 10-inch cylinder, with 8-inch piston, the first emergency application should give about 57 pounds, and from 60 to 63 pounds at the second. On service application, should give 50 pounds equalized pressure first time and 53 to 57 second time, depending on how clean the passages were and in what order the brakes were kept. N. B.—With old pressure retaining valve. The only reason friend Croden's tender triple-valve would not work, if nothing but cleaning was done to it, is as far as I can see, there may have been a smaller pipe than usual between tender and brake-valve, and triple-valve been so dirty and dry that it required the larger opening. GEORGE HOLMES.

*Roanoke, Va.*

THE ANSWERS.

First one.—A cinder got in exhaust port, sometimes it turned around so the passage was closed entirely, at other times it let the air escape slowly by it. When triple was taken apart to clean, the cinder got in somehow, after that, when it was taken down, the cinder was not seen. We turned a stream of water into the outside end of exhaust, out came the cinder.

Second.—The driver brake-rod piston struck the top cylinder-head when it released, and finally wore into the head and made an air-tight joint. When brake was set the air only pressed on a surface ⅛ inch in diameter. We cut some grooves in the center of piston to let the air get into the cylinder and brake works O. K. In this case piston-rod came through the spider too far. C. B. CONGER.

*Grand Rapids, Mich.*

### A Dangerous Mistake.

*Editors:*

"Air-brake instructors tell us that when a partial application is on and the emergency is desired, to move the handle to the extreme left for a moment and then to the extreme right, and its action is assured."

This quotation is taken from an article

by Mr. A. W. Long, in the May number of LOCOMOTIVE ENGINEERING. It expresses an idea that, to the certain knowledge of the undersigned, is responsible for more than one disastrous wreck. The origin of this idea is a matter of conjecture only. Possibly it arises from the mistaken belief held by many men that in some mysterious manner the pressure in the main reservoir is of some use in emergency application of the brakes.

When asked how to let the air out of the main reservoir, many engineers will say, "Put the handle in the emergency position." It is of vital importance that all engineers should be impressed with the fact that when the brake is partially applied a release can only be a loss—not only a loss of time but of *pressure* as well.

Even if the handle is thrown to release position so quickly as not to release any of the triple valves, time is lost in the act and nothing gained in the way of pressure. Besides this it is almost impossible, or, in fact, QUITE impossible, to make this movement so quickly as not to cause some of the brakes to come off (supposing, of course, that they are only partially applied).

Of course, to throw the valve handle to the release position increases the pressure in the train pipe, but it must not be forgotten that the brake will not set again or the pressure in the cylinder increase until the train-pipe pressure is again reduced below that in the auxiliary reservoir. This is true of BOTH the service-stop and emergency. Although the emergency does put train-pipe pressure into the cylinder, it is nevertheless dependent on the movement of the main valve for its action.

Under any circumstances, no matter what, it is a great mistake to release brakes or "throw the handle to release position" in case of emergency. Put it immediately to the emergency notch and leave it until the brakes are fully applied.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

## In the Transportation Building of the World's Fair.

[EDITORIAL CORRESPONDENCE.]

The exterior view of the World's Fair buildings presents such an attractive display that a stranger coming within the gates for the first time is at a loss which one to choose. If they wish to see the exhibit likely to be of the greatest interest to them, railroad men would do well to find their way direct to the Transportation Building. On reaching the building it is very well worth an inspection outside. It is a very handsome oblong structure, of what is called the Romanesque style of architecture. In reality it is a huge oblong building with a high monitor roof and a cupola in the middle. The arrangement appears to give very good light and ventilation. The main entrance is an imposing square block, surmounted by a shallow balcony and elaborately ornamented by carving. Four semicircular recesses make a striking border to the gateway. On one side of the entrance is an extract from Bacon, and on the other an extract from Macaulay; both dwelling on the importance to civilization of good facilities for transportation. On entering the main door the first thing seen is a model of one of the caravels of Columbus, flanked by some of the modern massive vessels built by Laird of Birkenhead, England. In close proximity to these are some Fox corrugated steel furnaces.

Glancing around from the doorway so many attractions strike the eye that I decide to take them in a diluted form by a view from the gallery. On climbing up the stairs I find the gallery is in no way behind the main floor in objects of interest. The gallery possesses an advantage in the fact that a visitor can look at the exhibits there and find relaxation from watching the exhibits below, and the moving mass of humanity walking around. One sees among the crowd at this Fair the most picturesque looking people to be seen out of Asia. All the varieties of color, all the diversities of garb and races belonging to the human family, appear to be represented within the Fair grounds.

A very attractive part of the gallery is the offices of Mr. Willard A. Smith, Chief of the Transportation Department. Here there will be offices set apart for the railway press, and the headquarters of LOCOMOTIVE ENGINEERING at the Fair will be here. Around the walls of the offices are hung a great variety of beautiful photographs showing scenes relating to the development of transportation. The pictures give a graphic illustration of the improving methods, from the time men's shoulders were used exclusively for the carrying of burdens, up to the proficiency which built the *Campania* and the "999." One looking over the pictures gets an admirable object lesson of the numerous methods that were tried from the era of the pack saddle with man as the bearer, to our day of luxurious steamers and palatial palace cars.

A curiosity to be seen in Mr. Smith's room is a plant for heating the place by electricity. Railroad men will find this well worthy of examination. It was put in by the Consolidation Car Heating Co.

Starting on a tour of the gallery one is first impressed with the great variety of manual mechanical means of locomotion in the form of velocipedes and their kind. This place is the paradise of wheel riders, and the Mecca of small boys. Next we come to boats of all kinds, from the crudest dugout and bark canoe to models of the finest steamers. The appliances used in all kinds of water transit are very well represented, both in the gallery and below. A railroad man will not find many of the appliances used by himself in the gallery, but it is, nevertheless, a very interesting exhibit, and one well worthy of close examination. There is a great variety of all kinds of road vehicles, from the baby-carriage up to the tally-ho coach.

Descending to the main hall after a turn around the gallery, one of the first sights to arrest attention is a pyramid of railroad rolling stock wheels exhibited by a French firm. The pile has four pairs of driving-wheels six and a half feet diameter as a base, and from this it is tapered up by wheels of decreasing diameter to an apex formed by a single pair of tiny car wheels. The wheels all have steel or wrought iron centers, and some of them are striking specimens of wheel work. This exhibit possesses a melancholy interest from the fact that it fell down while under construction and killed several men.

The Bethlehem Iron Co. have a very striking exhibit in the form of a full size wooden model of their largest steam hammer. It looks so much like iron that visitors believe it to be made of that material, and admire the enterprise that led to the transporting of such a ponderous article. Beside the hammer there are some immensely heavy forgings, one section of a shaft being the heaviest forging that I have ever seen.

An exhibit near here which attracts much attention is the section of an ocean steamer, erected by the International Steamship Co., New York. Thousands of people who have never seen an ocean steamer learn from this exhibit how such ships are arranged.

Towards the other end of the main hall, the most conspicuous object on the floor is the exhibit of the Johnson Signal Co. They have a forty-lever machine which has been in use eighteen months, and a variety of switch and signal apparatus, of which we will give more particulars in a future issue.

The next exhibit presents a variety of apparatus familiar to all train men, being that of the Westinghouse Air-Brake Co. Near this are the exhibits of the New York Air-Brake Co., the Boyden Air-Brake Co., the Mason air-signal, and an air-brake got out by the Crane Co. We will give descriptions of these after they are in working order. The brake exhibits extend into the annex, where we find the principal part of the railroad rolling stock. The space near the brake exhibits is devoted principally to track and construction appliances, among which are the Thatcher dump car and the Rogers ballast car. The former company have two cars, which are shown in operation and attract much attention.

The Rogers ballast cars make a most interesting exhibit, as they are shown distributing ballast. One car putting it down and the other spreading the stones, it is left ready for track raising. The large number of railroad men constantly to be seen watching this exhibit indicates the growing interest in the proper methods of ballasting track.

Another track exhibit which excites much interest is the section of a track fastened with the Greer spike, made by Morris Sellers & Co., Chicago. Sections of ties are shown with the Greer spike and the common spike alternating. It is seen that the common spike bruises its way into the wood and makes a crushed nest, which is ready to fill up with moisture and begin the rotting process that does so much to shorten the life of ties. The Greer spike, on the other hand, cuts its way in cleanly and is grasped closely by the grain of the wood. An onlooker does not need to be told that the Greer spike is twice as hard to pull out as the common one, and makes in that proportion a better fastening.

Near here, and rather out of place, as it appears to us, in this track department, we find Schoen & Co.'s exhibit, consisting of a great variety of pressed steel articles used in car construction. There is in this exhibit an end of a coal car, showing draft timber fastening, body bolster, corner plates, stake pocket, center plates and other parts for which pressed steel is well adapted. There are brake beams and specimens of all the other pressed steel forms made by the company. Among the novelties exhibited are a pressed-steel axlebox and a track tie. The box consists of two pieces, and is of the master car-builders' standard and dimensions. There appears to be a great future for this box. The pressed-steel tie is dished and bent down in the middle and ends. There are 18,000 of these ties in use on the New Central in New York. Mr. Schoen received a contract from the Government lately to supply the Post-Office Department with pressed steel letter-boxes. One of them is shown with its attachment.

Passing a great variety of appliances intended for the construction and maintenance of railroads, such as steam shovels, ballast-plows, and all sorts of switches, we come to the magnificent train exhibited by the Canadian Pacific, which is described elsewhere. Passing this and the fine exhibit of the London & Northwestern, described elsewhere, we find ourselves surrounded by English railway appliances. Among these you notice first the exhibit of the Great Western Railway of England, the principal figure therein being a green-painted locomotive, noticeable for its huge single pair of drivers and wide gauge of seven feet. The engine is the historical "Lord of the Isles." As we expect to illustrate this locomotive soon, there is no use to give particulars of it at present. The rolling stock of the road is represented principally by drawings and photographs. There are some vacuum-brake attachments among them of pressed steel cylinder and piston cut in sections.

Passing the imposing locomotive, "James Toleman," which we illustrate in this issue, we find a succession of booths containing exhibits of the Midland, the Great Eastern, the Great Northern of Ireland, and others that operate under the British flag. As they all consist mostly of pictures, we need not mention the details. One exception to this is found in the booth of one of the Irish railways, and consists of columns of pressed peat, which may be examined with interest. This is used for fuel, and appears to be as hard as coal and looks very much like that article.

On the next track from the British exhibit we find a line of space devoted to exhibits of car heating and lighting. This part was very incomplete when I was there, the Consolidation Car Company's exhibit being the only one in any kind of shape. Passing up towards the main building and inside of the same, we find a New South Wales exhibit. It consists principally of a clay model showing the tortuous course of certain railways in the Colonies in crossing a mountain range. There are a variety of attractive views showing the railway work shops at Eveleigh, the Hawkesbury bridge and a variety of other railway scenes.

Beyond this on the Annex, we find four tracks occupied by the splendid exhibit of the Baltimore & Ohio. The principal part of this collection consists of historical locomotives, and shows in striking form the gradual development of the engine. We expect to devote a great deal of space to illustrating and describing this exhibit. Meanwhile, it is just to mention that the Baltimore & Ohio Railroad Co. have expended nearly $100,000 on this display, which is from a historical standpoint the most valuable ever seen. The modern part of the exhibit consists of a royal blue train with a Baldwin engine in front. We expect to give more particulars about this train in another issue.

Throughout the remainder of the immense annex, there are groups of all sorts of locomotives and cars with every variety of attachments exhibited in separate displays. A visitor here is like a bee in a field of clover—he can only expect to take occasional sips, the luxury of choice being embarrassing. After many days devoted to this exhibit, I failed to digest the identity of the car display, but the various locomotives became quite familiar. Besides a great many foreign locomotives and engines exhibited by railroad companies, the following engines are exhibited by builders: Baldwin, 17; Brooks, 9; Pittsburgh, 5; Schenectady, 4; Rogers, 4; Porter, 4; Rhode Island, 3; Richmond, 1; Lima Machine Works, 1.

A. S.

## A Fancy German Train.

There is a German exhibit in the Fair consisting of a small tank locomotive and two carriages that are well worthy of inspection. The engine is six-wheel connected, with all the motion on the outside. Americans will be struck with the smallness of the working mechanism. The finish is very fine. The cars are built entirely of iron or steel, and are remarkable for the elaborate finish and rich ornamentation. One is a compartment car carried on three pairs of wheels, held in pedestals secured to the bottom of the main frame. The springs are about 80 inches long between pins, and rest on the top of the axle box. The other is a saloon carriage of the American type, with platform and entrance at the ends, and carried on two four-wheeled trucks. Very elaborate drilled brass railings surround the platform. Both cars are very luxuriously finished inside.

The trucks of the saloon car are curiosities, being of pressed steel and made not unlike the pedestal trucks used on the Boston & Albany. The spring arrangement is, however, different—a very long spring being employed which extends from box to box. Persons who like to see curious specimens of railroad rolling stock should not fail to find this train.

In the course of a private letter to one of the editors, Dr. Williams, of the Baldwin Locomotive Works, says that he recollects the "Cork Leg" engine mentioned in the April number of LOCOMOTIVE ENGINEERING. He says that she wore a flat spot on one of her tires. She had a single pair of drivers. As she came limping up to Northfield some wag wrote the words "Cork Leg" on the side of the cab. The name stuck. Dr. Williams has more curious reminiscences about railroads than any other man in the world.

## An Exciting Night on a Confederate Soldier Train.

BY C. S. ANDERSON.

Resuming my war narrative of our hurrying the remainder of Gen. Lee's army from Richmond to reinforce Jackson, who had gone to Gordonsville to meet Gen. Pope, I will tell of one of my trips out from Richmond with a soldier train.

Mr. John M. Kroft, the regular engineer of the "Albemarle," was called home to his family, and the master mechanic detailed a machinist named Dock Galloway to run the "Albemarle."

As I have before said, a machinist is not necessarily an engineer. However expert and competent he may be as a machinist, it requires experience for him to learn to handle successfully, engines and trains in emergencies and under difficulties. Put a healthy twenty-two-year-old boy on an engine and let him *there* learn the thousand-and-one difficulties that necessarily come in the path of a train runner, as, for instance, those that befell Galloway that night of which I tell. It is not down in the books, this knowledge, but it has to be driven in by hard knocks, and once in, cannot be lost. It seems to me that some of our old runners have such a mastery of the machine that they appear only to watch the track ahead. A first-class locomotive is to machinery what the lion is to beasts—the king. Nobody can blame ambitious young men for falling in love with an engine, for she is the picture of life itself. But to my story:

Dock Galloway was a small, nervous gentleman, very polite and quiet, as good and harmless as he could be. I was right glad to see him on the "Albemarle" when it backed down and coupled on to my train. I knew I would have no fuss, even if I did not get on so successfully with Galloway as with some others. We took some officers aboard in Richmond, and got orders to load soldiers between the Chickahominy and Hanover,—the soldiers who had come to the railroad *via* the Cold Harbor road. The cars were soon crammed full of soldiers, of course, inside and out, and we got along very well during the day, keeping pretty well up with our preceding train, which, fortunately, as it turned out, was in charge of Conductor Joshua Finks and Engineer John Davidson.

About 8 P. M. we got safely in Melton's Station, about four miles east of Gordonsville, and having turned over the Summit there rolled along down a 65-foot grade which runs nearly all the way from there to Gordonsville. Feeling that we only had to let her roll on into Gordonsville, and being anxious to reach there and rest, we forgot to tell our new engineer of the wayside wood pile where we usually had to stop and get wood.

Oftentimes during the war we had to stop at out-of-the-way places to get wood from the ricks along the road. It was very dangerous and was the cause of right many accidents. Running into the cut of Cain's old field, Engineer Galloway gave one sharp whistle for down brakes. I listened anxiously for the second blast, which would have meant "Stop," as one blast was often only intended to slacken speed. I was, of course, on the look-out, and saw our rear dash past a red lantern and I also got a glimpse of a mess of folks in the ditch. I did not care to run over the tops of all these freight cars loaded with soldiers, but decided to see why it was that Mr. Galloway did not call for brakes again, reverse his engine and stop the train. I signaled my brakemen and called to them to put on brakes on every car they could get to.

I had gotten up to within a few cars of the engine when I saw just ahead of me the rear of Finks' train, which was just moving off from the wood pile where they had stopped to get wood and had sent the red light back to stop us. I can never forget the scene, made awful by the powerful light which the "Albermarle's" headlight threw on it. The soldiers who were on top of the rear officers' car scampered ahead for the front cars, thinking that we had run into them. Capt. Finks in rear of his train waving his lantern with all his might, the door of the coach open and the headlight of our engine revealing all excitement therein, and all on the rear platform.

But John Davidson made the "Westward Ho" spit fire as she coughed and snatched from the jaws of death two trains full of soldiers. It was certainly a happy disappointment to us all that John kept ahead and prevented the "Albemarle" from smashing into the rear coach of officers. What on earth was the reason that my engineer, Galloway, did not do anything to stop his engine, under such circumstances, I could not imagine, unless possibly he had fallen asleep, not being used to running and being out at night.

I tugged on over the soldiers until I got to the front of the front car and looking down into the cab saw, alas! that it was empty! The soldiers sat in front of the cars with their feet hanging down like boys on a goods box.

"Where are the engineer and fireman?" I quickly asked one of these, who replied, "Pshaw, they both jumped off when they saw that red light yonder, Cap," continued they, as I was getting down into the tender to get over into the cab, "You'd better mind; we heard those officers on the train in front halloo back that they will shoot every railroad man on this train when they reach Gordonsville."

My first impulse was to give the engine steam in her reversed condition and come to a full stop to see what had become of Galloway. But the thought then flashed into my mind that the train following us had by this time gained on us, as we were running very slowly. I leaned out of the cab and heard it coming, evidently having turned the summit. I at once threw her in front gear, whistled "off brakes" and pulled out for Gordonsville, choosing death to myself in front rather than death to my train of soldiers and myself too in the rear.

I fully believed that I would be shot at Gordonsville by the soldiers before I could explain the situation, and show them that I was innocent.

Pulling into Gordonsville, going west, there is, after passing the last county road crossing, a straight line almost a half mile long, which runs up nearly to the east switch at Gordonsville. We were just coming around the curve into this straight line when I saw a red and white lantern coming rapidly towards me and waving us to stop. I, of course, called for brakes reversed and stopped. Good Capt. Finks, pale and trembling as he came up out of breath, seeing me, as I leaned out of the cab to learn of him the trouble, "Carter, you will all be shot! for God's sake run to the woods!" he cried. "Where are Galloway and the fireman?" I quickly told him what had happened. While in this state of excitement we heard the following train coming along around the curve back of us. Instinctively, I must say, for I hardly knew what I was doing, I whistled for "off brakes," and pulled the engine open, intending, certainly, to get far enough into the straight line for the following train to see me in time to stop and let me pull out of their way.

Conductor Finks pulled himself up on the engine, and we got almost in sight of the station yard at Gordonsville, when I concluded to stop and take care of No 1. The soldiers in the front car, seeing and hearing it all, had become very much interested, and said to me:

"Captain, stand your ground, you saved our lives and we will try to save yours," and they began to load their muskets.

"Let's run up to the station and tell the officers all about how it happened."

Capt. Finks said, "That's it, boys, come on." And they ran up the yard to the depot, while I with peace commissioners in front and bayonets and balls in the rear for my defense, sat serenely on the "Albemarle," and was soon assured by Capt Finks and his Confederate officers that it was all right with the soldiers.

I pulled up to the reception room as meekly and mannerly as I possibly could.

What on earth had caused Galloway and the fireman to jump off where they did was the next question. It was a mystery to us all. Capt. Finks and Engineer Davidson agreed to take care of our train, and a great crowd of us got lanterns and went back up the track to see what had become of Galloway and the fireman. Curiosity and anxiety were at their height. The old mountain country road and the railroad run alongside from Louisa Court-House to Gordonsville, a distance of fourteen miles, and never lose sight of each other. It is a curious fact that Contractor Elisha Melton located the railroad, running the levels with three sticks, and built the road, a slab track, the western extension of the Louisa Railroad about 1840. Notwithstanding the fact that it was built without the use of an engineer's instrument, the grades and curves remain just as "Lisha Melton" located them fifty years ago, and it now forms a part of the great C. & O. system of 1,500 miles of track with 500 locomotives and running entirely through three States. But to my story.

I only intended to say that in order for us to go down the railroad we had also to see at the same time all that passed on the county road, and some of our party soon met Galloway and the fireman both nearly dead, laid out in a two-horse wagon, with "rack body" and poles put in to make a bed for the wounded men. The brakeman who had signaled Galloway to stop, and whose nonsense had caused the accident, stuck to them after finding them injured, and secured the wagon which he happened to catch on its way home from the woods.

"Why did you jump?" was, of course, the first question. Galloway, it seems, not being an experienced engineer, and having heard so many exaggerated reports of soldiers bayoneting railroad men who caused collisions, thought that the red light was hung on the rear of Finks' train, and that he was actually into the preceding train filled with soldiers, and so he jumped off after doing all he could to stop. The fireman jumped, he said, because Mr. Galloway jumped.

We used then a square tin lamp, the back tin, the sides white lights, and a red glass in front, but the red glass had a tin door over it to open and shut on a wire hinge. The brakeman said that the tin door would not stay open, so he put it up against his breast and held it open with one hand perfectly still. That was what fooled Galloway.

Doc never pulled another throttle open, but being too disabled for war or railroad life, he assumed the more peaceful occupation of gunsmith, which he successfully carried on until his health failed him, and still following kind-hearted old Joshua Finks he rolled into the Eternal City.

*Richmond, Va*

### An Improvement.

Travelers who have carried along a 20-page folder, with a distorted map of their native land on one side and some Chinook statistics on the other, in the fond delusion that it was a time card, will appreciate a little kink of General Passenger Agent Daniels of the New York Central. This is a four-page folder with the statement about the "shortest" and "greatest" and what-not all condensed onto the first page. The second page tells just where *one* train will get breakfast, luncheon and dinner. The third is advertisements of leaving time and stopping points of seventeen fast trains and the last page is a condensed simple time table of *one* train—tells where it stops, time it passes important towns, etc., and gives instructions about disposal of baggage. These little slips are distributed to each person in the train; you get just what you want for this trip and no extra and you can't make a mistake. The time table of train No. 6 is before us—we got it at Buffalo—and noted more satisfaction in their use by the passengers than we ever saw with the Chinese laundry list usually furnished.

A CONFEDERATE.

### A Confederate.

The picture here shown was made from a photograph of the engine "Aeriel," on the S. C. road, taken at Charleston, S. C., in 1866. This engine was built at their shops in 1851, had a hook motion with independent cut-off and dome boiler. She was employed during the war as a rebel and did good service to the cause of the Confederacy.

Beside her can be seen some cannon, hundreds of them having been made in these shops during the war, many of the tools for which, and same of the jigs and templates are still employed or are laying around the shops yet.

### Another Piston Blows Up.

On the 4th of May an engine on the Queen & Crescent came into Chattanooga with a bent piston rod. The rod and piston were taken out and the rod heated over a blacksmith fire. While the smith was straightening the rod the head exploded, killing the blacksmith and his helper and seriously wounding a man standing near by. Solid heads, so called, those without followers and bull ring but cast in one piece, hollow, with the core-holes plugged up, have exploded several times of late years when heated and one case is reported where one blew up while under a drill press being tapped.

### Making Locomotive Engineers—Two Processes.

BY J. J. CLAIR.

Having noticed an article in LOCOMOTIVE ENGINEERING on the subject, "How to Become a Good Fireman," I will give some experiences on a good or bad fireman, or how to become an engineer.

Jones and Brown were raised in the country and got a pretty good common-school education. When eighteen years old they wished to go firing, for it was seemingly a pleasant occupation, little to do but throw in a few shovels of coal occasionally and spend the rest of their time watching the pretty girls along the road. The excitement, novelty and change of scene prompt them on and through the kindly offices of a friend the wished-for positions are obtained and they go on the road.

Of course they are green and willing to do exactly as instructed, for they want to be good firemen and more, they expect to become locomotive engineers. Things go along all right for a while, the engineer explains how they should handle the scoop; when they pile the coal in the center of firebox and steam goes down to 50 lbs., the engineer will get down and fire and tell them lots of things about the way to keep engines hot. The engineer will fire up the hardest part of the hill a few trips until they can manage to hold the steam up with injector shut off. After a while they can keep enough steam to get along somehow, even if they do waste large quantities of fuel unnecessarily.

After a while the engineer talks about closing the dampers when approaching a stopping place or a down grade and tells them that considerable coal can be saved by following closely the instructions; engineer explains the effect of a heavy fire, about the necessity of air getting through fire, how to guard against getting fire too heavy or too thin, how to fire evenly without using hook or scraper, if possible to get along without them.

At the end of six months Brown has done his work as well as possible and has got into the habit of performing his duties quickly, thoroughly and cheerfully; he has a copy of Forney's Catechism of the Locomotive and has subscribed for LOCOMOTIVE ENGINEERING and during his spare moments studies other literature relating to the occupation he has selected. It's hard work at first trying to understand all he reads about combustion, machinery, etc., but he keeps at it and after a while it gets easier as he gets to understand it better.

Old Billy, the machinist, tells him that he don't go much on reading, that practice is what is needed, and those book-writers have only a lot of theory and guess-work to go by. But Brown remembers hearing the engineer state yesterday about the bad job old Billy did on the engine, and that he must get the work done over again to-day.

Brown has to know many things to be a first-class fireman and engineer, and while he cannot learn all of them out of books, he knows that a careful reading of the literature of his calling will be a great help to him, and will increase his knowledge far faster than can be possible with the most favorable practice without such reading. He not only studies matters relating directly to his calling, but even reads books and papers relating indirectly to it; he knows that should he take up an article relating to bridge construction he will understand more clearly why the superintendent has a slow order on the new bridge.

If he reads about the effects of changes of temperature on iron and steel he will understand why it is necessary to run carefully during extreme cold weather, or why nuts and bolts are more liable to become loose about an engine after a cold spell; he knows something of sudden changes of temperature on firebox and flues, he learns something about a boiler, its material, construction and how to care for it.

Studying something of the chemistry of fuel and feed water, he learns how to fire intelligently, economically, with much comfort to himself, the engineer and passengers. He is aware of the effect of different impurities in the feed water, and appreciates the importance of watching that he does not waste large quantities of pure soft water through the pop needlessly in the form of steam to the discomfort of those within hearing distance and loss to the company, besides increasing the amount of impurities and mud in boiler unnecessarily in a given period.

He cheerfully performs important duties and trifling ones; perhaps he sometimes thinks the master mechanic or engineer never notices all his work. No, he is aware that the officers and his associates are noticing and passing a verdict on his work and conduct daily, and that patience will bring his reward. If he thinks he has discovered a fault in his engineer's work he goes slow about it; he may be mistaken; anyhow, the engineer has probably noticed a dozen faults in his work and has not complained about them. He guards his habits and character, is truthful and sober, he knows it don't require much intelligence to detect a lie, that those who lie forget about it but those who hear do not, and think less of those who deceived them.

Early in his career he gets on with a good engineer, carries out his instructions; keeps his good-will. After a while, in good season he is promoted, and finds the first year pretty hard work, for now he has to take the responsibilities and think for himself, meanwhile, he keeps increasing his knowledge of his work, becomes familiar with the mechanism of engine, studies injectors, brake valves, triples, lubricators, etc.; keeps read up on what is going on in his business, and becomes a successful engineer.

Now, we will go back and follow Jones. At the end of six months he is beginning to think he knows it all, he goes around with the gang that loaf outside the office on the branches, and a Smart Alec, who has had a number of engines to fire and kept none of them, tells him how he does it and how Jones should do things, says he is a fool for cleaning and bothering about the fire. Jones takes in all this, and next time he goes out lets Mr. Engineer know he is firing that engine, and fills firebox with coal to suit himself, leaves the dampers wide open at all times, lets engine blow away steam from one end of road to the other; easiest way is best, say she, this is the way Smart Alec does it and he knows. Jones don't bother putting on blower when steam is shut off, just lets smoke trail back in coach windows when on passenger. When he is told anything by engineer he don't give it any attention, or is ready with some absurd or false excuse, or differs with engineer, or disputes the point with him.

When he gets in he goes up town, meets Smart Alec and more like him; they show him around and post him up. Next trip, when he fills firebox with coal, and engine don't steam well after he has hooked over the fire for the twentieth time, he blames it on engine—not a good steamer, or perhaps engineer works the injector too much. If Jones can find anything about the way engineer performs his duties to kick about, he does it, and tells Smart Alec and the rest what a chump he fires for, what engineer ought to do, and expresses his opinion quite freely about engineer's business.

Pay-day he starts out to have a time, yes, a great time, taking in the town. Smart Alec has a wife and small family. Wife goes over to see the master mechanic on pay-day, makes inquiries about Smart Alec. She needs some money for the little ones, but Smart Alec is out for a time and has Jones along with him. If Jones has some spare moments for reading he studies the *Police News* or some detective stories. They are more exciting than reading about locomotives. When he learns that engineer is about to do some work on engine and he might be in it, he slips off out of sight, and when the work is done comes back innocently, and, of course, the engineer sits down and tells him all about it—Jones is so much interested in learning, you know.

Next day, when he goes over to other end of road, he don't take much trouble about engine; it is clean enough, and if it don't suit engineer he can go out and brighten it himself. Jones goes around back of roundhouse in the shade on the benches and finds the gang, and they criticise engineers in general and Jones' engineer in particular. After a while they notice master mechanic going down to station, and all retire up to old Jake's to play pedro or seven up for the beer.

After firing, or doing some alleged firing for three or four years, he kicks because master mechanic has promoted Sam and Tom and he is not given a show, swears that the master mechanic never did give him a show anyhow. After a while, during a rush of business, he is promoted; but he will be a bum railroad man, a disgrace to the engineers and a stumbling-block to many good people who may think that perhaps all railroad men are like him.

When Brown was promoted he got the 64 regular and Jones got the 65, engines were exactly alike and doing the same work, Jones complained that the No. 8 injector on the 65 was too small, would not keep boiler full, the machinist took the injector down several times, swore it was all right and Jones still complained until he had a No. 9 injector put on instead of No. 8. Afterwards he often used the injector on fireman's side of engine, as he finds it hard frequently to keep boiler full with the No. 9; indeed, he says engine ought to have a No. 10 injector.

Brown has no trouble with the No. 8 on the No. 64, he can easily keep boiler full with a fine feed, and should the injector at any time fail to give good satisfaction he knows at once what is wrong with it and has it fixed.

Jones works the engine pretty much wherever the reverse latch happens to strike the quadrant when he hooks up the links, and fireman performs his duties on the free and easy method that Jones practiced when firing, fill firebox with coal and let engine blow off all along the road.

Brown is particular to work links hooked up as far as engine will do the work and his fireman takes some pride in doing his work as well as possible. Result, Brown's engine is in better condition after a given service, the boiler has not been required to evaporate as much water and there is a saving of 20 per cent. in fuel as compared with the showing made by Jones.

When Brown is leaving roundhouse he opens the throttle a little and reverses engine a few times, then moves engine slowly. Jones starts the engine with a jump and slips it a few times, and, as water continues to comes from stack, slips engine some more.

Jones opens sandpipes with a coal pick and needs new pipes after a few trips. Brown taps pipes gently with a hammer and after two years' service pipes are as good as new.

Jones comes in roundhouse after a trip, meets Old Billy; they have a talk, Jones says engine is slow—has no snap—Old Billy looks wise; tells Jones the No 65 needs more lead, that lead gives engine more snap, and Jones lays for the master mechanic to tell him about the vital defect in engine. Brown don't bother about the lead, but gives attention that valves are gone over once in a while; he knows the eccentrics are set and keyed on, also knows that valves will not stay set always, but need a little attention occasionally.

I was down at roundhouse yesterday, and Old Timer came in mad; had lost fifteen minutes on account of air-brake not working properly last trip, and transportation people were grumbling about delay. I told him that I went over the pipes around engine and tender occasionally and kept them tight; examined, cleaned and oiled the driver and tender brake, triples and drained main reservoir when necessary. Old Timer said he reported brake when he came in, and the man who examined it said there was nothing the matter. Old Timer said further that he never did get to understand much about those new-fangled valves and triples and lubricators, did not think lubricators were much account—did not work good—then as his memory went back to the time when he used to pour a quart of pure tallow into each steam-chest and cylinder per trip, he added with some tinge of regret, "If the old man would only let him have a little taller fur them cylinders the 75 would do a heap better."

While we were talking Jones came along —he is serving ten days for burning a pin off the No 65—and tells Old Timer that the master mechanic wants both of them up at the office at once to explain how they managed to use so much valve and cylinder oil last month.

Being left to my reflections, I mused how we meet engineers every day who never read anything about their business. Ask 'em to take a paper, they don't need it, have not got time for reading, triples, governors, brake-valves, lubricators, combustion, the proper distribution of steam by the slide-valve and link-motion are things they have never studied seriously. Perhaps they might have had some excuse in years past for not working engine hooked up to shortest cut-off that would do the work, as it required considerable pull often to get reverse lever back another notch, for the pressure on valve-seat and strain on valve-gear were considerable, but with balanced valves these difficulties have been obviated, and engineer can easily hold reverse lever in any position with little effort, usually. Experiments and experience have demonstrated the value of good valve oil for keeping valves and cylinders in good condition in preference to pure tallow. The balance has contributed considerably toward saving oil, while keeping valve seats from cutting under the higher steam pressure carried.

How important it is that we should improve our spare moments, cultivate character, have self respect, few of us have learned it all. We should not imagine it requires luck or genius to be successful, from simplest round of duties to highest, work well performed makes success. Luck is, perhaps, but another name for good judgment, and genius often a capacity for nearly superhuman effort.

We should labor, study, think, be sober From the first shovel of coal as a fireman on the old yard engine until you take a regular place on right side of the new compound at front end of the vestibuled day express, put heart and soul into your work. Half-hearted endeavor may not command success, don't be satisfied that you can do as well as others—you ought to excel. Do not go around relating the old chestnut about two engines exactly alike, how one can pull more cars and run faster than the other. Do not be ashamed if you are sometimes called an engineman. Perhaps you have not yet learned the full significance of the word "engineer," but if you study your business, perform your duties well, you will at least be considered an intelligent man and fully deserve the highest pay in your calling in this country.

---

We would like to hint gently to "Engineer," Waukesha, that he wants us to do rather a thankless job. If he has ever told his fellow engineers unpleasant truths about themselves he would be likely to receive the same kind of return that we should get for criticising one of our rival papers.

---

A patent has been granted to Benjamin Reece, Chicago, and assigned to the Q. & C. Company, for a method of making tie plates.

## The Man Who First Dared Use Cast-Iron Driving-Wheels.

European engineers fail to see how Americans dare risk their big locomotives on cast-iron wheels. Americans fail to see why the foreigner persists in forging

wheels that have always been cast in this country—few of our master mechanics know when we commenced to use them.

It may be interesting to know that they were first placed under the "Best Friend," the very first locomotive built for service in this country, but after she had been put into use.

The engine was built at the West Point Foundry, in this city, in 1829, going into service on the South Carolina Railroad in 1830.

The machinist who set her up and ran her first was Mr. Julius D. Petsch, whose portrait is here given. Mr. Petsch had been in charge of the rolling stock of the road (motive power, mules) since 1828.

Mr. Petsch soon became master mechanic of the road (then the largest in the world), and made many improvements in the engines and the shops.

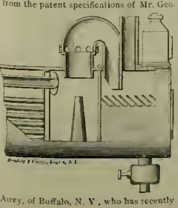
The first weakness developed by the "Best Friend" was in the spokes of her drivers, and Mr. Petsch had a set of cast-iron wheels made for her and put them into use, he used cast wheels from this on under locomotives and cars.

Mr Petsch afterwards became superintendent of the road and at once abolished the running of trains for the halfway posts and issued the first time-card the pioneer road ever had.

Before that, the man who got to the halfway post last had to back up to the first siding.

## Distillery Attachment for a Locomotive.

The accompanying chromo was taken from the patent specifications of Mr. Geo.



Airey, of Buffalo, N. Y., who has recently secured, by patent, the sole right to make all railroads who want to use this combination of distillery architecture and sanitary plumbing pay him a royalty.

He is going to "condense" the smoke, and assures us the front stack will give off steam only, while the cistern in the front end, with the window-blind attachment, will keep itself supplied with water from the condensation

We don't see why he didn't arrange to have the soup tank larger, so as to throw more weight on the trucks and lift it up off the drivers; this would help prevent hot boxes.

Then he ought to have a hand-hole in the side, so that the engineer could cook eggs and coffee.

This worm attachment would be a lovely thing in firing up a cold boiler, it would certainly increase the draft—through the fire-door.

A small machine (operated by condensation) might be placed under the arch, that would take the drowned remains of the cinders and work them up into brick or sewer-pipe that could be dropped at convenient places along the line, or perhaps this device would prefer to lay Easter eggs—we think it could do either as well as it will let an engine steam.

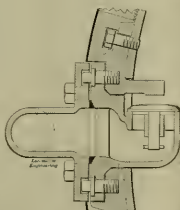
We don't say it won't prevent sparks, for it will—it will prevent them from living in the firebox.

## A New Form of Inside Check.

The check valve shown herewith has recently been patented by Mr. William Wright, general foreman of the P. W. & B. shops at Wilmington, Del. Inside checks are a great safeguard, but there has always been more or less trouble with hinged affairs not seating properly.

A vertical valve, seating fairly by gravity, is the most desirable form of valve, and Mr Wright has got that and on the inside of the boiler

As can be seen, this valve and seat can



be taken out and reground without disturbing the flange joint on the boiler itself. This has been impossible with other forms of this kind of valve.

That the outside check is a murderous thing in a wreck everybody seems to know, that putting the check inside the boiler is a safeguard and desirable is acknowledged. The next thing to do then is to find the best form of inside check. Mr Wright is working on that line.

During November and December last year and January of this year there was conducted a test of the holding power of cut vs wire nails, at the U. S. Arsenal, at Watertown, Mass., under the supervision of Major J W. Riley. 1100 nails were tested; these varied in length from 6 inches to 1¼ inches. The results were somewhat surprising, as in every case the cut nails showed a holding power of from 47.40 per cent up to 135.20 per cent. above wire nails. If the heads didn't pull off we never yet got a wire nail out of anything.

## Fitting Cylinder Saddles to Smoke Arch.

BY J. C. MILLER

A simple method for making the cylinder saddle fit on smoke arch, no fit and try about it, but sure thing every time—is shown herewith. I have never seen it illustrated or explained; have found it to work splendid, and so give it to the readers of LOCOMOTIVE ENGINEERING.

Have boiler level and plumb, put the frames in place on boiler with the back parts level fore and aft and level crosswise The front or tongue frames may be inclined or straight, as the case may be. Put straight edge *I*, Fig. 1, across the frames as at *I*, Fig. 2, at point where

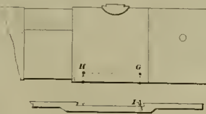


*Fig. 2*

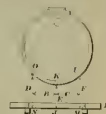

*Fig. 1*

front end of cylinder saddle comes. Get center *J* on line *AA* between frames, Fig. 1, and plumb or square up to smoke arch and put center punch mark at *K*. Then assume a distance a little less than the width of cylinder saddle, say the distance is equal to 30 inches over all. Take half this distance, 15 inches, *B C*, on either side of and parallel to center line *J K*, as shown on lines *D F*, and make center punch marks at *O L*. Now fit a short iron or wood template, *P*, Fig 3 (a little wider than cylinder saddle), to the smoke arch at *G*, Fig. 2. Then transfer the center punch marks, *O K L*, Fig. 1, to template *P* Now make a male template, *R*, Fig. 5, to fit template *P*, Fig 3, and transfer center punch marks from template *P* to template *R*. Next get the distances, *M L*, *N O*, *J K* and *B C*, Fig 1, and transfer to the cylinder saddle, as shown in Fig. 4 Take male template, *R*, and place it so the three center punch marks on template will coincide with the center punch marks on cylinder saddle, then with a scribing awl scribe the segment of circle *S*, Fig. 4. This line represents the chipping line, or line to plane to on cylinder saddle, repeating the operation at the back end of cylinder in the same manner. By trying a straight edge on the smoke arch at *H G*, Fig. 2, any unevenness will be detected and the proper allowances can be made. No matter how uneven the arch or at what incline the frames, this method will keep you correct.

*Fig. 5*

*Fig. 3*

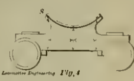

*Fig. 4*

## Some Fast Time with the Old-Time Locomotive, "Brother Jonathan."

Walter McQueen, vice-president of the Schenectady Locomotive Works, was master mechanic of the old Albany & Schenectady Railroad from 1845 to 1849

In 1846 he rebuilt the old locomotive, "Brother Jonathan" (that had been in service since 1832), changing her cylinders from 9 x 14 to 12 x 18, adding a second pair of drivers and reducing the size from five to four feet six inches.

In 1847 Mr. McQueen ran this engine from Albany to Schenectady (part of the road being still strap rail), pulling one car and carrying the Governor's message, in the unprecedented time of twenty-four minutes. The distance is seventeen miles and the grade the heaviest on the New York Central. Twenty-four minutes is just the running time to-day of the Empire State Express.

The Westinghouse Air Brake Co and the American Brake Co announce that their New York office has been removed from 160 Broadway to the Havemeyer Building, corner of Cortlandt street and Church place.

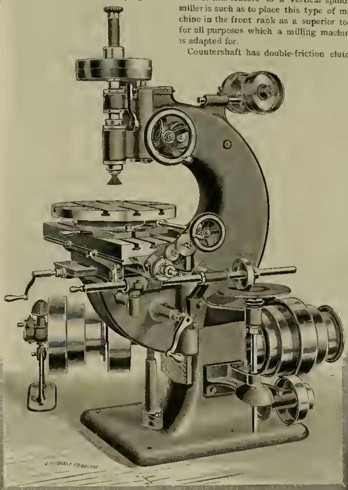
SHOWING ARRANGEMENT OF ROLLING STOCK AFTER FREIGHT TRAIN HITS REAR OF A COAL TRAIN.

LOCOMOTIVE ENGINEERING is one of the forty-two monthly publications in the city whose circulation is guaranteed by a $100 forfeit by the American Newspaper Directory. Last year the actual *average* circulation was 17,853 This year of the Lord 1893 will see the average go over 20,000. Just watch it grow.

### Improved Vertical Milling Machine.

We present with this an engraving of an improved vertical milling machine designed for a wide range of jobbing and manufacturing operations, including die-sinking, surfacing, plain and circular work.

The spindle, which is driven by a belt at speeds suitable for cutters varying in di-



IMPROVED VERTICAL MACHINE.

ameter from 6 inches (for surfacing) down to ½ inch for the finest work, has a vertical adjustment of 4 inches, with means of locking the spindle slide at any point. The mills or arbors are held by a draw-bar, which passes through the spindle, the latter being bored for Morse No. 4 taper shanks. It runs in long composition boxes, which are adjustable for wear, and is driven by a pulley 12-inch diameter, 3-inch face, supported upon a separate bearing, which is independently adjustable, and relieves the spindle of all side pull from the belt. The spindle is thus fitted to run at the very high speeds which make small cutters efficient.

The overhanging arm is carried well back to allow room for work of considerable size, and on the regular platen is mounted a circular one which may be rotated either by hand or automatically. This circular platen has T-slots, and is 20-inch diameter. Work 32-inch diameter can be swung upon this table, so that apertures up to 25 inches may be readily milled inside.

The main platen is 35 inches long, 10¼ inches wide, and as th saddle on which it moves is of the same width, there is always a bearing sufficient for gr at stability.

Centers may be mounted upon the platen in the usual manner, and the machine is then adapted to grooving taps, reamers, cutting gears, etc.

Feed is derived in the manner shown, by means of a friction disk giving feeds from the finest to the coarsest ever required in either direction. The knee has a vertical adjustment of 16 inches, and the greatest distance between platen and end of spindle is 16½ inches.

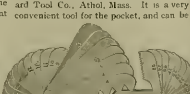
The spindle driving pulley is 12 inches diameter, 3 inches face, independently mounted upon an adjustable anti-friction bearing, by means of which the spindle is kept in alignment with the table, is relieved from the one-sided action of the belt strain, and its bearings prevented from overheating and from wear. The importance of this feature to a vertical spindle miller is such as to place this type of machine in the front rank as a superior tool for all purposes which a milling machine is adapted for.

Countershaft has double-friction clutch pulleys providing for two speeds besides those provided for by the cone pulleys.

The machine may be used for boring and drilling also, and, as will readily be perceived, is adapted to a wide range of machine shop work. It is manufactured by the John Becker Manufacturing Co., Fitchburg, Mass.

### Screw Pitch Gauge.

The screw shown is made by the Standard Tool Co., Athol, Mass. It is a very convenient tool for the pocket, and can be



SCREW PITCH GAUGE.

used for trying the pitch of either inside or outside threads. It takes in the pitches of all threads in common use.

### Crossing-Dangers in Chicago.

There is a great deal of agitation in Chicago, at present, on account of ordinances passed by the City Council to compel the railroad companies to raise their tracks so that street crossings and highways within the city limits may cross under the tracks. There is a dreadful loss of life constantly going on through the dangerous practice of streets crossing tracks on the level, but it is much easier to pass laws requiring a change than it is to make the necessary changes. The ordinance requires that the tracks shall be raised 16 feet above the streets. Throughout the city there are a great many viaducts crossing tracks, rivers and canals that are already raised 16 feet or more. The carrying out of the ordinance would send the steam railroad tracks away over the tops of the houses.

Some years ago the well-known civil engineer, Augustine W Wright, proposed a plan which would have prevented all the evils the city is now suffering from. He proposed completing a belt line that would handle all through freight, preventing the constant blockades that daily occur through the switching of such cars inside the city. Then he proposed to abolish level crossings by depressing the tracks as far as it could be done without interfering with sewers and water pipes, and making low viaducts as street crossings. The numerous high viaducts that have been built of late years would now throw expensive obstacles in the way of Mr. Wright's plan.

### The Biter Bit.

"The conventions are not what they used to be," remarked the bald-headed member. "Nowadays you hear of nothing but business, business at these meetings. In the good old days people who went to the conventions mixed some fun with their business, but nowadays if a man is away from the meetings for an hour some one is liable to tell him that he is neglecting the purpose for which he came.

"At one of the good old meetings some of us got off a very funny joke on Aaron French. Aaron intended to get off a joke at the expense of Jules French, and we turned it into a case of the biter being bit A party of us went into Aaron French's room and there were not enough chairs to accommodate the whole of us. Jules hung up his hat and went out. As soon as he had gone out of the door Aaron took the hat, which was a nice silk one, and put i. under the bed clothes, then went out evidently to wait for Jules. As soon as he went out, some one put Aaron's hat where he had placed that of Jules'. In a minute or two both gentlemen walked in and Aaron took care that Jules should sit down on the spot where the hat was. As soon as he felt the crunching of the hat, he jumped up and Aaron proceeded to show him the condition of his hat. It was great fun to watch the spring-maker's face when he discovered that it was his own hat that had come to grief."

### Something No Feller Can Understand.

We had retired to the smoking-room after dinner, and a ruddy-faced Englishman who had been very social and talkative, settled down into silence and sucked a strong cigar as if it were a long-stemmed pipe.

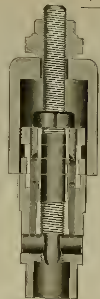
"Don't you think that our dining-car service is a great convenience?" we remarked, over the British practice of rushing to the lunch counter to make the best of a brief stop and parboiling one's mouth with the boiling coffee, in our mind.

"Your dining-car service is great," he grunted. "It gives a man time to fill himself comfortably. But some o' yer ways I cannot hunderstand. Now, when I'm at 'ome I like to 'ave a bite of Hamerican cheese after my dinner. It is fine, tasty cheese. Now, here in yer own country, I hasked for a bit of yer own cheese and they could give me nothink but stinkin' foreign stuff that turned my stomach. I can't make it out."

Neither could his hearers.

A Michigan Central man writes us that the large inset picture in the May number had a peculiar interest to their men, as both the engineer, Robert Brown, and the fireman, Wm. Deyall, shown with No. 433, are now dead.

### A Bushing Remover.



Our attention has been called to a very useful tool for engine-houses. It consists of an appliance for pulling the bushings out of Westinghouse air-pumps. It is very highly spoken of by those who have used it, saving much time and preventing delay when engines are wanted in a hurry. This bushing remover, unlike many of them, removes the bush without injuring it. The illustration makes the details plain.

The device is handled by George P Wilson, Philadelphia.

### The Smith Triple Expansion Exhaust.

The above cut shows this pipe in place on a heavy freight engine on the Reading road, where it has become the standard.

This device takes in and mingles the hot gases of the front end with the steam, re-expanding it and discharging it through an opening, larger in area than the port

The Manhattan Elevated are trying one on a hard steamer, and the Erie have applied one. They intend to give it very thorough tests to find out its effect on the working of the engine. Several other Eastern roads are arranging to try the pipe

The New York Central has got its fine new shops at Depew, near Buffalo, in running order, and about 250 men are at work. About forty engines are in waiting for repairs, and a large assortment are standing on the side track ready to go inside. There is great difficulty in getting mechanics to remain at work in the shops. Few houses have been erected, and those who live in Buffalo lose so much time going to and fro that they prefer to work in the city, where employment is plentiful at present. The companies that have got control of the land in the neighborhood of Depew hold prices so high that there is not likely to be much building of cheap houses until the artificial values now ruling collapse.

# Car Shops and Car Builders.

## Some Recent Car Improvements.

Not much attention is paid to the improvement of the common freight car, though it would save any road more money to gain 10 pounds in dead weight in each car than to compound their engines—there are so many cars.

Saving in repairs of freight cars is a field capable of showing great returns for a small outlay. The trouble has been that practical men did not pay enough attention to the design of cars with a view of repairing.

As every practical man knows, the parts of cars requiring the most repairs have been the draft-rigging and body-bolsters, while truck-bolsters come in for a large share of work.

We have recently noticed some improvements introduced on the cars of the Union Tank Line by the master car builder, Mr. C. A. Smith.

One of the best of these innovations is a composite body-bolster, as shown in Fig. 1. This is composed of a steel I beam 12 inches wide and 5½ inches deep, the sides filled with oak. This bolster is bolted up to froming of car as if it was an all-wood bolster, bolts going through web of beam, no trusses are necessary. This is amply strong to carry the load and its great width stiffens it to bear the buffing strains—the draft timbers being set against it in the usual way.

Mr. Smith's draft timber arrangement is fully shown in Figs. 2, 3 and 4. He uses the Butler draw-bar attachment to carry the springs and puts it up as shown. Three heavy carrying irons, each 1 x 3 inches, are placed each side of the draft timbers, one end of these hooks under the draft timbers and the other end hooks over the center sills; they are let into both the sills and draft timbers so that the two timbers come together solid. These carrying irons are held by 1-inch bolts. The draft timbers rest against the body-bolster, as shown in Fig. 3. Inch rods from the buffer timber run back to the body-bolster, are flattened and bolted to it, the end booking over behind.

This is about the strongest and stanchest draft-rig of the present necessary form that we can think of.

Another improvement has been made on truck-bolsters. Truck-bolsters are always trussed to carry the load, but few car builders have done anything to remedy the real cause of their breaking.

Truck-bolsters are not strong sideways, if turned on their sides they would break with less load or blow than if placed any other way. It is in switching that truck-bolsters are broken.

We will say that a truck weighs 3 or 3½ tons, it is held to the car by the center plate and pin only, when one car is thrown against another it is the *bodies* that are stopped, not the trucks, the latter are stopped by the center pin giving a side blow on the truck-bolster—this is in one direction at one time and next in another until finally the bolster is broken.

Mr. Smith puts a steel channel bar on top of this bolster, as shown in Fig. 5, this being 12 inches wide by ½ inch thick stiffens the bolster, for the shocks it receives protects the timber and strengthens it. This channel bar is long enough to carry the side bearings and ends inside the arch bar just the right length to butt against and support the plate to which the truss rods are bolted. Another lighter channel bar filled with wood is used as a spring plank.

## Mount Vernon Car Works.

One of the most prosperous manufacturing concerns in Illinois is the Mount Vernon Car Works. While many old car building concerns have been failing because the competition kept prices so low that a margin of profit could not be obtained out of the business, this young concern has been building up and making the work pay. The reason is obvious. Good business methods make one concern prosperous on the prices that lead poorly managed concerns to bankruptcy. The credit of the success of the Mount Vernon Car Works is due to President Settlemire, Secretary Arthurs and Superintendent Snyder. The following are a few facts mentioned in a statement lately given by Secretary Arthurs:

"Our business has steadily increased from the first day we started, and is still increasing. We now have contracts on hand that will keep the works running to full capacity until August or September. During the year ending April 1, 1892, our total output in finished work amounted to $1,888,149.49 and during the year ending April 1, 1893, our output of finished work amounted to $1,319,565.37, an increase for the year ending April 1, 1893, of $131,415.88.

"During the past year we built about 3,000 new cars, of which 346 were refrigerators and 309 patent stock cars, equal to about two or three ordinary cars, amounting in all to about 4,000 ordinary box cars.

"Our foundry has also become a very important branch of our business. During the year ending April 1, 1892, we made 22,508 car wheels and 8,023,872 pounds of castings, while for the year ending April 1, 1893, we made 32,756 car wheels and 9,595,598 pounds of castings, showing an increase for the year ending April 1, 1893, of 10,248 car wheels and 1,571,726 pounds of castings. We are furnishing a large number of car wheels to railroads besides what we are making for our own use under new cars we are building.

"During the year ending March 1, 1892, we employed an average of 630 men and during the year ending March 1, 1893, we employed an average of 761 men, an increase for the year ending March 1, 1893, of 123 men. Our pay-roll for the year ending March 1, 1892, amounted to $235,648.85, and for the year ending March 1, 1893, amounted to $276,730.40, showing an increase for the year ending March 1, 1893, of $41,081.55."

## Pullman Exhibit.

(EDITORIAL CORRESPONDENCE.)

The Pullman exhibit consists of two trains, with engines, five street cars, two six-wheeled trucks, all iron parts polished, and a model of the town of Pullman, showing all the buildings and dwellings.

The first train which we reach has a Rogers' ten-wheeled engine in front, very striking in appearance. The engine is painted the Pullman standard color, with Pullman standard decorations around cylinders, dome, sandbox, cab and tender.

A novelty about this train is that the tender is vestibuled to the first car, which is a United States mail car. Another novelty about both these trains is that the vestibules have the entrance flush with the side of car, the steps being below. There is also a window at each side facing the front. The postal car is 69 feet and 6 inches in length, and is carried on 6-wheeled trucks of the Pullman standard with Allen paper wheels. This car has a Baker heater on the platform outside of the body of the car, and the platform is closed by doors to the vestibule, the platform in this manner forming a room in itself. The car is fitted out with the most approved mail fixtures, and the postal authorities who have visited the car say it is the best equipped mail car in the world. One novel feature in the construction of this car is that it has a skylight in the roof with eight sections of light. There is a water-closet and lavatory on one platform and clothes closets and cupboards, in which manner every inch of room is utilized. The letter-racks are so arranged

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

that one of them protects the front door when in use.

One of the Government postal authorities explained some of the advantages of this car over ordinary postal cars, and stated that one of the principal advantages was that the stoves were removed from the body of the car and placed in the vestibule on the platform. The Government not only pays for the amount of mail carried, but also have to pay for the mail car by the lineal foot, and it was to their advantage to have the inside of the car unobstructed by stoves, etc., as nothing could be piled on or near them. In regard to the letter-boxes, he said that in the old style mail cars they formerly had two sets of boxes, one for the trip in one direction, and the other set in the opposite direction, the boxes being marked accordingly. When the reversible letter-case came out it was considered something wonderful, but in this car another new departure has been made. The case consists of double boxes, which can be tipped forward and reversed end for end, and then pushed back in place, and in this manner boxes do not have to be changed, one side being for trip in one direction and the other side for opposite trip. Another good feature of this arrangement is that in reversing the case it throws out any dust that may have accumulated as well as any stray letter that may have lodged inside. Another entirely new feature in the construction of this car is that the paper-boxes can be made to use either single or double as desired. The postal official, talking about the car, ended by saying there never was a car built with such conveniences for handling mail.

The next is a first-class day coach, 68 feet 11 inches in length. The car is finished in vermilion wood that looks like a dark mahogany, with a grain resembling rosewood. The car has twenty-eight Hale and Kilburn double seats, which are notable for the easy way they can be turned and the comfortable seat they afford to the traveler. The upholstering is unusually rich, being an embroidered haircloth with a gold-like hue. Each section of seats is divided by an arched crown, which seems to give the car the appearance of a series of arches, checked at the clear story, but continued around it. The arch panels are three-ply veneer, very richly decorated with floral work. The head-lining is of the same material as the arched sides, beautifully decorated and divided by broad vermilion bands, also artistically carved. On each side of the clear story there are seven half-elliptic windows.

There is nothing unusual in the ends of car, only that it has very handsome lavatories at each end, with toilet-room and white-metal water cooler and trimmings. The ceiling of car is in the shape of an ellipse, with deck sash groined into the ceiling. At the smoking-room end of car there is a family section, with a large space for luggage, making ingress and egress easy at stops. The bulkhead dividing smoking-room from body of car is fitted with plate-glass beveled mirror, with silk plush hangings, forming a very handsome finish, to view it from the body of the car. Passing from body of car through smoking-room passage-way, the gentlemen's vestibule toilet-room is reached. This toilet room is fitted with white-metal wash basins and water cooler. The smoking-room is entered from the vestibule, and is upholstered in olive leather, the wall panels being finished in decorated stamped leather, the ceiling being of same form as that in body of car, decorated to match upholstering and hangings. The windows opening from smoking-room into passage-way are draped with silk plush hangings. The bulkhead, dividing smoking-room from body of car is fitted with circular beveled plate mirror, in a handsome carved frame of vermilion wood, mirror being 3½ feet in diameter. The transoms over bulkhead at ends of smoking-room are fitted with handsome iron grilles.

Passing through vestibule from day coach, the parlor car "Santa Maria" is reached. The parlor of car is finished in vermilion wood, designed in sixteenth century style, trimmed elaborately with gold-plated metal. The ceilings under the side decks are handsomely carved, the whole surface of side decks being carved, with panels supported by enriched medallions. The main windows of parlor are built in triplicate in bay form, and the Gothic sash in all windows is glazed with the most delicate patterns in leaded glass. The main ceiling of this car is built in the same form as that of the day coach, the deck sash having more elaborate designs in glazing. The upholstering of the revolving seats and sofas is a Persian blue with gold-colored pattern, and the frame and design of the chairs is graceful and delicate. The ceiling is colored a natural green, the grainings in the same being gilded. The carpets are of the finest Wilton.

The main bulkheads, forming the ends of the parlor, are pierced by a doorway and a window, the lintel of the same being supported by three beautiful columns, between which heavy silk draperies are hung. Above two small side openings in the bulkheads are placed circular beveled mirrors in carved vermilion wood frames. At the gentlemen's end of the parlor is a private section, consisting of two double seats and a sofa; at each end of the sofa is a small locker, and above the double-seated section is a gold-plated curtain rod, from which hangs heavy silken draperies, which slip forward and may be used to screen section. Passing through passage towards gentlemen's end of car is a library, in which may be found pleasant reading. Next to the library, at the end of the car, is the gentlemen's lavatory and toilet room. The floor and wainscoting of the lavatory and toilet room are constructed of handsome tiling. The wash-basin is beautiful in form, of Mexican onyx, and all the plumbing, fixtures, faucets, etc., are gold-plated.

At the other end of the car is a drawing-room, finished in ivory and gold, of exquisite design and excellent workmanship. The ceiling is colored in Pompeiian pink, the raised carving being decorated with gold. The upholstering of this room is of silk plush, colored to harmonize with the walls and ceiling. The room contains a comfortable sofa and two easy chairs, upholstered in delicate silk plush, colored to match walls and ceiling. The draperies to the drawing-room window are of Pompeiian pink silk, richly flowered in silver, white and gold. The bulkhead at forward end of drawing-room is fitted with large circular beveled mirror, set in a carved and gilded frame, with gilded wreaths looped in upper part of mirror. The entire train is lighted by electricity, the electroliers being of exquisite design and workmanship, harmonizing with the general effect of the cars. The fixtures are all gold-plated, and those in the parlor car being hung with a silk fringe.

Nearly all railroad men are familiar with the appearance of handsomely finished cars, and may not feel inclined to walk through a train in an exhibition. They will make a mistake if they fail to look over the insides of all the trains shown in the World's Fair. A. S.

Iron-Clad Car—General Thomas' Headquarters in War of Rebellion.

### An Iron-Clad Car.

The engraving shown herewith is from a photograph of an iron car built by the Government as headquarters for General Thomas during the family quarrel among the States.

This car is made up of iron plate and panels entirely, strongly backed by wood. It originally had no truss rods whatever and has very slimpsy ones now. But out of many turn-overs the body came out straight and stiff—it was built for war.

In 1866 the South Carolina road bought this car at Government sale, and have had it in use ever since. It is now used to haul laborers from Charleston to the phosphate beds near town. There doesn't seem to be any more indication of the car wearing out now than there was thirty-three years ago.

It bears on its sides a few bullet-marks, scars like any soldier is liable to get, and keep.

### Car for Heating and Lighting.

The car shown in the annexed engraving is part of the exhibit of the Chicago, Milwaukee & St. Paul Railway Co. at the World's Fair. This company found that in the cold Northern regions traversed by the road that locomotives were not equal to supplying steam for the heating of cars when the trains were very heavy. To meet this difficulty the car shown was built. It contains a boiler which supplies steam for heating and also for running a dynamo to light the cars with electricity. The car is particularly well arranged, and is well worthy of examination by those attending the Fair.

The following are the principal dimensions of the car:

Length—Inside, clear, 32 feet 4 inches.

Width—Inside, clear, 8 feet 4 inches.

Engine—6½ x 6 inches, Westinghouse automatic.

Engine—Horse power, 18 at 100 pounds steam pressure.

Boiler—Locomotive type.

Boiler—Heating surface: Tubes, 390.17 sq. ft.; firebox, 55.38 sq. ft.; total, 445.55 sq. ft.

Capacity of coal tank, 2.5 tons.

Capacity of water tank, 300 gallons.

Dynamo—Edison 15 Kilowatts, 110 volts.

Weight, loaded, 76,000 pounds.

Two of these cars are used during the winter season on the vestibuled limited trains, running between Chicago and St. Paul and Minneapolis. Each train consists of ten cars and is lighted throughout by electricity, using 200 16-candle-power incandescent lamps and heated by steam from this car.

The first car was built in 1890, and has run up to date 191,008 miles.

Light and Heat Tender.

We are informed that the American Decorative Company, of Boston, will make a very attractive exhibit at the convention at Lakewood this month. It represents a section of a passenger car roof of the Boston & Albany standard. The head lining is of lignomur, a material made from wood fiber, which is particularly well adapted for car decoration. Mr. Adams, master car builder of the Boston and Albany, has applied this material to about forty cars and the material gives very great satisfaction. Mr. Adams talks very enthusiastically about its merits. When other master car builders have the opportunity of seeing the effect of lignomur in head lining they are certain to become patrons of the material.

The Ajax Metal Company are taking a very warm interest in the fast time the New York Central are making in the race to the World's Fair. Ajax metal is used for the driving-boxes and principal bearings of the fine locomotives pulling the trains, and the motto of the makers is Ajax metal never gets hot. There is a good deal of truth in the claim made by the motto.

# ? A. What You Want to Know. ? A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(61) S. W. A., Philadelphia, says:

Is there any reason why a compound locomotive should run faster than a simple engine? *A.*—No. There are some reasons why a simple engine ought to exceed a compound on speed.

(62) T. W. H., Holyoke, Col., asks

I have noticed some engines that wear a long hollow spot on their tires at a point just as they pass over the center. Would like to hear from some one as to the cause of this. *A.*—Caused by counter-balance and, perhaps, in some measure by momentary slip when engine takes steam on one side before release on other.

(63) Geo. D., Chicago, Ill., writes.

Will you please inform me through the columns of your paper of the relation the eccentries of a locomotive bear to the main crank-pin? *A.*—This question is very indefinite. If you mean to ask what *position* the eccentrics are in in relation to the crank-pin, the go-ahead eccentric is a little less than a quarter behind the pin, and the back-up the same distance ahead.

(64) G. H., Lunenburg, asks

1. Will you be so kind as to tell me why an engine without rods on being moved, say half a mile, and brought back without slipping driving-wheels, will not come back to the same stroke as she started. *A.*—It is hard to tell. 2. Why will an engine being towed, with main-rods and side-rods off, change her stroke, wheels being same size? *A.*—It is claimed the counter-balance does this, but this is not proven

(65) G. C. J., Gordon, Pa., writes

Is it customary to use lye in tanks and boilers? They have been using it on the Williamsport Division of the P. R. R. for the past two months, and, whatever it has done with the scale, it has opened up all the seams in the boilers and played the deuce with checks and injectors. *A.*—Lye in some form or other is quite commonly used in boilers; many of the patented compounds being little else. Lye is not a bad scale remover, and perhaps your trouble comes from using too much of it or lye that is too strong.

(66) Apprentice, Omaha, writes

I have several times lately met with the expression, "total heat of steam." Why speak of total heat as it it were divided into a number of parts? *A.*—Heat of steam is estimated in two parts, the sensible heat and the latent heat When the water is put into the boiler at, say, 66 Fah., it requires about 146 heat units to raise it to the boiling point. This is called the sensible heat. Then it requires 966.1 units more to convert the water into steam, which will be no hotter than the boiling water. The 966.1 units are called the latent heat of the steam.

(67) G. A. M., Hudson, N. Y., asks

I am using the new engineer's brake-valve, everything pertaining to air-pump train line and air gauges is in good working order, but the brakes will not hold. I can make a service application stop by using 8 or 10 pounds of air, but in about four seconds brakes pop off. Can you tell me what is the matter, and how to overcome the matter. *A.*—There is very likely a leak somewhere that supplies the train-pipe with air Look well to the rotary valve, be sure that the brakes do not leak off, do the pistons travel out beyond the leakage grove?

(68) Mr George Payne, Taylor, Tex., writes

1 I would like you to tell me if a man broke his right go-ahead eccentric strap could he fasten the blade to the other one and pull his train into terminal with it? *A.*—This has been done, but is risky. 2. Mr. Laukes, the traveling engineer of the M. K. & T., is giving the boys some hard nuts to crack on mechanics. He says if he broke a valve-stem or rocker-arm and was pulling an important train that he would not disconnect his engine. Could he run without? *A.*—He would have to take down main rod, but need not take down eccentric rods.

(69) J. C., Amory, Miss., writes

Will you be kind enough to give me some information? 1. If a vacuum brake was adjusted so as to allow the diaphragm to be at half or mid travel, could there be as much power exerted as when the diaphragm is set out to full or in its extreme forward position? *A.*—Yes. 2. Is the weight of the atmosphere exhausted from the diaphragm equal to the pressure upon the exposed area? *A.*—The amount of atmospheric pressure taken out of the vacuum cylinder determines the pressure of air from outside, they are equal. 3. If we had a cylinder 6 feet long and 6 inches in diameter, and exhaust all the air from within, would we obtain the same pressure upon each head as we would with a cylinder 6 inches long and 6 inches in diameter? *A.*—Yes. 4 When atmospheric pressure is forcing against a vacuum piston do we compute by the exposed area regardless of the contents of the vessel? *A.*—Yes.

(70) S., Frankfort, N. Y., writes

In plumbing the rocker-arms on an engine to-day I found the valve rod ⅝ inch too long, both rods exactly the same. I measured two or three others of the same class and found them about this length. The question arose, why was this, or were they so designed to work? The two questions I wish answered are the following 1. Is it always necessary that the rocker-arm should stand plumb when the valve is in central point? *A.*—Not necessarily. 2. Why are some rocker-arms thrown out of line, one arm with the other? What point in the designing of the valve-gear does this overcome? Not long since in the West I laid off a set of arms ½ inch out of line. I asked the foreman why it was done. He said "the engine was so designed." I thanked him, and I have never found any other reason. *A.*—This is done to make the lower arm stand at right angles to the center line of motion (a line drawn through center of axle to lower rocker-pin) when the top arm is at right angles to the valve stem. Rocker-arms are often made with offsets of one kind or another to avoid striking some other parts of the mechanism. An ordinary departure from usual practice makes no perceptible difference in the working of the engine.

(71) C. B S., Coal Gate, I. T., asks:

1 Why does heater-valve of Seller's injector lift and allow the water to run out through overflow? This is injector of 1887, in use about four years. *A.*—The new injector has an open overflow, same as Monitor or Little Giant, when steam fails the excess of water runs out through overflow, in the Seller's of 1876 the overflow is closed and the instrument will regulate and take up water automatically. 2 What kind of metal does the Baldwin Locomotive Works use for cylinder-packing? *A.*—Cast iron. 3. What causes driver-brakes to be applied with handle in running position? *A.*—A leak, in all probability 4. If tires on both back driving-wheels broke off how would I fix engine so as to get in? *A.*—Block up over forward driving boxes, taking weight off back wheels; run very slow; it may be necessary to support back end on a truck. 5. If little reservoir under running board on right side, which is an addition to engineer's brake-valve, should be broken off. Could I fix it so as to handle train with air-brakes and make service stops? *A.*—Yes, the small drum only increases the capacity of the cavity over piston of engineer's valve by exhausting very much smaller amounts of air through preliminary exhaust port; the train could be handled well.

(72) W. M. P., Dennison, Tex., asks.

Suppose I were out on the road with twenty cars of stock, broke left go-ahead eccentric and right link so could not use them, and knocked hole in reservoir on back of tank, so it would not hold air and could not use it, the train has no hand-brakes—all air. Can I bring this train in with engine working on both sides and handle it with air-brakes? Could I do it this way: Make go ahead eccentric out of left back-up one, fasten both blades to the one go-ahead strap, which would be sufficient for left side, take off back-up eccentric on right side and couple forward end of go-ahead blade on to bottom rocker and move that blade ahead enough in strap to give the required valve travel? I only will have two go-ahead eccentrics—no back-up ones; or, in other words, I would have the same as two stationary engines in forward motion or a direct motion. The reservoir on back of tank has hole in it. Can I couple air-pump directly to train pipe and charge train up, and when I go to make a stop, shut pump off, and when I want to release, start pump up and pump them off? *A.*—It is barely possible that this *could* be done, but it would be a slow and risky job, the blade would not fit lower rocker, and the loose link is a thing to be avoided. If this ever happens to you, disconnect your engine and send for assistance If you had the only engine on the road, it would do to repair in this way, but on a road doing business, the thing to do in a breakdown is to get out of the way with the least delay to other trains.

(73) S. D., Chicago, writes.

1. Please give a rule for estimating the number of tons an engine 19 x 26-inch cylinders, and carrying 180 pounds of steam, will take up a grade of 30 feet to the mile at the rate of twenty-five miles an hour. *A.*—An important factor is missing in this question The size of drivers are required to estimate the tractive power of a locomotive. We will assume that the driving wheels are 54 inches in diameter. To find the tractive power we square the diameter of the cylinders, multiply by the stroke in inches, multiply the quotient by 85 per cent. of the boiler pressure and divide by the diameter of the driving-wheels in inches, thus $19^2 = 361 \times 26$ $9,486 \times 153 = 1,451,358 \div 54 = 26,877$ pounds, the tractive force exerted at the rail, less about 10 per cent. for internal friction, leaving 24,190. The total resistance of a common freight train is about 15 pounds to the ton at twenty-five miles an hour, so this engine ought to be able to pull at that speed 1,612 tons on a level. To figure on lifting a train up a grade of 30 feet to the mile, we multiply the pounds in a ton by 30 and divide by 5,280, the number of feet in a mile, thus $2,000 \times 30 = 60,000 \div 5,280$ 11.36 pounds, the power per ton required to overcome the resistance due to the gravity of the train. Then by adding the two resistances we have $15 + 11.36 = 26.36$ pounds of resistance per ton. Dividing the available tractive force of the engine by these figures, thus $24,190 \div 26.36 = 917$ tons, the weight the engine can pull under the conditions given. 2 Why are cylinder heads dished out on some forms of compound locomotives? Is it to hold more steam? *A.*—No, it is to suit the form of piston head used.

(74) V. J B., Waycross, Ga., writes

Please favor an appreciative subscriber by answering the following questions as plainly as possible 1. In disconnecting a locomotive on one side, should the ports be covered with valve before main-rod is disconnected, which is best, to cover ports before disconnecting valve-stem or disconnecting valve-stem first? *A.*—Cover ports first always, steam might be admitted to cylinder and do damage while piston is disconnected from main rod. 2—What is a dutchman on a locomotive and where is it located and what is its use? *A.*—This is a local nickname; means nothing. 3. What is best to do when a driver wedge-bolt is lost? *A.*—A nut or block can be placed under wedge and tied to frame 4. What is best way to get a driver-wedge down that is hard stuck up and cannot be got down with a pinch-bar? *A.*—Running engine over wood block will sometimes bring down stuck wedges, sometimes pedestal brace has to be taken down. 5. Please give illustrations (if possible) and best, easiest and quickest way to put in a spring in back, main and front drivers on a Mogul engine, and what convenient small tools (such as railroads do not furnish on engines) can be bought that will help to expedite the work? *A.*—All depends on design of individual engine. Many little kinks shown in back numbers of this paper none that we know of are for sale. 6 Suppose a locomotive breaks loose from tender and tears hose off so badly that they cannot be screwed back to pipes or goose-necks, what is best plan to adopt? *A.*—Try and make one water connection with remains of both hose 7. What is best and quickest way to put a truck spring in pony truck of a Mogul when spring fits over box and frame? *A.*—Jack weight off truck and the spring will go in easy enough. Ask a shopman, or watch him do the job.

We are in receipt of the large bound catalogue lately issued by the Berry & Orton Co., makers of wood-working machinery at Philadelphia, Pa. It illustrates and describes all the machines made by the firm.

Wm. Sellers & Co., of Philadelphia, Pa., have just issued, in neat leather binding, the able paper on "The Modern Traveling Crane," recently read before the Franklin Institute by Mr. Alexander E. Outerbridge, Jr. This paper tells all one cares to know about the modern crane, illustrating the latest and best Any one interested in shop cranes should send for this work, which is sent free.

Those who are interested in the development of the railroad rail will find a very interesting exhibition in the space occupied by the Great Western Railway of England, in the World's Fair. They show specimens of all the sections of rails which they have used since 1838 up to the present time There are no less than forty-four specimens shown, the weight rising from 45 pounds to the yard up to 120 pounds. Some of the forms are very curious. If some of our inventors who have been striving to improve on rail sections lately, would go and examine that display, they would find a good many of their ideas have already been put into practice.

The works of the Westinghouse Machine Company have been running for a year with a full night force. The shops are crowded with a large amount of heavy work in addition to their regular line of manufacture There are now coming through ten 600-horse power compound engines, of which eight are for the Philadelphia Traction Company, for direct coupling to multipolar generators, and two are to fill an order placed by E. D. Leavitt for the Calumet and Hecla mines, to be used in driving electric pumps for mine drainage The company has just completed the shipment of six 1,000-horse power engines for the Westinghouse Electric Company, to be used in filling its contract for lighting the World's Fair. These engines are also coupled direct to 1,000-light generators They stand eighteen feet high and make 300 revolutions per minute.

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK.

VOL. VI, No. 7. NEW YORK, JULY, 1893. 20 Cts. Monthly. $2.00 Per Year.

### "David and Goliath."

The picture shown herewith was made from a photograph of two engines exhibited by the Pittsburgh Locomotive Works at the World's Fair—the largest and smallest engines of their exhibit.

The magnificent heavy ten-wheel passenger engine is a model modern engine and the little one about as small as does useful work in this country.

The big engine was built for the Vandalia line; she is 4 foot 9-inch gauge, has 20 x 26-inch cylinders; a total wheel base of 23 feet 8 inches; a driving-wheel base of 13 feet 4 inches; driving-wheel 72 inches in diameter; weighs 139,000 pounds, 110,000 of which rest on her drivers.

The small engine is one to be used about the new shops of the Pittsburgh Locomotive Works. Her track gauge is 24 inches, she has cylinders 6 x 10 inches, a total wheel base of 3 feet 6 inches, all on her drivers; driving-wheels 26½ inches in diameter, and weighs 12,500 pounds.

The large engine is more than eleven times as heavy as the small one. They make a very attractive exhibit, and have been dubbed "David and Goliath."

The railroad companies are continually complaining about the iniquities of ticket scalpers, although no ticket scalpers could live a month but for the aid and comfort given by railroad passenger agents. The howling on this subject has been so persistent in the West of late, that the Federal Grand Jury has decided to investigate the matter and find who are violating the Interstate Commerce Law. If the investigation should be made thorough we are afraid that the railroad companies will come out of the fray more badly wounded than the scalpers.

### Self-Lighted Fires.

In the course of a private letter to the writer, an engineer of high scientific attainments observes that there are many curious phenomena besides those mentioned in our article on the subject last month, connected with the power of certain substances to absorb gases. The faculty which carbon has for absorbing gases is no doubt the cause of many mysterious fires. If people in charge of shops and factories were more thoroughly informed about the behavior of carbon in the presence of gases which it absorbs readily, there would be greater attention devoted to isolating the mixture from other inflammable material and there would be fewer mysterious burnings-down of buildings. When you tell the ordinary practical man about dangers which laboratory experience has proved to exist and which are not readily apparent, he is nearly always inclined to undervalue the information given. When men accustomed to the making of laboratory tests first directed the attention of boiler-makers to the danger of flanging steel at the critical temperature, they were laughed at, and it took years of patient writing and talking on the subject before the men in charge of boiler-making realized that there was something worthy of attention in what the scientific fellows had been saying about the danger of working metal at the blue heat.

No information can be more profitably discussed than that which relates to the science of common things. Among these, the behavior of carbon under different conditions comes home to a large number of the readers of LOCOMOTIVE ENGINEERING. When fresh wood charcoal is allowed to cool down in a closed vessel it has the peculiar property of absorbing gases much greater than its own volume. It has a peculiarly strong thirst for oxygen, which it readily draws from the air, but it also takes in nitrogen and all the inflammable hydrogen and hydro-carbons. On account of this the charcoal is very ready to burst out into flame through the heat generated by the mixture. Charcoal left exposed is less ready to absorb inflammable gases, but it does that freely enough to call for close watching.

When common coal badly slacked is stored in a building it deserves careful watching, for the carbon absorbs oxygen, and under favorable conditions will take fire. When the mass is open enough to permit free circulation of air, the heat of chemical combination is carried off as fast as it is generated, but if the coal heap is dense, the temperature rises steadily. When any part gets higher than 100° Fah. it is getting dangerously near the point where spontaneous ignition becomes an active, all-devouring flame. A little care and watchfulness will frequently prevent a conflagration.

"DAVID AND GOLIATH." NOW AT THE WORLD'S FAIR.

### Peat as Fuel.

Visitors to the World's Fair who are interested in fuel ought to go and examine some pillars of compressed peat that are to be seen in a booth containing exhibits of an Irish railway. The material is compressed till it is as dense as coal, which it strongly resembles. Where coal is dear and peat is abundant the latter material can be used economically as fuel.

When peat is solidified under a powerful hydraulic press the operation which Nature takes ages to accomplish is completed in a few minutes. A peat moss is a coal bed in course of formation. It is a vegetable growth which decays and is pressed down by the accumulations on top till the mass below receives sufficient pressure to convert it into mineral coal. The peat on the surface of a moss contains from 50 to 60 per cent. of carbon and the percentage increases the deeper the explorer goes.

There is not much likelihood of peat being used for fuel on this continent, although there are vast accumulations of it in some regions. But good perfected coal is so abundant that it will not pay to use material that needs compressing. In some quarters of the globe, however, peat is likely to be used largely for steam generating purposes.

The Traveling Engineers' Association have issued a circular asking information about the examination of enginemen for handling air-brakes. These men, on whom devolves the responsibility of determining the efficiency of men handling brakes, can be depended upon to formulate a plan that will insure efficient handling without any unnecessary expert testimony being required of the enginemen.

It sounds comical to the railroad men of this country to hear so many prominent preachers, editors and others advocate boycotting the World's Fair on account of Sunday opening. When the railroad men did a little boycotting a few weeks ago, they were anarchists, etc., etc. It makes all the difference in the world who is boycotting and who is getting boycotted.

During the year 1892, 41,893,220.18 tons of anthracite coal were mined and sent to market. It is easy to estimate the extra profit made by the operators on the raise of 25 cents per ton.

### William Buchanan.

Railroad men are a unit in believing that the splendid locomotive "999," built by the New York Central Railroad Co. for the World's Fair, has attained the highest speed ever reached by a locomotive on any railroad. We have pleasure in submitting to our readers a portrait of Mr William Buchanan, superintendent of machinery of the New York Central, who was the designer of the locomotive. Mr Buchanan was born in Dunbarton, Scotland, in 1830, and came to this country with his parents when a boy. His father was a mechanic, and his son followed in his footsteps and learned the blacksmith and machinist trade, in the Burden Works, at Troy. These two trades were very closely combined in those days When he was about twenty years of age he went to work as a machinist on the Hudson River Railroad Then he ran a locomotive for a year or two, and was from that promoted to be shop foreman His rise to master mechanic came shortly afterwards

The attention which he bestowed to his business soon brought him the confidence of the management, and his responsibilities increased gradually with the growth of the Vanderbilt lines, until in 1881 he was made superintendent of motive power of the whole New York Central system and controlled lines He is a progressive man but intensely conservative, and his vast experience has taught him to avoid making mistakes He appears to remember everything that has been tried with locomotives, and he is careful to avoid the rocks that have sent others to grief. His principal characteristic as a designer is the choice of simple forms and strong parts The fast locomotives that have brought the designer so much honor form the highest development of simple forms. The result is efficiency and durability. The engines can be relied upon to do their hard work every day without failure, and they will match anything on wheels for the miles they will run without repairs.

WILLIAM BUCHANAN,
Supt M. P., N Y C & H R Ry. Designer of the "999."

### Charles Hogan.

Nearly all the phenomenally high speed made by New York Central trains, the runs which have broken all records and set men looking forward to the time when 100 miles an hour will be a schedule speed, have been made with Mr Charles Hogan at the throttle Mr Hogan, whose portrait is shown herewith, is a modest, retiring sort of man, whom none but railroaders would expect to make himself famous for fast running. Nearly all his railroad experience has been on the New York Central. His first railroad work was done here, and he was away from the company only a short time when he was seized with the Go West fever. While that lasted he ran on the Union Pacific, but after a few years' experience there concluded that the effete East was good enough for him, so he returned to the Central. He runs regularly between Buffalo and Syracuse The secret of Mr. Hogan's success in keeping up high speed is his steady manner of working up to it. He evidently makes a careful study of how to work the engine into high velocity with the least possible drain on the boiler. He feeds the water very regularly, and never has the lead high enough to cause priming, no matter how fast the cylinders may be drawing the supply of steam. He runs with a full throttle and regulates the speed by the reverse lever. No accident has ever happened to his engine at the high speeds which put terrific strain upon the mechanism. The exemption from accident is doubtless due to persistent and rigid inspection. Mr. Hogan does his own inspection, and is certain that it is done properly.

In speaking of the "999," Mr. Hogan refrains from all braggadocio, and recently wrote "Mr. Buchanan can well be proud of her, for she is all that a locomotive can be."

C. H. HOGAN,
Engineer of the "999." Made the Fastest Time Ever Recorded.

### The Fox Truck.

The New York Central people are remarkably well pleased with the experience they have had with the Fox pressed-steel truck. It is in use under a large number of freight cars, and some of the trucks have been in service over a year. The men in charge of the car department have good opportunities to judge of the merits of the Fox as compared with the excellent standard diamond truck used by the company, and the conclusion arrived at is that the pressed-steel truck is going to be remarkably light on repairs The New York Central people are reported to favor the making the Fox truck standard for all roads. A rule of the Master Car Builders' Association which prevents the making of a patented device a standard will prevent the association from taking action in favor of the Fox truck, which is much to be regretted. If a general desire were manifested to make the truck a standard of the association, it is probable that the patentees might be induced to enter into a satisfactory agreement.

---

A great many high-pressure marine engines are now fitted with a simple device, independent of the other lubricators, to force into the steam-chest a small amount of pure graphite daily. This material, if pure, is an excellent lubricant, prevents corrosion and polishes the walls of the cylinder and other moving parts. Some of our compound locomotives should have something of this kind, for it is found very hard to lubricate the valves and pistons with steam at 180 or 200 pounds pressure.

### Smoke Preventing—Jim Skeevers and the Fourth Vice Try Experiments.

There is going to be a reform on Jim Skeevers' road about smoke making, or smoke preventing We know there is going to be a reform because the fourth vice-president says there is, and he knows.

The fourth vice has read three scientific books on combustion and all by his lone self wrote out a bulletin notice about preventing smoke, that showed he was master of the subject When the boys consulted the bulletin board one morning they read the following

Official Order No. 39.

[The fourth vice was educated at West Point and married the president's daughter.]

Official Order No. 39.

The careless habit of enginemen in allowing black smoke to issue from their engines must be discontinued from this date. By firing in such a way as to distribute the carbon evenly on the grates and admitting about four-fifths of the total volume of air to the ash-pan and one-fifth above the fire, the oxygen and hydrogen will mix and all smoke will be consumed before reaching the flues, thereby abating a nuisance and showing a great economy in fuel. Controllable air jets will be put on all passenger engines at once, but men on freight can prevent smoke by putting their fire door on the first notch of the latch for one-and-a-half minutes after each new supply of fuel, then closing it. When the engine is standing, open fire door and put on the blower slightly.

The penalty for a disregard of this rule will be instant dismissal from the service.

SAM BLANK,
*Gen'l. M. M.*

Approved,
A. VERRY NEWE,
*Fourth Vice-President.*

Of course all the boys knew that "the old man," Sam Blank, was never guilty of writing anything about oxygen or hydrogen, and that he knew too well how heavy the trains were and how much coal they had to burn per hour, then, years ago, "the old man" fired and run, and he would just as soon expect the men to obey an order to hold their left hands on the seats of their pants when passing all mile posts as to half close the fire door for one-and-a-half minutes after each fire.

Skeevers pulls the express freight—it's heavy, the time is lively and the "93" never was known to go over the road without burning coal; never was known to burn much coal without some smoke, never was known to steam any too well with tl [illegible] or shut, and never was known [illegible] it all with it half open

Skeevers determined to work in an object lesson on the man that wrote that bulletin. (Skeevers' specialty is object lessons).

Skeevers went home and put on his store clothes and presented himself at the office of A. Verry Newe, fourth vice-president.

He worked his way past the outside guard, made the grand hailing sign of distress before the altar of the "assistant to" and was permitted to send in his name and business on a little piece of paper. He wrote·

"Skeevers, engineer '93,' come to get help and advice about smoke prevention."

He was admitted to the holy of holies, salaamed before the fourth vice, hung his hat on his left thumb, and said:

"Mr. Newe, I am very much interest in smoke prevention, I think it can be e tirely stopped if the men are instruct right. Now, what I called for is this; think if you can get one engine to run without smoke, you can make the other crews do as her crew does and the job is complete; it would take two years to instruct all the men on the road. Now, I want the honor of having the first smokeless engine. You know my train is considered of the most importance on the road, you sidetrack passenger trains for it every day. Now, I thought I could get you to put on some old clothes and go out with us this afternoon. You know more about smoke prevention than anyone else, because you have made a study of it (the fourth vice smiled here and stroked his mustache approvingly); the signals are so thick and the importance of time so great that I cannot watch the fireman and give him the right instruction, but if you would sit on his seat for half a trip and tell him when to shut the door and when to leave it on the latch and prevent him from using too much coal at a time I think the '93' would throw no smoke and be an example to all the rest."

The fourth vice agreed to Skeevers' plan, and Skeevers went home with a pay-day smile on his phiz.

That afternoon as the "93" backed down on to her train, A. Verry Newe, fourth vice-president, stepped upon her hurricane deck, and Skeevers introduced him to the fireman, Pete Doyle.

"Mr. Newe; my fireman, Mr. Doyle Pete, Mr. Newe is going over the road with us to give us a few pointers on smoke preventing. You fire just as he tells you; I am anxious that the '93' should be the first to run without smoke."

Pete said "All right, sorr," but there was a sneer under the coal dust as he glanced at the "dood collar" and effeminate face of the fourth vice.

The fourth vice got a clean piece of waste to wipe his hands, and looked around nervously. He had never been on an engine before with any responsibility at all.

Skeevers oiled around, and then shut himself up on his side of the boiler—the "93" was a mogul—and said to Mr. Newe·

"I shan't be able to notice you much, as it keeps me pretty busy with the signals and all; but Pete will do just what you tell him, and I am sure we shall learn something before we get over the road.

But here's the orders. Are you all right, Pete? Well, we're off."

The "93" picked up her twenty-four loads and started out of the yard.

"Phwat about the firin', sorr?" asked Pete of the fourth vice.

"Well, fire lightly, and don't close the door at first."

"Shall Oi putt in a foire now?"

"Well, yes, I suppose so; fire about as often as you do regularly."

Pete jumped for the shovel and fired in three or four scoops of fine coal, the black smoke rolled the second the door closed, the fourth vice glanced at the stack and spoke sharply to Pete:

Skeevers was wrestling with the sand-lever, for the "93" was slipping.

"Stop!" shouted the fourth vice, "are you crazy? you put in ten shovels of coal there at once; leave that door on the latch."

"But she jerked a hole in her foire, sorr."

"How's that—a hole in her fire?"

"In course, phwen he slipped her she histed the coal aff the front av her grate, the foire wor too thin."

"She didn't throw smoke until you put in the fourth or fifth shovelful."

"Oi'm onto that, sorr; phwen there wor no smoke I knowed there wor a hole, an' all the draft wor goin' in there."

there's an ordinance against it in this town," said Skeevers.

Skeevers went to the telegraph office for orders, and returned with this message

"Report cause of delay to your train at once. J. E. B."

This he handed to the fourth vice.

"What's this for?"

"Bluff wants to know what has delayed us. We were four minutes late and he has held us six more to ask a useless question; does it every day we get three minutes late."

"Don't pay any attention to him."

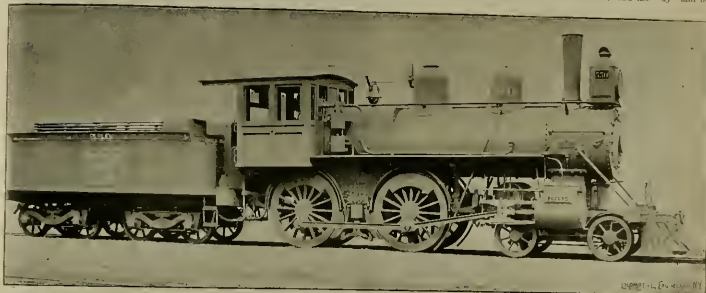
Skeevers jumped onto the engine, glanced at the gauge and said

"Pete, why in the devil didn't you blow wide and then fired in a half-dozen shovels of coal. She smoked, but the finger on the gauge commenced to crawl up toward a hundred and enough.

"Mr. Newe, don't you think that if we could get more oxygen to combine with the hydrogen over the fire that we could complete combustion better?" asked Skeevers.

"Well, I don't know but we could, but what we need is in——"

The Flyer went by here, and the fourth vice didn't finish, for the "93" was tugging at her train when the last sleeper passed. Pete and the fourth vice "fired her for smoke," and the "93" laid down



ROGERS' EIGHT-WHEELED PASSENGER ENGINE. NOW AT WORLD'S FAIR.

ROGERS' TEN-WHEELER PASSENGER ENGINE. NOW AT WORLD'S FAIR.

"Open that door on the latch, sir; don't you see how the smoke is coming out?"

Pete opened it, waited a couple of minutes, then the fourth vice motioned with his hand to have it shut.

"That's the way to do it, my man, do you see there was no smoke at all?"

"Oi do, sorr, but she dropped foive pounds of stheam, do ye moind, an' it's harder to git than to lose."

There was just the trace of a wrinkle on the brow of the fourth vice, as he glanced at the gauge.

"Shall Oi putt in another foire, sorr?"

"Yes, if it's time."

Pete chucked in three shovelfuls, well distributed, and the fourth vice watched the stack with joy—there was no smoke. Pete turned his shovel over and held it in the door for a second, looked up at the stack, and jumped for the tank, commencing to fire coal into the furnace like mad.

Skeevers kept himself busy, and apparently paid no attention to the play on the deck.

The "93" lost another 5 pounds of fog. The fourth vice, Pete and Skeevers each had a wrinkle on his brow now, and Skeevers looked at his watch, then at the steam gauge anxiously, whenever the fourth vice looked his way. This kind of anxiety is catching.

Pete left the door on the latch one-and-a-half minutes by the watch after every fire; fired as he was told, worried to see the steam go down, sweat like a butcher and wished the fourth vice was in Halifax.

Skeevers kept his eagle eye on the rail and looked anxiously at his watch. Steam was down to 105 pounds, ten miles out, and at Peeksboro he was four minutes late and there was a red flag out.

"Please put Pete onto the way to use that blower and door to prevent smoke; her up and get her hot, she ain't gained a pound?"

"The gintlemon said, kape the doure open and the wind-jamber on aisy loike."

It was hard storting with 105 pounds of steam, and when they got back to speed they were fifteen minutes behind time, and had to lay back one station for the Flyer. Skeevers pretended to be mad at Pete and raved about being disgraced; never was so late before. Why in the —— —— couldn't he keep wind on the engine?

"Is it fog yer wantin', Misthur Skeevers?"

"Yes, here's sixteen mile hill ahead of us, thirty minutes late, and no steam."

"Well, sor, Oi can fix ye out if ye will let me foire this kittle fur *stheam*, but Oi am foirin' her now under instructhins fur *schmoke*, and yez can have yer chice"

"Well, get her hot anyway, now."

Pete shut the door, opened the blower half way up sixteen mile hill and had to be "blowed up."

At Hilltop they got another sassy message about delay of train, and at Sumerton they were an hour and five minutes behind the schedule and had delayed most of the other trains on the road—the "93" hadn't done such a thing in years.

The coal dust and sweat mixed with the wrinkles on the brow of the fourth vice. As they were taking water at Springvale he asked Skeevers how much steam he needed to keep the train on time.

"One hundred and sixty."

"Do you generally have it?"

"Always."

"Why won't she keep it up now?"

"Oi can give yez a straight tip on thot," said Pete, sliding into the pit.

"Well?"

"Foire her for stheam."

"Well, fire her for steam, then; we've

got to get this train over the road some time," said the disgusted official.

"But she'll schmoke a little, sorr."

"Damn the smoke."

"That's what Oi say all along, sorr."

The fourth vice slid off and took No. 4 back to town.

Pete, the "93," and Skeevers finished the trip with 160, and, well, she did throw some smoke.

When they got home the next day there was a note for Skeevers to report to the general superintendent at once.

He reported.

"Old Calamity," as the boys called the general superintendent, was in a swearing rage.

"What's the matter with your engine, Skeevers?"

"Nothing at all, sir."

"How came it, then, you lost an hour and forty minutes yesterday, missed your connection, delayed half the trains on the road and raised hell in general?"

"Experimenting to save smoke."

"What right have you got to *experiment* all the trains on the road late, tell me that?"

"I wasn't doing the experimenting."

"Well, who was?"

"The fourth vice-president, sir."

"What in the name of the bald-headed Abraham does he know about smoke?"

"You saw the new bulletin about it, didn't you?"

"No."

"Well, any engineer who can't burn soft coal with a forced draft at the rate of a hundred or two pounds per square foot of grate per hour without smoke is to be discharged."

"Who says so?"

"The fourth vi——"

"The fourth jackass!"

"I asked him to show my fireman how to combine the hydrogen and oxide and the chuloric and the carbolic and the debolic, so as to do away with smoke—and that was what was the matter with the '93' yesterday."

"She didn't steam?"

"Pete says she was fired for 'schmoke.'"

"Well, you make time, smoke or no smoke. I know you fellows make too much smoke around stations and can prevent it some, but you can't burn coal without *some* smoke any more than you can boil water without making steam."

"Well, what about the bulletin? There are already a lot of rules and orders in force that if obeyed would stop every train on the road. You officers know we have to disobey them to do our work, but if anything happens we were disobeying orders. Mr. Newe might just as well have ordered us to have burned no coal at all—it's one or the other, which shall it be: smoke steam and time, or no smoke, no steam and no time?"

"That bulletin will come down *and the man that put it up will take it down.* I'm getting tired of this kindergarten railroading."

"What about stopping a train that is three minutes late to ask what delayed it, and give it five minutes more in the neck?"

"It's bad business, they do that on the G. M. & T."

"They do it right here."

"Who the h——"

"Read that, ask Mr Newe, he was with us," handing him the message received about delay.

"Look here, Skeevers, you knew how this smoke business would come out, didn't you?"

"I could guess fairly well."

"What did you let this new Newe go out to bother you for?"

"To teach him an object lesson."

"Well, what do you suppose he learned?"

"That you can figure out more about smoke preventing on a mahogany desk than you can show in practice and do the work at the same time. That it would be easy enough if all you had to do was to prevent the smoke, and that there was more cry than wool in this smoke nuisance howl, anyway. That what can be done with a big stationary boiler with natural draft, burning twenty pounds of coal per square foot of grate per hour, cannot be done on a locomotive burning more than a hundred, any more than a Corliss valve-gear will do on an express engine."

"Well?"

"You put up a request something like this and you will have little cause for complaint, and take down the old one."

Then Skeevers sat down and wrote out a bulletin.

"Considerable complaint comes from various towns about the throwing of heavy clouds of black smoke. The management of the road recognize the fact that the enginemen cannot burn coal without some smoke, but know that where they try, they can, in a large measure, prevent it in towns and villages by intelligent firing, the use of the door and blower.

"Away from towns smoke is of little consequence. Fire then so as to keep an even and full pressure of steam with the least fuel.

"Those firemen who are the most successful in preventing smoke at stations will be given the best engines to fire and this record will not be forgotten when it becomes necessary to promote men.

"The company has no set rules or pet plans of firing, but leaves this to the judgment of the men on the engines, you will be judged by results, not by methods."

"Try that on 'em and see if you don't have less trouble."

"Old Calamity" put on his specs, read the order over twice and then said

"That's worth trying, young man; it's worth trying, and damme if I don't think you'd make a pretty good railroad official yourself."

"I think so, myself," said Skeevers, "but the president has no other daughters and I'm married, anyway."

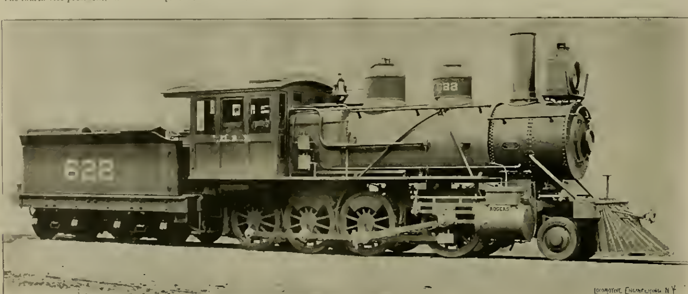
## The Rogers Locomotive Co.'s Exhibition Engines.

On pages 291 and 292 we show some splendid engravings of engines sent to the World's Fair by the Rogers Locomotive Co., of Paterson, N. J.

The first picture is of a standard American engine, with Belpaire boiler, built for the C., B. & Q. She has 18 x 24-inch cylinders, driving-wheels 69 inches in diameter, a rigid wheel base of 8 feet 6 inches and a total wheel base of 22 feet 11½ inches. She weighs, in working order, 102,000 pounds, 65,500 of which is on her drivers.

The second picture is of a heavy ten-wheeled passenger engine, built for Florida passenger service, which is heavy during the winter season. She has cylinders 19 x 24 inches, driving-wheels 72½ inches in diameter, a rigid wheel base of 13 feet 6 inches and a total wheel base of 24 feet 8 inches. She weighs 133,000 pounds, 98,500 of which is on her drivers.

The engine shown on page 292 is a consolidation freighter built for the Illinois Central road. She has cylinders 21 x 24 inches, drivers 56½ inches in diameter, a rigid wheel base of 16 feet 9 inches and a total wheel base of 24 feet 5 inches. Her total weight, in working order, is 137,300 pounds, 118,600 of which is on her drivers.



ROGERS' 21 x 24-INCH CONSOLIDATION. NOW AT WORLD'S FAIR

## Railroads in Georgia.

The Georgia Legislature has acted for the last few years as if railroad property had no right to exist, although the railroads have performed a most important part in dragging the State out of the condition of bankruptcy in which it lay at the close of the War. Capitalists, willing to help in the building up of Southern industries, invested money freely in Georgia railroad securities, and they are getting paid back by Acts that are pure confiscation. There are fifteen railroads insolvent in the State and are being operated by receivers. Three railroads have been sold by the United States Marshal at public auction, and the stocks of all the railroads that have escaped bankruptcy have declined as the values of no other property has ever done.

The outrageous laws that have brought this about have not always confined the inflictions to capitalists in other States. The incomes of hundreds of families in Georgia have been suddenly wiped out and poverty has visited homes where plenty would be found but for the robbery practiced by the law-makers. Many charitable institutions have had to close their doors because their incomes were cut off by the plunderers of railroads.

A curious law was enacted last year by the Georgia General Assembly. They conferred upon the State the monopoly to sell all alcoholic beverages, and made regulations requiring the drinks sold to yield a profit of 100 per cent. Not contented with putting this tax upon the thirsty citizens, the enactment compels railroad companies to transport the drink at a specially low rate. It is generally believed that the working of the new liquor laws and the distress resulting from the adverse railroad legislation will end the sway of the Communists, who form a majority of the Georgia Legislature.

## Call for Meeting of Foreman Blacksmiths.

At a recent meeting of foreman blacksmiths, the subject of forming a national association was discussed, and the undersigned were directed to correspond with foreman blacksmiths throughout the country to ascertain their views on the subject.

It is not intended to form a labor organization, so-called, but an association such as that of the master car builders, for mutual information, improvement and benefit.

The suggestion is made that if the proposition is favorably received, a meeting of those who are able to attend be held in Chicago at some convenient date during the World's Fair. Foreman blacksmiths are requested to write me at earliest convenience how the proposition strikes them, and, if favorable, whether or not they could attend such a meeting. If a sufficient number of favorable responses are received, a meeting will be appointed and notice thereof sent.

J. J. THORNTON,
C. H. WILLIAMS,
W. G. LOTTES,
GEORGE F. HINKENS,
*Committee.*

Address replies to GEO. F. HINKENS, Gladstone, Minn.

An old rule in force fifty years ago on the South Carolina road read: "In cases of dense fogs all freight trains on the road will go into nearest turnouts, and there remain until it clears off. The passenger and night express trains will, in such cases, run strictly within schedules."

## Baltimore & Ohio Railway's Exhibit.

[EDITORIAL CORRESPONDENCE.]

The exhibit of the Baltimore & Ohio Railroad Company in the World's Fair showing the development of the locomotive, forms three rows of machines. If we begin at one end and follow the line to the extremity, then go up the other side taking the next row, and return by the third row, we follow the development of the locomotive from its first germs to its present condition.

THE FIRST ENGINE WITH A LINK MOTION, BUILT BY HENRY T. JAMES, NEW YORK, 1832.

THE PHILOSOPHER'S IDEA OF A LOCOMOTIVE.

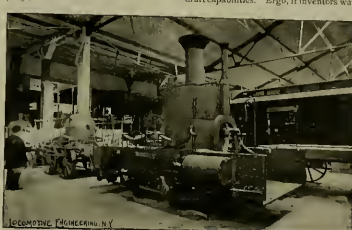
The first apparatus we find is a globular copper ball, with a spout projecting from one end. This was the philosopher's idea of applying steam for the propulsion of vessels, and represented an idea of Sir Isaac Newton's. For more than 2,000 years learned men have been more or less familiar with the power of compressed steam, and they have speculated on the means of applying it to useful purposes. A sort of rotary engine was used as a species of toy in Alexandria some 2,000 years ago, power being developed by the reaction of escaping steam, but learned men failed to design a harness which would transmit the power of steam to machinery. It had made no progress in Sir Isaac Newton's time, when he expressed the idea that is embodied in this machine. The only way that the force of steam could be applied in a machine of this kind, was by the reaction of the escaping steam on the atmosphere; this was the idea of the most accomplished scientific men in the world in 1680.

Philosophers continued their speculations about steam, as the growing industries of the world demanded something better than animal horse-power, but nothing tangible came of their efforts, until a working blacksmith put a piston in a cylinder and used the steam pressure to drive the piston. The first important link in the train of mechanism that forms the locomotive, was thus put into practical shape by Thomas Newcomen, in 1705.

As soon as steam could be applied by this means, even through crude apparatus, military engineers, who have always been looking for new means of increasing their destructive agencies, attempted to make a steam engine that would be useful for military purposes. This desire led to the inventing of the second machine shown in the line; it was designed by Cugnot, a French engineer, in 1769, and his machine is still to be found in a museum in Paris. This was really the first attempt to build a locomotive engine. Two cylinders were employed transmitting the rotative power to a single wheel. The power was applied through ratchets connected with the wheel. Reversing the direction of travel was done by turning the pawls. The fatal weakness of this first locomotive was deficiency of boiler capacity.

MURDOCH'S MODELS.

The next machine is a steam engine invented by Murdoch, one of Watts' assistants, in 1784; it was a small model and worked well enough to demonstrate that the applying of the steam engine to locomotion was practicable. The inventor, who was an accomplished engineer, was, however, too much engaged with other engineering business to follow out this idea, and it fell to others to carry out the work. One upright cylinder was employed, the piston being connected to a long pivoted bar, which in turn moved the connecting-rod. The next machine,



THE FIRST "CRAB." IN FRONT OF HER STANDS THE "HERCULES," THE FIRST ENGINE WITH EQUALIZERS.

NATHAN READ'S TUBULAR BOILER.

which looks like a flat car with a boiler at one end, is not an engine, but it shows something which performed a very important part in the development of steam locomotion. This is the first multi-tubular boiler ever built, and was invented by N. A. Read, of New England. He demonstrated the rapidity in which steam could be generated in a boiler of this sort, and urged its adoption upon the engineering world of his time, but he was in the field too early, having built the first boiler in 1791. His ideas, however, were taken by others and utilized to make the locomotive a success.

The next machine is Trevethick's first engine, and was built about 1800 for the purpose of running on common roads

The next engine, with the big fly-wheel and nest of gear-wheels, was the developed idea of Trevethick's, and was built three years after the first one; it was also intended for common roads.

OLIVER EVANS' AMPHIBIOUS MACHINE.

To Americans, the queer-looking oblong box with four wheels, ought to be one of the most interesting exhibits on the grounds, for it represents the first vehicle ever moved by steam in America. It was a scow, built by Oliver Evans in 1804 Oliver Evans was a great advocate of the use of steam for locomotive purposes, and to demonstrate its practicability he put wheels under a scow which he built, and by means of his high-pressure steam engine ran the scow through the streets of Philadelphia. Evans was the inventor of the high-pressure, high-speed steam engine, which was for half a century distinctly American.

The next machine, with its four large wheels and vertical cylinder, transmitting power through a walking-beam and long rods, is another locomotive of Trevethicks' design, also intended for common roads. It contains all the elements of the first practical locomotives. This engine was built in 1808.

Four years later the next machine was built by Blenkinsop, an English inventor. Like most other early engineers, he believed that smooth wheels could not be used under locomotives, and he accordingly made his engine with geared wheels to secure the necessary adhesion. The engine was not a practical success.

To overcome the difficulties of obtaining adhesion of the driving-wheels, the next engine was built by Brunton. It will be seen that the cylinders transmit power to a pair of levers with shoes trading on the ground. These were to push it along, in the way that a man or an animal steps, giving the required propulsion to the machine. Many engineers believed eighty years ago that the method of Brunton was going to be the line of development of the steam engine to land transport. They argued that Nature was the true mother of invention, and Nature had shown that the horse embodied the highest speed and draft capabilities. Ergo, if inventors want to succeed in making a perfect traveling engine let them imitate the motions of the horse.

One of Brunton's engines was built, and a great eager crowd gathered to see it start on the expected speed that was to rival the pace of the fleetest Arabian steed. The engine started with many jerks and groanings, as is apt to be the case with new machines, but she went without shoving, which is more than could be said of many other early locomotives. As she moved away the engineer became excited and shouted to the fireman to "keep her hot." That person labored with vigor and zeal, and a giddy velocity of three miles an hour was reached. Still the men in charge were not satisfied, and there seemed to be some prospect of adding another mile an hour to the speed if the fireman did his duty. At this point, when breaking the record seemed within the grasp of the inventor, the boiler blew up, killing six or seven persons and ruining the engine. Stock in the Brunton invention dropped to zero and remained there.

HEDLEY'S WORK IN BEHALF OF THE LOCOMOTIVE.

Wm. Hedley, superintendent of one of the coal mines in the north of England, who, like others of his class, was interested in applying the steam engine to locomotive purposes, seems to have been a very keen observer, and did not take for granted that the adhesion of plain wheels was not sufficient for traction; as it was the opinion, however, of the engineering world of the time that plain wheels would not do, Wm. Hedley constructed a machine to test the proportion between the weight and adhesion, that is shown in the four-wheeled vehicle, with gears in the middle and handles outside for turning the wheels. By experimenting with this machine he demonstrated that geared wheels were not necessary for locomotives.

About the time this experiment was tried he had a locomotive almost ready to put in service; this engine is the four-wheeled machine seen next, and it became the model of locomotive builders up to the time that the Liverpool and Manchester Railway was opened in 1829. This locomotive of Hedley's, which was called the "Puffing Billy," was built in 1813. She was the first locomotive to do practical every day work on a railroad, and it was a highly sensible machine considering it was built before high-pressure boilers and high-speed engines had made any progress in England. The boiler was of wrought-iron plate, with a return flue. Two vertical cylinders were employed, the piston-rods being connected to beams from which motion was transmitted by means of gearing to four smooth wheels. The exhaust steam was discharged into a drum, from whence it passed into the smokestack. This engine remained at work till 1862, when it was removed to the South Kensington Museum, London.

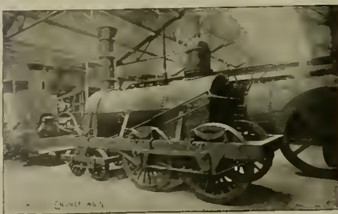
GEORGE STEPHENSON'S FIRST LOCOMOTIVE.

George Stephenson, who was foreman of a coal mine a few miles from where Hedley had his engine at work, went to see Hedley's engine, and on examining it declared he could build a better one. George was never overwhelmed with any sense of native modesty, and he convinced the proprietors of his mine that he could build an engine superior to Hedley's. The result was that they furnished the means and he built the engine next in line; this engine was called the "Blucher."

It gave George a good deal of experience in locomotive construction and maintenance, but it was not much of a success. Nobody but George thought it was a better engine than Hedley's. George made two radical mistakes in the construction of

FIRST EIGHT-WHEEL CONNECTED ENGINE. BUILT BY WINANS'.

the "Blucher" to use a single flue, thereby losing the heating efficiency that Hedley's engine possessed, and he multiplied the gearing that intervened between the connecting-rod and the driving-wheels. The engine had two cylinders, 8 x 24 inches, placed vertically half way within the boiler. The engine did not work long before the cog-wheels wore so badly that radical changes had to be made. This experience with gearing as a means of transmitting power to locomotives taught subsequent builders to make direct connection with the driving-wheels.



The First Eight-Wheeler Patented by Henry R. Campbell, of Philadelphia, in 1836.

While the English were laboring to develop locomotives for hauling coal cars, engineers on the continent in Europe were also engaged in working out the problem of applying the steam engine for land transportation. The next engine, which has two sets of driving-wheels with a cylinder set above each and a tender with an article like a fan on each side, was designed by Seguin, a French inventor. His idea was to use the fans for blowing the fire. The engine has a return flue boiler, ... became a common form in those ... of the development of the locomotive. ... next machine, with the ratchets ... of the wheels, is interesting because it represents the first form of locomotive patented in America, this was done in 1827, but the engine was never built.

The next three engines are interesting, because they are those which competed at Rainhill in 1829 for a prize of £500 offered by the Liverpool & Manchester Railway Company for a locomotive that would come up to certain requirements regarding pulling, weight and speed.

STEPHENSON'S "ROCKET."

The first engine is the "Rocket," built by George and Robert Stephenson, at their works in Newcastle; it took the prize. The model of this engine is well worthy of critical examination. A more correctly built model will be found in the exhibit of the London & Northwestern in the British section. This was the first locomotive that had a firebox and multi-tubular flues. This combination gave the first element of success, since it enabled the boiler to generate steam enough to meet the drain of cylinders having a fast-working piston. The engine is a remarkably compact machine for the time in which she was built. She has all the elements of the modern locomotive, including steam blast and direct-connecting cylinders. In this engine we find the bar-frame, which was afterwards developed by English builders and then abandoned, to be taken up as a regular feature of the American locomotive. This engine attained the speed of twenty-nine miles an hour on a trial trip, which caused a tremendous sensation among the general public, who believed that twenty miles an hour was a speed too great for safety.

The next engine is the "Sanspareil" of Timothy Hackworth. It was a favorite before the race, but did not equal the "Rocket" in performance, although it was said to be a more powerful engine.

The next engine, with the boiler, cylinders and diamond-shaped box on the same frame, was the engine built by the famous engineer, Ericsson, for the competition. The box contained a fan for stimulating the fire, and to its failure to work at a critical moment was due the failure of the engine in the race.

"STOURBRIDGE LION."

The engine at the end of this row is interesting to most Americans, from the fact of it having been the first to turn a wheel on an American railroad. This was the "Stourbridge Lion," built at Stourbridge, England, by Foster, Rastrick & Co., for the Delaware & Hudson Canal Company, and brought to this country under the supervision of the famous engineer, Horatio Allen. The engine made a single trip over a portion of the road, but proved too heavy for the track, and was abandoned in consequence.

The next engine we come to, returning on the next line, which has horizontal boiler, firebox, single pair of driving-wheels and a small pair of leading wheels, was the first of what was known as the "Planet" type, this form of construction was for years followed as a model by English designers.

COOPER'S "TOM THUMB."

The next engine that we come to represents our first native efforts to make locomotives for railroad service. It was a small working model, built by Peter Cooper, and run on the Baltimore & Ohio Railway in the summer of 1829. Its performance demonstrated that working a railroad by locomotives was practicable. The most interesting point about the engine is that it shows the first element of what was afterwards known as the "V" hook motion. This will be apparent to anyone who examines the valve motion. The engine was little more than a working model, having had only one upright cylinder and a small vertical boiler in which gun barrels were used as flues. This engine was built before the "Rocket," and Peter Cooper deserves the credit of first designing a multi-tubular boiler for locomotive purposes. The engine, however, attained a speed of eighteen miles an hour and pulled a car containing thirty-six passengers. The trial of the little engine was made before the famous Rainhill trials in which the "Rocket" obtained the famous laurels. It is probable that the performance of Cooper's "Tom Thumb," as she was called, would have convinced American railroad men that steam locomotives were practicable for high speed, even if the trials in England had never taken place. The cylinder of the engine was $3\frac{1}{4}$ inches in diameter with a stroke of $13\frac{1}{2}$ inches. Power was transmitted to the driving wheels by gearing. The wheels were 30 inches in diameter. The whole engine in working order weighed about 1 ton.

American locomotive men ought to examine this model carefully. The accident of a more conspicuous success alone prevented the "Tom Thumb" from holding the high place in history now occupied by Stephenson's "Rocket."

"THE BEST FRIEND."

The next engine ought also to be of great interest to American railroad men, as it was the first practical locomotive built on this continent. The engine was built at West Point Factory, New York, under the supervision of Mr. David Matthews, one of the pioneer engineers of this country, who is still alive, and will, no doubt, visit the World's Fair. She was built for the South Carolina railway according to designs furnished by Mr. E. L. Miller, president of the railway. As will be seen, she has a vertical boiler, the furnace at the bottom being surrounded with water and filled inside with teats running out from side to top with alternate stays to support the crown of the furnace. The gases of combustion passed through the sides at several points into an outside jacket from which they escaped into the smokestack. The boiler and cylinders were carried upon a frame resting on four coupled wheels. The cylinders were 6x16 inches, wheels $4\frac{1}{2}$ feet diameter, the whole weighing $4\frac{1}{2}$ tons. This engine was shipped to Charleston, S. C., in the fall of 1830, and was put into service at once and did very good work. She afterwards came to grief through the fireman hanging a weight on the safety-valve to prevent the noise of blowing off steam, which exploded the boiler, killing the fireman. She was afterwards rebuilt with a horizontal boiler and worked on the road up to the time of the War.

First Engine Built by Norris Locomotive Works.

BALTIMORE & OHIO PRIZE LOCOMOTIVES.

The next group of models represents a very interesting event in the history of American railroad development. After the successful trial of Cooper's little engine on the Baltimore & Ohio Railroad, the company offered prizes for locomotives that would meet certain requirements, and the models shown represent the engines that were built for the competition. The terms of the competition were rather curious. The engine was required to burn coke or coal and consume its own smoke. The weight was restricted to $3\frac{1}{2}$ tons in working order. The wheel flanges were required to be inside the rail and coned according to a shape submitted. If the engine was four-wheel connected, the wheels were not to exceed 3 feet in diameter, but if a single pair of drivers were used, the diameter might be 4 feet. The pressure of steam was not to exceed 100 pounds to the inch, and a less pressure was preferred. The company took the right to test the boiler with water to four times the steam pressure. The engine was required to be carried on springs, and the height of the smokestack was restricted to 12 feet. The sum of $4,000 was to be paid for the engine that most successfully met the conditions, and $3,500 for the next best. The prize was taken by an engine designed by Phineas Davis, who was afterwards master mechanic of the road, and was killed by one of the engines turning over. The model of his successful engine will be identified from the fact that she had vertical cylinders connecting direct to the middle of the side-rods. This plan of driving was found to be very defective, as it put too many stresses on the side-rods, and the engine was afterwards altered and put into a shape shown further on in this group.

Among this group is an engine built by Milholland for the competition. The most interesting point about Milholland's engine is that it has a distinctly developed form of "V" hook motion. She also seemed to have the germ of the extended smokebox.

"Sandusky," First Engine Turned Out by Rogers Locomotive Works.

One of the engines in this group, which will be identified by two sets of copper pipes leading from the boiler-head to the steam-chest, is a great curiosity. She was designed by Stacey Castello, of Philadelphia, and built for the Baltimore & Ohio competition. There are several curious things about this engine, the most prominent feature being oscillating cylinders that admit and exhaust steam in a peculiar fashion. The steam-pipes lead to a cored disk at the side of the cylinders. When going ahead the forward pipe admits steam and the other acts as the exhaust, while to go backwards, the pipe becomes the steam-pipe and the other the exhaust.

FIRST LINK MOTION ENGINE.

There are two other experimental machines here, one built in Philadelphia by Childs, the other by Henry T. James, of New York.

The James engine is of peculiar interest owing to the fact that a link motion was used upon it. This ingenious inventor understood the merits of the link motion as they are now recognized; knew that by linking up towards the center the steam cut-off was accelerated, and the period of compression advanced. The weak point about his inventions was lightness of the parts. He made neither boiler nor mechanism strong enough for the work to be done. The mechanism was much given to breaking down, and several of his boilers exploded, which was the cause of a very valuable invention being lost to the engineering world at the time. Through the explosion of the boiler of the best engine he built, the whole thing was destroyed, and the link motion dropped out of sight until it was re-invented fifteen years later.

The next engine to claim our notice is the grasshopper "Atlantic." This is merely a development of Davis' first engine, and became the standard of the Baltimore & Ohio for several years. This "Atlantic" was the first of her class, and is a real engine of historical interest. At first a revolving fan was employed for blowing air into the fire; but that was afterwards abandoned and the steam turned into a smokestack.

Among other models near at hand is that of Matthias Baldwin's first locomotive, the "Old Ironsides." Then comes a double-ender, designed by Horatio Allen for the South Carolina Railway. It did not prove much of a success; but another ahead of it, a single connected engine with a four-wheel truck, demands attention, for it was the first locomotive to which a leading truck was applied. This was done by John B. Jervis, the well-known engineer. This improvement was first applied to an English-built engine running on the Mohawk & Hudson Railroad.

Walking along, we come to an eight-wheel engine built by the Baldwin Locomotive Works many years ago. This engine is interesting on account of being the prototype of the modern eight-wheel American engine. She was designed by Henry Campbell, of Philadelphia.

Next we come to an engine with an upright boiler and horizontal cylinders called the "Mazeppa." This was an advance on the rasshopper type of engine and is the first "crab" ever built. The trainmen gave the engine this name because she appeared to move backward, the cylinders being behind. Like the grasshoppers, she transmits the power to a driving-shaft having a gear-wheel, which in turn engages with a cog on the driving-axle.

The next engine is Eastwick & Harrison's "Hercules," and is of historical interest from the fact that she was the first engine built with equalizers. The engine is of a style that was very popular in this country for years, having the dome form of firebox introduced by Bury, of England. This engine had a peculiar form of valve motion, with only one eccentric for each side, a movable plate on the steam-chest having changed the position of the ports to make them suitable for back or forward motion.

The next engine we come to, with a single pair of drivers, dome firebox, engine truck and drop-hook motion, represents the first locomotive built by Norris, of Philadelphia.

THE ENGINE THAT ESTABLISHED THE TRACK-GAUGE OF OHIO.

Across the aisle we find the "Sandusky," an engine of historical interest from several circumstances. The engine was the first built by the Rogers Locomotive Works in 1837. She has a half crank connection and eccentrics set on the driving-axle outside of the frame, actuating a rocking-shaft placed under the deck. The engine has the wagon-top form of boiler, which afterwards became so popular in this country, and to which the splendid boiler work done by the Rogers Locomotive Works contributed in no small degree. A novelty about this engine was the counterbalancing the weight of the crank and its connections by putting lead in the cored rim of the wheel. This plan was patented by Thomas Rogers at a time when few people considered counterbalancing necessary. A bonnet spark-arrester was applied to this engine, and it was considered the most advanced form of spark-arrester at that time.

The "Sandusky" was built for the New Jersey Railroad & Transportation Co., which had a gauge of 4 feet and 10 inches. About the time the engine was finished some capitolists in Ohio were about to begin building a railroad to form connection with the Ohio River, at Cincinnati, and Lake Erie. One of them came to Paterson and bought the engine for the Mad River Railroad Co. She was taken out by canal and lake transport to Sandusky, and was landed before a foot of railroad was built. They built the road to suit the gauge of the engine and the legislature of Ohio afterwards passed an act making 4 feet 10 inches the legal gauge of the State. We believe this is the only case on record where one locomotive led to an act of legislature, or where a locomotive established track-gauge for a State or country.

READING'S FIRST LOCOMOTIVE

The next engine, with the favorite name of "Rocket," is a real engine, and was the first used on the Philadelphia & Reading Railroad. As will be seen by a plate on her side, she was built by Braithwaite & Co., London, in 1838. The engine is of a kind that was very common in those days, and all railroad men can remember when many of them were still in use in Great Britain. This engine is very well worthy of a critical examination; she is inside connected, has the Bury style of boiler, and the eccentric rods extend beneath the smokebox to a rocking-bar under the front end, which is actuated by drop-hooks. This is the most perfect of the old types of locomotives on the grounds. She is in perfect order and is still fit for service after the many years she has been in use. She has what was known as the Bury bar-frame, which was dropped by English builders, but was adopted by Americans and has become an established feature of our locomotive construction. A point about the engine well worthy of examination is the springs, they contain twenty-one plates, of about the same size of those now used in driving-springs of our heavy locomotives.

The next locomotive is the "Samson," which was built by Timothy Hackworth in 1836 for a coal railroad in Nova Scotia, and was kept in service up to within ten years ago. She has a return tubular boiler and vertical cylinders, and was one of the type that was very popular with English builders for heavy service in early railroading.

The next engine is the first of the eight-wheelers built for the Baltimore & Ohio. It has horizontal cylinders, which was a departure from their older form, which transmitted power to driving-wheels in the second motion. She was a favorite engine with Ross Winans, and did useful work.

The next engine is the "Albion," an English engine sent to Nova Scotia early in the railroading era

The next engine shows the progress towards heavy freight engines made by the Baltimore & Ohio Company. She is carried on four pairs of drivers, connected, has cylinders under smokebox and transmits the power through a supplementary shaft and gearing. This was the line in which Ross Winans developed the locomotive towards the camel-back

Greater progress is represented in the next engine, which has horizontal cylinders on the outside and four pairs of driving-wheels, connected, and with a very large dome in the middle of boiler. This is the first of the "camel-backs;" it is also notable in having a magazine chamber beside the stack for a spark-arrester.

The next engine is one of the older form of locomotive, still used by the Baltimore & Ohio, and was taken out of service to come to this Exposition, and will go back into service after Exposition is over. She has been in use longer than any locomotive in this country.

The next engine is the first "camel-back" built by Ross Winans. She is the ordinary form of "camel-back" still in use.

The engines in the remainder of the row will be readily understood by railroad visitors.

## Brooks' Twelve-Wheel Freight Locomotive.

Gauge—4 ft 8½ in.
Fuel—Bituminous coal.
Weight in working order—156,000 lbs.
Weight on drivers in working order—136,000 lbs.
Rigid wheel base—9 ft. 8 in.
Driving-wheel base—15 ft. 6 in.
Total wheel base—25 ft. 3 in.
Diameter and stroke of cylinders—20 x 26.
Diameter of driving-wheels—55 in.
Diameter of boiler—68 in.
Length and width of firebox—114 x 32 in.

TENDER.

Coal capacity—8 tons.
Capacity of tank—4,000 gals.

ENGINE AND TENDER.

Total wheel base—52 ft. ½ in.

This engine was intended to stand on a pedestal at the Fair entrance, another huge engine of Baldwin build to be opposite, but the Fair officials deciding to cut down the pier from 23 to 4 feet, the builders put their engines inside.

BROOKS' HEAVY TWELVE-WHEELER. BUILT FOR ONE OF THE PEDESTALS AT WORLD'S FAIR ENTRANCE.

---

A rule in the M. C. B. interchange code has worked iniquity to some people since it was adopted. This is the rule which read "That in case a foreign draw-bar is removed from a car upon a defect card, a credit shall be allowed of the full value new of the material in the bar" The effect of this has been to induce unscrupulous parties to turn old bars upon other roads and make claims for four times their market value. A change has been made allowing only the value of the bar as scrap.

---

A patent has been granted to Mr. S. M. Vauclain, of the Baldwin Locomotive Works, for an improvement in injectors. The improvement consists of a method for saving the overflow water by returning it to the feed-pipe.

---

The Strong Locomotive Manufacturing Co., of Cincinnati, have dissolved. Only $8,700 of the $1,000,000 capital was ever paid in.

### Durability of Hollow Bolts.

Claims have repeatedly been made that hollow stay-bolts are more durable than those made of solid iron, but very few mechanical men put any faith in the theory. As broken stay-bolts is a subject of vital importance to every one connected with the care and handling of locomotives, we believe that thorough tests ought to be made to find how far the claims of those who allege that hollow stay-bolts will stand stresses better than solid ones are correct. The practice of drilling stay-bolts to indicate when breakage occurs is becoming very common, and is, we believe, an increased means of safety; but even this practice has its detractors, who assert that the bolt is weakened, without being made a certain means of indicating rupture.

There is too great a tendency to take snap judgment about everything where there is a possibility of difference of opinion. We do not think it is wise for any man to jump to the conclusion that anything which can possibly make a boiler safer is wrong, without painstaking investigation. The incompetent way in which investigations of mechanical subjects are sometimes carried out was strikingly illustrated in a case that came to the knowledge of the writer concerning a test of solid and hollow iron intended for stay-bolts. The iron to be tried was said to be of the same tensile strength. The hollow stay-bolts broke under the same strain per inch of section as the other, and the conclusion jumped at was that it could not be any better in sustaining the strains of service.

The claim made for hollow or drilled bolt is that it has greater elasticity than the solid one, and better withstands the deteriorating action that causes crystallization. Although no satisfactory test has been carried out to demonstrate the truth or fallacy of this theory, analogy indicates that it is well founded. Years ago Mr. Stroudley, locomotive superintendent of the London, Brighton & South Coast Railway, began the practice of using bolts drilled hollow for all important connections, and the failures were greatly reduced thereby.

Lately, the Straight Line Engine Co., of Syracuse, N.Y., have adopted the use of hollow bolts for their main rods because it reduced the chances of breakage. Professor Sweet, talking on this subject lately, said that hollow bolts were not only less given to breakage than solid ones, but they had so much elasticity that a single nut would hold a bolt secure, as the spring of the material obviated the necessity for using a jam nut. They have made a variety of tests to find out how hollow bolts withstood strains and shocks. Under pulling tests the solid bolt began to stretch under the same strain per inch of section as the hollow bolt, but the former broke after stretching one quarter of an inch, while one hollow bolt stretched two inches before it broke. Under the shocks caused by blows the hollow bolt displayed even greater superiority over the other. The solid bolt broke under a certain weight dropping twenty-eight inches, and the hollow bolt did not break until the fall was raised to forty-three inches

Facts of this kind show that there is more in a hollow bolt than the critics, who rely on their "common sense" alone, would lead us to suppose. A form that displays superior power in withstanding blows is likely to endure vibration and cross movement in a similar degree. Marine engineers are in the habit of drilling a hole through the center of propeller shafts under the belief that it lessens the crystallization action due to stress and vibration. If this is a fad, as some ultra practical men pretend to believe, it is a very expensive one not likely to be followed if good cause were not shown to prove its utility. There certainly appears to be sufficient good engineering testimony to justify faith in the improvement embodied in drilled or hollow stay-bolts.

### Is it Saving Money to Save Oil?

A prominent superintendent of machinery of a large road recently remarked to the writer "I'm afraid to ask my boys to be very economical with oil. I could save oil by forcing matters a littl , but the company would lose money by it." Undoubtedly this statement is true. Men forced to it by orders or induced by hope of earning premiums will skimp a bearing of oil close up to the heating point. If heating takes place permanent damage is done the bearing, and it will require far more oil to cool it down than would have been required to keep it cool in the first place. Every bearing of a locomotive or car should have all the oil that can be gotten between the rubbing surfaces; excess that runs off is waste, but there will be less power consumed in overcoming friction, less liability of bearings to heat and cause of delays to trains, and expense in repairs, if the bearings are flooded with oil.

It is mistaken economy to buy cheap, thin oils; they are much poorer lubricants, and being thin and volatile they run away from bearings, allow cutting to take place at a lower temperature, and are themselves fuel to a hot box. Once a bearing becomes heated it can hardly be gotten cool again with the miserable stuff known to the trade as "six-cent oil," and to the men as "purchasing-agents' slop."

Where plenty of reasonably good oil is furnished to enginemen there will always be found an absence of delays from hot pins and cut bearings, less repairs to machinery, *and less money invested in oil per mile run*, than on a road trying to save *oil* when they should try to save *money*.

How many master mechanics are there in the country who absolutely pay no attention to saving coal, who will let one man use, regularly, twice as much fuel as others do, but who will haul him over the coals at once if he runs a few miles below the average to a quart of oil?

Any master mechanic can save his company a dollar on coal with half the effort, and without any of the risks he takes in trying to save a cent on oil.

Coal is the big expense in operating locomotives; if a pound can be saved it is pure gain; it can do no harm in another direction; therefore it is the place to try to save

Oil is one of the small expenses, stinginess in its use or economy (?) in its purchase may cause expense, delays, and annoyance in a dozen ways, each more expensive than it would be to furnish good oil and plenty of it.

### Train Wrecking.

Within the last month the daily papers have recorded several cases of attempted train wrecking, and in only one instance has an arrest been recorded. In this case, the man who attempted to commit wholesale murder upon innocent passengers and trainmen gave as an excuse that he had been badly treated by the railroad company. The man would have been equitably treated had the people whose lives he put in jeopardy strung him up to the nearest telegraph pole. Public sentiment is far too lax in dealing with the crime of train wrecking. It is the worst species of murder, yet it has very rarely been treated as a capital crime. If the criminal has influential friends or money behind him, he is certain to escape the highest penalty of the crime, no matter how many lives he may have sacrificed

We are familiar with several cases where worthless wretches obstructed the track or moved rails, causing the death of enginemen, and in no instance was a punishment of ten years in the penitentiary inflicted. In one case a youth got off with eighteen months in jail, although his diabolical act caused the death of an engineer. This laxity of punishing crimes that are of peculiar atrocity encourages people to commit them. In cases of train wrecking, railroads ought to combine to prosecute the offender There is so much hatred to railroad companies as corporations that a lawyer can generally enlist the sympathy of the jury by pretending that the criminal is vindictively prosecuted by a soulless corporation. If he was prosecuted by the men whose souls he was trying to let loose ahead of time, the sympathy would seldomer be found on the side of the murderer. The way to make ruffians understand that the lives and limbs of railroad men are worthy of respect is for railroad men to show that they demand the kind of protection that prevents crime through wholesome fear of the consequences.

### Obstructing Car Movement.

A discussion arose in the Master Car Builders' Convention, that strongly illustrates how the want of judgment or the illiberal spirit of one railroad official may obstruct the prompt movement of freight cars. It will be remembered that several years ago certain destructive wrecks of freight trains were traced to brake rigging being hung so low that it was torn off by guard rails or other truck attachments, derailing trains and causing loss of life and serious damage to property. As a remedy for this danger the Master Car Builders' Association inserted an article in the Rules of Interchange of Cars, permitting cars to be refused if the brake-beams, levers and attachments were less than 2¼ inches from top of the rail. The rule has worked well, and although there are thousands of cars with their brake attachments lower than that specified by the rule, it caused no inconvenience or dispute till lately. One decided benefit of the rule has been that all new cars and all cars rebuilt have had their brake-rigging set high enough to prevent danger.

The members of the last convention were surprised when the Rules of Interchange were under consideration with a motion to change the rule respecting brake-rigging, making the distance from the rail not less than two inches. The move led to a lively discussion, and several of the New England members insisted that their managements were anxious for the change to be made in order to facilitate the movement of cars.

It appears that the New England railroads were in the habit of accepting cars at interchange points with the brake-rigging lower than the specified limit, and no inconvenience was experienced till a new master car builder was appointed for the New York, New Haven & Hartford lines, who issued a positive rule that all cars should be refused unless the brake-rigging was up to the required height The rule stopped cars by the wholesale, and a sort of panic ensued. The Master Car Builders' Association was appealed to for assistance, and they promptly refused to change their rules.

This evidently was not a case for the master car builders, but for the general managers, whose cars were delayed. If they had represented to the management of the N. Y., N. H. & H. that their M. C. B. was acting without good judgment and was interfering with the movement of freight cars without serving any good or rational purpose, there is no doubt that a change of policy would have been dictated.

Meanwhile the roads whose cars were delayed did not deserve much sympathy. While others have been raising their brake-rigging to prevent accidents, and in compliance with the M. C. B. rule, they have been doing nothing.

### Proposals of Change on the Rules of Interchange of Cars.

We have been urging for years that the Master Car Builders' Association give the car inspectors a little consideration when they undertake to discuss proposed changes on the Rules of Interchange of Cars. Complaints are constantly heard that the inspectors at the numerous interchange points are celebrated mostly for making diverse interpretations of the rules under which they are supposed to work We have attributed much of the confusion of opinion that exists about these rules to the practice of making changes on them every year. Changes have often been made without any real necessity, but it seemed that some members could not let the rules alone. To gratify a little desire to pose as the originator of a new rule, changes have been carried out which led to confusion among the inspectors on every road in the country. It seems that the seed of our arguments against the practice fell on some fertile ground, for the last Master Car Builders' Convention was notable for the firm manner in which the majority of the members opposed changes on the Rules of Interchange. A wholesome, practical sentiment seemed to prevail. When a change was proposed, the questions were immediately considered: How is it going to work? What good will it effect? If there was not very apparent reasons for a change, it was rejected by a large majority We consider that the railroad companies will profit largely by the good sense that ruled the councils of the last convention.

### Advantages of a Stiff Rail.

The New York Central Railroad Company, in all their renewals of track, are using a section of rail designed by Professor Dudley which has a very deep section, making a remarkably stiff track. The rail has several peculiarities which contribute to making it an improvement over all other rail sections in use. The metal is so distributed that it has an unusually wide head, and the fillets between the head and base are so formed that these parts get compressed in the act of rolling This makes strong what are usually weak points.

In the course of a conversation with Mr. A. G. Leonard, assistant to Vice-President Webb, about rail matters, we were surprised and somewhat skeptical about a statement which he made to the effect that their engines were able to haul two more cars on a fifty-foot grade after the Dudley rail was put down. We now believe that the statement correct, extraordinary as it may appear. With a weak rail and heavily loaded cars the wheels are constantly ascending and descending a series of small grades due to the deflection of the rails. A stiff rail gives the wheel a flat surface to roll on, thereby decreasing the resistance. An incidental advantage obtained by use of the wider rail-head is increased durability of tires, the larger bearing surface reducing the tendency to wear.

### A Standard Height of Draw-bar Made Compulsory.

A circular received from the Secretary of the Interstate Commerce Commission intimates that the railroad companies which have so long refused to adopt a standard height for the draw-bar of freight cars will now be required by law to adopt a uniform height of 34½ inches. It was high time that something was done to put an end to the diverse height of draw-bars used by different railroad companies, and in some instances by the same company. There has been for many years a standard of 33 inches for the height of freight car draw-bars, but it has been ignored by many railroad companies, and the actual heights in use vary from 31 to 36 inches. This has been a most dangerous condition of affairs for trainmen and switchmen, and great loss of life and injury to persons has resulted from two connecting draw-bars varying so much in height that one passed over the other.

Those who realized the dangers of this defect have over and again tried to induce railroad companies to adhere to the standard or to agree upon a height that would bring about greater uniformity. All efforts in this direction were futile because a few large railroad companies had adopted a height above the M. C. B. standard, and they would not yield an inch to meet the wishes of those who were inclined to effect a compromise. It is gratifying to know that the strong hand of a United States law will now come into force to end the heartless methods of the companies, which permitted no considerations of humanity to influence their actions on car design.

### Locomotive Tests.

We have heard considerable criticism among members of the Railway Master Mechanics' Association and others about the excessively elaborate method of locomotive tests proposed by the committee on the subject. To subject a locomotive to all the details of the proposed test will certainly involve a great deal of labor, but after the work is done there will be material to form accurate conclusions from that cannot be found after the slip-shod tests in vogue are finished. The report recommends considerable useless and unnecessary work, such as weighing the ashes in smokebox, in the ash pan, etc., but on the whole the work mapped out is of a kind that will bring good results.

The fact is that nearly all master mechanics are inclined to make tests of locomotives with data not sufficient to draw conclusions from. In the last convention speakers described their methods of arriving at conclusions about the relative value of compound and simple locomotives which were simply ridiculous. We heard some of the railroad men making fun of a New England master mechanic for the plan he adopted to find out the relative value of two kinds of coal. It seems the general manager wanted to find out how a new quality of coal would compare with the quality they had been using, so he directed the master mechanic to find out. A few weeks afterwards he called for a report, and the master mechanic went to the general office and said that he had talked to the engineers using the coal, and some of them said it was better than the old kind, while some of them said that it was not as good. This method of reaching conclusions on a measurable quantity was carrying loose practices to such an extreme that it struck most master mechanics as being ridiculous, yet it was not a shade more inaccurate than practices that were gravely described as having been followed by speakers in the discussion on compound locomotives.

### Crude Committee Reports.

One of the most exhaustive reports of committees which we have ever seen was one on freight car trucks submitted to the Master Car Builders' Convention. As a means of drawing out information the committee sent out a circular containing fifty questions, and these appeared to have been exhaustively answered. The report consisted principally of extracts from the replies. While the report was a monument to the industry of the committee, and although it was well received by the association, we consider it one of the worst reports we have ever seen. A report is not a good one unless the information is put in a digested form that can readily be grasped by the reader. The mass of reading which this report contained formed the material for a good one; but in the crude shape submitted to the association, the report had no more claim to be considered good than the collection of wood and iron that go to build a car has the right to be considered a good car when it is heaped together without form or order.

The truth is not palatable, but it needs to be told about this species of report, which is still too common. No sane editor would accept a report of that character as an article on freight car trucks, even if he was extremely desirous of having the subject treated as exhaustively as possible. It is an editor's duty to see that the articles present the desired information in the most intelligible form, and if he does not follow this practice, readers will not be satisfied. We regard the framer of a committee's report as an editor of the report, and he has a very poor conception of his duty if he merely repeats the words of replies to circulars. If a member answering a circular does not give information, his reply is of no value to the association and ought not to be repeated. Mere opinions are of little more value. Facts are what are wanted. These should be arranged under the various headings, and summaries made which would be readily grasped. Then the committee should carefully consider all the facts presented and make out their conclusions concerning the same. These words are applicable to other committees besides that particularly mentioned.

---

In the closing hours of last Master Mechanics' Convention, a resolution was passed unanimously giving it as the sense of the association that the president ought not to be elected a second time. This voiced a sentiment which is very strong in both the mechanical associations, although delicacy has prevented it from being publicly expressed. There is a feeling that railroad companies consider it an honor to have their mechanical officers elected to the head of these associations, and that the compliment should be given to as many men as possible. The only way to carry out this idea is to elect a new president each year, and it looks as if the Master Mechanics' Association will follow this course in future. So long as it was customary to elect the same president for two terms, to deviate from the practice appeared to be a reflection on the man who was elected only for one year, but when the rule is established and understood there will be no mortification felt at seeing the compliment passed to the next vice-president.

---

A very exhaustive report on a standard method of conducting locomotive tests was presented to the last Master Mechanics' Convention. The great labor of preparing this report was performed principally by Mr. F. W. Dean, Chairman of the Committee, and is similar to one prepared for the American Society of Mechanical Engineers. Mr. Forsyth, who is a member of the committee of the latter society having the subject on hand, submitted to the Master Mechanics' Association a proposal that they join with the Society of Mechanical Engineers in paying the expense necessary to conduct a series of tests of locomotives on the apparatus provided for the purpose at Purdue University. The association agreed very heartily to the proposal, and the Executive Committee undertook to raise the necessary funds.

---

There is an idea among some railroad men that a considerable part of the time spent by the master car builders and master mechanics at their annual conventions is devoted to pleasure-seeking and sociality. This is a mistake. We are not aware of any societies that devote closer attention to business during conventions. It has always been a surprise to us to find so many members sitting out the long sessions during a season of the year when the heat is nearly always oppressive, the more so, as the meeting-rooms to be obtained are generally very unsuitable, badly ventilated and hot. At the last M. C. B. Convention there were seldom less than 90 members present out of 120 and the Master Mechanics had during one session over 140 present all the time out of a total attendance of about 160.

---

The *Railway Age* has been persistently urging the Master Car Builders' and Master Mechanics' Associations to institute a movement for raising funds to build a permanent home and meeting place for the organizations. The members do not enthuse very readily on this. The funds would have to come from railroad companies, and contributions of this character are difficult to raise. If the *Railway Age* realized how difficult it is to prevail on some railroad companies to subscribe a small sum annually to the printing fund of one of the associations they would understand why the initiated are reluctant to ask for large contributions.

---

The Master Car Builders' Association have decided to send to letter ballot a recommendation made by a committee to have working drawings of the standard journal-box made on transparent sheets from which blue-prints can be taken. This will prove a decided help in making the dimensions of this standard uniform. We do not see any reason, however, for sending the matter to letter ballot, as it ought to be dealt with by the Executive Committee.

---

The Committee of the Master Car Builders' Association, appointed to make tests of air-brakes, reported that the Pennsylvania Railroad Company had offered to establish for the association at the Altoona shops a building and complete apparatus for the testing of brakes. The Westinghouse Air-Brake Company have placed sufficient apparatus to represent the brakes of two trains of fifty cars each. This most generous offer was thankfully accepted.

A communication has been received from the agent in charge of the locomotive "James Toleman," criticising the remarks we made when describing the engine. The letter reached us too late for publication in this issue, but it will appear next month.

---

The people of Lakewood and Jamestown, N. Y., are a unit in their praise of the people who attended the mechanical conventions. "They are the jolliest, freest-handed crowd we have ever had to do with," was the expressed sentiment.

The railroad supply business of the late H. L. Leach will be continued at 55 Oliver street, Boston. Mr. A. E. Leon will act as manager. Their air sand-feeding apparatus is becoming very popular and will be widely used.

### PERSONAL.

Mr. James Mooney has resigned as master mechanic of the Southern Pacific at Victoria, Tex.

Mr. A. S. Douglas, for some time superintendent of machinery of the Texas & Pacific, died last month.

Mr. W. B. Doddridge has been appointed general manager of the Missouri Pacific, with headquarters at St. Louis.

Mr. David Meadows has been appointed traveling engineer of the Canada Southern division of the Michigan Central.

Mr. Eulalio Encinas has been appointed roundhouse foreman of the Interoceanic Railway of Mexico at Pueblo, Mex.

Mr. Horatio F. Forrest, chief engineer of the Great Northwest Central, has been appointed receiver and manager of the road.

Mr. J. A. Edson has been promoted to general superintendent of the St. Louis & Southwestern, with headquarters at St. Louis.

Mr. Geo. H. Graves has been appointed superintendent of the Indianapolis, Decatur & Western, in place of L. A. Boyd, resigned.

Mr. A. A. Daniels has been appointed master mechanic in charge of the Paducah shops of the Newport News & Mississippi Valley.

Mr. Thomas J. Hennessey, traveling engineer of the Michigan Central, has been promoted to the position of division master mechanic.

Mr. J. L. Brown, master mechanic of the Pittsburgh & Western, has been appointed superintendent of the Allegheny Water Works.

Mr. M. Borden has been appointed superintendent of transportation of the Atlantic Coast Line, with headquarters at Wilmington, N. C.

Mr. J. M. Scroggins has been appointed foreman of the motive power and car department of the St. Louis & Southwestern, with headquarters at Waco, Tex.

Mr. T. F. De Garmo, who has been for several years general agent of the Trojan Car Coupler Co., has accepted a similar position with the Glidden & Joy Varnish Co., of Cleveland, O.

Mr. H. D. Galbraith has been appointed general master mechanic of the Fort Worth & Rio Grande, with headquarters at Fort Worth, Tex. He was formerly on the St. Louis & Southwestern.

Mr. Thomas Fleming has been appointed superintendent of the Denison & Washita Valley, with headquarters at Coalgate, I. T., in place of Mr. Edward Perry, who has resigned.

Daniel R. McBain has been appointed traveling engineer of the Michigan Central road west of the Detroit river. Mr. McBain has heretofore had charge on the Canadian end of the road alone.

Mr. E. A. Peck has been appointed general superintendent of the St. Louis & Iron Mountain in place of Colonel Ricker, resigned. Mr. Peck was formerly general superintendent of the C. C. C. & St. Louis.

Thos. Smith, for some years past machine shop foreman of the A. T. & S. F., at Topeka, has been promoted to the position of general foreman of the New Mexico Division with headquarters at Raton, N. M.

Mr. Fred Glover, formerly master mechanic of the St Louis, Cape Girardeau & Fort Smith, has been appointed general foreman of the motive power and car department of the St. Louis Southwestern shops at Tyler, Tex.

Mr. J. P. Hemdell, who recently left the Brooklyn, Bath & West End road on account of its consolidation, has been appointed superintendent of the Pittsburgh division of the W. N. Y. & P., with headquarters at Oil City, Pa.

Mr. L. T. Westrich, of Delphos, O., has been appointed superintendent of the St Louis division of the Toledo, St. Louis & Kansas City, with headquarters at St Louis. He will have charge of the lines from St Louis to Frankfort, Ind.

Mr G. A. Zemlin, for several years master mechanic of the Michigan Central at Detroit, died there last month. Mr Zemlin has been on the Michigan Central for twenty-three years, and was highly esteemed by the officers of the road.

We regret to learn that Mr J. S McCrum, superintendent of motive power of the Kansas City, Fort Scott & Memphis, has been suffering from severe illness. He is well nigh recovered now, and will be "at the old stand" after the Fourth.

Mr. George A. Goodell has been appointed superintendent of the Burlington, Cedar Rapids & Northern, in place of Mr Williams, promoted. Mr Goodell was formerly chief train dispatcher of the road and was subsequently assistant superintendent.

We have to acknowledge a pleasant call from Mr Herman von Littrow, reporter on railroads for the Austrian Government. He has been sent to this country to make an elaborate report on what there is in the exhibition and on our railroads likely to be of value to the Austrian Government.

Mr. Robert Williams has been promoted to be general superintendent of the Burlington, Cedar Rapids & Northern. Mr Williams has been with the company about fifteen years and has risen through the positions of general manager's assistant, purchasing agent and superintendent.

Mr. S. W. Mullinix has been appointed traveling engineer of the Newport News & Mississippi Valley, with headquarters at Paducah. Mr Mullinix is promoted from the position of master mechanic and, while only holding the title of traveling engineer, is practically assistant superintendent of motive power.

A notice has been issued that Mr. William Garstang, superintendent of motive power of the C. C. C. & St. Louis, has changed his office from Cincinnati to Indianapolis. We regret to hear that Mr. Garstang is in poor health. He contemplates taking an ocean voyage in hopes that it will help him.

In the course of a private letter, Mr Daniel Coxe, superintendent of motive power of the Delaware, Susquehanna & Schuylkill Railroad, says they are getting to have quite a railroad. As testimony worthy of sustaining this statement, he mentions that they are getting to have as bad collisions as any of the other roads.

Owing to impaired health caused to a great extent by overwork, Mr George W McGuire has resigned the position of general manager of the Butler Draw-Bar Attachment Co. A substitute was appointed to take his place, but it appears to us, from what we saw of Mr. McGuire at the conventions, that he is working as hard for the company as he ever did.

Several personal changes have been made on the Old Colony part of the New Haven & Hartford system. Mr. J. R. Kendrick, third vice-president, relinquishes the position of general manager, which is assumed by Mr E. G. Allen, one of the superintendents of the road. Mr. A. L. Ainsley is promoted from the position of station agent to the superintendent of the Middle division.

Mr. Isham Randolph, a well-known civil engineer, has been appointed engineer in chief of the Chicago Sanitary district. Mr. Randolph was for years chief engineer of the Illinois Central Railroad, and is regarded as one of the ablest engineers in America. He is the inventor of an interlocking signal system of great merit and of several other valuable railroad mechanical devices.

A. W. Gibbs, Asst Supt M. P. of the R. & D. at Atlanta, Ga., has been appointed to the position of assistant mechanical engineer of the P. R. R., with headquarters at Altoona, Pa. Mr. Gibbs is a graduate of the P. R. R., and has been for some time in responsible positions on Southern roads. It is a very high compliment to Mr Gibbs to be recalled to the old road. They are not much given to that sort of thing.

Horace W. Eddy has resigned as master mechanic of the B. & A. at Springfield, Mass., to devote all his attention to the extensive properties owned by his father and himself. Mr. Eddy's father, Wilson Eddy, was foreman of the Springfield shops from 1840 to 1850, and master mechanic from that date until 1880, when he resigned, and his son, H. W. Eddy, was appointed in his place. Thus these shops have been "in the family" fifty-three years.

Engineer Walter W. Mansfield, of the St. L. & S. F. Railway, recently received injuries in a wreck from which he died. Mr. Mansfield was one of the progressive, thinking engineers whose loss is always felt by their employers and their associates, one of the men who are proud of their calling and try to honor it and make it honor them. Mr Mansfield had been in the employ of the St. L. & S. F. for twenty-two years, he leaves a wife, mother, and three sons.

Mr Chas. Barnes, son of General Manager Barnes, of the Boston & Albany, has been appointed master mechanic of the Springfield shops in place of H. W. Eddy, resigned. Mr Barnes served his time in the Boston shops of the road, was for some years in charge of the machinery of the car shops at Alliston, Mass., and for the past five years has been in the traffic department. Mr. Barnes comes to the position with some fifteen years' experience on the road, and will doubtless fill the bill to the entire satisfaction of all concerned.

The announcement is made that Mr. H. H. Vreeland has been elected president of the Metropolitan Traction Co. Mr Vreeland has been for several years general manager of the New York & Northern Railroad, and is a particularly able railroad man. He rose through train service to the position of general manager, He filled in succession the position of brakeman, conductor and train master on the Long Island Railroad, and from there he went to the New York & Northern. This road has always been financially embarrassed, and Mr. Vreeland became noted for the way which he developed the resources of the road and for the small operating expenses incurred.

Senator Leland Stanford, the Pacific Coast millionaire who gave the State of California the Leland Stanford University, was one of the men who built the Southern Pacific Railroad. He had a great respect for locomotive engineers, considering that on them rested greater responsibilities than any other class of men in the republic, he left a request that part of his pall bearers should be selected from among the engineers of the S. P. road. So eight of the oldest runners were selected to serve with twelve other men, such as would naturally become the pall bearers of an old associate who was thirty five times a millionaire. Men in Senator Stanford's walk of life often do have a great respect for locomotive engineers, but they usually keep it to themselves.

The Master Car Builders' Association, in Convention at Lakewood, N. Y., elected the following officers for the ensuing year: President, E. W. Grieves, who is elected to fill this position for the second term. He is master car builder of the Baltimore & Ohio. First Vice-President, John S. Lentz, of the Lehigh Val., who has for years been one of the most prominent and useful members of the association. Second Vice-President, S. A. Crone, assistant superintendent car department of the New York Central. He is a comparatively new member, and does not take much part in discussions, but is a hard-working member of committees. Third Vice-President, T. A. Bissell, the well-known general manager of the Wagner Car Works, and long one of the most active members in the association. The Treasurer is Mr. G. W. Demarest, master car builder of the Northern Central, one of the veterans of the association. He is a quiet, retiring man, but takes a great interest in the work of the association, and is one of the most regular attendants of conventions.

Mr A. G. Leonard, whose name we have several times mentioned in connection with improved appliances used on the New York Central's fast trains, is a young man whose career ought to be a good example for others. When a young boy he entered the office of Mr. William Buchanan, superintendent of motive power, where he displayed so much zeal, intelligence and industry that he rapidly rose to be assistant to Mr Buchanan. He has an extraordinary grasp of details, and there is nothing connected with machinery and operating that he does not understand particulars of. When Mr. H. Walter Webb was elected vice-president of the company he selected Mr. Leonard for his assistant. The selection was a most fortunate one, for it gives the vice-president a living encyclopedia of everything connected with the motive power and operating departments. Mr Leonard has a strong love for mechanics, and much of his spare time is devoted to inventing improvements on railroad apparatus. The car vestibule handled by the Gould Car Coupler Co. was invented by Mr. Leonard, and so was the equalizing hydrostatic buffer arrangement used on the Columbian Flyer trains. He is a particularly modest and retiring young man, and does not look the kind of person who would ward off the fiends and cranks that haunt the lobby of a managing vice-president, but he keeps them out. We have been there and know whereof we speak.

At the Lakewood Convention the Railway Master Mechanics' Association elected the following officers for the current year: President, John Hickey, who is elected the second time. He is superintendent of motive power of the Northern Pacific, and has been for years noted for the encouragement he gives to the educational work done by this and similar associations. He was for several years president of the Western Railway Club. Second Vice-President, William Garstang, superintendent of motive power of the Cleveland, Cincinnati, Chicago & St. Louis. He has been an officer for three years, and takes a very active interest in the association, but was kept away this year by sickness. Third Vice-President, R. C. Blackall, superintendent of motive power of the Delaware & Hudson. He is extremely popular in both the mechanical associations and both have claimed him as an officer. He was anxious to retire from office this year, but the members would not consent. Mr O. Stewart is treasurer. He was long superintendent of motive power of the Fitchburg and has always been a hard worker in the business of the association. He is a good speaker, but seldom rises unless he is master of the subject under discussion. Mr. Angus Sinclair, of LOCOMOTIVE ENGINEERING, was elected secretary for the seventh time. He is very proud of the association and proud of being secretary. It is also a matter of personal satisfaction to the secretary that 106 active members and three associates have been added to the association in the last two years.

Mr. Walter McQueen, the famous locomotive builder, died at his residence in Schenectady last month at the age of 7[illegible]. He was born in Scotland, and came to this country with his parents when a boy. He learned the machinist trade in Troy, and when his time was out he returned to Scotland and worked there with the view of widening his experience. Returning to this country shortly after railroads began to extend, he went to Schenectady and obtained a position on the Utica & Schenectady Railroad, part of his time being put in as machinist and part as a locomotive engineer. Two years afterwards he was made master mechanic of the road. Here he remained for four years, and here he began his career as a locomotive builder, his road having been one of the first in America to build locomotives for themselves. A locomotive called the "Mohawk," which he built with cylinders 15 x 22, became famous for the tractive powers developed, and gave Mr McQueen a reputation as a locomotive designer. From the Utica & Schenectady road he went to the Hudson River Railroad and remained there until 1852, when he accepted the position of superintendent of the Schenectady Locomotive Works, which he held until 1876. His reputation as a designer grew and flourished, and the "McQueen" locomotives became famous all over the United States. As a young man Mr McQueen was noted for his progressive ideas, but as years grew upon him he became conservative and had a tendency to cling to the glories of the past. He was elected vice-president of the works in 1876 and retired from active management to give the lead to men of younger ideas. He never was much in sympathy with the designs or the methods which has given the Schenectady Locomotive Works so much celebrity during the last seventeen years. His most valuable life's work was done in the first ten years, when he held the position as superintendent. When he took the locomotive in hand it was a very crude machine, and he did as much as any man to establish correct forms and dimensions. He invented many improvements on the locomotive, but took out no patents on the same, being willing to make his inventions public property. Among his inventions that became most popular were the air-chamber for the water-pump and the solid saddle for cylinders.

### President Hickey's Address.

The address of President Hickey in opening the Master Mechanics' Convention at Lakewood, was one of the most comprehensive inaugurals we have ever heard. It discusses in a succinct, clear manner most of the topics that are before the railroad mechanical world. Most men in Mr. Hickey's position carefully avoid the quicksands intervening between labor and capital, but the president of the Master Mechanics' Association took a bold stand on the side of right and justice, and his brave words will give offence to no one whose opinion is worthy of notice.

A great portion of the address was devoted to the improvements in locomotive construction, operation and maintenance which are likely to reduce the operating expenses without impairing the efficiency of the motive power. The subject of compounding is discussed through several paragraphs and a belief is expressed that the prospect of making this form of engine a permanent success is encouraging. The necessity for enlarging bearing surfaces and for reducing as far as possible the number of working parts received lengthy attention.

That troublesome subject of engine ... was also intelligently discussed, and ... use of a simple form of draw-bar dynamometer to indicate the pull on the draw... was recommended. A somewhat novel suggestion was made to the effect that a standing Advisory Committee be appointed to advise with members on any disturbing and unsettled questions relating to motive power interests. It might also arbitrate matters of difference arising between persons selling, leasing or renting rolling stock or in matters relating to the construction of new machinery. It is evident from the address that President Hickey ... devoted a great deal of thought-planning to extend the usefulness of the association.

### An Excursion to the Oil Regions.

On Saturday, June 17, in the interval between the Master Car Builders' and Master Mechanics' Conventions, the New York, Lake Erie & Western and the Western New York & Pennsylvania Railroad Companies gave an excursion to the oil regions of Pennsylvania, which was heartily enjoyed by a large number of the members and their friends. The party was under the guidance of Mr. A. E. Mitchell, superintendent of motive power of the Erie system, who was untiring in his efforts to promote the comfort of all. At Meadville, the party was met by Messrs. Miller & Sibley, and conducted to the famous kite shaped race track and stables owned by the gentlemen named. A number of the finest horses were run out to show their form and style, and the visitors agreed that they had never seen such a display of splendid horses. But the sights in this line were only begun. The train proceeded to Franklin, and there Messrs. Miller & Sibley escorted the excursionists to a stock farm on the top of a hill where a princely lunch was provided. Then they adjourned to a grand stand and a magnificent display of blooded horses was made for the entertainment of the party. After a long array of fast trotters had been brought out for inspection, a change of "type" was introduced, and Jersey cattle, the finest of their kind, were led past. Then there was an immense herd of ponies and miscellaneous breeds of horses and other animals driven past. There was not much in the line of railroad appliances seen on the trip, but the party returned highly gratified with the unique display prepared for them by Messrs. Miller & Sibley, and with the interesting country where oil flows out of the ground in greater profusion than water.

During the time the Master Mechanics' Convention was at Lakewood, the members and their friends were invited by the Brooks Locomotive Works to visit the shops at Dunkirk. A large party accepted the invitation and went to Dunkirk by boat and a special train furnished by the Western New York & Pennsylvania. The visiting members devoted the principal part of the time to a careful inspection of the various shops. The fine tools in use, the expeditious methods of doing work and the admirable arrangement of the buildings, all excited much interest and admiration. We heard several of the members say that it was the first time they had seen a locomotive building shop, and it is safe to say that many new things were learned during this outing which was the only one taken by the association. The Brooks people provided a lunch for the party. A vote of thanks was given for the courtesies received.

---

Before leaving Lakewood the leading members of the Committee of the Master Car Builders' Association, which decide on the next place of meeting, intimated that their preference was Saratoga. The Committee of the Master Mechanics' Association unanimously favored Saratoga, so it looks as if the next place of meeting would be settled without any necessity for the Joint Committee coming together.

---

The exhibition of car couplers was unusually small at the Lakewood Convention. Among those shown, the American excited particular attention owing to its simplicity of form and because it stood an unusual number of blows in the M. C. B. tests before breaking. It stood an average of 12.5 blows before breaking, and 153,450 pounds of a pull. The coupler is of the M. C. B. standard, is of steel, and is made by the American Coupler Co., Chicago.

---

A small boiler was exhibited at Lakewood with the Mack water circulator shown in operation by means of a glass tube on the pipe that connects the front part of the boiler with the water leg. It worked admirably, and was a striking and attractive sight. All day long a crowd of men could be seen around the exhibit watching the steady flow of water from the front of the boiler to the firebox. We understand that several master mechanics made arrangements on the spot to apply this circulator to their locomotives.

---

Much interest was displayed by the master mechanics attending the convention at Lakewood in an exhibit made for Mr. William Halpin, of the taking off and putting on tires that were heated by the Wells light. The work was done very expeditiously and to the satisfaction of the numerous observers.

---

A circular issued by the Edwin S. Jackman Co., of Chicago, intimates that Park Brother & Co. make more steel than any manufacturer in the business. Their tool steels are produced by the old English blister-bar method, the only method which has the test of years to prove its merit. This process is expensive and tedious, but the results are sound ingots, uniformity of temper, customers satisfied.

### EQUIPMENT NOTES.

The B., C. R. & N. are figuring on six new locomotives.

---

The Fitchburg R. R. Co. are about letting contracts for one thousand cars.

---

The Manhattan twenty engines were let to the Pittsburgh Locomotive Works.

---

Mr. Silvius, of the J., St. A. & I. River, is about to begin work on 100 flat cars for service in the winter trade.

---

The South Baltimore Car Co. have begun deliveries on the seven hundred box cars for the Boston & Albany.

---

The 150 cars building for the Lake Street Elevated by the Gilbert Co. are to be equipped with the Morton system of steam heat.

---

The Jacksonville, St. Augustine & Indian River road have placed orders for several engines, and will be in the market this fall for from seven to ten additional engines.

---

The Delaware, Susquehanna & Schuylkill R. R. are in the market for one 17 x 24 passenger engine, two coaches and a 22 x 28 consolidation engine, adapted for hill work.

---

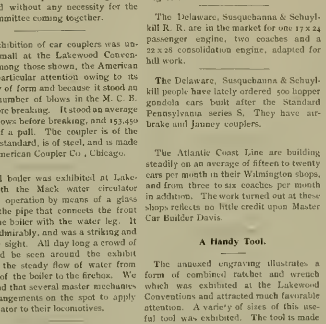
The Delaware, Susquehanna & Schuylkill people have lately ordered 500 hopper gondola cars built after the Standard Pennsylvania series S. They have air-brake and Janney couplers.

---

The Atlantic Coast Line are building steadily on an average of fifteen to twenty cars per month in their Wilmington shops, and from three to six coaches per month in addition. The work turned out at these shops reflects no little credit upon Master Car Builder Davis.

### A Handy Tool.

The annexed engraving illustrates a form of combined ratchet and wrench which was exhibited at the Lakewood Conventions and attracted much favorable attention. A variety of sizes of this useful tool was exhibited. The tool is made of the best steel and the work upon it is exceptionally good, the proprietors having expended a large amount of capital on special machinery for this useful shop appliance. It can be used for a great many purposes. As a ratchet-drill it can be turned equally well in either direction. It can be used with either Morse, taper or square shank-drills and with an easy made change it can be converted into a monkey-wrench or a holder for a bit-brace, a screw-driver, a reamer or a tap. We have not seen a tool for a long time that would be so useful in a roundhouse or on a locomotive. It ought at once to be considered a necessity for every tool room and we have no doubt that it will be so regarded when its merits become known. The tool is made by the Keystone Manufacturing Company, Buffalo, N. Y.



---

The B. F. Sturtevant Co., Boston, Mass., have printed a third edition of 10,000 copies of their 200-page general catalogue No. 61, which describes the uses of their blowers, exhausters, engines, forges and heating and ventilating apparatus, and they desire to place a copy in the office of every superintendent, purchasing agent, engineer or manufacturer using such machinery. All who have not received a copy will confer a favor by applying at once to the above address. It will be mailed free of charge.

### Westinghouse Co. on the Karner Brake Trials.

*Editors*:

Your June number publishes a communication from the New York Air-Brake Co., which contains statements and implications not in accordance with the facts.

There is absolutely no warrant for the statement that the Westinghouse Company furnished fifty special air-brake equipments of delicate adjustment for the Karner tests. Upon the request of the New York Central road, we supplied fifty sets of our standard apparatus, differing not in the slightest degree from the standards that were originally established when the quick-action brakes were first placed upon the market, and wish now to finally and definitely state that we did not, upon the occasion of the Karner brake tests or at any other time when there have been competitive trials with the New York Air-Brake Co., use any other than our regular brake equipment, or procure results that cannot be at any time obtained from our apparatus in regular service when it is in good working condition.

We presume their reference to "the delicately adjusted triple valves" is occasioned by the temporary use of a graduating spring somewhat stiffer than our standard, and while the circumstances in this connection are a matter of record and are generally understood, there may be some of your readers who are not fully acquainted with the facts, which are substantially as follows:

When the quick-action air-brake was developed by the Westinghouse Air-Brake Co., all standards connected with it were fully established by experiment before the brake, as now used, was exhibited. A standard graduating spring was adopted at that time. The train of fifty freight cars which was exhibited by the Westinghouse Air-Brake Co. at a large number of places in the United States was equipped throughout with that standard spring. All the quick-action brakes which were then made, sold and put into operation upon railroads contained the standard graduating spring.

Several months afterward, when the quick-action brake had come into extensive use, it was found that in handling them by means of the old three-way cock upon the engines an emergency application of the brakes sometimes occurred when a service application was desired. As the three way cock was unsuited for operating the quick-action brake and as a great many were then in use upon locomotives, it was decided, after consultation with the railroad companies using the brakes, that temporarily, until these three-way cocks could be replaced by a suitable engineer's valve, a slightly stiffer form of graduating spring should be used in the triple valves, and it was distinctly understood that the stiffer spring was to be used only until the proper engineers' valves were substituted on the engines. More than a year ago these conditions were sufficiently realized to warrant a return to the standard graduating spring, which was done. Since that time it has been regularly and uniformly furnished in all quick-action triple valves sent out. The Westinghouse Air-Brake Co. has, therefore, never had more than one standard graduating spring, which was the spring used in our triple valves at the Karner tests, and which we have also supplied in many thousands of our quick-action triple valves, now in regular service.

In February, 1892, a series of brake trials was made at Burlington, Iowa, upon the Chicago, Burlington & Quincy Railroad. In those trials a series of four stops was made with a fifty-car train equipped with the Westinghouse brake having the standard graduating spring. Two slidometers for measuring shocks were used in the rear car, and the movements of each were measured. The record shows that the average shock for the four stops, as shown by one slidometer, was nothing and, by the other slidometer, one-

**GOULD'S STEAM and WATER PACKING**
(Patented June 1, 1881.)
Especially adapted for Locomotives.
(The Original Ring Packing.)
In ordering give exact diameter of Stuffing Box and Valve Stem.
None genuine without this trade mark.

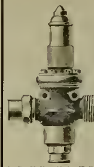
## THE BROTHERHOOD SEAT.

Only locomotive cab seat on exhibition at the World's Fair. Perfectly equalized. Adjustable to any weight. Back can be quickly changed to any desired angle. Seats made in any size. We make a specialty of Drop Seats for engines where boiler extends through the cab. Our upholstering is the very best. Both seat and back covered with grained Ooze-hide Leather. No engineer can afford to be without this seat as it adds comfort and improves health. Over one hundred in use on second division of the P. R. R.

Satisfaction guaranteed or money refunded.
Seats sent on one week's trial.
Send stamp for our twelve page catalogue and price list.
STANNARD & WHITE, Appleton, Wis.

## AIR BRAKE REGULATORS
FOR
Air Brake Pumps.



The MASON has for the last 5 years proved itself reliable and durable. The Pennsylvania alone has 800 of them in use, and among other roads which are ordering in quantities, having adopted them as the standard, are

C. R. I. & P., B. & A., Conn. River, Fitchburg, Penn Co., W. N. & Penn R. R., N. Y. & N. E., T. R. R. of St. Louis, and many others. We will send one on trial to any road not already using them.

Air-Compressor.

# The Brotherhoods' Jeweler.

THE only substantial, moderate-priced clock on the market. Movement has escapement jeweled; case cast bronze; front screws on; side wind; 6-inch, porcelain dial. Very elegant and accurate.

The red hand, shown at VI o'clock, is on the inside of the glass and is moved by a knurled nut on the outside. This is John Alexander's "**Red Reminder.**" When it is moved out of its regular position (6 o'clock), it is put at the time of the next meeting point, order station or what not, and serves to remind you that you must make a meeting point, get orders or sidetrack at that time. No extra charge for the "Reminder." Clock furnished with or without it.

**PRICE, $12.**

JOHN J. McGRANE,
187 BROADWAY, NEW YORK.

THE
# LOCOMOTIVE INSPIRATOR

These machines are especially constructed for, and adapted to railroad service and

## STANDARD FITTINGS

in common use. Modern locomotive service is more exacting in its demands, and requires a more efficient apparatus to meet its requirements, and we believe that these are met in this instrument more fully than ever before. It is simple in its construction, easily taken apart, and, readily repaired at small cost.

It will lift water, or take it under a head, as desired. It will lift water when Inspirator and suction pipe are hot, or when water is at a temperature of 120 degrees Fahr., and deliver to boiler at steam pressure of 35 to 200 lbs. without adjustment.

It has a minimum capacity of less than 50 per cent. of its maximum by actual test and service.

**The Capacity increases with the increase of Steam Pressure up to 200 pounds.**

We guarantee it to be reliable and effective under all conditions and requirements of railroad service. Correspondence solicited.

THE HANCOCK INSPIRATOR CO.,
BOSTON, MASS.

...nth of an inch. Another series of four stops was then made with the same train and the same brakes throughout, except that the standard graduating springs were replaced by the heavier temporary springs in all the triple valves. The average shocks for the four stops were, by one slidometer, four-tenths of an inch and, by the other slidometer, five-tenths of an inch. A third series of three stops was then made with a fifty-car train of Westinghouse brakes, taken from regular service. These cars were picked up at random in the West Burlington yards, having been in use an average of more than two years, and their condition was not inspected in any respect except that of piston travel. As the brakes of this train also had the heavier graduating spring. The average of shocks of the three stops was as follows: by one slidometer, nothing and, by the other slidometer, four-tenths of an inch. It will, therefore, be seen that the use of the different springs produced no difference in respect to shock as there was practically no shock in either case—the sole purpose of the heavier spring being to avoid quick action, by careless or unskilled manipulation of the three-way cock, when a graduated application was desired.

The New York Brake was also tested in these trials at Burlington, and representatives of the New York Air Brake Company were present, and they are perfectly well aware that this company did not object to the very trying test of taking fifty cars from active service and without inspection or adjustment of any parts, except to take up the slack, submit them to a comparison with the new apparatus of both this company and that of the New York Air Brake Company. They are also aware that there was no proposition by the New York Central people to make use of brakes that had already been in service upon their road, for the Karner tests, or that we refused to make a competitive test under those conditions, and, being thus fully informed as to these facts, it is unnecessary to characterize their statement that we "were unwilling to submit brakes for test that had been in actual service."

The inaccuracy of their statement, that the Westinghouse triple valves used in the New York Central trials were unusually sensitive, will be fully understood by reference to the standing test No. 13, in the official report of those brake trials. This test was made to determine the sensitiveness of the quick action triple valves.

Without stopping to discuss the question whether the conditions were exactly what they should have been in the test, the conditions were unquestionably alike for both kinds of brakes, and the results of the test were the same for both kinds of brakes, except that when two cars alone were connected to the engine, the New York brake produced an emergency application in one trial out of three, while the Westinghouse brake gave only the required service application in each of the three trials. This conclusively demonstrates that the New York triple valve is liable to give an emergency action when not desired, and if, as stated in their communication, there was less than one pound margin between the service and the emergency action of the Westinghouse triple valve, the margin was still less with the New York triple valve. Their communication states that "the New York brakes were made to meet the Westinghouse standard used on the railroad, and would have been condemned without trial if they had been adjusted to such a narrow margin." It would therefore appear that, at the end of the standing test No. 13, the New York brakes "should have been condemned without trial."

The statement that shocks occurred upon the Westinghouse train in the Lehigh Valley brake tests is true, and the cause of those shocks is apparent to any one who has had any considerable air-brake experience. Tests were made upon trains just as they were taken from the car shops; the brake-shoes were not worn to the wheels, and the consequent variable friction of the brake shoes in the different parts of either train would wholly account for the unusual results of these tests. Such conditions might very easily cause shocks to occur with a good brake upon one train and prevent shocks with a poor brake upon another train. That the stops made were nearly 50 per cent longer with both trains than would have occurred under any regular service conditions, will sufficiently vouch for the existence of abnormal conditions. Had the cars of these trains been in service long enough to have worn the brake-shoes to the wheels, the conditions would have been usual ones and no shocks would have occurred to the Westinghouse train. The records show that, beginning with the tour of the Westinghouse exhibition train and up to the present time, there has never been a fifty-car train test of the Westinghouse quick-action brake, under any practical conditions of service, whether with the standard graduating spring or the heavier temporary spring, in which a shock so great or nearly so great as 12 inches has been produced in the train.

It must be manifest to any sensible observer, therefore, that very unusual conditions must have obtained to have caused an average shock in four stops of $12\frac{3}{16}$ inches with one slidometer, and $16\frac{1}{16}$ inches with the other slidometer. Such were the shocks recorded for the Westinghouse train in the Lehigh Valley tests, and they are characterized by the New York Air-Brake Co., in their communication, as "terrific." Since they consider such shocks "terrific," they doubtless realize that the shocks caused by the New York air-brake in the New York Central tests, the least of which is greater than the greatest of the Westinghouse brake in the Lehigh Valley test, and the average of which was more than 28 inches, can only be described, comparatively, by some stronger adjective, which they are privileged to provide.

THE WESTINGHOUSE AIR-BRAKE CO.

*June 23, 1893.*

HEAVY TWELVE-WHEELER, 169,000 POUNDS. BUILT BY SCHENECTADY WORKS FOR DULUTH & IRON RANGE. NOW AT WORLD'S FAIR.

### Schenectady Twelve-Wheeler.

The heavy twelve-wheeler shown in the annexed engraving is to be found in the exhibit made by the Schenectady Locomotive Works at the World's Fair. She is one of the heaviest engines in the Transportation Building and weighs 169,000 pounds. The cylinders are 22 x 26 inches and the driving wheels are 54 inches diameter outside the tires. The traction of the engine is 233 pounds per pound of cylinder pressure. As the boiler carries steam of 180 pounds pressure, the engine will be capable of exerting 35,000 pounds traction on a slow pull. The boiler is straight, 72 inches in diameter and is made of steel ⅝ and $\frac{11}{16}$ inch thick. The engine has been built for the Duluth & Iron Range and will go there when the Fair closes.

John J. Leighton, an engineer from the Wisconsin Central road, is doing a nice business in Chicago conducting a free hotel register office. Visitors go directly to his office at No. 311 So. Sixty-third street, which is just opposite the Illinois Central depot and the grounds, and there have the choice of any priced room in several good hotels. If one location or one price does not suit, Mr. Leighton places visitors in other rooms or other hotels. This plan makes it unnecessary for visitors to secure rooms in advance—buying a cat in a bag—but can go direct to this office and take the choice of all available rooms. Mr. Leighton gets his pay out of the hotels, and they are glad to list their rooms with him. Mr. L. is a Brotherhood engineer, and has the indorsement of the officials of his road and many others. We advise railroad men who object to being held up to put themselves in communication with Mr. Leighton before or on arrival at Chicago.

The most important railroad event of last month was the opening of the Great Northern to Puget Sound. This makes what is practically another transcontinental railroad. Closely following the ceremonies of opening this new system came the announcement of a material reduction of rates. The other lines carrying the business between the Atlantic and Pacific States have not been making much money and it looks as if the new line would tend to make some poor companies poorer.

After a long test of one pipe the Central R. R. of New Jersey have ordered ten Smith triple-expansion exhaust-pipes for their heaviest consolidation engines in freight service. This invention seems to be attracting a good deal of attention, and is being tried on a dozen different roads.

The Master Car Builders' Association have always been intensely jealous about motive-power men being nominated as presiding officers, but this has not prevented them from doing nearly all the real work of the association. To carry on the work of investigation thirteen committees were appointed last year consisting of fifty members. Among these there were twenty-seven motive-power men and nine of them acted as chairmen of committees.

The hydrostatic apparatus used so successfully in operating the equalizing buffers on the trains composing the Columbian Flyer, were made by Watson & Stillman, New York.

## A Method of Maintaining Standard Bolts and Nuts.

Editors:

Having noticed in some of your recent issues a discussion of the question of standard bolt threads and the means of maintaining the adopted standards by car and locomotive builders, I take the liberty of calling your attention to the accompanying article which was published in the *American Machinist* of May 12, 1892, and describes a method and a system by which the largest possible allowance can be made in the size of iron while still adhering to the standard and securing interchangeability of bolts and nuts. Special attention may be called to the fact that in Mr Bauer's system the bolts which are cut by dies that are adjustable to size are kept precisely to standard. This can be done by providing the proper gauges for use at the bolt cutters, these gauges being preferably adjustable, as those made by the Pratt & Whitney Company are, and kept to size by means of standard threaded plug gauges. It may be proper to add that personal experience with this system at the time of its adoption and observation of its working since that time have convinced me that it is entirely practicable, and that by its means the standard bolt threads can be rigidly adhered to with very little trouble; though of course with this as with almost everything else, there must be first, a recognition of the importance of adhering to the standard, next, a determination to adhere to it, and finally, intelligent supervision of the bolt and nut work.

FRED. J MILLER.

The production of standard screw threads involves problems, many of which have been satisfactorily solved, while others, mechanics and manufacturers generally, are not so certain of. In a sewing-machine shop or armory, where all threads are cut upon stock previously reduced accurately to size, the problem differs essentially from that which is presented in a car-shop or in a manufactory of agricultural machinery, where a large proportion of the threads are cut upon rough iron. And when it happens that threads of both kinds are to be cut in the same establishment, the problem is still further complicated.

The adoption of the Sellers thread as the standard form simplified the problem considerably, from the fact that taps and dies keep their size much longer in use when flatted in accordance with this system than when sharp, though it has been found advisable in practice in most cases to make the taps of somewhat larger outside diameter than the nominal size, thus carrying the threads up a little further towards the V shape and giving corresponding clearance to the tops of the threads when in the nuts or tapped holes, this plan also allowing for some wear on the extreme points of the threads of the taps without affecting the fit of the sides or angles of the threads, at which point good practice now requires that all threads shall be measured.

The most serious difficulty encountered after the adoption of the Sellers thread was found to arise from the difficulty in getting stock rolled close enough to gauge to admit of threads being cut upon it which should conform to the standard. Car builders especially were bothered by this problem, and finally, by the action of the Master Car Builders' Association, at their seventeenth annual convention, held in Chicago in 1883, limit gauges were adopted, to which it was understood all round bar iron to be used in the construction of cars, and especially for the bolts of cars, was to be rolled. According to the scheme of these gauges, ¼" round iron must pass through a snap gauge .255" in size, and must not pass through one .245" in size, thus limiting the variation in this size of iron to not more than .005" below the nominal diameter and the same above it, the total range of permissible variation being .01". The limit of variation then increases .001" with each larger size of iron, the limit for 1¼" iron being .0105" each way from the nominal diameter, or .021" total variation. This would seem to give ample range, and there is no doubt that iron ought to be kept within these limits; but as a matter of fact it is not generally kept within these limits, as an investigation of the matter will show, and many car builders and others who make rough bolts are finding great difficulty in keeping to the standard threads on this account.

Makers of taps and dies, who are almost without exception in favor of the exclusive use of the Sellers or U S Standard threads, often have calls for taps and dies, U. S. Standard "for rough iron," such orders coming from those who believe that such a thing as a U. S Standard tap or die can be made larger than the nominal diameter or to suit the size to which iron may be rolled; and no doubt most of those who so order think that if there are no such taps and dies then there ought to be.

An examination of rough iron will show that much of it is rolled out of round to an amount exceeding the limit of variation in size allowed.

In view of all this it may be desirable to know what the extreme variation in iron may be, consistent with the maintenance of U. S. Standard threads, *i. e.*, threads which are standard when measured upon the angles, the only place where it seems advisable to have them to fit closely, and in this connection we propose to review what has been done by Mr Chas. A Bauer, the general manager of the Warder, Bushnell & Glessner Co., at Springfield, O.

In this establishment 4,000,000 to 5,000,000 bolts are made and used annually. Most of these are made from rough iron, but many of them are, previous to being threaded, turned or finished to size in screw machines. These two classes of bolts are used mostly in nuts or holes which have been tapped with machine taps made in the establishment, while there are yet others which are usually turned and threaded in the lathe, these being used in the building and repairing of special machinery and tools used in the works; Pratt & Whitney's make of U. S. Standard hand taps, in sets of three, being used for this work. Previous to Mr. Bauer's advent the system there was the same as that found in most establishments of that character, then and now, *i. e.*, there was no system, and every practical mechanic will understand what that means without further explanation. The problem of how to bring order out of this particular chaos presented itself to Mr. Bauer about the time of the adoption of the standards of the M. C. B. A., and his solution (the scheme described below) has been in use there since 1883.

The main features of the plan may be stated briefly as follows All bolts, whether cut from rough or finished stock, are standard size at the bottom, and at the sides or angles of the threads, the variation for fit of the nut and allowance for wear of taps being made in the machine taps. Nuts are punched with holes of such size as to give 85 per cent. of a full thread, experience showing that the metal of wrought nuts will then crowd into the threads of the tap sufficiently to give practically a full thread, while if punched smaller some of the metal will be cut out by the tap at the bottom of the threads, which is, of course, undesirable. Machine taps are made enough larger than the nominal to bring the tops of the threads up sharp, plus the amount allowed for fit and wear of taps. This allows the iron to be enough above the nominal diameter to bring the threads up full (sharp) at top, while if it is small the only effect is to give a flat at top of threads, neither condition affecting the actual size of the thread at the point at which it is intended to bear. Limit gauges are furnished to the mills, by which the iron is rolled, the maximum size being shown in the third column of the table given herewith, while the minimum diameter, which is not given, may be the same as that of the M C. B. A., since a smaller limit is practicable below the nominal size than above it, the tendency in rolling being nearly always to exceed the nominal diameter.

In making the taps the threaded portion is turned to the size given in the eighth column of the table, which gives 6 to 7 thousandths of an inch allowance for fit and wear of tap. Just above the threaded portion of the tap a place is turned to the size given in the ninth column of the table, these sizes being the same as those of the regular U. S. Standard bolt, at the bottom of the thread, plus the amount allowed for fit and wear of tap, or, in other words $d' =$ U. S. Standard $d + (D' - D)$. Gauges like the one shown below the table are furnished for this sizing In finishing the threads of the tap a tool is used which has a removable cutter finished accurately to gauge by grinding, this tool being correct U. S. Standard as to angle, and flat at the point. It is fed in and threads chased until the point, or, rather, the flat of this tool just touches the portion of the tap which has been turned to size $d'$. Care having been taken with the form of the tool, with its grinding on the top face (a fixture being provided for this to insure its being ground properly), and also with the setting of the tool properly in the lathe, the result is that the threads of the tap are correctly sized without further attention.

The table, with the formula as given by Mr. Bauer, explains itself, and we are able to say, as a result of personal experience with the system, that it works well. Of course it is evident that one of the points of advantage of the Sellers system is sacrificed, *i. e.*, instead of the taps being flatted at the top of the threads they are sharp, and are consequently not so durable as they otherwise would be; but practically this disadvantage is not found to be serious, and is far overbalanced by the greater ease of getting iron within the prescribed limits; while any rough bolt when reduced in size at the top of the threads, by filing or otherwise, will fit a hole tapped with the U. S. Standard hand-taps before referred to, thus affording an easy practical proof, and one frequently given incidentally, that the two kinds of bolts or screws made for the two different kinds of work are practically interchangeable. Assuming the same minimum diameter for iron as that allowed by the M. C. B. A gauges, ¼" iron by this system can be .005" smaller or .0108" larger than the nominal diameter, or, in other words, it may have a total variation of .0158", while 1¼" iron can be .0105" smaller or .0309" larger than nominal—a total variation of .0414"—and within these limits it is found practicable to procure the iron.

STANDARD SIZES OF SCREW THREADS FOR BOLTS AND TAPS.

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---|---|---|---|---|---|---|---|---|---|
| Nominal Dia. of Bolt. | Number of Threads per Inch | Actual Dia of Bolt | Dia. of Bolt at Bottom of Thread | Depth of Thread | Flat of Bottom of Thread | Dias of Top | U. S. Standard at Top of Thread | U. S. Standard Bottom of Thread | Hole in Nut before Tapping |
| A. | n. | D. | d. | h. | f. | D′—D. | D′. | d′. | H. |
| ¼ | 20. | .2608" | .1855 | .0371 | .0062" | .006" | .2668" | .1915 | .2024 |
| 5/16 | 18. | .3245 | .2403" | .0421" | .0070" | .006" | .3305 | .2463 | .2509" |

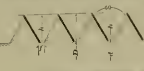
$$D = A + \frac{.2165}{n}$$

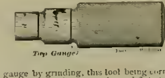
$$d = A - \frac{1.29904}{n}$$

$$h = \frac{.7577}{n} = \frac{D - d}{2}$$

$$f = \frac{.125}{n}$$

$$H = D - \frac{1.288}{n} = D - .85\,(2\,h)$$





Tap Gauge.

## Origin of Railroads.

It is common practice now, where U. S. Standard bolts are used, to make the machine or nut-taps with threads which are sharp at top, the essential points in which Mr. Bauer's system differs from those in common use being in the wide limit of variation in size of iron which it admits, in the fact that bolts are kept to the standard, the variation for fit and wear of taps being made in the nuts, so that by using taps adapted to the kind or class of work being done, the fit of bolts may be as desired, whether they be cut in the bolt cutter from rough iron, by dies in the screw machine on previously finished stock, or in the lathe.

The exhibition of old locomotives at the World's Fair is creating a great deal of talk about the first locomotives used in this country. On this subject a quotation from "Wood's Treatise on Railroads," a book published in 1831, the year that the "John Bull" was built, will be of interest

"Wooden railroads have been used from time immemorial in the mines of Germany. From the continent they were introduced, in the beginning of the seventeenth century, by foreigners, into England. The claim of the latter country to their invention is preposterous; although her writers have exposed their characteristic nationality by such frequent and confident assertions, that it has induced the uninformed to believe that the claim was founded in justice.

"The invention of iron railways—the greatest improvement of modern times for facilitating commerce—is, unquestionably, due to England.

"Railroads were, for a long time, imperfect, and limited in their extent. They were confined to collieries, mines and ironworks, and were deemed to be inferior substitutes for canals. The world is indebted to Oliver Evans, a native citizen of Pennsylvania, for the discovery of their latent and hitherto unsuspected value and pre-eminent importance. In 1784 he first conceived the idea of his high-pressure steam-engine, and the application of it to carriages on common roads, as a motive power

"He foresaw the superiority, and strenuously urged the adoption of railways and locomotive engines in lieu of canals, some time before the termination of the eighteenth century, and long before it had entered into the imagination of any other human being. His zealous efforts to promote this favorite scheme were in advance of the opinions of the age, he attracted no attention, and was charged with insanity for believing in the possibility of effects which are now daily witnessed. In 1799 he commenced the construction of a locomotive steam engine, which was to be tested on a railway to be made for the purpose. After frequent interruptions, he completed the engine in 1801, but the locomotive carriage was not finished for public exhibition until the latter part of the winter of 1803-4, when it commenced its majestic march through the streets of Philadelphia, in the presence of at least twenty thousand spectators.

"Mr. Evans urged, in repeated addresses to the public, the construction of a railroad from Philadelphia to New York and in 1809 attempted to form a company for the purpose of effecting it, purposing the investment of his whole fortune in the enterprise, experience having convinced him that the prejudices and ignorance of mankind could only be gradually removed and that time would demonstrate the truth and value of his plans.

"He published the following remarkable prophecy in one of his well-known essays, in which he reproaches his contemporaries for their tardiness in not adopting his suggestions The present generation will not use canals, the next will prefer railroads with horses, but their more enlightened successors will employ my steam carriages on railways as the perfection of the art of conveyance. In the meantime the steam carriages may be tested even on the present turnpikes. The reader will not fail to remark the perfect fulfillment of his prediction. The extent of the information respecting railways that Mr. Evans possessed was very limited. He knew merely that a greater load could be drawn on them by a horse than on a common road, but he was wholly ignorant respecting their structure and properties."

The immense plant of wood-working machinery of the J. A. Fay & Egan Co. at the World's Fair is attracting considerable attention, and has already secured them several foreign orders.

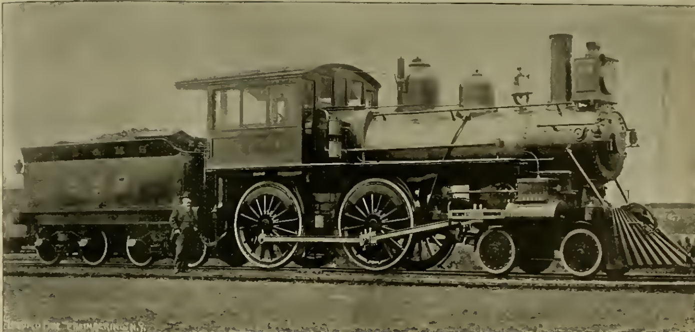
### OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates. They are made by BRADLEY & POATES, 251 William Street, New York City.

## Lake Shore Locomotive for the "Exposition Flyer."

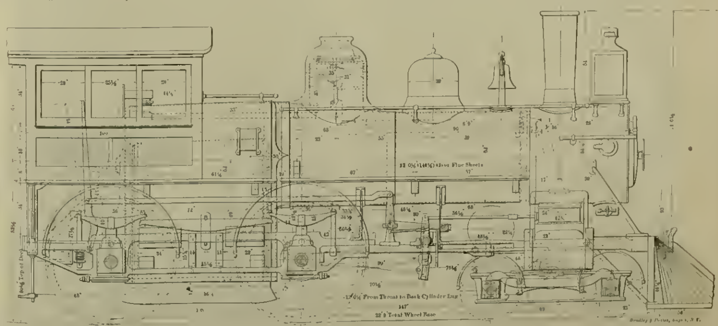
The photo reproduction and detail cuts, together with accompanying specifications, will give our readers all the information wanted about the construction of the locomotives recently turned out by the Brooks Works, at Dunkirk, for the Lake Shore road, to pull the "Exposition Flyer" over their line. This train runs from New York to Chicago in twenty hours, and maintains a speed of forty-seven miles per hour for over 500 miles on the Lake Shore section of the line.



Lake Shore Engine for the "Exposition Flyer" New York to Chicago in Twenty Hours

### SPECIFICATION

Of an eight-wheel express passenger locomotive engine having two pairs of coupled wheels and a four-wheeled swiveling truck for the Lake Shore & Michigan Southern Railway Co.



Elevation.

### GENERAL DESCRIPTION

Cylinders 17 in. diameter, 24 in. stroke
Driving-wheels—72 in. diameter.
Gauge—4 ft. 8½ in.
Fuel—Bituminous coal
Rigid driving-wheel base—7 ft.
Total wheel base of engine—23 ft. 9 in.
Total wheel base of engine and tender—45 ft. 8 in.
Weight of engine in working order 114,600 lbs.
Weight of engine on engine truck 34,500 lbs.
Weight of engine on main drivers 33,100 lbs.
Weight of engine on back drivers—32,000 lbs.
Weight of tender loaded 70,000 lbs.

### BOILER.

Type—Improved wagon-top Belpaire, with conical connection, dome on connection-sheet.
Working pressure—180 lbs.
Material—Steel, ⅝ in., 9/16 in., ½ in. and 7/16 in.
Riveting—Longitudinal seams, quadruple lap, without weit.
Riveting—Circumferential seams, double lap.
Waist, diameter at smokebox—52 in.
Waist, diameter at throat-sheet—60 in.
Tubes—268 in number, 2 in. diameter, charcoal iron.
Tubes—Length 12 ft., No. 13 B. W. G.
Firebox—78 x 34 in., inside ring
Firebox depth—81 in. at front end, 79 in. back end.
Firebox crown-sheet—Arched 1½ in., laterally in center
Brick arch—Carried on three 2½ in. water tubes
Heating surface—Firebox and arch pipes, 155 sq. ft.
Heating surface—Tubes, 1,258 sq. ft.
Heating surface—Total, 1,413 sq. ft.
Safety valves—1 Richardson muffled and 1 Richardson plain.
Extension front—Deflector in front of exhaust-pipe.
Stack—Cast-iron straight, 16 in. diameter
Exhaust-pipe—High double
Grates—Cast-iron rocking-bar

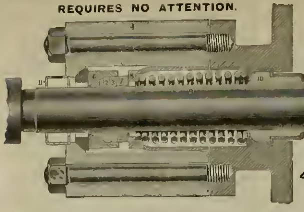
### MACHINERY

Cylinders—17 x 24 in., 84 in. centers.
Cylinder packing—Dunbar.
Piston-rod packing—Jerome.
Valve-stem packing—Jerome.
Steam ports—1¼ x 16 in.
Bridges—1½ in.
Exhaust port—3 x 16 in.
Valves—Allen Richardson
Valves, Allen port—⅜ x 16 in.
Valve, lap outside—1 in.
Valve, lap inside—⅛ in.
Valve lead in full gear—1/16 in.
Valve travel, maximum—6½ in.
Eccentric travel—5 in.
Link radius—68 in.
Link face—3 in.
Link centers of eyes—13 in.
Link block wearing face—5 in.
Link block flanges—7½ x 3½ in.
Link saddle-pin—1¾ x 6 in.
Link rocker-pins, top and bottom 1¾ x 4 in.
Link hanger centers—18½ in.
Link lifter arms, length—20½ in.
Reversing lever, multiple latch—Player's patent.
Reversing lever, throw on top—42 in.
Driving-wheels, diameter—72 in.
Driving-wheels, centers' diameter—66 in.
Driving-wheel tires, Midvale—With Mansell retaining rings.
Driving-axles—Hammered iron.
Driving-axle, journals—7½ x 9 in.
Connecting-rods, hammered iron, fluted—Fitted with straps and keys.
Coupling-rods, Midvale steel, fluted—Fitted with brass bushings.
Crank-pins—Midvale steel.
Crank-pins, main—4½ x 6 in.
Crank-pins, main coupling—5¼ x 4 in.
Crank-pins, main wheel fit—5⅜ x 7 in.
Crank-pins, back—3½ x 4 in.
Crank-pins, back wheel fit—4 x 7 in.
Frames, 46-in. centers forged solid 3¾ x 4½ in.
Frame, back end dropped down 5 in. to accommodate standard tender
Frame pedestal ties—Player's patent.
Engine truck, four-wheeled—Swiveling spherical center
Engine truck-wheels—31-in. Allen paper.
Engine truck-axles—Hammered iron.
Engine truck-axle journals—5 x 10 in.
Engine truck-axle springs—Detroit.
Driving spring rigging—Equalized. [hangers.
Driving spring auxiliary—Under rear spring
Driving spring—Detroit.
Lubricator, cylinder—No. 9 Nathan triple
Feed-water—Two No. 8 Monitor injectors
Oil cups, rods and eccentrics—Adjustable spindle feed.
Oil cups, eccentrics—Fitted with swab cups top and bottom
Oil cups, guides, etc.—Adjustable screw feed
Cab—Ash
Cab fitted with three windows on each side, front stationary, middle and back to slide.
Pilot—Fitted with shackle-bar
Brakes, train and tender—Westinghouse
Brake drivers—Westinghouse
Train signal—Westinghouse
Steam-heating apparatus—R. R. Co's. standard
Headlight—R. R. Co's standard.
Classification and signal lamps—R. R. Co's. standard.

### TENDER.

Frame—10-in. Channel steel
Tank—5/16 in. and ¼-in. steel
Tank capacity, water—3,100 gallons
Tank capacity, coal—6 tons.
Tank, water-scoop—Improved Ramsbottom.
Tender trucks—Diamond pattern
Tender truck-bolster—Steel I-beam
Tender truck-wheels—36-in. Allen paper
Tender truck-axle—Hammered iron
Tender truck-axle journal—4 x 7 in.
Tender coupler and buffer—Gould.

REQUIRES NO ATTENTION.



IN USE ON THREE HUNDRED RAILROADS.

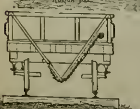
# RODGER * BALLAST * CARS.



These cars are 34 feet long, and are built either 50,000 or 60,000 lb. capacity, M. C. B. Standard. They carry from 18 to 20 cubic yards of gravel or broken stone. In using them no ballast is thrown in the ditch, and none is wasted, as the precise amount of ballast needed can always be discharged. A train of 25 cars, carrying 500 yards of ballast can be unloaded and the ballast distributed, leaving the track perfectly cleared and flanged, as shown in the cuts, in from 12 to 15 minutes. This is all done by the regular "train service" (a conductor and two brakemen), no extra help being required. The track is perfectly cleaned by the spreader, so that a train can immediately pass over it at any rate of speed, without meeting any obstruction. No aprons are needed; no wire cables are used. There is no shoveling ballast from between the cars and no cleaning the tracks with shovels. The ballast is left between the ties and on their ends, directly in position for tamping, when the track is raised without being shoveled in from the ditch. The average saving per mile, in the amount of ballast needed to make a "raise" of 10 or 12 inches, will be about 400 yards, and often far exceeds this. The total saving per mile in material, labor, time, use of cars, saving in transportation, etc., is found to amount, in gravel, to from $250 to $400, and in broken stone it often amounts to $500.

These cars are in use on the Great Northern Ry., the Illinois Central, the Gulf, Colorado & Santa Fé, the Chicago & Eastern Illinois, the Penn. Lines West, and other roads.

Detailed information will be furnished by circular by addressing the

RODGER BALLAST CAR COMPANY, No. 1215 Monadnock Building, CHICAGO, ILL.

PITTSBURGH, PA.

### Curious Statement of an Engineer Who was Discharged for Burning an Engine.

I pulled down through —— siding to lay there for No. —, while going down through siding engine began working water. I kept my injectors on, though, until I got down to the water-works; then I took them off, thinking if she was not full I could fill her up when I got down to the lower end of the siding. When I got down to the lower end of the siding I stopped, tried my water and found three gauges of water in her, but to make *sure* that it *really* was *water* I lighted a *match* and saw that it really was water. I then took up oil-can and oiled up. By that time No. — came, and after —— was gone I went to pull out and the steam dropped from 125 pounds to 60 pounds, and I shut off steam. I then tried my water again and found that there was no water. I jumped out in the tank and got the pokers down and hauled the fire.

Q. What time did you leave —— ?

A. About 7.40 or 7.50 took water at——.

Q. How long did you lay there?

A. Long enough to take water. That would take me to —— unless I got laid out.

Q. Did you stop anywhere else on the road for water except at —— ?

A. No, sir.

Q. Did you find anything wrong on leaving —— ?

A. No, sir; injectors worked all right.

Q. How long did you lay there?

A. About fifteen minutes.

Q. Where did the water go?

A. I think the boiler was filled up with *gas* and when I opened up it went right out of the *stack*.

Q. Firebox was tight when you started?

A. Yes, sir.

Q. Did flues leak after you discovered there was no water in her?

A. No, because there was no water in her to leak out.

Q. How long have you been running?

A. About three years.

The above statement was made recently in the office of the M. M. of an Eastern road by an engineer who had dropped a crown-sheet.

### Criminal Negligence.

One of the most horrible forms of railroad accident is that where a switchman gets his foot caught in a frog and is held there till the wheels of the car cut him to pieces. Since all well-managed railroad companies have adopted the practice of filling their frogs with safety packing, this form of accident has become very rare, but it still happens sometimes. A dreadful case of the kind occurred on the Brooklyn, Bath & West End Railroad last month. This is a summer travel road on Long Island, and has no safety appliances that can be dispensed with. A man walking along the track got his foot caught in a frog, and before he could release it a train was upon him and cut him to pieces. If the Railroad Commissioners of New York were worth their salt they would make it hot for any railroad company that neglected to apply the safeguard provided so cheaply by filling frogs with wood.

Some years ago two Baldwin 10-wheel locomotives were bought by the Railway Co. of South Africa, and they are said to be so popular that this style of design is likely to strongly influence the forms of locomotive that will be purchased in future for this railway. A friend, writing on the subject, says that the engines are much easier repaired than the others on the road, which makes them popular with the management, and they are comfortable and convenient to handle, which makes them popular with the men.

A bad runaway accident happened at Courtland, N. Y., last month, on the Delaware, Lackawanna & Western R. R. An engine was standing in the engine-house yard, which evidently had a leaky throttle. It started off of its own accord and went on to the main line, colliding with an express train on an iron bridge. It was said that the shock of the collision was so great that the light engine went almost entirely over the one pulling the train. The engineer and fireman of the express train were killed.

Riding over the Erie the other night a loquacious, tipsy Hibernian kept the passengers in the smoker in a constant good humor by his continued witty comments concerning the trainmen and the road. As the brakeman thrust his head in the door as the train pulled out of Waverly and called out, "O-we-go, next station," Pat yelled, "Ye ilhu, eh? Well, it's dommed glad av it Oi am, ye cud av gon long ago fer ahl we caired.'" Rogers tells this, and, of course, it is so.

### Handling the Brake-Valve.

BY WILL W. WOOD.

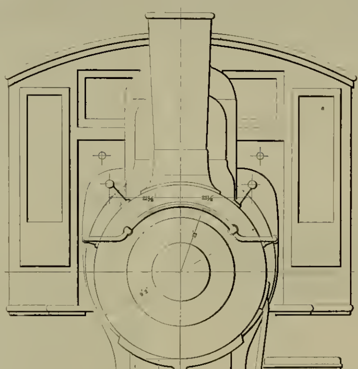
In this paper for May, a letter over the signature of A. W. Long states that air-brake instructors direct that when a light application of the brakes has been made and it becomes necessary to make an emergency stop, the brake-valve should first be moved to the full release position, held there a moment, then thrown to the extreme right and the emergency action of the triple-valves is assured.

The letter was reproduced from the *Engineer's Journal* for February, and is an extract from the article by Paul Sords, who is, to judge from his regular monthly contributions to the journal, a very fine expert in air-brake practice, and it is surprising that he accepts such an absurd and dangerous theory; but in the following number of the journal, another air-brake writer of weighty opinion ("Div. 31") affirms the idea that brake power may be gained in this way.

The triple piston must pull the slide-valve far enough to uncover a port leading to the emergency-valve before an emergency action can take place. The movement of this triple piston is governed by the air pressures against it, the train-pipe pressure on one side and the auxiliary reservoir pressure on the other. To make an emergency stop the train-pipe pressure must be reduced at least ten pounds lower than the pressure in auxiliary reservoir in order that the auxiliary pressure may be enough greater as to force the triple-piston against the resistance of the train-pipe pressure and to overcome the retarding effect of the friction of the slide-valve and the resistance of the graduating spring. Now, this differential pressure must occur before the quick action or emergency feature of the brake will operate. When the brakes are applied at service stop and the handle is thrown to full release position, the excess or normal pressure restored to the train-pipe from the main reservoir must all be discharged at the brake-valve until it is at least ten pounds less than that in the auxiliary reservoir; then the emergency action takes place. The brake-valve would not be left in the release position long enough to allow the auxiliary reservoirs to recharge or the brakes would release, as they begin to release at the same time the auxiliaries begin to recharge, and if the auxiliaries gain no pressure from that source it is plain that just as much more air must be discharged by the brake-valve as has been restored by it to the train-pipe; it takes time to do it and seconds of time are a great deal in an emergency.

Both the Westinghouse and New York Air-Brake Companies have labored to perfect their brake-valves, and have succeeded in producing engineers' brake-valves that may be handled successfully by those unfamiliar with the finer points of the brake mechanism if the engineman will only follow the directions in his instruction book. Young runners do a great deal of reading nowadays, and, naturally enough, many will believe the statements of those air-brake "experts" printed in technical publications and handle their brakes accordingly. Now, it doesn't require an air-brake wizard to work these new valves. They are simply three-way cocks with the addition of the equalizing discharge, which may or may not be used, and the excess pressure or feed-valve attachment. There are five indicated points for the brake-valves, both the Westinghouse and the New York, and the instruction books explain clearly when and how to use those different points.

Don't juggle the valve. If you want to make an emergency stop with the Westinghouse valve or the New York valve, throw the handle into the position for emergency stop, and leave it there until you have stopped. To release the brakes, put it back in the opposite direction as far as it will go, and when brakes begin to release draw it back to running position. To apply the brakes gradually, move the handle to service stop position and watch the black pointer of the gauge; it will show how much air you are letting out of your train-pipe, and you can graduate your stop by the distance it falls back. When you have exhausted 20 or 25 pounds of air your brakes are fully applied. Don't let out any more air; save it to help release the brakes and recharge the auxiliaries. You may run by—you will once in a while—but don't get rattled. After discharging 20 pounds of air the emergency-valve is inoperative, so don't shove the handle clear around into emergency position and waste all of your train-pipe pressure. If you run by you may have to back up, and you must release your brakes before you can do it, and it takes compressed air to release brakes as well as to apply them, but after making an application of the brakes, never turn the valve back to the release position, unless it is necessary to release the brakes, as there is nothing to gain by it, but a great deal to lose.



CROSS SECTION THROUGH TRUCK. FRONT ELEVATION.

### Breaking the Record.

The fast running made on different railroads during the last few months has excited among many locomotive engineers an ambition to do likewise. There is a feverish desire prevailing to break the record. Fast running on a perfect track, with locomotives in perfect order, and fast running on a track that is badly out of line, with locomotives having crank-pins out of true and side-rods none too strong, are very different operations. The safety margin under the latter conditions is too small for comfort. Men who have the record-breaking fever do not, however, pause to reflect on this and the men in charge of more than one Western road have had to resort to strong measures to prevent dangerously fast running.

About the last kind of service in which to make extraordinarily fast running is in the pulling of suburban trains, yet even with these, attempts have been made at record breaking. The trains on the Illinois Central that take people out to the World's Fair, provide what most travelers would call rapid suburban transit. They run six miles in about fourteen minutes, slowing up once to cross the tracks. An engineer engaged on this service was one day seized with the ambition to break the record. Before starting he directed his fireman to get her hot and to have a fire ready to keep her in that condition throughout the run. The signal was given, start was made and two of the brakemen failed to catch on, but the others climbed to the top of the cars and braced on their caps. It was time to do this, for within three minutes the Rogers double-ender had forced the train into a fifty-mile pace with the speed still rising. By the time the train was three miles out the conductor and brakemen on top of the cars were so busy clinging to the running-board that they could devote no attention to their caps and a small shower of the latter was seen falling into the lake. But the engineer never looked back. His only thought was on reaching Sixtieth street station and he got there in seven and a half minutes, almost cutting in two the fastest time previously made. It was a remarkably proud engineer who calmly moved that engine into the relay.

On returning to the starting-point he received fourteen days to rest up.

### Too Much Personal Attention.

A somewhat novel consideration persuaded Mr. J. Y. Smith, inventor of the Smith vacuum brake, to decline erecting a factory in eastern New Jersey for the manufacture of the brake. The officers of the Jersey Central Railroad took great interest in this brake when it was under development, and a great many of the first equipment made was turned out of the shops at Elizabethport. Mr. Smith was present a great part of the time, directing the manufacture and watching the details of the apparatus. He was greatly given to figuring on cost of production and on observing influences which accelerated or retarded the work done by mechanics. His observation of the habits of the men working at Elizabethport was edifying.

The question of erecting shops was taken up, and Mr. Smith's colleagues favored Elizabethport as a location, and strong local influences were used to get the works built there. Mr. Smith strongly opposed the locating at that place, but held off from giving any reasons for his opposition. When his friends were beginning to think that mere prejudice was influencing Mr. Smith, he explained that to do work satisfactorily a mechanic must have nothing to detract his attention from the operations in hand. He found that a considerable part of a man's time in Elizabethport was diverted from his work fighting mosquitoes. At a moderate estimate he considered that ten seconds out of every minute were consumed in slapping at mosquitoes or in soothing the wounds inflicted. That left too small a margin for useful work. The shops were not built there.

### Benefits Acknowledged.

It is refreshing in these days to find the people of a town willing to acknowledge that after a manufacturing concern has been fairly established it is a benefit and a source of prosperity to the place. Of the Mount Vernon Car Works, the Mount Vernon *Daily Register* says:

"There are scores of people living here, however, who have a very vague idea of the immense business transacted by this concern. All their money, which is paid out at the rate of \$75,000 to \$100,000 per month, comes from other communities. An average of \$25,000 to \$30,000 per month finds its way through the mechanics and laborers into the tills of our business houses, and this of itself is enough to give a good, healthy business vein to the community. The immense increase in population, the extension of the territorial limits of the city, the hundreds of new homes erected, the increase in business houses, the building of water works, the paving of our streets, and a score of other improvements are directly the results of the location of these works in our city."

Several railroad companies have given notice to their employés that leave of absence would be granted to attend the World's Fair, and that free transportation would be provided for themselves and families. The Pennsylvania Railroad Company, whose management are always in the front with kindnesses to the army of men employed, was the first to start this movement, and it was quickly followed by the Lake Shore & Michigan Southern. The public press commended the movement so cordially that a number of other railroad managers have hastened to intimate that they were prepared to do likewise. We hope the practice will become epidemic, and that all the railroad men in the country will have the opportunity to enjoy the great educational advantage offered by the splendid exhibit at Jackson Park.

We have received from Crosby, Lockwood & Son, London, the new and revised edition of Stretton's "Develop.. ent of the Locomotive," a work which we reviewed in December of last year.

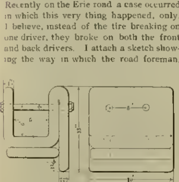
## Bringing in a Consolidation Engine with all Flanged Tires Broken.

*Editors:*

The question has often been asked by engineers and others how a consolidation engine with both the middle drivers blind, could be brought in in case of the tire breaking on the back or forward drivers.

Recently on the Erie road a case occurred in which this very thing happened, only, I believe, instead of the tire breaking on one driver, they broke on both the front and back drivers. I attach a sketch showing the way in which the road foreman,



Mr. Merritt Turner, of the Delaware division, brought the engine in. I think the sketch will very clearly illustrate what was done. The wheels were slid on these slippers.

H. A. Gillis,
General Foreman.

*Roanoke, Va.*

## Compound the Conductor.

*Editors:*

Reading your valuable paper so long and finding so many articles every year on fuel-saving devices, also the saving of the compound over simple engines, has kept me thinking on this subject, same as every other man that reads, but none of the boys say anything about the rear end of the train. I can haul a local freight train 100 miles on our division with a ton less coal, with two or three of our conductors in charge, than with some of the others, all things equal other ways. We have men who will switch thirty minutes at terminal getting air-brake cars behind engine. They will handle them switching on every side-track, no matter if they go through to end of runs, knocking down merchandise and stock and doing more damage to freight, with the extra coal burned, than their wages come to.

We have one man that switched twelve air-brake cars together this winter. The first side-track he had to go into had to double out, as it was very cold and flanges full of snow. That means fewer miles to the ton of coal. What I propose is to work these men compound, have a traveling conductor on each division that will pound some brains into their thick heads. Their port openings are large enough if they would retain them. Now, I am after the local passenger conductor, who is popular and has lady friends at most of the stations, who have no business but to come to the depot to have a chat with the boys. He loses two or three minutes every little while. This means one bucket more coal for 100 miles. I claim, every brakeman who is examined for promotion ought to be questioned on his knowledge of economy in handling a freight train. There is skill to be displayed there as well as at the head end that will pay any railroad company to take into consideration.

A. Eagle.

*Fond du Lac, Wis.*

## The Old Locomotive, "John Bull."

*Editors:*

In the May issue of your journal I have read with interest the article which relates to the "John Bull" engine of 1831, and beg to give the following information on the subject.

Just before leaving England I carefully examined Messrs. Stephensons' working drawings from which that engine was built in 1831, and last week I, with equal care, examined the engine "John Bull" as it now stands at Chicago, and I am perfectly certain that *the engine at the World's Fair is the real old Stephenson-built engine of 1831*, but at some time unknown to me the present circular firebox has been added, as when the "John Bull" was built it had a square firebox.

The "John Bull" was in every respect similar in design to the well-known Samson class, of which Stephenson & Co. built such a very large number in the years 1831, 1832 and early in 1833. Yours truly,

Clement E. Stretton, C. E.,
of Leicester, England.

*Pittsburgh, Pa.*

## Boss-Turner and Flue-Hole Cutter.

*Editors:*

I herewith send sketch of a very useful tool for turning or facing the bosses on rocker-arms or cutting various sized holes in boiler sheets and many other kinds of work. This tool is calculated to be used in an ordinary drill-press, and it was designed by F. H. Dersch, machine foreman at the Dubuque shops, C., M. & St. P. R. R. Tool-holder *A* slides through body *B* and carries tool *E*. The cross-feed screw *C* gets its motion from star *D*. The up and down feeding is done with the feed-screw of the drill-press. A hole is to be drilled in the article to be operated on the size of guide *F*, guide *F* steadies the tool, and where special machinery is scarce this tool will be found very useful and easily made.

J. C. Miller,
General Foreman.

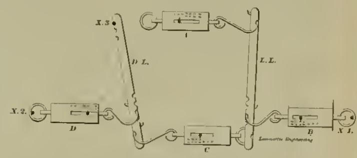
*Dubuque, Ia.*

## An Object Lesson in Brake Leverage.

*Editors:*

There are lots of men in this country looking after the repairs and adjustment of the air-brake gear to whom either calculating or understanding the brake leverage on a car is a mystery. They want to know how badly enough, but they do not get the right start, and have to depend on some one else for the "know how." With an ordinary knowledge of arithmetic and a little study of the subject of leverage as given in the Westinghouse instruction book, it can be made clear. As long as nothing breaks or gets lost from the brake-levers and rods it does not matter much whether all of us understand it or not, but it is mighty handy to know how all these things are calculated. To get a good start, get hold of four spring balances, such as can be found at any hardware store, graduated to weigh at least 24 pounds. They will not cost over $1 altogether. If you stand in with the merchant, maybe he will lend them to you. Go into the carpenter shop and get two light wooden levers, say 1 inch wide and ¾ inch thick, about 38 inches long. Cut notches in each end so they will be 36 inches apart, and also some notches near one end, 6, 7, 8 and 9 inches from the end notch. The sketch of *L L* shows how this is done. Drive some nails into a wide board or the top of a wide bench, as at *X 1*, *X 2* and *X 3*. Pull on *A*, which represents the top or pull rod. *B* and *D* show the strain on the brake-beams and *C* the bottom rod. By changing the hook of spring balances *B* and *D* into different notches you can get a good idea of the way the strains are divided. You will notice in each case that the strains on *A* and *C* added together always equal that on *B* or *X 1*, the brake-beam. Alter the position of *X 3* in the notches in the top end of *D L*, which represents the dead lever, and see how it affects the strain on *D* or *X 2*.

If you have an idea that the dead lever is only used to take up the slack of rods and shoes and has nothing to do with the strain on the brake-beam *X 2*, just hook



*C* and *D* together and you will find that *X 2* has as much less strain on it as the pounds pull at *A* subtracted from *B*. That will explain why in a tender or car that has no dead levers and the bottom rod "*C*" is connected directly to the brake-beam, that the pair of wheels next to the live lever always skid first. If you have a Westinghouse instruction book look at Plate 3, Fig. 7, and see the length of the standard levers used in passenger cars. The proportion of force marked there, 4½ to 1, is found by dividing the length of short end of lever 8 inches into the entire length, 36 inches. If the proportion was 4 to 1 the short end would be 9 inches long, if it was 5 to 1 it would be 7⅕ inches long, if 6 to 1 the short end would be 6 inches long. To work the other way, if you want four times the strain on the brake-beam that you have pulling on the top rod, divide the entire length between the outside holes in live lever by 4 and that will give you length of short end, or for any other proportion of strain on brake-beam the same way. As the levers for same style and size of truck should be all alike and a standard size, the difference in braking strain on the beams of a light and heavy coach or tender should be made at the cylinder lever of that particular coach or tender. This seems a more difficult subject to master, but it is just as easy after you arrange your levers and spring balances in the same manner as the two cylinder levers and accompanying rods, and test the strains at various points for fastening the connection which is near the middle of lever.

When you come to do your figuring, get the weight of car first, take not over 90 per cent. of the weight for braking strain, divide that between all the brake-beams. If the car weighs 50,000 pounds, 45,000 would be the extreme limit for braking force, divide by 4 for four brake-beams and we have 11,250 pounds for each beam. If the proportion of leverage on live lever is 4½ to 1, divide 11,250 by 4½; it should be 2,500 pounds, which will be the strain on top rod. If it is the Hodge system and has a floating lever which has top rod connected to one end and brake chain and rod connected to the other end, remember that the rod from floating lever to cylinder lever should have two times 2,500 pounds, or 5,000 pounds, which is the strain on outside end of cylinder lever. With a

10 x 12-inch cylinder, quick-action triple, and 70 pounds train line pressure, we have about 4,700 pounds pressure on piston. That, added to the 5,000 on rod at other end of cylinder lever, makes 9,700 pounds. Now divide the whole length of cylinder lever by 97, and $\frac{47}{97}$ of the whole length of lever goes next the piston, and the other $\frac{50}{97}$ comes next the rod end. Any other proportion can be found the same way. You will notice in Plate 3, Fig. 7, of Westinghouse instruction book, down in the bottom corner, that the cylinder lever has amounts opposite it running from 28,600 pounds to 44,000; this is the entire strain on all brake beams when connected in the holes opposite figures, which would seem to some to be the limit of breaking strain on a coach. Probably they think that is all the beams will stand, but there are coaches running that weigh over 70,000 pounds, and 44,000 is not enough to stop them to avoid an accident.

In these calculations it is possible there are errors made, check them up and prove them for yourself; if you find errors in these figures given in this, it will show you that your figures may be wrong also sometimes. When you get hold of the bottom facts in coach-brake leverage it is an easy matter to calculate freight-car leverage. I wish someone would contribute an article on driver-brake leverage, when cams between the wheels on spread brakes are used, as we see no computations on this subject in any of the instruction books.

Locomotive Engineering is a sort of school for all of us; we should contribute something once in a while on these subjects so the boys in the primary class can "catch on," and the other fellows who think they are going through the high school will brighten up wonderfully.

Clinton B. Conger.

*Grand Rapids, Mich.*

### Laying Out Back Cylinder-Heads.

*Editors:*

I noticed on page 357 of the October, 1892, issue of Locomotive Engineering an article from Mr. C. F. Gregory, of Detroit, Mich., criticising pretty severely my article on laying out a back cylinder-head, which appeared in your January, 1892, issue, and in his article he promises to explain a better method of doing this work. I have been watching for this promised explanation, but as yet have failed to see it, but perchance I have missed it, for Locomotive Engineering always contains so many good articles that a person is liable to miss one.

Brother Gregory says he does not like the paper template. Neither do I for general use; but please bear in mind that the work criticised was a roundhouse job, and the paper template was given as the quickest way and the way most easily grasped by a novice. But perchance it could be done as quickly with the dividers, in the following manner.

First put a center punch mark, *A*, Fig. 1, in the center of that part of the head which projects into the cylinder. Then drive a piece of light board with a piece of tin tacked in the center of it into the back end of cylinder the exact distance from the seat that the projection on the head arises from the seat on the head. Upon the tin get the center of counter-bore of cylinder. Then from this center with the dividers scribe a circle which passes through the center of each stud-hole in the cylinder-flange, and from the center, *A*, Fig. 1, scribe this circle on the flange of cylinder-head. Now move the board in cylinder out flush with the seat and be sure that the center mark on the tin is again in the center of cylinder counter-bore. Then take a straight-edge of sufficient length to reach across the end of cylinder and hold its top edge in line with the center mark on tin, and in this position make it conform to the level as taken from the long straight-edge resting on the frames back of the cylinders, and from the top edge of the short straight-edge thus held scribe a line through the center mark and across the face of cylinder-flange on right side of cylinder. Then with the dividers on the right side of cylinder-flange space the distance from this horizontal line's intersection with the circle through stud-holes, *B*, Fig. 2, to the bottom end of back steam port.

Now, without changing the divider points, use the *left* end of clearance space in head for a center, and make a mark on left side across the circle on flange of head, prick-punch the point of intersection, and through this punch mark and the center of head draw a line across the flange face on each side of head. Now, using the same point of intersecting lines on right side of cylinder flange for a center, space with dividers the distance to center of first stud-hole *above* the horizontal line, then using care not to alter distance between divider points, use as a center the intersecting point of lines on *left* side of head and scribe the distance across the circular line, and above the horizontal one; this will be the proper place for center of first stud-hole. Then space off distance from center to center of each stud-hole in cylinder from *right* to *left*, and lay off these distances on flange of head from *left* to *right*, and when holes are drilled $\frac{1}{16}$ inch larger than diameter of studs, the head will slip to place nicely. Now transfer the horizontal line across the flange of head to opposite side of head, and from thence across the flanged part to which the guide-blocks are fastened, and the holes for guide-blocks can then be laid off, as described by me in January, 1892, issue.

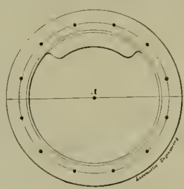


*Fig. 1*

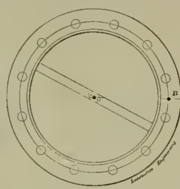

*Fig. 2*

Now, every one of my articles contributed to this paper have at all times been open to fair criticism. And please allow me to state right here, that before criticising an article, I believe it to be a person's duty to at least read carefully the article to be criticised, and thus become thoroughly acquainted with all of its points, with the object that no unjust criticism may be made.

Let us now look over Bro. Gregory's article, and see if he read my article carefully before "tearing it to pieces." In the first place he says, "Some roundhouses have no means of drilling except by hand," and that perhaps I did not make allowance for that, and a little further along he says, "After block-holes are laid out the head is again taken off, and taken *somewhere* to be drilled." Now, it does not appear reasonable to me that even a helper who was endowed with common "horse sense" would take the head to the grindstone to be drilled while there was a drill-press in the roundhouse, as stated by me in the first part of my article, and I believe, had Bro. Gregory read my article carefully, he would have spared himself this humiliating "break."

Then he says, "I proceed to lay out holes for guide-blocks, by *leveling* engine, using long straight-edge across frames, etc." Now, I beg to say I did *not* level the engine, and if Mr. Gregory was "on to the job" he would have seen that I used the long straight edge purposely to avoid taking the time to level the engine. I placed the long straight-edge across the frames, and made an adjustable level conform to it in that position, and thereby did not have to move the engine from the position in which it was left by the engine dispatcher. And again he says the block-holes would not be in the proper places if my instructions were followed, as "the crosshead might have their gibs on the bottom." I do not see how the position of the blocks as described would affect putting on thicker gibs at any time, for in such a case the only thing to do would be to put more liners between block and bottom guide, and this has to be done in all cases where the thickness of crosshead lugs is increased and the same blocks are used.

Relative to giving the thickness of the head, I think it would be as well to do this, although I believe that most main shops keep the sizes of such parts as back cylinder-heads. Then, in regard to the impossibility of obtaining a piece of paper with which to make a template. Well, we will not discuss that point; and I am glad to read Brother Gregory's criticism, for it demonstrates how easy it is for some people to criticise the work of others, and his statement that he does not wish to criticise my writings reminds me of the boxing match in which one fellow said he did not wish to hurt the other, then knocked him through a board fence the first clip. Still, I believe that Brother Gregory means well, and will "get there" yet, and I wish he would give us his promised article, as I am sure it will be something instructive.

L. C. Hitchcock.

The "Pioneer."

### The "Pioneers"—Which?

*Editors:*

Inquiry was made for the old locomotive "Pioneer." Now, which "Pioneer" is it? I send a sketch of locomotive "Pioneer," built by Seth Wilmarth in 1851, for the Cumberland Valley R. R., and this is only one of the many engines of that name. In the away-back days two old locomotives put in an appearance on the old Pennsylvania State road (they were borrowed); they were single drivers and had the crank throttle-lever, so common in European practice. They were named respectively, "Pioneer" and "North Star." It is of these old engines I would inquire. They came and ran awhile and went away. I never knew where they came from, unless they came from the Portage road, which ran west from Holidaysburg, Pa., this road being a part of the main line of public improvements owned and operated by the State of Pennsylvania, afterwards absorbed by the P. R. R.

### Why Should We Attempt to Set Eccentrics Before Wheels are Placed Under Engines?

*Editors:*

I have been particularly interested in the communications in regard to setting cams on axles in position before putting under engine. Everyone so far has said, "My way is not *exactly* correct, because there may be a variation in some parts of valve-motion which can be overcome by offset keys or an adjustment somewhere else."

If that is true, what is gained by setting them before putting under? If time is consumed in readjusting them, or something else, to make them right, then they might just as well be keyed on under engine after valves are squared and we are certain, by actual measurement, that they are in proper position.

The claim is made by some, that too much time is lost on account of engine being ready for the road, but waiting to key on eccentric cams. I think that argument is absurd. If it is so, there is a lack of system in doing the work.

An engine can be built or repaired, cams keyed on under engine and eccentric-straps and rods put in position in ample time, while the other necessary finishing work is being done.

It is done here (L. V. R. R.) right along without any detention whatever, the rule is, eccentric-cams are keyed on, straps and rods put up, everything complete, a day or two in advance of engine being ready to leave erecting shop. The method is as follows:

Cams are set on axles with set screws a certain distance from quarter lines (distance taken from an engine of same class having eccentrics correctly set), eccentric-straps are then fitted to a bearing before wheels are set under engine, requiring no fitting under engine, then at a convenient time we take the eccentric-rods and lay out holes in straps to fasten rods the proper length.

For forward motion we drill and ream all the holes in straps, and fasten rods permanently to straps with snug-fitting bolts, we never alter the length of forward eccentric-rods when fitting up new. But in back-motion eccentric-straps we lay out and drill one hole in strap for rod, making a slot $\frac{3}{16}$ in. longer than diameter of bolt, which allows of an adjustment of $\frac{3}{32}$ in. each way, which is ample enough to allow for any adjustment when setting valves; after valves are set we take back-motion eccentric-straps and rods to drill-press and get the remaining holes drilled and reamed (this is done while cams are being keyed on axle).

When valves are set we take down straps and mark position of cams on axle, mark off keyways, slip cams taward center of axle, and commence keying on our cams. We slip engine so that both forward key-

ways are on upper side of axle, one back of center line of axle and the other in front of C line. We then lay out four holes the length of keyway with a special c'amp, which is fastened on axle, permitting of easy adjustment, and a small ratchet, fitted with a flat bit drill, having a shoulder on, preventing it drilling out too deep. The holes are drilled out the required size and depth. With chise' the metal between holes is cut out, and with a steel drift the size of key the keyway is finished out, making a true, clean keyway, which is a perfect fit for key. Ends of keyways are left round, filing keys to suit. As two men usually do this class of work, while one man is drilling out the keyway the other man is preparing ends of keys to suit keyway; and while first man is chipping and drifting keyway, the other is drilling out the keyway on opposite side. Putting keyways in this position prevents any delay. Two keyways and keys are being fitted at one time.

Everything being ready, we drive on forward motion cams in position, making them a snug driving fit, tighten up set-screws and slip engine, bringing back-motion keyways in same position of forward motion for convenience of drilling and fitting, doing back motion in same manner as forward motion.

Cams are now permanently keyed on axle in correct position in a perfect mechanical way. We have no offset keys to bother us in case of a breakdown. We know that we can take a new cam from shelf, put in position and feel satisfied that it is right, as all keyways are cut in cams to template, making them interchangeable, and keys are standard. Straps are put on, rods coupled to links and the job is complete. There is no hard work about it, and when you compare the time occupied in doing it with other methods, and the accuracy of the work, I think there will be a saving all round.

It generally takes about ten hours for two men to do this work, it has been done in eight hours from the time of taking down straps and marking keyways to finishing job complete.

I certainly think it is a good thing to know how to set cams on axles before putting under engines, but see no practical advantage in doing it, as it is apt to consume more time and result in making too much alteration in valve motion.

### The Invention of the Steam Whistle.

*Editors*:

I notice on page 231 of the May number of your most interesting and widely-read paper, that in paragraph 54 you state that the steam whistle "was first applied to a locomotive in 1835 by Bury, an English builder." But according to good authority the steam whistle was first applied to a locomotive in May, 1833. I have by me now the "Midland Railway, Its Rise and Progress," by Williams, and on page 91, speaking of the Leicester & Swannington Railway, he says: "Soon after the appointment of Mr. Ashlen Bayster (January, 1833) a locomotive, while crossing a level road near Thornton, ran against a horse and cart. At that time the drivers and guards of trains were able to give the signal of alarm only by means of a horn, and when Mr. Bayster heard of the misadventure he went over to Alton Grange and mentioned the circumstances to Stephenson. 'Is it not possible,' he suggested, 'to have a whistle fitted on the engine which the steam can blow?' 'A very good thought,' replied Stephenson. 'You go to Mr. So-and-So, a musical instrument maker, and get a model made, and we will have a steam whistle and put it on the next engine that comes on the line.'" Then, again, in looking over the *Engineer* for 1892, I find on page 290 a letter from Mr. Clement E. Stretton, the best authority on locomotive history in England, in which he says: "It was put on in ten days and tried in the presence of the board of directors, who congratulated Bayster and Stephenson, and ordered other trumpets (or whistles) to be made for the other engines which the company possessed." He also says: "I herewith send a copy of the company's drawing, dated May, 1833, signed by Mr. Henry Cabry, the engine superintendent, showing that no possible doubt upon the matter can exist." And so I believe that the Bayster and Stephenson whistle of May, 1833, was the first ever used on a locomotive.

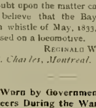
### Badges Worn by Government Engineers During the War.

*Editors*:

I have noticed for some time, articles by men who ran locomotives for the United States during the War and have been much interested by them.

I have in my possession (inclosed proof) the original badge presented to James Campbell by Gen. Joseph Hooker, in 1861,



upon Mr. Campbell's enlistment for three years as locomotive engineer on the U. S. M. R. R. It occurred to me that possibly "Old Soldier" might recognize the badge, as I understand all engineers had to wear one while in service of the United States.

Would like to learn their value, if any, outside of a personal relic; also, to ascertain how many of them are in existence at the present time.

J. G. CAMPBELL.

### Some Points on Tempering Tools.

*Editors*:

Toolsmiths should be adapted to their work and like it, be patient and of an investigating turn of mind.

Tool steel should be selected for the work it has to do, one kind being good for one kind of tool, but totally unfit for another. The selection of smith and steel can not always be regulated to our taste, but methods of working can be.

To attempt to handle too many tools in the fire is a bad practice; it is like handling eggs, in bulk, generally disastrous. The toolsmith who attempts to heat too many tools at a time, is very liable to burn or soak his steel, thus rendering it valueless. In some instances, when a large number of tools are required to be dressed, it becomes necessary to heat several at a time, but in the majority of cases it is a bad practice.

Taps, hobs, reamers, milling cutters and other tools of that order are subject to warping, cracking and general distortion in tempering, all of which can be overcome to an extent. First, by simply obtaining an equality of temperature or heat in all parts of the object to be hardened; secondly, the water to be used in hardening should be of the proper temperature. For example, a feather-edge cutter will not bear as much strain as a more bulky tool; hence it will not stand as cold a bath, for the colder the water the quicker the abstraction of heat, which will cause a sudden contraction of the thin edge. The method of tempering, so as to graduate to any desired degree or depth the hardness of the tool, is to immerse it in water, keeping it there just long enough to harden the surface and cutting parts to the desired depth, then quickly transferring to an oil bath. The object of this method is to overcome the strains and stresses which sudden cooling develops. The oil abstracts the heat in a slow, gradual and uniform manner. The water has produced the denseness of hard steel on the exterior, while the center is amorphous and soft, thus allowing the outside to compress and close up those minute fissures or openings caused by expansion.

Long tools tempered in this manner, if sprung or crooked, can be straightened without much difficulty after they have been hardened and tempered.

I sprung a 1⅛ x 16-inch reamer $\frac{3}{16}$ inch out of true and straightened it between two centers by means of a block and steel bar.

It is best to heat the steel, but not enough to start the temper before attempting to straighten.

In addition to the foregoing, it is well to relieve the tension where the hardened part joins the unhardened by drawing the temper, thus allowing a harmonious arrangement of the particles, or in other words to allow the particles to assume a normal condition. The idea is to equalize tension wherever it is possible to do so, thereby lessening the risk of cracking.

GEO. F. HINKENS.

*Gladstone, Minn.*

### Tools Shorten When Tempered.

*Editors*:

Why we draw the temper on tools after they are hardened, and what effect has it on a tool, is a question asked very often. For a sample take a reamer 1 inch in diameter, 10 inches long, get the exact length of it, then heat it to a perfect uniform heat and to as low a heat as it will harden at, then quench it, and when it gets to a temperature of 75 degrees get the exact length of it again, and, if your steel has refined as it ought to on the cutting edges, your reamer will be about $\frac{1}{32}$ inch shorter; then take and draw the temper to a straw color and let it cool slowly to a temperature of 75 degrees, and you will find that your reamer has shortened from $\frac{4}{1000}$ to $\frac{6}{1000}$ in drawing the temper.

Now, we are asked why does it shorten in drawing the temper.

In quenching your steel at the lowest possible heat it will harden at, and in a solution that will cool quickly enough to refine your steel, which a salt brine will do at a temperature of from 35 to 50 degrees, it will cool your cutting edges so suddenly that they will be at a temperature of 70 degrees when your center is still red hot; now, the cutting edges naturally draw the center with them while it is hot, and when the center gets to the same temperature of the cutting edges it must have a tendency to draw the cutting edges with it, which it does in quenching when it shortens your reamer $\frac{1}{32}$, but it still leaves a powerful strain on your cutting edges, which is relieved by drawing the temper and proven when your reamer shortens in drawing the temper.

A great many say they can prevent this in hardening. It is very easily prevented, providing you don't care whether you refine your steel or not; but you cannot prevent it if your reamer is of good steel and has been properly annealed before you send it to the machine shop, and refined as it ought to be in hardening.

### Responsibility of Running Cars Without Sufficient Braking Force—Naming the New Brake-Valve—Danger in Practice of Restricting Supply of Catalogues—Value of Quick Action.

*Editors*:

I have often read of the quick-action feature of triple-valves being plugged, although I had heard of such things, I did not think I should have a practical illustration so soon, but a few days ago an inspector asked me to look at the valve on a coach that would blow out of the exhaust port, after he had cleaned valve and put in a new seat, No. 11, Plate D 26. I looked at the seat, which appeared tight, then took out emergency-valve seat to look at emergency-valve piston No. 8. It was not a piston at all, but a stop or plug, with a shoulder to keep it from falling through the seat; it fitted so tightly that the emergency-valve No. 10 would stick in it and could not close tight.

This is not the worst of it, by any means. This car was in a measure a special car put up by a well-known company, who run their cars over the different railroads, and who themselves furnish men to take care of their cars wherever they run; they also in their advertisements make great claims about not hesitating at any expense that will add to the comfort and safety of their patrons; but their cars are often found leaving terminals with brakes in such condition that I have been led to think there is a deliberate intention to make their cars do as little braking as possible—I presume, to get them to last longer.

Is there any one else who is having such an idea continually brought to his mind, while he feels that it would be an injustice to all parties concerned to entertain it seriously, but who cannot help seeing that such mistakes are invariably in favor of the parties who would be financially benefited thereby, and who, not being responsible in case of wrecks, would be in a position to collect damages from the very parties whom they were imposing upon?

LOSS FROM STINGINESS IN FURNISHING BRAKE CATALOGUES.

As for naming the new brake-valve, why is not Plate D 5, a good enough name? and, besides, this valve was in use here in '92. But right here let me say that there is a method of restricting the supply of air-brake catalogues by not placing them in the hands of the men who do air-brake repairs. That is very costly to the companies pursuing such a policy. I find it difficult to keep these men supplied, having some men who have worked a year or more on air and have never seen a catalogue. The writer, when beginning air-brake work, was often led to understand what work a piece or part did by looking at the names in the catalogue but I find many men who have to ask for "thingumbobs" and "cinfunnys" when they have to replace old parts with new, and in one case there was an hour lost by two men trying one night to agree about a valve-chamber bush No. 43, Plate D 6. The air man called it a "-ubley-whack" and the storeroom man a "skew-gee," and he could not be made to understand the chalk sketch made for his benefit.

Of course, this was an extreme case, but I have no doubt that the majority of air inspectors will agree with me when I say the catalogues that such repair men have not had, but which were needed, have cost their companies at least their weight in gold, and to this cause is due to a large degree the horrible and misleading names of parts and the very expensive air of mystery that has until recently enshrouded the air-brake business.

A BUSHING REMOVER.

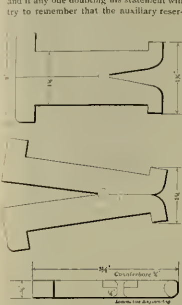
By the way, I once got up a valve-chamber bush puller, which we believe to be the thing here, and which seems to be even handier than the one illustrated in June, in that it will pull the bush if the upper receiving valve No. 31 has spread so it cannot be gotten out.

I am not a rival in the business and there is no patent on it, nor is it very expensive. It is made of ⅜-inch steel 1¼ inches wide, and in using it the short ends are brought together and slipped into the exhaust holes in valve-chamber bush No. 41, Plate D 6. The top part is then shut, and any open wrench, fitting valve-chamber cap No. 29, Plate D 6, or an alligator wrench, is placed under the projecting upper ends

and used as a lever. We have never known it to fail and I should have sent it sooner but had an idea I had done so. Of course, the edges are rounded off to fit 1¼-inch bore.

THE VALUE OF QUICK ACTION.

I must say Mr. Synnestvedt struck the mark in grand shape in his June article on the quick-action brake. Being pressed in my work, I had not realized what the May article meant until I saw his answer, which certainly ought to be satisfactory, and if any one doubting his statement will try to remember that the auxiliary reser-



voir pressure is in the nature of a fulcrum on which the quick action works, that it can only work when both brake-cylinder and train-pipe pressures are lower than auxiliary reservoir pressure, and that it requires generally thirty seconds for auxiliary to recharge from fifty to seventy pounds, they would tender him a vote of thanks for wakening them up.

GEORGE HOLMES.

*Roanoke, Va.*

### Why Didn't This Pump-Governor Act?

*Editors:*

A few weeks since one of the new model engineers' brake-valves with pressure reducer was put upon an engine by a representative of the Westinghouse Co., and a new pump governor, known to be adjusted to cut off at 90 pounds, was put on at the same time. The engine was run a week or more, but engineer complained that the governor did not appear to be of any use. This is the way it acted. Starting at zero, and pumping up, with brake-valve handle in running position, the red and black hands traveled together until 70 pounds pressure was attained, when black hand stopped and red one kept working up. So far, all right; but the pump did not stop at 90 pounds. It maintained the even tenor of its way until 120 pounds were stored, and had it not been stopped by engineer closing throttle, would have continued until air and steam pressure balanced. When the red hand indicated 90 pounds or more, if the handle was carried into release position for an instant, the pump would stop, but would commence work again shortly after the handle was returned to running position. If pump was started from zero with handle in release position, both hands would travel together to 90 pounds, when pump would stop. It would go to work after a little, however, if handle was carried to running position. It is but fair to state, for the benefit of those who would solve this puzzle, that there was a noticeable leak in train line under tender. On examination, the difficulty was quickly located and corrected. What was it?

CLARK L. PIERCE.

*St. Albans, Vt.*

### Some Odd Actions in Air-Brakes.

*Editors:*

I recently had a little experience with air-brakes that may be of interest to readers of LOCOMOTIVE ENGINEERING.

While looking over some freight cars my attention was attracted by an escape of air at the pressure-retaining valve. My first thought was that the emergency-valve was affected, but in this I was mistaken, as the trouble was not in the triple at all. When the brakes were applied the escape discontinued. This car was equipped with the Westinghouse standard freight brake.

I found a small hole in the pipe that runs through the auxiliary reservoir to connect that chamber with the brake-cylinder. It is said that these pipes have been known to burst or split occasionally, and in such cases the cylinder becomes part of the auxiliary reservoir and the brakes will set the moment the air is let into the auxiliary.

On another train I had brakes applied by a 20-pound reduction, service application, and, finding that the piston on the first car had a travel exceeding 8 inches, I closed the cut-out cock in the cross-over pipe and opened the drain-cock to auxiliary reservoir to effect a release of this brake without disturbing the rest. Instead of the triple responding instantly, it remained motionless for about five seconds and then moved, opening the exhaust-port and allowing brake cylinder piston to drop back about an inch and a half; when it closed the exhaust-port again, held it for about two seconds and again opened it, allowing the piston to drop back again about another inch and a half. The triple repeated this action two or three times until the piston reached the leakage groove when, of course, the brake came off. This car was equipped with the Westinghouse passenger brake.

I do not know exactly how to explain this action, and if any other air-brake men have met with the same experience I wish they would tell what they think causes it. In my estimation, there would have been no such action had an emergency application been made. The brakes were applied, service application, with a 20-pound reduction. The emergency-valve was defective, and after closing the cut-out cock and opening the drain-cock, the air in the train pipe, being of small volume, would leak through the defective emergency-valve faster than through the auxiliary drain-cock, thereby causing a variation in the pressures that were in communication with each side of the piston No. 5 in the triple. The check-valve No. 15 in the meantime acted, I suppose, upon each variation of pressure.

J. V. K. WALKER.

*Portsmouth, Va.*

### Defects of Air-Brake Cars—A Plan of Report.

*Editors:*

As almost all railroads are equipping their freight cars with air as fast as they are rebuilt, I would like to say there is no use in having air-brakes unless they are taken care of, especially air-hose and triple-valves. Keep good hose on cars and clean triple-valves once in a while.

In almost every train of fifteen or twenty air-brake cars there will be two or three air-hose burst in going over a division and they almost always burst between stations, so that the train will stop in about the length of itself; or before any one can comprehend what is the matter, the train will be standing still before a flag can be started back, and if there is another section following close, with no air-brakes, there is sure to be a smash-up.

You will very often see the first section with from five to twenty air-brake cars and the second section without any air-brakes. Car repairers do not repair air-brake defects, so that the air-brake car has to go until the car goes to the shop again. Car repairers will not even put hose on unless told to do so by the trainmen, and if train pipe is broken, or triple-valve will not work, they will cut car out and let it go and car will run two or three weeks without air-brakes working. You will find air-brake cars every day that can't be used on account of a broken train pipe or triple-valve not working, or no hose.

Car inspectors will not mark cars in bad order for air-brake defects; there should be some system adopted for trainmen to report defective air-brake cars, as car inspectors cannot tell without an engine attached to cars, whether they are in good working order or not. If trainmen should be ordered to mark the defective air-brake cars and also mark the defective parts same as car inspectors do the cars for other defects, I think that would be as good a plan as any, if lived up to.

FRED. F. LEE.

*Ottumwa, Ia.*

### Call Things by Their Right Names.

*Editors:*

One of your best correspondents, in speaking of eccentrics, uses the word *cam*, which is misleading. A cam is generally understood as giving an irregular motion, as in the case of the valve-gear of Western river steamers, although we get no irregular motion in the valve-gear of walking-beam engines from an ordinary eccentric. The eccentric gives a motion, but the lifters or wipers on the rock-shaft give irregular motion to the valves.

In speaking of valve-setting, the word "stretcher" is used in connection with the valve-rod. It is supposed it means a right and left thread nut, in which case it is liable to be a "shortener," but we suppose it is a local term.

The writer once had a fireman who spoke of the draw-bar between engine and tender as the "stiff shackle." No doubt but what railroad men in his part of the country knew it by that name. An old-time name for it was "draught iron," but 90 per cent. of railroad men will call it "draw-bar."

Another word that is misleading is *Babbitt* metal. Looking over the well-written "ad" of the Ajax Metal Company I see that they use the word "Babbitt." A great many persons who see a metal melted and poured into a bearing call it Babbitt, simply because it is melted in a ladle and used as a lining metal. Babbitt metal is an alloy of copper, zinc and tin, and is an anti-friction metal called after a man named Babbitt. Anti-friction metals were used before this man was born, so the word Babbitt does not signify metal. If a great many of the so-called Babbitt metals on the market were put under the "999," she would have to run through a canal to keep cool. Call it "Ajax," not Babbitt. We might pick up a cake of common soap and call it Babbitt's best, when, in fact, it was Siddall's worst. The soap the boys use here they call "Swanston's Toilet," when, in reality, Swanston knows nothing about it. Give things their right names.

W. DE SANNO.

*Indianapolis, Ind.*

### Mixing Quick-Action With Old Brakes.

*Editors:*

I know one railroad company that is equipping their cars with the quick-action triple-valve, and fixing the emergency-valve so that the emergency-valve is made inoperative until such time when they get them all equipped with the quick-action valve, when they expect to remove the obstruction and put the valves on all the cars to work at once or at the same time. They claim that a train with mixed valves, that is, some old-style and some quick-action valves, would not work together right. (I do not know what the company thinks about it, but I am told by men in the railroad service that is the reason they are doing it.) They say some cars would get more brake pressure than others and jerk the train, then again, some say they are doing it because the engines are not all equipped with the "Engineer's Brake Valve," and engineers cannot control the amount of air that discharges from the three-way cock so easily, and it is liable to make an emergency application too often, and when they don't want to. I think the last excuse or reason is the most plausible, as the ports in the three-way cock-plug run up and down, and after a port commences to open a movement of one-half of one inch opens the cock all the way.

I don't think the jerking would pull out many drawheads in making an ordinary service stop, even with mixed valves and three way-cock, on passenger trains if the engineer should use judgment in applying the brakes. I don't think the cars with the quick-action triple would stop suddenly enough for that, from the fact that the cars with old-style triple-valves would help to push them a little, and the springs that are a part of the drawhead, would prevent any great damage in that line. As railroad men know that, as a general thing, brakes are not always regulated so that they apply with the same force when the triple-valves are all the same, on account of bad adjustment of the brakes, some pistons travel nearly whole length of brake-cylinder, and some cars in a train will have six-wheel trucks with brakes only applied to four of the wheels, and other things that will cause an uneven braking of the different cars in the train, and we do hear of many complaints about trains jerking on that account.

If an engineer should be in a very tight place and want to stop in a very short distance, he would not stop to calculate how many drawheads he would pull out, he would try to prevent his train from taking a dive into an open bridge, perhaps, or landing in the middle of the other train in front of him. Then, we know that cars in a train are sometimes cut out, and in that case there is no brake on the car cut out, and a good brake on the cars front and back of it. Why would that not pull out drawheads or make a train jerk? I think it is a lame excuse to make the emergency-valve inoperative because it applies 20 per cent. harder. In emergency application of the brakes with quick-action triple-valves, the brakes will apply on twenty-five cars in the fraction of a second, while in an ordinary service stop it takes eight seconds, so you see the speed is 8 to 1 in favor of the emergency brake in time of danger.

FRED B. ARMSTRONG.

*Camden, N. J.*

### That Tank Triple.

*Editors:*

In regard to triple-valve, spoken of by Thos. Croden on page 219, I would say that piston in triple-valve being gummed up, it took quite a jar to start it, and by opening stop-cock at end of tank train-line pressure was exhausted much quicker than through engineer's valve, on account of the stop-cock being nearer the triple and no obstructions, and a large opening. Exhausting by engineer valve was more gradual and would not start the piston.

*Newark, N. J.* W. A. EAGLES.

### Wouldn't Work Automatic.

*Editors:*

I recently took an engine from shop that was using straight air on drivers and tank, but when I cut in for automatic it would work on the drivers but not on tender. Cleaned tank-triple without result, and then changed triple-valve, but still the tank-brake would not go on automatic, yet it worked straight air all right. What was the matter with it?

C. C. McMULLIN.

*Allegheny, Pa.*

### Sords and Long Not the Same Person.

*Editors:*

Your May issue contained an article signed by A. W. Long, which was written by me for the *Engineer's Journal* some time ago.

I had intended to let the matter pass,

but since you have called attention to the possibility of A. W Long and Paul Sords being one and the same person, it behooves me to refute the charge of being a repeater.

The article in question was sent to Locomotive Engineering without my knowledge or permission, and not by me

*Bellevue, O.* PAUL SORDS

## Mr. Long's Article on Air-Brakes.

*Editors*

I see a letter in the June number of Locomotive Engineering from Will W. Wood, in which he claims that the letter from A. W Long which you printed in the May number is almost verbatim copy of the article over the signature of Paul Sords, published in the *Engineers' Journal.* Is it a miracle or any great crime if two men should express their opinion in the same language, especially when speaking on the same subject? I will just say for the benefit of all concerned, that the communication which Mr. Wood refers to was written by me last November and was intended for Locomotive Engineering at that time, but I neglected sending it. This spring, after reading several air-brake articles, I decided to send my letter to Locomotive Engineering, not dreaming of the wrath to come. A. W LONG.

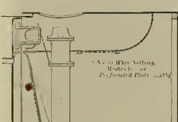
*Creston, Ia*

[All parties having now had their "say," we will publish no more communications on this subject.]

## Was It the Draft Sheet or the Engine Crews?

There has been a revival down on the old South Carolina road in the matter of saving coal. Superintendent of M. P. Roberts tried an experiment on one engine by putting in a deflector plate perforated with large openings (just as shown in iron doors for front car, illustrated elsewhere). This engine did so well that other engineers asked to have their engines equipped.

It was but a short time before most of



the men on the road were seeing how good a record they could make on the fuel report

They have shown a saving over their old performance sheet that beats any compound saving we have heard of. The men themselves say this is due to the new front end arrangement, and have induced Mr. Roberts to patent it.

While we are willing to believe good things of the perforated sheet, we are still firmly convinced that much of the saving results from the care taken and interest shown in their work by the engine crews, and that Mr Roberts holds this same view and gives his men due credit, as is proven by the posting in the roundhouses of the company of the following bulletin notice

CHARLESTON, S. C.

*To Engineers and Firemen:*

I desire to express to you my hearty appreciation, and to commend the spirit which has recently been displayed and the co-operation with myself and foreman in attaining fuel economies on this road. Our record of coal consumption in the past has compared favorably with other roads, but with the new draft-sheet and the efforts of our enginemen our record is most flattering, and is a credit to all concerned, and which can, I have no doubt, be greatly improved, which will be far in advance of the best performance of any of the compound engines that I have been able to get data from, and will result in attracting much attention from all parties interested in operating railroads Your efforts continuing in this line shall always have full measure of credit. The fuel account of railroads is greater than any other individual account of the machinery department, and on our road it is 35 per cent. of the total expenses of engines, including repairs, supplies and wages of engineers, firemen and wipers.

I can only add that I hope that all of our men will take the same interest in this fuel economy that the majority of our men are displaying, and I shall be able to show you a record that will make you all proud.

Yours respectfully,

(Signed) E M. ROBERTS, S. M P.

Men who give their engineers and firemen credit for effort and results, and not claim it all for themselves, are very apt to get their men interested in their work, and such an officer will save more money for his company per month than the inventive genius can show with all his devices in a year. There is more chance to save fuel through improvement in the men than improvement in the cylinders or valve motion.

## Reading Rooms on the Santa Fe.

The members of the Brotherhood of Locomotive Engineers have opened a reading room in the front part of their hall building on Main street, Newton, Kansas. The room is open free to the public, and is well patronized. All the leading daily papers and magazines are kept on file and all the railroad papers are to be found there.

Reading rooms are badly needed along the Santa Fe system. There used to be reading rooms at nearly all of the principal points along that system, and the men contributed money for the purchase of books and papers. One of the worst acts ever done by the late Allan Manvel was the closing out of these reading rooms. In his unscrupulous cheese-paring policy he closed the reading rooms to save the trifling expense of attendants and house room. It was a very short-sighted policy, and no doubt cost the company a great deal more than the trifling sums saved The man who throws obstacles in the way of the acquirement of knowledge sows seed that is reaped in a harvest of discord.

## An Improved Stand-Pipe.

This locomotive stand-pipe has been designed by Mr. Robert White, of Kingston, N Y, who has charge of the water supply of a prominent road.

The main improvement is in the valves, and, as can be seen in the detail cut, there are two water-valves, a large and a small one. This allows the fireman to start the water slowly, obtain a full open pipe, and, when his tank is nearly full, close the large valve and fill the tank full, without running over, by using the small valve only.

To the valve-stem is attached a piston, as shown, that prevents the too sudden opening and closing of the valves

A safety-valve prevents the ram of the water, when valve is shut quickly, from rupturing pipe or fittings.

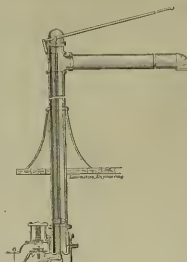
All the valves have hard rubber faces or seats, that last a long time and are easily removed and replaced.

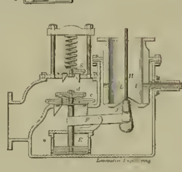
As might be expected of a practical man, this stand-pipe is designed to stand all kinds of repairing with the least trouble and expense and the shortest possible interruption of the water supply. No pipe joints need to be disturbed to refit it throughout, a hand-hole covers every part that needs to be get-at-able.

The base of the upright pipe turns on rollers or wheels, and in bringing the pipe into position for use it is raised considerably, and when released returns by gravity to its proper position.

The drain-cock is ingenious, and is shown in detail cut. A hole in the stand-pipe is brought opposite a pipe fitted with a spring packing, that keeps a bush pressed solidly against the column, allowing any water in the pipe to drain into pit. When the pipe is turned around for use the joint between it and the drain-pipe is broken.

Since these engravings were made the





inventor has designed a flexible joint, that allows the horizontal pipe to be depressed to any height of tank without the use of sacks.

The Joseph Dixon Crucible Co., of Jersey City, N J., have sent out a statement saying that their graphite paint is a sure remedy against the seven paint destroyers mentioned by Professor Dudley For further testimony under this head, we refer interested parties to the Dixon Crucible Co.

An order has just been received by the J A Fay & Egan Co., of Cincinnati, O., for a large lot of machinery to go to Padang, Sumatra, Dutch East India. This firm has recently issued a very handsome business card containing handsome engravings of the works of the company in Cincinnati The card also contains imprints of a great number of medals received by the company as prizes at the various exhibitions where their well-known wood-working machine has been shown

## Organization of Air-Brake Men.

The men who keep up and care for the air-brakes of our railroads have been talking for some time of forming a little association of their own, and, pursuant to a call issued in Locomotive Engineering for May, a large number of them met in Pittsburgh, Pa., on June 8th, and perfected an organization to be known as "The Association of Railway Air-Brake Men." The object of the association is briefly stated as "The uniform instruction and improvement of the air-brake service on the various railroads" A laudable cause for life and good reason for their encouragement

The following officers have been elected for the ensuing year

*President*—Robert Burgess, L. & N Ry., Louisville Ky.

*First Vice-President*—C C. Farmer, M K & T Ry, Parsons, Kan

*Second Vice-President*—S D Hutchins Big 4 Ry, Columbus, O

*Third Vice-President*—R N Martin, P R R, Renovo, Pa.

*Treasurer*—Otto Best, L & N Ry Nashville, Tenn.

*Secretary*—P. J Carney, M, L S & W, South Kaukauna, Wis.

It has been decided to leave the books of the new association open until September 1st, to enable any air-brake men who care to do so to become charter members

The cost will be small and the exchange of ideas, plans and kinks will be worth more than all the time and trouble taken by the association

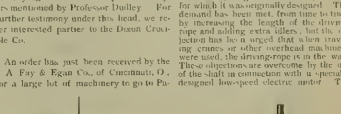
The only tendency of such a combination of men is to educate, to make them better mechanics and better able to care for the equipments in their charge, they should be encouraged by every railroad officer in the land

Notices of the work in hand, meetings, etc, will appear from time to time in these columns

## Electric Motor for Stow Flexible Shaft.

One of the handiest things around a railroad shop, especially the boilershop, is the Stow flexible shaft, so well known In a recent circular the Stow Mfg. Co. say

"There has been a growing tendency to increase the range of this tool beyond that for which it was originally designed This demand has been met, from time to time by increasing the length of the driving rope and adding extra idlers, but the objection has been urged that when traveling cranes or other overhead machinery were used, the driving-rope is in the way. These objections are overcome by the use of the shaft in connection with a specially designed low-speed electric motor The company has had this combination under consideration for two years, and now offer an electric portable drilling, tapping and reaming plant that can be carried to any distance from the source of power This motor has a normal speed of about 600 revolutions, which can be increased by a rheostat to 1,000 and 1,200, and reduced by gears to 275 without loss of power. These motors are for a voltage of either 110, 220 or 500."



ELECTRIC MOTOR FOR STOW FLEXIBLE SHAFT

On June 10th a large party of railroad men, doctors and newspaper men went over the line of the New York, Ontario & Western road to the summer resort at Liberty, in the mountains of Sullivan County, N. Y. The train was a new one, just from the Ohio Falls Works, and was pulled by the "140," an engine exactly like the one illustrated on page 197, of May. These moguls are exceptionally good engines for heavy traffic, and are extraordinarily alive on the start. It was for one of these that the claim was made a month ago that she ran a mile in twenty-five seconds. When interviewed on the subject General Manager Childs is reported to have said. "Well, we haven't got such large drivers as the Central, but, by gracious, we've got just as big a liar." A mile in fifty-five seconds was the best speed on the 10th. The new cars are very handsome and convenient. They are finished in oak, have Hale & Kilburn seats, Consolidated Company's steam heat, with Baker auxiliary; Frost lights, Gould couplers and vestibules, with brass handrails, Westinghouse brakes and signals. The "Ontario" does a big summer business, and should do more, for it runs through a beautiful country.

THE RECENT FLOOD AT MEADVILLE, PA. THE ERIE ROUNDHOUSE.

THIRTY-ONE INCHES OF WATER IN MEADVILLE SHOPS OF THE ERIE ROAD. MAY 16, 1893

---

It was Master Mechanic E. M Roberts who was commenting to an appreciative audience on the remarks made by Mr Sampson Fox on steel making. "You see, don't sher know," said Mr. R., "It's in the way the bloom is handled that the quality of the steel depends. If you roll the bloom as it is poured you have a pore plate, but if you take the bloom and hammer it and work it properly, your sheets will be a blooming success." We disclaim all responsibility for the quality of the alleged jokes.

# Car Shops and Car Builders.

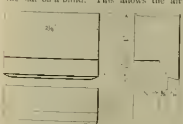
## South Carolina Fruit Car.

Words are hardly necessary to describe the car shown in the splendid engraving herewith.

This line of fruit cars was designed and built by E. M. Roberts, superintendent of motive power at the Charleston shops, and as they are properly marked, the length, weight, age and kind of attachments used are shown on the side of the car.

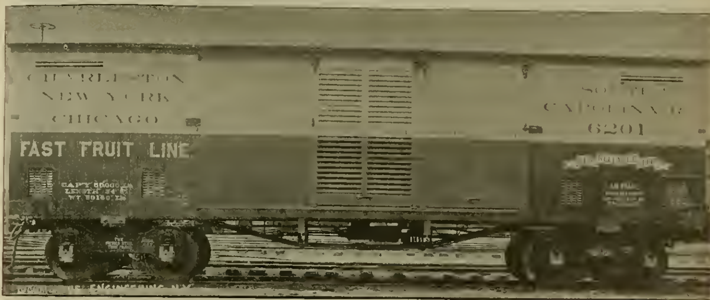
The upper half of the body is painted white, the lower half black.

A solid or ventilated door can be used at will, and there are four ventilating slides in the sides of the car. These slides are made of ⅛-inch iron, and are perforated, but the perforations are not cut entirely out, but are cut at the bottom and sides and the piece turned out, something like the slat on a blind. This allows the air to circulate, but prevents, in a large measure, the accumulation of sparks.

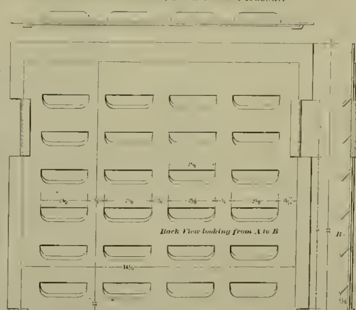


We also show a cut herewith of the punch used in making these perforated doors.

The car has Standard couplers, with Butler attachments, New York air-brakes, Hutchins roof and Fox pressed steel truck with 4 x 7-inch journals.



NEW FRUIT CAR, SOUTH CAROLINA RAILWAY.



## A Mechanical Oil-Box Lubricator.

Another form of the roller device for carrying the lubricant up to the journal of a car has been patented, this time by Mr. William H. Daniels, of St. Louis. We are sorry for Mr. Daniels. Not because he is an inventor or because there is any structural defect about his lubricator. Our sympathy pours out to him on account of circumstances over which he has no control, which will prevent him from making a commercial success of his invention. The invention is remarkably well worked out. It is a roller held up to the journal with spring arms, the stand of the apparatus being substantially secured by brackets cast on the oil box. If this invention were applied to the oil boxes of a car, it would work splendidly and give the journal just the quantity of oil necessary for lubrication. If a car inspector was to accompany the car so equipped over this whole continent he would find that the car would run cool with the smallest possible waste of oil. It would probably require no attention whatever in running from Maine to California, only the presence of an inspector would be necessary to prevent some blunderer from destroying the whole thing.

Car-box oilers entertain no malice towards patented lubricators, but this class of men are not leisurely and careful enough in their habits to suit the requirements of roller oil-box lubricators. When a car with these things in its boxes arrives at an oiling station, the man with the dope bucket knocks open the lid of a box, and not seeing any waste, jams in a supply with his battering ram. If any great resistance is offered, it is good day to the mechanical lubricator, for the dope man swears that some stupid cow has left half of a brass in the box, and if a jerk from the hook will not pull the thing out it is hammered in, even if the end of a pinch-bar has to be employed.

An improved axle-box lubricator is badly wanted, but it will never be a success until the dope man accepts the gospel of letting strange things alone, or looking before he leaps—at the end of a pinch-bar.

## Disputes in Car Exchange.

The Hannibal & St. Joseph rendered a bill against the Missouri Pacific for replacing coiled draft springs and charged 5 cents a pound for the same in accordance with M. C. B. rule 26, of 1891. The M. P. disputed the bill and said that manufacturers' prices ought to be charged. The Arbitration Committee decided that the charge was correct.

A dispute arose between the Union Pacific and the Northern Pacific in car interchange on a case which has repeatedly been brought before the Arbitration Committee under slightly different forms. The U. P. rendered a bill based on a defect card issued by the N. P. calling for one intermediate sill cracked. Charge was made for manufacturing the sill besides the 3 cents per foot for material and the twenty-nine hours for labor allowed under the M. C. B. rules. The N. P. disputed the charge made for manufacturing the sill and the position was sustained by the Arbitration Committee. Railroads belonging to the M. C. B. Association ought to understand by this time that they will not be sustained in charging more for repairs than the scale laid down in the Rules of Interchange. It is no use to say that the actual cost was greater than the sum allowed. There is a hard and fast rule and the Arbitration Committee will abide by it every time.

An interesting case came before the Arbitration Committee in a dispute between the Southern Pacific and the Chicago & Northwestern. An S. P. box car was given to the C. & N. W. at Council Bluffs, carded for 2 deadwoods, 3 draft timbers, 1 intermediate sill and 1 center sill, 1 end door-rail, 1 end door guide, 1 side door-stop split, 1 side and 1 end facia pierced, 12 end boards, 2 center plate-bolts, ends of 14 boards broken, mixed brake beams, 2 brake-beams cut, 30 side boards scraped, and 1 side sill half broken. The C. & N. W. accepted this car, and it broke down in the train and caused the destruction of the body. The C. & N. W. then asked the S. P. for permission to charge for defects mentioned in the card, to be deducted from the price of the body. The S. P. would not agree to this, and made a charge for the value of the car, less the regular deduction under the rules for depreciation. The C. & N. W. would neither agree to this nor to the referring of the case to the Arbitration Committee, which indicated consciousness of a weak case. The S. P. sent the case to the Arbitration Committee, however, and the latter decided that there was no authority for the deducting the cost of carded defects from the value of the car body. The car was evidently unsafe to run, and the C. & N. W. did wrong in accepting it.

The Central Railroad of Georgia sent a bill to the Norfolk & Western for the expense of renewing a Hinson car-coupler, for which the latter road had issued a card. The coupler was changed a year after the card was issued. The Norfolk & Western refused to pay the bill on the grounds that when a car is safe to run none but owners have the right to replace a draw-bar to bring it back to the original standard. The Arbitration Committee held that the bill should be canceled.

A curious dispute between the Missouri Pacific and the Burlington & Missouri River, was lately appealed to the Arbitration

## FIVE STANDARD BOOKS.

**NO TOUGH MATHEMATICS.**

IF YOU DON'T BELIEVE IT, ASK THE EDITORS OF THIS PAPER.

**1. INDICATOR PRACTICE AND STEAM ENGINE ECONOMY.**

HEMENWAY. With Plain Directions for Attaching the Indicator, Taking Diagrams, Computing the Horse-power, Drawing the Theoretical Curve, Calculating Steam Consumption, Determining Economy, Locating Derangement of Valves, and making all desired deductions; also, Tables required in making the necessary computations, and an Outline of Current Practice in Testing Steam Engines and Boilers. By FRANK F. HEMENWAY, Editor *American Machinist*, Member American Society Mechanical Engineers, etc. Sixth edition, 12mo, cloth, $2.00.

**2. BOILER MAKING FOR BOILER MAKERS.**

FORD. A Practical Treatise on work in the Shop, showing the best Methods of Riveting, Bracing and Staying, Punching, Drilling, Smelting, etc., and the most economical manner of obtaining the best quality of Output at the least expense. By W. H. FORD, M.E. Second edition, 18mo, cloth, $1.00.

**3. A TREATISE ON STEAM BOILERS.**

WILSON. FLATHER. Their Strength, Construction and Economical Working. By ROBERT WILSON, C.E. Enlarged and Illustrated from the Fifth English Edition by J. J. FLATHER, Ph.B., Purdue University. 108 fine Illustrations, Tables, etc. Third edition, 12mo, cloth $2.50.

**4. LOCOMOTIVE-ENGINE RUNNING AND MANAGEMENT.**

SINCLAIR. A Practical Treatise on Locomotive Engines, showing their performance in running different kinds of trains with economy and dispatch. Also, directions regarding the care, management, and repairs of Locomotives and all their connections. By ANGUS SINCLAIR, M.E. Illustrated by numerous engravings. Twentieth edition, carefully revised and enlarged. 12mo, cloth, $2.00.

**5. MODERN LOCOMOTIVE CONSTRUCTION.**

MEYER. With many Illustrations. By J. G. A. MEYER, Associate Editor of the *American Machinist*. 4to, cloth, $10.00.

CONTENTS: Classification of Locomotives, Train Resistance, Tractive Force, Weight of Engines, Construction of Cylinders, Steam Pipes, Slide Valves, Valve Gear, Construction of Links, Construction of Pistons, Cross Heads, Slides, Stuffing Boxes, Frames, Axle Boxes, Driving Axles, Driving Wheels, Counterbalance, Main Rods, Side Rods, Crank Pins, Throttle Pipes, Throttle Valve Gear, Safety Valves, Whistles, Pumps, Checks, Spring Gear, Boilers, Grate Surface, Heating Surface, Riveted Joints, Extension Fronts, Ash Pans, Smokestacks, Exhaust Pipes, Sand Boxes, Bells, Pilots, Braces from Boiler to Frames, Engine Trucks, Oil Cups, Cocks, Injectors, Tenders, Useful Rules, Formulas and Data, Compound Engines.

"The book will become a standard and remain so until the form of the modern locomotive shall have been radically changed."—*Locomotive Engineering.*

**Galena Engine, Coach and Car Oils, the Standard Lubricating Oils of America.**

SAFETY, SPEED and ECONOMY are the results of the use of Galena Oils. COLD TEST, 10 to 15 BELOW ZERO. These oils do not freeze in the coldest weather, while they are adaptable to the hottest climates.

In the use of Galena Oils there is an entire freedom from hot boxes, except when these are caused by mechanical defects.

The adoption of Galena Oils as standard railway lubricants by a large majority of the leading railways of this country is an evidence of their superiority, while the fact that the same roads use these oils to-day that used them more than 20 years ago, is an evidence of their uniformity from year to year and year in and out.

Galena Oils are in exclusive use upon three continuous lines from Boston and New York to the Pacific coast, and upon one continuous line from the City of Mexico to New York, thus demonstrating their adaptability to all temperatures and climates. Being entirely free from gum, these oils are not affected by dust and sand as other oils are.

We also furnish our customers SIBLEY'S PERFECTION VALVE OIL, which is also used exclusively upon a majority of the leading railways of America.

Send for Illustrated Catalogue.

Committee. A car belonging to the latter road lost an end door when on the M. P., and the road issued a defect card, so that the car could be returned to the owners. The owners charged $3 for replacing the door, the sum specified in the Rules of Interchange. The M. P. objected to this charge on the plea that the door used was cast-iron and that the charge ought to be made by the pound rates for that material. The Arbitration Committee decided that as the rules allowed $3 for an end door, that charge was correct, no matter what material might be employed.

A dispute arose between the Southern Pacific and the Chicago, Milwaukee & St. Paul over an odd question. The former company carded a car belonging to the latter for "one foreign cast stem draw-bar complete." On making the repairs the owners sent a bill charging for the expense of a new draw-bar, and crediting the S. P. for the old one. The S. P. claimed that they had a right to be credited with certain pieces of wrought-iron scrap used as attachments to the draw-bar removed. The Arbitration Committee decided otherwise.

A dispute that has been repeatedly decided by the Arbitration Committee again arose between the Nickel Plate and the Lake Shore. A car belonging to the former road was destroyed on the latter, and a claim for the full value of the car, less ten months' depreciation, was made. The car had been thoroughly rebuilt ten months before, and it was considered fair to regard it as new then. The L. S. people thought otherwise, and wanted the age of the car reckoned from the time it was first built. The Arbitration Committee sustained the position taken by the L. S. Company.

One of the most fertile causes of dispute in the interchange of cars, is the practice of accepting cars having defects that ought to be carded, and then trying to trace back the responsibility. A case of this sort arose between two Western roads and was again referred to last meeting of the Arbitration Committee. The Ohio & Mississippi rendered a bill against the Missouri, Kansas & Texas for the cost of twenty-three journal bearings placed under M., K. & T. cars. The claim was made under the M. C. B. rule which permits charge to be made for brasses worn out. The M., K. & T. held that the cars had been on the road only two weeks, and that therefore the brasses could not be worn out. The O. & M. answered that the brasses were not worn but burned out, yet that they were entitled under the rule to make the charge. This was disputed and the case went to the Arbitration Committee. They decided that as the brasses were in bad shape when the cars were received by the O. & M., defect cards should have been required. The rule relating to payment for worn-out brasses did not cover the case and the charge was not sustained.

### An Improvement.

One of the most thorough revolutions that we have ever witnessed in a manufacturing establishment has taken place within the last six months in the works of Rood & Brown, at Lancaster, N. Y. Mr. E. Chamberlin, the well-known master car-builder, took charge at that time and he went to work cleaning up and reorganizing things till he has now one of the neatest and smoothest running works in the country. They have kept turning out work while the improvements were going on, and the capacity is now materially increased, but still behind the requirements. They have introduced the use of gas for heating their annealing furnaces and for their coal ovens with very much saving of time and expense. They are engaged mostly on railroad work, malleable iron car couplers forming a large part of their output.

### New York to Chicago in Twenty Hours.

The New York Central Railroad Company began running on May 28th what they call the Columbian Exposition Flyer, which covers the distance of 966 miles between New York and Chicago in twenty hours. A representative of Locomotive Engineering was one of a party of journalists and others who were the guests of the railroad company on the first run. The train started promptly on time and every stopping point on the long journey was reached a minute or two ahead of time, the terminus at Chicago having been reached three minutes before the train was due. All along the route crowds of people were watching to see the train pass, the population alongside of the lines traversed evidently realizing that the train marked a new era in passenger transportation.

From Instantaneous Photo Taken Near Elkhart, Ind., by A. J. Horton. Train Running Over Sixty Miles per Hour.

Gould Vestibule, With Folding Steps and Leonard Hydraulic Buffers.

The putting on of this splendid train service is a very important event, since it enables a man to attend to his business in New York one day, travel to Chicago and be there during business hours, then return home in time for business the following day. It practically saves a day for a man who has to go to New York from Chicago, or the reverse.

The train was worthy of marking a new era in railroad passenger transportation, for all previous efforts had been surpassed to secure luxury and comfort for the passengers. The regular train consists of four Wagner coaches. The first is a combination car containing baggage-room, smoking apartment equipped with easy chairs, a buffet equipment, a library, a barber's shop and bath-room, besides lavatories. The three other cars are sleepers, two of them having large state-rooms, which reduce the main body of the car to ten sections. One of the cars has sixteen sections. All are finished in mahogany elaborately carved and the inside is very artistically decorated in designs specially prepared for these trains.

Striking novelties about the cars are the vestibule, the movable car steps and the hydraulic buffer, these improvements having been invented by Mr. A. G. Leonard, secretary to Vice-President Webb. The buffer, which also acts as a rubbing plate, extends across the whole platform, and is held up against the buffer of the other car by hydrostatic pressure. It is so arranged that the water pressure becomes an equalizer, and maintains an even pressure on the rubbing plate all the time. In rounding curves there is always a rubbing surface extending from the coupling or center to the end of the plates. The effect of the arrangement is almost entirely to eliminate the vertical and lateral shocks, the cars riding as if the whole train was one long car.

The platforms extend almost to the outside line of the cars, room merely being left for the width of the steps, which are folded up when the train is in motion, making a platform floor as wide as the car. The arrangement can be readily understood by an examination of the annexed engraving.

The vestibule has already been applied by the Gould Car Coupler Company to a great many cars, and is well known to travelers as the finest vestibule in use.

The train started promptly at 3 P. M. After getting through the long tunnel and over the various obtacles to high speed in the suburbs of New York, the engineer got into the regular swing of about sixty-five miles an hour, which has become familiar to those keeping the Empire State Express on schedule time. When we got clear of the city most of the newspaper men began making notes of the speed. There seemed to be a vague expectation that something striking would be done. Mr. M. N. Forney was one of the men most keenly interested at first. He alternately gazed at his watch and took notes of the time between stations, while Mr. John Player, of the Santa Fe, called off the passing points. Presently the practice got monotonous, the speed of fifty-five seconds to each mile being tiresomely uniform. Then Forney shut up his note-book with an emphatic snap and leaned back in his chair.

"What's the matter, Forney?" queried a friend.

"Well," he replied, "I feel concerning this train's speed as the man did about the minister's sermons. He always went to sleep at the beginning of the sermon, giving as his reason for so doing that he was perfectly satisfied as to the soundness of the preacher's theology. I am ready to sleep and agree to whatever speed any of you fellows may say we have made."

The spirit throughout the train was of perfect faith that the managers of the Vanderbilt lines could run trains at any speed they wanted, and that they would make the time promised. After the first hour it was rare to see any person watching the speed, although those who had not been accustomed to fast riding could not understand that a train going along so smoothly could be maintaining extraordinary velocity.

The engines that hauled the train were of the "800 class," particulars of which are well known to our readers, owing to the numerous illustrations and descriptions we have given them. They are eight-wheel engines with cylinders 19 x 24 inches, the driving-wheels 78 inches diameter. Handling these light trains is away below the capacity of the engines in ordinary weather, but the margin of excess power becomes very convenient in tempestuous weather, for no storm has ever been wild enough to prevent the Empire State Express being taken through on schedule speed. An extraordinary test of the endurance and steaming capacity of these engines was made when the "999" was run on the Empire State Express from New York to Buffalo, a distance of 440 miles.

The engines on the Flyer were changed twice on the New York Central—at Albany and at Syracuse. A slight ripple of excitement was present on the train on part of the last division where the phenomenal speed is usually made. The engineers of the train were remarkable for the uniformity of speed maintained, but the man running the engine into Buffalo could not forego the pleasure of showing off the capabilities of his iron steed. A few miles east of Batavia he tried what horsemen call a spurt, and covered 25 miles in 21 minutes and 26 seconds—an average speed of 70 miles an hour. One mile was made in 43 seconds—a speed of 84 miles an hour. The average schedule speed of the train from New York to Buffalo, or for the same class of train in the reverse direction, is at the rate of 50.3 miles per hour. On the Lake Shore the average speed for the distance of 530 miles is 47.1 miles per hour. The entire distance of 970 miles being made in 20 hours gives an average speed, including stops, of 48½ miles per hour.

The train does not run into the Union Depot at Buffalo, but passes through a cut-off at East Buffalo, thus avoiding the delays incident to the crowded yards. Here the train was coupled to a Lake Shore engine that looked very insignificant compared with the New York Central machines. Keen interest was manifested

by the railroad men on the train to see how the small engines would handle the fast train. They proved quite equal to the work to be done, and reached every stopping place with a few minutes to spare.

The Lake Shore & Michigan Southern is a remarkably fine line for fast running, as there are no curves worth mentioning and the gradients are nearly all less than sixteen feet to the mile. The new engines built for this road to run the Flyer have cylinders 17 x 24 inches, driving-wheels 72 inches diameter and a boiler 52 inches diameter at the smallest ring, providing a total heating surface of 1,413 square feet. A working boiler pressure of 180 pounds to the square inch is carried. The total weight of the engine in working order is 104,600 pounds, of which 65,100 pounds are on the drivers. The general appearance of the engines will be understood by an inspection of the engraving shown in this issue. The engines have every appearance of skillful designing and careful construction. The proportions of cylinders and driving-wheels give 93.3 pounds for every pound of pressure in the cylinders and 14,735 pounds of tractive power when working full stroke, and reckoning 85 per cent. of the boiler pressure as mean effective pressure. The co-efficient of adhesion is 4.4—a low proportion, but likely to be sufficient for an engine that has little starting of trains.

Pittsburgh Compound Eight-Wheeler. Now at World's Fair

The question has frequently been asked the writer since this first train was put on running between New York and Chicago in twenty hours, What did you learn about high speed on the trip? Our readers may also feel like asking the same question. The answer is that it is just as easy to keep up an average speed of fifty miles an hour for 1,000 miles as it is to do the same thing for 100 miles, if the necessary equipment is provided and the track kept clear. The impression imprinted by the trip was that the railroad companies could easily shorten the time one or even two hours if they were inclined to make a great effort.

It may be seasonable to add that the Flyer is already a very popular train. While the number of people going to see the World's Fair is very far behind the expectations of railroad managers, and few people going to the Fair patronize the Flyer, the business men of New York and Chicago are giving it liberal patronage, so much so, that it is already said to be the best filled train running between the two great cities.

## Mineral Wool.

Railroad companies are extensive users of asbestos, but few of the men who handle the material have a very clear knowledge of what it is. The most extraordinary thing about asbestos is its resistance to destruction by heat, and this constitutes its most valuable quality. Although its extensive use in the arts is quite recent, asbestos was well known to the ancient civilizations, but was used for different purposes from what it is now generally devoted to. A very fine quality of fibrous asbestos was called amianthus by the Greeks, meaning unpollutable. They made this material into shirts, and it was a great luxury in this garment, because it could be cleansed by being put on a fire. The cleaning process was done so seldom in these days that nothing short of a fiery ordeal was considered effectual.

Pittsburgh Compound Mogul Now at World's Fair

Asbestos is a silicate of magnesia, and generally contains about 40 per cent. of silica, 40 per cent. of magnesia, and 20 per cent. of lime, iron, alumina and water. The finest of the supply used to be brought from Italy, but this continent now furnishes asbestos that is equal to the best found anywhere, the most select part of the supply coming from Canada.

Asbestos is not considered valuable unless it is suitable working with twisted fiber for the making of cloth and rugs that are used in places where there is danger from fire. The waste left over from the long fiber is converted into packing cement, and the various other forms in which asbestos is used.

In some parts of the country there are large deposits of inferior asbestos which does not have fiber long enough to utilize for spinning. Efforts have been made to utilize this sort of asbestos for making brick arches and for similar purposes. It does not appear to be adapted for the functions to which fire-clay is usually applied, as it disintegrates under a comparatively low heat.

The introduction of asbestos has been of great service to the engineer and to the architect, but there is a tendency to use the material for purposes that it is not adapted to. Because it does not burn, the assumption is made that it will endure any temperature, which is not correct. Asbestos is also employed for a great many purposes for which mineral wool and other cheap substances are just as suitable.

W. G. Wattson, division superintendent, and Jos. B. Stewart, superintendent of telegraph and signals of the West Shore road, have recently invented a signal system for tunnels. One of these plants is in use in the Weehawken tunnel (4,200 feet long), on the West Shore. Every 100 feet there is an electric lamp. These are placed on a line with the engineer's eyes, the tunnel is divided into two sections, and the lamps operated by a track circuit. When an engine goes into the tunnel the outside lamps—lamps are strung 500 feet outside of each end—are put out, as well as those for 300 feet inside, and also every other lamp for 900 feet more. As the train proceeds there is 1,100 feet of lamps that are out, or at danger, behind it. Lighted lamps mean safety; lamps out, danger—stop. The circuit passes through the nearest signal towers, so that at any time the operator can put the lights out in any section or all sections of the tunnel, thus stopping all trains.

## An Unjust Rule.

The extreme reluctance of the Master Car Builders' Association to deal with questions which have not been calling urgently for settlement was very well illustrated at last convention when the question was presented for discussion "In case of vertical knuckles being worn out, would it not be proper to class them with brake-shoes and brasses, the owners being responsible?" The question is timely and the voice of the association ought to have been expressed upon it. These knuckles are wearing parts, and the owners are as much entitled to renew them as they are entitled to bear the expense of renewing brake-shoes and brasses. But the fact is that no rule has ever been so unpopular as that which made owners of cars responsible for the renewing of brake-shoes and brasses when the car is away from home, and the members of the association did not feel inclined to add another source of annoyance, dispute and injustice.

The rule which holds the owners responsible for the renewal of weakening parts when a car is away from home, works entirely in the interest of those who are inclined to act unjustly towards their connecting lines. A case came to our notice lately where a car was sent by its owners in New York State to Pittsburgh, expecting to get it back within a month. After it was away about a year a claim came in from Denver for renewal of brasses and brake-shoes. Then another claim came in from Las Vegas, N. M. Meanwhile, a chaser was searching for the car, and discovered that it had been wandering about in nearly every State in the Union. It was bad enough for the owners to lose the use of their car by fraudulent practices, and it seemed a satire on fair dealing to ask them to maintain the wearing parts when other roads were using the car illegally for their own benefit.

---

One of the attractions of Lakewood, N. Y., as a place for holding conventions is the pleasure and amusement afforded by the fine Chautauqua Lake. The people who go to conventions have about as much liking for water as ducks, and their acme of enjoyment appears to be boating and fishing. The pursuit of the favorite enjoyments sometimes calls for a good deal of personal sacrifice. One party of about twenty persons made a start one morning about 3 o'clock and fished with great persistance till mid forenoon. All the idlers about Lakewood were at the landing, expecting to see heavy proceeds of the long endeavor. They were rewarded with some amusement, for the total was one fish about three inches long. The unerring skill of brother Krauth had saved the party from being whitewashed.

The system of steam heating was fairly successful in passenger trains last winter, yet we learn that a great many private cars, the owners of which adopted steam, are now being fitted with the improved form of Baker heater.

# ?A. What You Want to Know. ?A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(75) J. L., Savannah, Ill., writes

Will you please explain to the Savannah Machinists' Lodge why the left side driving-wheels have flat spots before those on the right side? *A.*—If this is true in more than one case we do not know the cause of it. Think it will be found in one class of engine or under some peculiar circumstance only.

(76) T. W. Boyle, Long Island, asks

I would like to know the proper way to tell which side blows of a Richardson balance-valve, when a spring is broken, without taking off the steam-chest covers, also, of what use is the hole in center of the said valve? *A.*—By covering ports with valve and using steam a heavy blow will occur through hole in top of valve to exhaust port. The hole is put there to relieve the valve of pressure if any slight leak should occur.

(77) J. E. S., Mobile, asks

Having read the article of J. C. Miller in May, upon setting eccentrics before placing wheels under engines, I would ask what would be the objections to using your eccentric instead of template as shown; and why does he scribe circle equal to travel of valve? *A.*—It is always better to use a template to measure by than work laid out by the template; it is handier and there is less liability to make errors. The valve travel circle is drawn so as to determine point of cut off, etc.

(78) Gobo, Auckland, New Zealand, asks

1. Can you tell me how much an engine will increase her lead when hooked up close to the center, when she has, say, ⅛-inch lead in full stroke? *A.*—This all depends on the length of the eccentric rods or blades, the shorter these are the more the lead will increase as the links are hooked up. In this country we have some engines with less than 30-inch eccentric rods that increase their lead from $\frac{1}{16}$-inch in full gear to ⅜-inch at 6-inch cut-off; engines with rods about 80 inches long scarcely double their lead. 2. Does an engine with a stationary link increase lead by hooking up or not? *A.*—No; lead remains constant. 3. Are there any Joy gears in America; could you illustrate them? *A.*—There are only three or four locomotives with Joy gear in this country. 4. Could you give me a record of the accidents caused by drink and by excessive hours of duty? *A.*—There is no record of the *cause* of accidents kept in any country that we know of; the two mentioned are well up toward the head of the list.

### Novices in Sleeping-Cars.

The travel to the World's Fair is giving a great many people experience of sleeping-cars who never had been inside of that kind of car before. An observant man hears and sees a good many funny things said and done by the unsophisticated folks who are gaining their first experience in sleeping-cars. During a recent journey in Iowa the writer was greatly amused with a party of men, women and children who took possession of the sleeper. They appeared to have brought a large part of their household goods along and enough provisions to feed the party during a two weeks' stay at the Fair. On entering the car they began depositing their loads on the seats that were freest from impediments, and my section was quickly filled up till it looked like a pawnbroker's shop doing a thriving business. My head looked like a jack-in-the box peeping out of a case formed of sachels, bundles, rugs, cages and paper boxes.

The party comprised several men and matrons, a number of girls verging on womanhood, some three-quarter grown boys and a lot of promiscuous children. The girls began at once to exclaim about the wonders of the car, and one, who was particularly ill-bred, never ceased to shout revelations of her ignorance and want of sense. When the porter began making up the beds she giggled incessantly, and yelled remarks about how different he did things from what they did "to hum."

Not liking the idea of being pinned into a corner by other people's baggage, I mildly requested that the owners take their goods and chattels to their own seats. This appeared to give general offense, and scornful glances were darted at me from many eyes. Shortly afterwards, I went to the smoking-room and there met one of the men of the party and had a pleasant chat with him, giving some suggestions about sleeping-car etiquette. When we returned to the body of the car, he vindicated me to his friends by shouting loud enough for all in the car to hear "The old idiot is not such a bad fellow, after all! He told me how to dispose of my clothes when going to bed."

This was Uncle Ralph. He now became the oracle of the party on how to proceed in a sleeping-car. He explained what I told him—that there was a hook at each end of the berth where clothes could be hung, and a net extending the whole length for holding small articles. The first decided excitement of the evening was caused by a bevy of the women taking possession of the men's lavatory. With some difficulty they were turned out of that place by the porter. When the party began to retire, questions were showered upon Uncle Ralph:

"Oh, uncle, where can I put my bonnet? Uncle, shall I put my shoes in the net?" One girl asked her mother in a penetrating whisper to find out where the article was deposited which Byron refers to in the lines:

"They searched beneath the bed, and there they found—
No matter what, it was not what they sought."

But the most general interest of the people in the car was manifested when a young fellow reached over the rail of an upper berth and called out "Uncle Ralph, shall I take off my pants?" On the answer being in the affirmative, scarcely less fun was caused by his further question, "But how will I get them on up here in the morning?"

The party was up before the lark in the morning, full of chatter about the experiences of the night. They were getting accustomed to the strange surroundings, and the only bad breaks made were—one of the men sitting on the front of the bed changing his linen and a young matron using one of the basins in the gentlemen's wash-room to wash a child's soiled linen.

When the berths were made up, the materials for a princely breakfast were drawn from hampers, boxes and bottles. Fun and good humor prevailed and the experiences of the first trip in a sleeping-car are likely to form the subject of many a story for years to come.

---

A correspondent writes asking if the report, published in the *N. Y. Press*, that an Ontario & Western locomotive ran at the rate of 144 miles an hour, on the 25th of May, is true. We think the daily press reporters are a little intoxicated on the 100-mile-an-hour elixir. It has never been made yet—except on paper.

### The Rise and Fall of the Erie Foremen's Mutual Admiration Society.

"A long time ago," said the Erie man, reflectively, "but not so darned long ago, either, we had a comical thing happen in the Jersey City shops.

"One of the foremen who had been located at an out station was ordered into Jersey City and given another job.

"His duties concerned the roundhouse work, which gave him some time to loaf in the shops and chin the other foremen.

"This man conceived the idea of forming an association of the road's foremen, as he said, for sociability and good fellowship.

"He named his idea to old man Boyle, the boss boilermaker, and Boyle at once said it was a good scheme, and added that the occasions of meetings could be made pleasant by a little presentation of something from the association to some one who had done something to make things pleasant.

"The old man proposed that they all meet the next day at noon. This suited the father of the order.

"Boyle was a dry old Scotch joker, and he at once went to all the foremen, put them on to the racket, and collected four cents from each to get a present for the founder of the Mutual Admiration Association.

"The next morning, at 11 o'clock, he slipped out, and returned in half an hour with a new Knox hat-box under his arm.

"When the whistle blew, the foremen, one by one, dropped into the boiler shop, and the father of the M. A. A. caught sight of the box, gave a shrewd guess where it was going, and kept in the background with commendable modesty.

"They had just got together when Master Mechanic Vreeland wandered into the shop, and was at once in a quandary as to the cause of the meeting, while strikes and demands for more pay flitted across his mind.

"But Boyle was equal to the occasion. He went right over to Mr. Vreeland and told him just what had happened (except what was in the box), and asked him to make the presentation speech.

This was a job that Mr. V. was peculiarly fitted for, and he made a happy little speech presenting the founder of the association with a hat, and hoped that their meetings would be pleasant, and that some such episode would occur at each gathering to bind them closer, etc., etc.

"'Speech, speech,' greeted the founder as he came forward to receive his present, and he made a feeling reply, in which he said that he should never wear this present without remembering each and all of his fellow workmen—it was entirely unexpected, etc., etc.

"There was a little awkward delay for a minute, and then Mr. Vreeland said

"'Well, put it on and let's see how you look.'

"With an 18 x 24 smile and a palpitating heart the founder of the M. A. A. cut the string and lifted the cover, a package in tissue paper was carefully lifted out, and he held up—not a hat, but one of those plain, every-day pieces of crockery, without which no well-regulated bedroom is complete.

"The M. M. was as much surprised as anybody, and as soon as he realized how ludicrous the whole thing was he made a sneak for the door and did his laughing outside.

"The founder of the association poised his present in the air for a minute, as if in doubt what to do, and then dashed it to pieces against a stack of crown bars, and that was the last meeting of the Erie Foremen's Mutual Admiration Association.

"Old man Boyle liked to got apoplexy laughing, and I really believe that there has been more fun out of that one meeting than if the order was in full swing yet."

### Don't Forget to be Heroic.

We often hear after accidents happen that certain enginemen stuck to their posts and were willing to face death and mutilation rather than do what in Colorado is called "striking the sod."

This is all right in theory, but in practice men with nerve try to save themselves after performing the little all within their power to save the train. There is not generally much time for reflection, when an accident is impending, much less for the expression of pleasantry and joking. Exceptions, however, sometimes happen.

On one of the Eastern railroads lately, where very high speed is common with passenger trains, the side-rod of an engine broke while running at a terrific velocity, and the broken parts were smashing things at a lively rate. The running-board and part of the cab disappeared like a flash, and Tom Maloney, the fireman, described an acrobatic feat in the promptitude with which he got to the back part of the tender. Philip Rogers, the engineer, was a little bewildered at first with the flying fragments of wood and iron, and the screaming steam, but he had sufficient presence of mind to shut off steam and apply the air-brakes.

Suddenly looking around and seeing Maloney in a place of safety, he began climbing up on the tank. On seeing this, Maloney exclaimed in a tragic voice, pointing his finger at the man who was deserting his post, "Phil Rogers' go back to your post, you son of a gun, and die like a hero." Philip did not rise to the heroics of the hour, but staggered back, and wanted to creep into the tank, from which humility he was saved by his cool-headed fireman.

### The End of It All.

A religious service was held in Chicago last month for the benefit of colored railroad men. There is an idea prevalent that railroad life of any kind is sadly demoralizing to those who follow it, and religious people particularly believe that profuse spiritual nourishment is necessary to neutralize the contaminations that all railroad men must receive.

At the Chicago evangelist meeting referred to, the most persuasive colored preachers of the land raised their voices in warning against the moral dangers of railroad and sleeping-car life. A layman who had been there agreed generally about the hardships of sleeping-car life, and dwelt distressfully on the iniquity of the growing custom that passengers are falling into of giving the porter only ten cents. De dime passenger was pictured as the most contemptible being that roamed the earth.

One of the elders waxed very eloquent on temperance. His peroration was striking. "Brudders," he shouted, "you hab too many high examples to 'scuse de sin of drinking. But beware of de habit. I'se heartrended to know dat drinking is encouraged in dis great Gomorrar by M. D.'s, and D. D.'s, and Ph. D.'s, and LL. D.'s, but dey will all bring up in Hades, where dey will be everlasting dry."

---

Trainmen in New Hampshire are about to receive the benefit of an Act passed by the last Legislature, requiring railroad bridges to be raised sufficiently to allow trainmen to stand on the tops of cars without being knocked off. There are so many low bridges in New England that a brakeman's life is very precarious, and a change was very much needed. We think, however, that a more progressive plan would have been to give the railroad companies the option of putting air-brakes upon their cars. This is an improvement that the Interstate Commerce Law will require to be carried out soon, and it is scarcely right that the railroad companies should be required to spend a great deal of money on bridges, when the necessity of men going on the tops of the cars will soon be ended.

Effect of a Lap Order

## The Real Inventor of the Steam Engine.

We think that there is an important link left out of the most interesting chain of locomotive development which the Baltimore & Ohio Railroad display at the World's Fair. They have embodied Sir Isaac Newton's ideas of a locomotive in a model, but they leave out the first practical steam engine whose performance led the way to locomotives being introduced. This first practical steam engine was built by two mechanics, Newcomen and Cawley, of Dartmouth, England, and contained the essential part which succeeding inventors and engineers improved upon. It had a cylinder and piston. Numerous other inventors and philosophers had tried to make steam do work, but they could not devise any sort of practical harness.

The Newcomen engine was an exceedingly crude machine, but it was the real genesis of our vast array of steam machinery. The engine was built in 1705, and it set the wheels of progress in motion as no other invention has ever done. Nothing else ever invented exerted half as much influence on the world. No event in the whole history of the world is equal in importance to that of these two mechanics putting their all into the construction of a machine to be moved by the power got from steam. The World's Fair ought to have honored these men, but we have seen nothing in Jackson Park that would serve to tell what Newcomen and Cawley did for mankind.

The progress of the steam engine dates from Newcomen's time, and there has been constantly a reduction going on of the quantity of fuel required to do a given amount of work. Newcomen used steam of atmospheric pressure to produce a vacuum under his piston, and the cylinder was employed as a condenser. The engine was not automatic in its action, a boy having been employed to open and close the valves. The engine made about ten strokes a minute and raised at its best 105,000 foot pounds of water to the pound of coal consumed.

Smeaton, one of the most famous engineers of last century, directed his attention to the Newcomen engine and effected various improvements upon it, among others giving it a valve motion. He raised the steam pressure to 8 pounds above the atmosphere, and succeeded in raising 120,000 foot pounds to the pound of coal used in the furnace.

James Watt got a model of a Newcomen engine to repair, and having some knowledge of natural philosophy, perceived that great loss of heat was occasioned by the cylinder being cooled down in order to form a vacuum at each stroke. He applied a separate vessel for a condenser. With steam of 10 pounds pressure he raised 320,000 foot pounds to the pound of combustible. Engines like what Watt used can now be trusted to show a duty of 600,000 foot pounds when using steam of 50 pounds pressure. The best forms of compounds with boiler pressure of 150 pounds now give a duty of 1,200,000 foot pounds per pound of fuel. Newcomen started this.

### A Reminder of Wood-Burner Days.

Old-timers who loved and swore by Mason engines—and there are many of them—will be glad to see the pictures of some old friends shown herewith. For his time, Wm. Mason built the best-looking and neatest-proportioned engine in this country, and but for size his engines would show up well with the crack engines of to-day. That the works kept abreast of the times in design is shown in the trim-looking "66" on next page, for the Old Colony, that was one of the last machines turned out before they gave up locomotive building.

STRAIGHT-BOILER MASON, LONG A FLYER ON THE LAKE SHORE.

ONE OF THE LAST FIVE-FOOT GAUGE ENGINES, BUILT BY MASON FOR THE ATLANTIC, MISSISSIPPI ... —NOW NORFOLK & WESTERN.

### How the Merit of American Locomotives was First Established.

In the July number of LOCOMOTIVE ENGINEERING there was a picture of the first locomotive built by the Norris Locomotive Works, Philadelphia, to be seen in the Baltimore and Ohio exhibit at the World's Fair. The engine is not a very imposing looking machine, but she is nevertheless well worthy of examination, for it was a close successor of this one, built almost on the same plan, which first gave the American locomotive a reputation abroad.

When railroad building first began, the British workshops were in a good position to build locomotives, for a vast business was already carried on in making other classes of machinery. American workshops were trifling in comparison, and many railroad companies on this continent looked upon England as the natural manufactory of locomotives. Consequently, the John Bulls, as they called several of the first imported locomotives, were looked upon as the best that could be made. Railroad men on this side of the Atlantic had no more pride in home-made locomotives than their daughters had in home-made dresses when the products of Paris could be purchased. A Norris locomotive sent to the home of the enemy proved superior to the best that English makers could put in competition.

In 1838 the Birmingham & Gloucester Railway was finished, and one part went up a hill with a gradient of 1 in 37, or nearly 143 feet to the mile. This grade was known as the Lickey incline. Such a grade was unprecedented in England for locomotives, and the most eminent engineers of the time, among them Brunel and the two Stephensons, expressed the opinion that it was impracticable to operate such a grade with locomotives.

Captain Moorson, who was chief engineer of the road, had heard about the extraordinary tractive power of American locomotives, and made up his mind to try one of them. He came to Philadelphia and returned with a Norris engine.

The day on which the trial of ascending the incline was to be made, a large crowd of spectators was there to witness the sight, many engineers and locomotive builders being present. The "Yankee," as the Norris engine was dubbed by the rival interests, went up the incline 2½ miles long with a load of 34 long tons at an average speed of 14½ miles an hour. Mr Burry, the famous English locomotive builder, was present and declared that "whatever American locomotives could do his could equal." He went to Liverpool and brought one of his best engines. This engine without a train was permitted to make a run at the hill, but she failed to go up, and the builder brought her back amidst the jeers and laughter of the crowd.

Owing to this triumph, the Birmingham & Gloucester Railway was equipped with Norris engines. The fame of the performance was the means of obtaining for Norris a contract to equip the Russian Government railways with locomotives, and the merit of American locomotives was established the world over.

### Breakage of Frames and Cylinders.

A discussion which arose at the Master Mechanics' Convention concerning the breaking of frames and cylinders was very seasonable, for this is a species of trouble experienced on nearly all railroads having heavy locomotives at work. The breakage of a frame or a cylinder is so expensive and causes so much delay that any information throwing light on the causes of breakage will be welcomed by all persons embarrassed by the difficulty. Quite a number of members spoke upon the subject, but we consider that the remarks made by Mr. J. M. Boon, of the West Shore, cover the whole trouble. Mr. Boon said:

"The starting-point is bad workmanship. Almost invariably, when a cylinder works loose on the frame it will be found on examination that the bolts originally put in were not a good fit—were too loose. At the very moment there is the smallest particle of play there, it makes a starting-point for breakage. Another cause of frames breaking is that too large-sized bolts are put into the frames. I know of locomotives that have got frames 4 inches wide and they have got 1¼-inch bolts

th ... se frames to hold the cylinders.
Tl ... way more than 25 per cent. of
th ... of the frame with that bolt
Tl ... is the frame breaks through
th ... it could not be otherwise.
... ne line of weakness exists to
ac ... cylinders working loose. We

...now increasing the diameters of the cylinders. We are throwing up the centers of the boilers far above the cylinders. The leverage due to the distance between the center of the boiler and the center of the cylinder, in comparison with the old practice, is enormous, and in working full steam on these cylinders with boilers carrying from 150 to 180 pounds pressure, the strain there is terrible, and yet we find locomotives that are going out, designed for that kind of practice, with a cylinder plate too small, too light. The result is the moment the engine gets working, something must go. If it is the frame that is the weakest point, it is going to break there. If it is the cylinder, it is going to let go there.

Another thing, a great many cylinders are cast that are not properly designed. We all know that in making a casting like a cylinder, the difference in shape, the change of circle and changes of direction, the disposition of metal—all have to be taken into consideration. Yet you will find large masses of iron placed in one point while another part is light. When the cylinder is cast trouble commences. It is cast on a ...—unequal expansion, and the cylinder gets hot and cold alternately, and the ...e comes, and very rapidly, when something is going to let go. The only way to stop frames from breaking and to get cylinders to last is to make them right at the start, and you will then have no trouble."

ONE OF THE LAST ENGINES BUILT AT THE MASON SHOPS.

### Steel-Making.

At the last Master Mechanics' Convention a resolution was adopted requesting Mr Samson Fox, the well-known steel-maker of Leeds, England, to speak on steel-making before the Convention. Mr. Fox said:

"Gentlemen, I consider you have done me a great honor in asking me to say a few words on the all-important question of the material of which our boilers have to be built. I would, in the first place, ask you to consider that I did not come here in the character of a teacher. I did not come to teach any one his business. But, happening to be in this country for the last few weeks, I have met a number of gentlemen who are interested in the question of firebox plate. No; steel plate for the purpose of fireboxes at sea has been with me a considerable manufacture for a long number of years. I think if I was to say to you that I have turned out within the last fourteen years at least 100,000 tons of firebox plate, which have been used solely for the purpose of making steam furnaces, I should be within the mark. You know very well that a man who has done a large amount of work must necessarily have made a large number of blunders, and it is out of the blunders that he finds what may be considered the best way of keeping on the straight path. (Applause.)

"First of all, I would put what I have to say more on the basis of what we consider is right at the present time. There may be great improvements yet, I dare say there will be. But what we consider in firebox plate-making, first of all, is to select very pure materials. That is to say, we will take pig iron, which contains in nature the smallest amount of sulphur and phosphorus. We do not mind very much about the amount of carbon. But we must have these two enemies, sulphur and phosphorus, away from the material that we start with. Further, we consider that it is necessary to know exactly the composition of the fuel that we use in every part of the work, so that the gas from the fuel has the same value in purity as the pig iron that we have already started to work with. Bridging these together, and both being cleared from these very serious enemies, sulphur and phosphorus, we may then go to work and expect to obtain a fair, reasonable result. But it is important also that the linings of the furnace, such as the sand and the ganister that we use, and also the bricks of which it is composed, shall be as pure as the gas and the pig iron.

"Now, bringing these materials together in their various forms and getting the chemical actions of one on the other, none of them possesses the qualifications to bring in with it something that it never contained, and, therefore, when the action is thorough there is no doubt that after such a start you will get as a result a pure plate. That is to say, that it should have for firebox purposes about .11 of carbon. You may put from .50 to .55 of ferro-manganese into it, but you should get your sulphur and phosphorus down to as low as .04 to .05. If you do that you will find that you have got a material which, if properly manufactured from the ingot down to the shorn plate, will do almost anything as regards standing fire and every other manipulation of turning it into a first-class boiler.

"But there are some considerations to be given to the manipulation. I believe, in some factories in this country, it is thought not necessary to put any work on to the ingot. That is to say, that the ingot is rolled direct into the plate. We hold a different opinion. We prefer for the best class of work to hammer the ingot, reducing it from about a 15-inch thick ingot down to about 5. Now, that ingot is hammered on the flat and it is hammered on the edge and the ends are cut off. But even after that it is necessary to exercise care in reheating such a slab, because we all know that we are troubled at times with lamination in the plates, and it generally occurs at the end of the plate. That has been clearly proved over and over again to be the overlapping of one side of the plate over the other, and in practice you will often find that men who are rushing their work will bring out their slabs not so well heated on the one side as on the other, and the consequence is that when such a slab enters your roll the soft side will run ahead and draw farther than the hard side, and the hard side is, as it were, rolled partially into the soft slab. Consequently, you will find that one part has overlapped the other. This may not show itself, even when the plate is short, even when it has been annealed, but still it will show itself in working some day. If that same chemical contact does not exist from the beginning to the end, and in every cubic inch of the plate, it will show itself when it comes to deal with the expansion and contraction due to its work in the boiler.

"Now, it should be the question for the user of such plates to buy only on the condition of certain mechanical tests and chemical composition. If a committee was to look fairly into the different tests set forth either in France or in Germany, or in England, they would find that there is a steadfast growing of the principle of standard tests, especially for firebox work. Those tests need not be anything further than specified, and the inspectors ought to see the plates tested on these grounds. The Board of Trade and the Admiralty of England, and many other associations such as Lloyds, and Bureau Veritas, set down that a piece of material shall be cut from a plate which shall in 10 inches of length extend from 20 to 25 per cent. The British Admiralty is 25 per cent. as the minimum, so is the Russian Admiralty, so is the French Admiralty. But the Board of Trade go down as low as 20 per cent., so that the elongation shall be, whether 20 or 25 per. cent. the elongation taking place within 10 inches of length pulled in an ordinary testing machine. In addition to that the Admiralties fix a standard of tensile strength. They say it shall now be more than twenty-five tons to the square inch, and they usually say it shall not be less than twenty-four—that is, our gross tons of 2,240 pounds. Now, if you are bound within the range of ton, you have got to have your chemical composition pretty uniform all through all the plates you make, and if you get an elongation, such as I have mentioned, of 20 to 25 per cent., that is a material that will be very good work.

"There is another point that I might mention in practice. We have found by experience that there should be a little difference in the amount of carbon, according to the thickness of the plate you are making. For instance, if you start with .11 for a quarter-inch plate and you are going to make half-inch plate which shall bear the same twenty-five tons and not lower than twenty-four, and with the same elongation of 25 or 20 per cent., then you must put a little more carbon into the half-inch plate than you did into the quarter-inch plate, and so on with the three-quarter-inch plate, and so on with the inch-plate—a little more still. If you keep the same carbon and expect the same tensile strength, you won't get it, because your material is made more dense in rolling down to a quarter plate than to a half-inch or three-quarters. These are features that have led to a pretty fair success on our side. I have made many thousands of tons of plate where we have undertaken to be only not more than ten hundred-weight on either side of a given point. In our thickest shell plate, at twenty-seven tons, I would not be more than ten hundred-weight on either side of the twenty-seven, and that can only be done by watching the carbon as to the thickness of the plate. We have been very successful indeed by varying the carbon.

"I am sure that, in this country, you have all the raw material that any one else has, in coal and in pig iron and in fire clay. You have all the conditions of purity of material, and if the purchasers and users of the plate were to lay down a standard of purity, and strength and elongation, that would be the very first thing to do, in order to get that uniformity in your firebox which is so much required. Of course, at first, your inspectors would have great trouble. They would have to throw out a good many plates. No one has any idea of the want of uniformity in plates, who has not acted as an inspector to the firms that are not so closely pinned down. The maker finds that he has got a good lot of material thrown out, and there is nothing like having such a lot of material thrown out to make him find out what is the right thing for him to do.

"I am very pleased to have had the opportunity of speaking to you. I want you clearly to understand that I do not say what I have said in any spirit other than as a suggestion, drawn from what we have learned in our experience on the other side, especially my own firm." (Applause.)

---

The railroad companies running freight cars equipped with air-brakes are beginning to complain that the work of holding nearly all trains put upon the small percentage of cars having air-brakes is seriously increasing the expense of repairs. It is understood that the running gear of the cars must be made stronger, and all new designs are prepared to make the cars equal to the heavier strains put upon them. If the hard usage due to the use of air-brakes makes heavy repairs necessary to a car in the first few years after it has been built, it is likely to bring little profit to its owners. Some years ago a leading member of the Car Accountants' Association reported that the profits made by a car were nearly all earned in the first five years of its life. After that its mileage was so much reduced by the delays getting repairs that it practically cost as much as it earned.

---

Two new patents on improvements in compound locomotives have been lately granted to Mr. Vauclain, superintendent of the Baldwin Locomotive Works.

---

The *Railroad Car Journal*, of this city, has issued in pamphlet form an abstract of the decisions of the M. C. B. Arbitration Committee for the use of those interested in car interchange who do not keep the complete reports of this committee on file. The abstract makes a very complete index for the reports, and is, therefore, very handy.

### Unexpected Information From Tests.

There are too many tests of devices intended for use in railroad rolling stock that are made with a set purpose in view. A certain result is expected and everything is done to aid in bringing about what is desired. In too many cases this brings temporary success to articles that do not have merit. If knowledge of the real value of a device is wanted, it ought to be put in the hardest service to be found and kept there long enough to demonstrate what it is worth

A very good practice was mentioned by G. W. Rhodes in the course of a talk at the Master Car Builders' Convention. He said

"We sometimes find things on our lines in an unsatisfactory condition and we branch out in an endeavor to get something new. We should remember that we do not know anything about the new device—do not know of its bad points—although we do know the bad points of what we have tried of old. To select for a test the under part of a freight car we take what is probably the worst place It has been our practice to make our tests under the tanks of our engines In a good many cases we have had a curious sort of reply from those interested in the devices we are testing We are told they were not intended for tanks but for freight cars I do not attach importance to these replies The results I get under the tanks in three or four months would take me three or four years to get under a freight car Take the matter of brake-beams We have got some very interesting information from tests of freight-car brake-beams under tanks The manufacturers say their beam is not intended for tanks but for freight cars The brake-beam companies should recollect that tank service is not as hard a service as that obtained on a quick-action brake freight car. In making investigations, I believe if you put your truck under the tank the results will be much more satisfactory."

### Williams the Inventor of the Link Motion.

On another page of this paper we publish an interesting article from Mr. James Hedley, giving some reminiscences relating to the invention of the link motion. As Mr Hedley was an apprentice in Stephenson's works, at Newcastle, when the link motion was brought out, his views concerning the invention are of historical value The account generally current in engineering historical works, concerning the invention of the link motion, is that it was proposed by Mr Williams, a gentleman apprentice in Stephenson's works, and a sketch made covering his ideas. This drawing was given to George Howe, pattern-maker in the works, who found that the plan proposed by Williams was impracticable, but improved upon the invention and produced a link motion that worked satisfactorily.

The important point made by Mr. Hedley is that the drawing made by Williams was all right, and that the model made by Howe merely covered Williams' ideas, but that Howe tried to steal the credit of being the inventor of this important improvement. We are glad to be the means, at this late day, of publishing the real facts of the case

### The "Lord of the Isles."

This famous old engine, of the now extinct 7-foot gauge, attracts a great deal of attention at the World's Fair, and she is indeed a fine piece of work for 1851, the date of her building It will be interesting for our readers to see a picture of this engine "as she was. Many believe she has been much rebuilt in the last forty-two years. Our picture was taken of her as she was decorated for her run carrying the news of the close of the Crimean War in 1854. It will be seen by those who visit the Fair that she is unchanged. The fancy decorations off, and she was then as she is to-day—a fine piece of work. We got this picture from T Moore, of 1 Channing Crescent, London, N., England, who is a dealer in photographs, and has a very large collection of foreign locomotives. Those who have been asking us for English pictures should write Mr. Moore.

LOCOMOTIVE "LORD OF THE ISLES."

### Developing Railroad Shop Tools.

We frequently find railroad shops nowadays that are far from being well provided with tools for doing work properly, but our poorest shops are well off compared to what the best were fifty years ago. The following is a description by Mr. James W Holmes concerning what a Yankee master mechanic had to do when he took charge of what were then the shops of the most important railroad on this continent, the Philadelphia & Reading

"In the fall of 1843 that wide-awake engineer, mechanic and draughtsman and noble Yankee gentleman from Lowell, Lewis Kirk, was engaged and took charge of the shops on the 1st of October. At the time that Mr. Kirk took charge of the shops here there was but very little machinery. All that was here was one small lathe that would swing about 6 inches, used for the brass work for necessary repairs, and run by that old engineer, Thomas Barnet, one other small lathe, used for turning iron ferrules to drive into the copper flues at each end of the boiler to keep them from leaking; one good strong slide lathe, built in Norristown by Hugh Reed, and one old lathe placed on wooden shears for turning car axles, and two old lathes bought of the Reading Locomotive Works and used for turning engine and car wheels.

"Here I must explain to some of the rising generation, as I do not think there are ten men now employed by the company who know that at that time there were lots of freight cars on the road that had wrought-iron tires on their wheels the same as a locomotive. Three of these lathes had nothing but wooden shears for the heads to stand upon. There was also one old drill-press, and that was of no account.

"Mr Kirk saw the need of more and better machinery. He began by building a machine for planing iron, and an upright boring machine for boring car wheels, and followed this up by building other machinery of different kinds, such as a heavy all-iron large lathe, drill-presses, other lathes, planing machines, steam hammers and other machinery.

"In the following year he commenced to rebuild the old engines. He rebuilt two of the English for passengers. One he named the 'Antelope' and the other the 'Gazelle.' He altered these engines by taking one pair of wheels away, enlarging the other pair by welding out the spokes and placing a truck in front. These engines were put upon the passenger trains for a while, and certain men who claim the honor of having run the genuine 'Rocket' (but never did) may have run one of these engines. Mr. Kirk, about the latter part of 1844, began the erection of a brass and iron foundry alongside of the other shops. About this time, and during the beginning of 1845, he built the forge on the ground where it still stands, and commenced making the company's own tires for engines, which no other railroad in this country, or, I believe, in the world, did at that time. I think there was at that time but one place in the United States that made tires. They were nearly all imported from England."

### A Car with a History.

There is a car with a history running on a branch of the Nashville, Chattanooga & St. Louis which entitles it to consideration when it is the fashion to bring all historical members of the rolling stock family into notice. This car is worthy of attention for several reasons. It is old, and has traveled miles enough to give it celebrity. It is a novelty, inasmuch as it is made entirely of iron, and is a relic of very interesting events of the war.

The car was built by the United States military authorities, and was made of boiler iron, with doors of the same material. For several years it was used as a traveling powder magazine, and its regular purpose was the transportation of powder and ammunition to the Federal stations in the South. The car afforded perfect safety to its contents from those terrors, the bushwhackers, who threw away their ammunition in practicing upon the iron car, as their bullets flattened on its sides and did no harm. After following the armies all over the Southern States for four years, the iron car lost its mission with the return of peace. It was then sold with other railroad plant, and fell into the hands of the present owners.

For fifteen years the iron car was used as a baggage car on the Shelbyville branch. Then it was taken to the main line and used as an extra baggage car and sometimes for carrying passenger train freight. From that it was sent to the Lebanon branch, where it still does regular service for baggage

---

The Pennsylvania Co. have changed their new compound from oil back to a coal burner. She will soon be tried on the New York division, where her seven-foot legs ought to make some show at the world's record.

---

We received a great many complimentary notices about LOCOMOTIVE ENGINEERING and are careful not to bore our readers by repeating them. A letter that came in lately from Erie, Pa., is, however, too much for our self-denial. It was written because the paper had not been delivered, and added. "Although I am only a boy and I suppose my opinion won't count much, I wish to say, that for my part, if I could have but one paper in the world, that paper should be LOCOMOTIVE ENGINEERING. I begin about the 15th to wish for the 1st of the month, so that it will be time for the paper to come."

### A Fracas with Bushwhackers—An Undesirable Uniform.

In 1864, from among the loyal Georgians the Federal Government recruited two regiments of cavalry at Dalton. One of the trains loaded with arms, clothing and horse accouterments for these regiments

IN THE BLACK HILLS. SHIRT-TAIL BEND, IN DEADWOOD GULCH. GRADED THROUGH ORE WORTH $25 PER TON.

passed Tunnel Hill about 6.30 A. M. one fine morning, engine 136, Dan Clendening engineer. When near a small trestle the iron got too short, resulting in a bad wreck of the thirteen cars of the train, twelve of them followed the engine into the ditch and all hands "took to the bush." The train guard immediately formed lines on each side of the train, expecting to be attacked by guerillas. Two men were started back to flag trains following, and to notify the wrecking crew of the wreck; also, to have the commandant send reinforcements to the relief of the train guard.

Col. Ford of the Twenty-second Connecticut dispatched two companies of his regiment to the wreck. The soldiers who came back told us that the old fortifications at Buzzard's Roost were full of bushwhackers ready to attack their men; that the train was loaded with supplies for the first Georgia cavalry and would be a fat take for the "Johnnies."

As soon as possible we followed the soldiers and soon arrived at the wreck. The guard of the wrecked train had succeeded in holding the train until reinforced by Col. Ford, who had deployed his men as skirmishers on the mountain south of the track, where they could search the woods and old fortifications for "Johnnies," while we proceeded to clear the track for the passage of trains.

While looking over the situation and giving orders, Seth H——s, the wreck master, found a car loaded with uniforms for the First Georgia. It being a beautiful morning and Seth feeling a little "kittenish" thought it would be fun to dress himself in soldier clothes, so he donned the uniform of a cavalry sergeant, saber and all. The first I knew of this was when I heard the command, "Attention, squad." The men had got out the rigging and were ready for a pull. "Engine to the rear, march, steady," commanded Seth. I had just caught on to what he wanted, when the "Johnnies" opened fire on us from the north side of the road.

Fortunately none of our guard or crew were killed or wounded. After the volley, Lieutenant Wilson, commanding our train guard, gave the order to his men to deploy as skirmishers and look out for themselves. While all this was going on Old Seth was lying as close to the ground as possible, trying to get out of his soldier clothes, but he had become entangled in the harness of the carbine and saber and was making but slow progress of freeing himself. In his excitement he began calling for help. I had been hugging Mother Earth as close as possible on the side of the engine farthest from the danger. Seth's cries sounded so pathetic I went to him, thinking, perhaps, he was wounded and needed assistance. When I got near him I asked what the matter was; he replied "For God's sake help me out of this pesky rig; for if the 'Johnnies' get us and find me togged up in soldier clothes and with arms in my hands it is Andersonville sure."

IN THE BLACK HILLS. B. H. & FT. PIERRE CROSSING THE DEADWOOD CENTRAL.

Here let me say they always paroled railroad men. As there was but one volley fired, we very soon were at work again, but I had to do all the bossing on the north side of the track until Lieutenant Wilson and his gallant Spencers came marching down the mountain with thirty-nine bushwhackers, twenty seven horses and a mule. The bushwhackers had divided into two squads, one taking the north, the other the south side of the track. The squad on the south side retreated before the superior force of Colonel Ford, for the purpose of giving the squad on the north side an opportunity to overpower the guard in charge of the train; they had made no calculation on the wrecking crew arriving so soon with an additional guard of forty-two tried and true men armed with Spencer rifles.

The First Georgia received their clothing and accouterments and did some good work in the mountains around Dug. and Carter's Gaps. I know several of their widows who are receiving pensions from Uncle Sam, also several of the men who lost an arm or a leg in the good cause.

JAS. H. HESLEY.

*Rome, Ga.*

### Testing Locomotives on Rollers.

Some years ago, the authorities of Purdue University, at Lafayette, Indiana, purchased a Schenectady locomotive, and set it on rollers as large as driving-wheels, for the purpose of running the engine so that the university students might receive instruction concerning the handling and operation of a locomotive. When the engine was put in running order, it was discovered that many things could be found out in the working of this engine that could not be correctly ascertained in road-service tests. Accordingly, the American Society of Mechanical Engineers and the Railway Master Mechanics' Association have determined to make tests of locomotives on the Purdue University apparatus, for the purpose of finding out things that cannot be settled by road service.

At the last Master Mechanics' convention, Mr. D. L. Barnes gave interesting facts concerning the working of the Purdue University locomotive. He said

"The locomotive is mounted on a pair of carrier wheels exactly like a pair of locomotive drivers. It is provided with the same force, makes the same noise and acts exactly as a locomotive does on a road, excepting such things as pertain to the road-bed. I have never been an enthusiast for shop tests, believing that there are a great many other things that cannot be settled on the road. For instance, no one knows how to set the valve for a compound locomotive, so far as I know, to get the best results. No one knows how large to make the receiver, or the proper ratio between the cylinders of high and low pressure The two-cylinder compound locomotives are getting lots of trouble for the lack of that knowledge, and four-cylinder locomotives are giving a lot of trouble because the valves are not properly arranged We

IN THE BLACK HILLS. THE F. E. & M. V. CROSSING THE DEADWOOD CENTRAL.

have not yet seen, as I said the other day, an indicator card from a compound locomotive at sixty miles an hour that is a credit to the engine or that is as good as a card taken from a simple engine at the same speed. It has been asked whether it is economical to run a locomotive with the throttle partly closed or wide open. That question was settled by the Purdue University last year They tried that test, wire drawing from 180 to 140 pounds As had been predicted before, the wire-draw- produced superheating. The super- ating was as much as 25 degrees, but economy fell off immediately. The . of potential or the loss of possibility of doing work by losing pressure due to wire-drawing makes a loss of 20 per cent in the efficiency of the engine In every case where the dry pipe pressure was 60 to 80 pounds less than that in the boiler, the loss was from 15 to 25 per cent Such a question as that is very much better settled in the laboratory

"Then, again, in regard to counterbalancing. We have never known, so far as I am aware, just what to do This Schenectady engine was built with great care. They are known to make very well counterbalanced engines. But she would not run in the laboratory. At 55 miles an hour, she got dangerous to the apparatus. When the engine went one way the counterbalance went the other. With the pointer on the engine, you could see right away what the trouble was. They put on more counterbalance, and the engine worked very satisfactorily.

"The temperature of the smokebox is another thing we want to know more about. The pyrometers we have used are wholly unsatisfactory. They vary as much as 200 degrees, when put in the same smokebox and under the same conditions. At the University, they use a copper ball, which they put in next to the flues. They know the weight of the copper ball They drop it in water when it comes out, and in that way get a record of the temperature.

"Another interesting thing they found down here was the lifting of the drivers due to the counterbalance. I got down under the machine—it is very accessible—and I could see in between the drivers and the carrier when the counterbalance was up But, to settle that question, they fed a wire around between the two wheels, and first found that the wire was flattened down when the counterbalance was down. When the counterbalance was up, the wire passed through whole, showing that the driver does lift from the rail. These are only a few questions that can be settled in the laboratory, that cannot be settled on the road. This is a very expensive piece of apparatus. No one rail-

IN THE BLACK HILLS. WASHOUT IN GOLD RUN, ON THE DEADWOOD & LEAD CITY. TRAIN BETWEEN TWO WASHOUTS FOR A MONTH

road company would feel justified—unless it was very wealthy—in building it. It is only by the joint action of railroads and locomotive builders that these tests, which are very necessary, can be carried out."

### Reminiscences of Early Reading Mechanics.

We have received a great many valuable reminiscences concerning early railroad matters from Mr James W Holmes, of Reading, Pa , a very old employé of the Reading road. Mr. Holmes writes

"In looking over the May number of your valuable paper, I see that you want to know who has drawings of a picture of any kind of the locomotive 'Excelsior,' whose boiler was carried on separate trucks. You expressed the belief that the engine was built at Reading.

"There was such an engine built here forty-seven or forty-eight years ago, but her name was not 'Excelsior,' but 'Novelty.' She was built by that exceedingly live gentleman, Lewis Kirk, after a design furnished by the able superintendent of the Reading, Mr. D W. Nicholls. I worked on the engine, and naturally know something about her. I turned all her driving-wheels.

"In your May number you give us a likeness of the late Charles R. Peddle, of Terre Haute. You are correct about his working here forty-six or forty-eight years ago under Mr. Kirk Your readers might perhaps be interested in knowing what has become of these men whom you call his associates That ingenious and inventive mechanic, Lewis Kirk, died from too much hard brain work in studying out improvements of machinery. His head became affected, and he died in the insane asylum, at Harrisburg, about twenty-five years ago. Mr. John O. D. Lilly was killed on the railroad that he served his time on. He went to visit his brother, General William Lilly, and went to walk up the track of the Hazleton branch of the Lehigh Valley, from Packerton to Mauch Chunk, and got struck by a train and killed. That was about four years ago. Mr Andrew C Vauclain died at Altoona, while in the employ of the Pennsylvania Railroad, a few years ago. His brother James is away out West somewhere, and, I think, is still alive. Mr David Clark is a master mechanic on the Lehigh Valley Railroad to-day, and is still hale and hearty and able to tell the old railroad reminiscences himself. If he were aware that you were anxious to have a picture of the 'Novelty,' he would have a drawing made and sent to you, as he is a very accommodating gentleman.

"All these men were gang bosses at the time you speak of, except Clark Peterson, who was foreman of the Pennsylvania roundhouse, in Philadelphia, the last I knew of him.

"Colonel Frank Hain, general manager of the Manhattan Elevated Railroad, who is also a Reading man, has in his employ Emanuel J. Rauch, one of the old Reading pioneers, whom I think can give you a great deal of information about the 'Novelty,' for I think he was employed here about the time the engine was built.

"In one paper you speak about President Lincoln's private car, and you say that it was built about the beginning of the war. That is a mistake, as the car was built only twenty-nine years ago, in 1864. I did some of the finishing of the ornamental work of that car, which was finished brass work."

The Thompson Smokeless Fire Company, Pittsburgh, Pa., have sent us an illustrated catalogue showing their smokeless furnace applied to various kinds of boilers, house ranges and stoves In this system the firebox is so arranged that the fuel is continuously distributed in a finely regulated rain-like feed, and the air supply so adjusted that the gases arising from every ounce of coal are provided with an equivalent volume of air, and special facilities which positively insure the thorough mixing and uniting of the oxygen and other gases prior to reaching that temperature when they all ignite, and thus result in the most perfect combustion of fuel—there being nothing but pure flame passing into and through the flues, which, after doing service, escapes in the form of carbonic dioxide gas.

A late issue of the *Patent Office Gazette* contains particulars of a patent granted to Mr. S. M. Vauclain, Philadelphia, for an improvement on pistons It is described as a combination in a piston of two sections, each section composed of a disk, hub and ring, one section being the counterpart of the other, and each having an annular cavity to receive packing There is to each section a series of radiating ribs extending from and terminating in enlargements at the ring portion. Bolts are passed through the enlargements for the purpose of holding the parts of the piston head together independent of the piston-rod. This combination forms a hollow piston head which combines lightness and strength.

### Specifications Favored Cheap Material.

That analytical tests are by no means conclusive concerning the quality of steel for certain purposes, was proved by the action of the French Spring Co. several years ago. They had been in the habit of making all their springs of crucible steel and no springs had ever proved so durable But with the growth of railroad laboratories, a movement arose to purchase steel springs that had to meet certain analytical and physical specifications. This enabled the makers of inferior steel to compete on equal terms with those whose product had been famous for durability and uniform service. The company named was compelled by competition, fortified by the

IN THE BLACK HILLS WORK OF A MOUNTAIN FRESHET

specifications, to enter upon the use of open hearth steel for springs. The most inferior springs now upon the market will come up to the ordinary specifications Those that are known as the makers of the most inferior steel springs could not have worked up a business but for the movement in favor of specifications as a satisfactory condition for the purchase of spring material.

### Size of Compound Locomotive Cylinder.

A question that comes up very often among railroad men in connection with compound locomotives is · What ought to be the size of the cylinder to produce a compound of equal starting power to a simple engine? This question was discussed by Mr. Reuben Wells at last Master Mechanics' Convention, and he called for information bearing on the question. Mr. William Forsyth, in answer to this, said:

"In reply to Mr. Wells' question as to the proper diameter of compound cylinder, when you want to meet the power of a simple engine, the English designers and the German designers gave us a rule, quite early in the day, of compound engines, which was to make the compound high-pressure cylinder 1 inch larger in diameter than the simple engine which you want to make it equal to, and within the small range of diameters which we use in high-pressure cylinders—this rule seems to have worked out very well. It is near enough, because if you need a little more power you can make it up in the extra pressure."

Mr. Wells, in answer thereto, said "Mr. Forsyth spoke of the rule given us by English mechanical engineers in regard to the increased size of the high-pressure cylinder in a compound locomotive over its equivalent in a single engine. They give it as one inch. But if you will make the calculation, the difference between a cylinder of 12 inches and a cylinder 13 inches in diameter, amounts to about 18 or 19 per cent., but when you go up to the difference between a 20-inch and a 21-inch cylinder it is only 9 per cent., so that the rule is not a correct one for the different sizes. It may be correct enough as between a 12 and a 13, or between a 15 and a 16, but it is not sufficient when you get up to a 20 and 21—those higher diameters.'

### A Decided Change Needed.

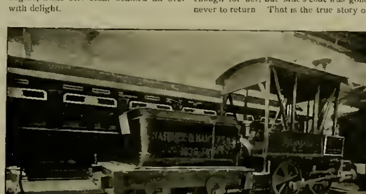
"Nearly all inventors are blind to the faults of their own progeny, but we think that the inventors of smokestacks that are certain to arrest sparks, and everything else, have been a little more infatuated than any others with their inventions." These were the sentiments expressed by an old traveling engineer at last meeting of the club.

"When I hear about new spark-arresting smokestacks," he continued, "I always think about one that Seth Ham got out, when he was engine-house foreman at Alexandria during the war time. It was a very imposing invention when it appeared on the engine, and seemed to be a half-breed between a tobacco hogshead and a balloon. Mr. Ham was very enthusiastic about it and felt certain his stack was going to effect a revolution in spark arresting. He applied it to one of the best Rogers engines owned by the Government, and every detail of construction received his careful personal attention. Engineer Billy Blank took the engine out after she was ready and made a trip with her to Manassas and back

"Mr. Ham was waiting anxiously to hear the particulars about the success of his invention. He was on hand when the engine arrived at Alexandria, but stood around the engine-house till the fine-steaming Rogers got to the turn-table, before he asked the good news from Engineer Blank.

"'Well, Billy, how did she do?' inquired Mr. Ham.

"'Splendid, splendid,' answered Mr. Blank. 'That is the greatest spark arrester I ever saw,' he continued, and he looked up quizzically at the front of the engine, while Mr. Ham beamed all over with delight.



The "Mississippi" an Old-Timer, Now at the World's Fair.

"'It works first-rate, then?' remarked the inventor, pleased as a boy with a new pop-gun.

"'Yes,' said Mr. Blank, 'it is a splendid spark arrester, but there is a small change which I would like to suggest being made on it.'

"'What is that?'

"'Well, I think it would be an improvement if you would turn the stack upside down, for the draft all appears to be downwards.'

"The smokestack disappeared next day, but Mr. Ham never spoke to Billy Blank again."

### What Became of Mac's Overcoat?

It is not correct that James Macbeth had his overcoat stolen at the Convention, although he returned without it. The fact is, Mac believes that no locomotives can run freely except those belonging to the New York Central. On his way to Lakewood he desired the opportunity to pick flaws in the performance of the W. N. Y. & Pa. engine pulling the train, so he displayed to the engineer his badge of the Convention and asked for permission to ride. The thermometer was 95° in the shade, and, of course, Mac had his winter overcoat on, but it occurred to him that comfort would be increased by taking it off. Sitting on the fireman's side, he began to realize that summer had come and that a little more air would be welcome. So he rose to open the window. At that instant the fireman opened the fire door, and Mac's overcoat gently wafted off the seat and slipped into the firebox. The fireman protested that coal was good enough for her, but Mac's coat was gone never to return That is the true story of why he did not take his coat home from the Convention, and all the insinuations heard about uncles were covert slanders.

---

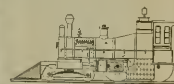
The Master Car Builders' Association has had for several years a committee investigating the subject of "Protection of Trainmen and Lettering Fast Line Cars." We have several times been asked what intimate connection there was with the two subjects to account for their assignment to one committee. We have always given up the guess. Perhaps some of our car-building readers could explain it.

### A Device for Fooling Steam.

The cut herewith was taken from the patent specifications of a recent invention that is intended to put heat into the water in the boiler, without wear and tear on the firebox, and at the same time furnish a high and dry altitude for consumptive steam.

The inventor is going to put a double air pump under the boiler somewhere, run the piston by a cam on the axle and pump air, that has been heated in passing around the firebox, into the boiler. He says "Compressed hot air serves a double purpose, first, to aid in heating the water, and secondly, to hold the damp steam down and to thus increase the effect of the fire upon the water. The invention is particularly applicable to locomotive boilers, because more power is developed within the same size of boiler.

What an elegant scheme coming down hill. She could be made to pop all the way "just as easy," and at the same time the engineer would know that the damp steam



was down on its back and that the hot air was calmly setting on its chest while holding its bare posterior against the firebox.

Of course this kind of a thing costs little and runs without friction—takes no power to force hot air into a boiler against 150 pounds of steam. Then there would be no more mysterious (?) boiler explosions where *gas* gets into the boiler and raises Cain; air will neutralize any kind of gas, and when explosive gas sneaks into the boiler it's altogether more than likely that the hot-headed air wouldn't get up off the chest of the poor old steam at all—it would just stick out its foot, trip up Mr. Gas, get him by a leg and butt his brains out against the dry pipe. Oh, there will be lively times when they get this cyclone sucker on. It'll be a cold raw day in March for any damp steam that shows up then, and it will save many a cylinder-head, too.

### A Striking Wheel Exhibit.

One of the interesting exhibits at the Master Car Builders' and Master Mechanics Conventions were specimens of the manganese steel wheels, made by the Taylor Iron Company, of High Bridge, N. J This metal is so hard that it cannot be cut with tools and is water toughened. Some of the mine car-wheels shown had been in use for months, being "spragged" (slid) every day without a perceptible flattening The tested wheels shown went far to prove the maker's claim that these wheels are unbreakable Referring to tests in this direction, they say:

"We have dropped many wheels edgewise from a height of 30 feet on a 2,500-pound anvil block, each many times upon the same point in the circumference, without effect other than to bend and batter the flange until it was flush with the thread. It also requires from forty to fifty blows of an ordinary car-wheel drop, weighing 1,120 pounds, falling 12 feet, to knock the hub out of a manganese wheel. A cold weather test was made—the thermometer was below zero—by laying the wheel on the ground, flange down, and striking the flange 150 blows at one point with a 20-pound sledge, without effect, except to bend the flange. Expansion or contraction tests made by pouring a ring of molten cast iron 1¼ inches by 4 inches around and against the tread of a wheel, leaving it on for fifteen minutes, (making a much more sudden and higher heating of the rim than it is possible to get in service from brake friction) then suddenly removing it, produced no effect on either plate or spoke-wheels."

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER and ROLLING STOCK

### Location at World's Fair.

We have opened an office at the World's Fair, and want all our friends to call and get acquainted. A representative of the paper can be found at Section U N, post 18 Transportation Building Annex—just at the rear and one aisle to the left of the Canadian Pacific passenger train. Any of our friends can have their mail addressed there in our care if they desire. The files of the paper can also be seen.

### Steel Under-Frames for Cars and Tenders.

When the strength and durability of steel is compared with wood, it seems strange that car builders on this continent have done so little to apply the stronger material to the principal members of a freight car. The repair yards of every railroad in the country supply convincing testimony that the weakness of wooden under-framing causes no end of expense, danger and delay, yet practically no progress is making to substitute strong steel for weak wood. The steady increase of car loads and the heavy locomotives coming into general use, add greatly to the destructive shocks that must be resisted by car framing, yet there has been very little additional strength added to the parts subject to the constant blows. Hence, nearly all repair yards are filled beyond their capacity, and ill feeling is engendered between the traffic and car departments, owing to delays of freight caused by broken-down cars. It appears to be high time that the men responsible for the designing of cars were doing something to introduce a stronger material for under-framing.

At the last Mechanical Convention two reports were submitted bearing directly and indirectly on this subject, but it did not appear that the members of the convention considered that there was yet urgent necessity for a change from the prevailing practice. We believe that the subject needs to be agitated and that railroad companies would be the gainers by extended investigation and discussions on the subject of metallic under-framing.

Steel under-framing for all sorts of cars is rapidly coming into use in several European countries, and they have been used with great success on the railways in India. Wherever this material is used it results in greatly reducing the expense of car repairs.

A report was submitted to the M. C. B. Convention on steel center sills for freight cars which, after outlining the experience with metal frames on American railroads, says:

"The advantages that may be expected from the use of metal center sills lie almost solely in the increased durability and the reduced cost of inspection. A metal center sill, when it is properly made, is the equivalent of a continuous draw-bar arrangement from end to end of the car; and being composed of material having a high tensile strength, steel center sills can be readily made so secure as to require but little inspection. The center sills of a car and the draft-rigging attachment are the parts of the car body which require the most attention from car inspectors and cost more to maintain than other parts of the car body, therefore it might be expected that the introduction of steel center sills would reduce the cost of running repairs.

"In case of wrecks it is a question whether the steel center sills would not be more expensive to repair than wooden ones, but the total cost of repairs to center sills and draft riggings caused by the class of wrecks which would seriously damage a steel center sill is not very large; and although the use of a steel center sill might increase materially the cost of repairing center sills after bad wrecks, yet, owing to the fact that on a well-appointed road bad wrecks are not numerous, the result would not be an increase in the total cost of all repairs, in fact, the greater durability of a suitable steel center sill ought to so reduce running repairs as to give a decrease in the total cost of all repairs to car bodies.

"It is, of course, true that wooden sills frequently last for fifteen years where the cars receive reasonably good service; but the present tendency is to use a sub-sill the entire length of the car to prevent damage to top and draft sills. With the present heavy equipment the result of this is that the total weight and cost of a car is greater with the present construction of wood than it would be with steel center sills, at the prices at which steel is now offered. In any considerable quantity, steel sills can be purchased for less than 2 cents per pound."

A report was submitted to the M. M. Convention on tender frames in which it was stated that of those who answered the circulars about half the number were in favor of iron frames. This indicates considerable progress, for a change to a new material naturally moves slowly.

Those who oppose the use of iron frames are nearly all inclined to lay great stress upon the cost of repairing iron frames in case the engine has a wreck. The same argument is used against the economy of using steel for under-frames of cars. We believe that this objection is based on a fallacy. The expense of repairing the damage done in wrecks is not so great as it is reputed to be. Apart from that, it is not good policy to refuse to adopt a superior article for fear it might be damaged in a wreck. If a steel under frame is properly made it is likely to prove so much stronger than a wooden frame in case of a wreck that more money can be spent to advantage in repairing it.

When iron tender-frames were beginning to come into use we had the opportunity of noting the behavior of two of these frames. One of them went through a bridge with the engine and the tank was entirely destroyed, but the frame was little worse and did not cost $5 to put in perfect order. A year or two afterwards it was in a head-end collision, and came out little worse, although the wooden frame belonging to the other engine was destroyed, as wooden frames generally are when they go into a bad wreck. The other iron frame had better fortune, and did not meet with accident. We watched it for five or six years, and in that time it cost nothing for repairs. We had been previously prejudiced against iron frames, because everybody said that a wreck would ruin them. One of these convinced us that they came through ruin in very good shape, and the other appeared to teach that a frame that required no repairs in five years could afford to take the chances of going through a wreck.

### Compound Locomotives.

A very valuable and interesting report on compound locomotives was submitted by the committee of the Master Mechanics' Association of which Mr. George Gibbs is chairman. The report was devoted principally to the reviewing of the progress made in compounding during the year and to the testimony of those who have compound locomotives in use concerning the performance of such engines. The increase of compound locomotives in service since last year is considerable, and a large number are still under construction. The committee gave figures which showed that in June of this year 422 compound locomotives were in use in this country, as compared with 114 in use a year ago. They also had information that 108 compounds were under construction in this country and 75 American compounds in use in foreign countries.

The report discusses the testimony for and against compounds in a thorough and impartial manner, as might naturally be expected of Mr. Gibbs, who did the principal part of the work. The following conclusions were come to: The compound is suitable for a variable class of freight service. Its range of economy in such service is fully as wide as the simple. Its increased coal economy over the simple in the average freight service will be found to be between 10 and 15 per cent. when in good running condition and handled with intelligence. A well designed compound should not be more difficult to keep in a serviceable condition than a simple. The net running cost of a compound will be less on many roads than of simple. In passenger service the availability of the compound is undetermined. Complicated designs of compounds are not likely to prove successful or economical.

The report elicited a long discussion. The drift of it was that those best informed concerning compound locomotives considered that they saved about 20 per cent. of fuel in freight service, and that the saving in passenger service was very doubtful. It was evident that the members of the association considered that the compound was a moderate success, and that there is a future for it in the motive power of American railroads.

### Dangers of Inferior Material.

In the controversy that has arisen lately among railroad companies and makers of boiler steel about the quality of the material furnished, there has been an inclination on the one side for purchasers to blame the makers for supplying an inferior article, and for the other side to retort that the tendency towards an inferior article has been encouraged by the disposition manifested to purchase the cheapest regardless of quality. We are inclined to believe that railroad companies are much more to blame for the inferior steel supplied for boilers than the makers of steel. There is nothing more certain than that the quality of a material in demand will eventually regulate the supply. Some railroad companies talk very bravely against all material of an inferior quality, but somehow they will buy the cheapest, tests and specifications notwithstanding.

It is very important from the standpoint of self interest that railroad companies should purchase nothing but first-class material for fireboxes and boilers, but those who are willing to pay one cent a pound extra for material that will give superior service are in the minority. Nearly all railroad companies buy their steel in the cheapest market and depend on luck to get good results. Luck does not favor this species of stupidity, and fireboxes have to be renewed after half the service that good material would insure. And this is why the shout is heard all over the land that firebox steel is not as durable as it used to be. There are roads, with the reputation of being first-class, that never purchase a pound of first-class steel for boiler purposes. All they consider is cheapness in first cost.

Inferior steel for fireboxes generally brings its own reward in the shape of premature renewals, and the greatest injury done is to the railroad companies following the policy of purchasing inferior material. But there are other lines of inferior purchase in which others besides the buyers are sufferers. A great many steel axles have been put under cars of late years and certain companies purchase these axles in the cheapest market. When this is done, Bessemer steel axles are invariably supplied, and articles of this material are not safe to put under a car. Several companies recognize the danger of using Bessemer steel axles, and place them only under freight cars, where they are not likely to commit wholesale slaughter in case of breakage. The slaughter, however, is merely a matter of degree. The breakage of a Bessemer steel axle is likely to kill only a few trainmen, and they do not inquire so strictly into the causes of an accident as passengers are likely to do. It is, however, a scandalous condition of things that railroad companies are ready to jeopardize the lives of trainmen in order to save a few cents on the cost of an axle. It is scandalous, but it is done daily, all the same. Who is going to deal with this outrage? We understand that the subject is under investigation by members of the Interstate Railroad Commission. We cordially hope, in the interests of humanity, that they will find the means of prohibiting the use of inferior axles under any kind of cars. An amendment to the law relating to safety appliances could be easily framed which would make the use of dangerously weak axles too risky from a financial standpoint. That would end their use.

Since writing the above we have received a copy of "Proposed Specifications for Steel Axles" prepared by the officers of the Pennsylvania Railroad. The proposed specifications will require the same chemical composition for both passenger and freight car axles; and the freight car axles, in addition to the chemical tests, will be submitted to a severe drop test. All axles will be rough turned throughout. This new rule will practically call for the same kind of axle for passenger and freight cars. It is a move in the direction of safety and follows the dictates of humanity. We most cordially trust the proposed specifications will be adopted and that other railroad companies will quickly follow the example shown by the Pennsylvania.

### One-Sided Contracts.

A good many railroad companies might get a lesson worth learning in a decision lately given in a suit against the Western Union Telegraph Co. It is a common practice with many companies to issue tickets with a great many conditions attached that the buyer never thinks of reading and to which he is no party. The Western Union has been in the habit of doing the same thing, one of their conditions being that they will not be responsible for the correctness of the messages that are not repeated and paid for twice. A business man whose message was distorted sued the company for damages, and obtained judgment in spite of the rule requiring a message to be twice paid for to insure accuracy. The court held that putting these conditions on the message form did not constitute a contract. Many railroad companies might as well save the printer's ink that they waste in putting conditions on tickets that the purchaser never reads.

By the way, it shows the long suffering

of American business men that they endure without revolt the inflictions put upon them by the Western Union Telegraph Company. Unless it be at the principal stations an operator is seldom found who can read ordinary handwriting. The very cheapest kind of labor is employed, and any message departing from the most elementary expressions is certain to be distorted. A collection of what are commonly called "bulled" messages would be a curiosity. Some of our readers with plenty of leisure would find collecting such messages a most amusing pastime.

## Boiler and Cylinder Proportions.

So many men have the opportunity, this year, of studying the development of the locomotive, by means of the splendid exhibit shown at the World's Fair, that there is more than usual interest in the subject. A remark frequently heard by those examining the splendid specimens to be found in Jackson Park is, The engines of to-day are larger than those that preceded them, but are they better proportioned? Are they built so that they will perform more work for the units of heat expended than the engines that are now considered ancient? A careful study of the American locomotives exhibited at the World's Fair, and of the run of engines built during the last year or two, convinces us that the modern engine is more efficient, as a means for converting heat into work, than the average locomotive of the past.

At all times there have been locomotive designers who had the power to distinguish the proper proportions for producing high efficiency, and their engines were celebrated in their day and generation. There have been other influential designers who persisted that certain essential principles could be violated with impunity, and their engines were wasteful. The same characteristics are to be found among locomotive designers to-day, and the same results follow, but the engineering world is nowadays so thoroughly informed about the proportions of every new class of locomotive that public criticism is calculated to restrain personal vagaries.

To discuss all the proportions of the modern locomotive as seen at the World's Fair and elsewhere, would be beyond the scope of one article; but we may profitably devote some space to looking into the proportions of boilers to cylinders. The proportion of these parts has never been the subject of a settled rule; but calculations made respecting the amount of heating surface to cylinder content of a great many locomotives, old and new, convinces us that there is an intimate relation between the two which cannot be much deviated from with impunity.

An English engineering journal writing on this subject says: "However much change may be effected in the type of a locomotive, certain proportions appear to be incapable of alteration without doing harm, 2½ square feet of heating surface ought to be provided for each square inch of piston area, or what comes to the same thing, one piston's area in inches multiplied by 5 will give the square feet of heating surface the engine ought to have."

This empirical rule is not far from being correct, but it gives a ratio too low for the ordinary run of American coal. It gives, however, a greater heating surface than many of our old locomotives were provided with. Take an American engine that was famous a decade ago, viz. the 17 x 24-inch eight-wheel engine popularly used for general service, freight and passengers. This engine seldom had more than 1,000 square feet of heating surface and the above rule called for 1,135 square feet.

The rule based on square inches of piston area, although it suited fairly well for engines with 24-inch stroke, was away off with shorter and longer strokes. A rule likely to be much more accurate, is the heating surface per cubic content of cylinder. Taking the proportions of heating surface and cylinder capacity of our older classes of engines, we find about 160 square feet of grate area provided for each cubic foot of cylinder. In a list of twenty-four locomotives selected from those at the Chicago Exposition and others that are doing well-known passenger service train work on different roads, we find that they average 220 square feet of heating surface to the cubic foot of cylinder capacity.

Some of the engines on our list are decidedly inferior specimens of locomotive designing, and they depreciate the general average. It will be noticed, however, that the allowance of heating surface to the cylinder that measures out the steam has been materially increased in the last ten years. Among extremes on our list, are Buchanan's "999," with 295½ square feet of heating surface to the cubic foot of cylinder; a Norfolk & Western, with the same proportion; a Baltimore & Ohio engine, with 131 square feet of heating surface to the cubic foot of cylinder, and the latest New York, New Haven & Hartford hard-coal burner, with 136 square feet of heating surface to the cubic foot of cylinder. The class I engine on the New York Central, to which the celebrated "870" belongs, has 232 square feet of heating surface to the cubic foot of cylinder. This may be regarded as the standard fast passenger engine of the road, and no locomotives running are more successful. A fast passenger engine designed by Mr. J. W. Cloud for the Erie, in 1888, which was considered a particularly well-planned engine for the time, had 200 square feet of heating service per cubic foot of cylinder. The fast passenger engines on the Old Colony, which are noted for their efficiency, have 194 square feet of heating surface to the cubic foot of cylinder. The latest Lake Shore flyers have 224 square feet of heating surface to the cubic foot of cylinder.

It is certain that designers who venture below 200 square feet of heating surface to the foot of cylinder are on precarious grounds, especially with passenger engines, which are now required to supply steam for car heating.

The proportion of the steam-making capacity of the boiler to the cylinders which have to be filled ought to receive the most careful attention of those who are responsible for the successful operation of locomotives, but it sometimes receives little consideration. Abnormally large cylinders are reputed by some designers to be economical, since they will do the required work with a short cut-off and admit of using steam expansively. We have known of a great many locomotives that have been built in Europe and in this country with large cylinders that were to get along with small boilers, but they never gave satisfaction in service, and the cylinders had eventually to be bushed. A representative case of this kind happened in England some years ago which excited a great deal of attention and discussion at the time.

When compound locomotives were coming into use, and claims were made that they were saving coal, Mr. Johnson, locomotive superintendent of the Midland Railway, insisted that the only way saving could be effected was in the use of the enlarged cylinders, which admitted of the steam being used expansively. He held that the same results could be obtained in an easier way by enlarging the cylinders of simple engines. To show the faith that was in him, he had a group of engines built with cylinders 19 x 26 inches and about 1,150 square feet of heating surface, giving 146 square feet to 1 cubic foot of cylinder. Every encouragement was given to the enginemen to make a success of the new class of engine. The best enginemen on the road were selected to work the engines, the best coal to be found was provided for them, the tubes were cleaned carefully at the end of each journey, and the best adjustment of draft appliances possible was made.

In spite of all this the engines were a failure from the start. They would not steam. The locomotive engineering world took sides about the engines. One side said, What else could you expect? You can't expect to run express trains with engines that have cylinders large enough to half empty the boiler at each stroke. The other side argued that the boilers were large enough for the cylinders, but too small for the engineers; the real trouble being that the engineers could not be prevailed upon to work the engines hooked up close enough. Valves with long lap were put in to make the engines use the steam expansively in spite of the engineer; but the only effect of this was to cause the engines to lose time in starting and to give firemen practice with the pinch-bar. Eventually the engines had to be altered.

Similar experience was gone through with a class of engines built for the Erie seven or eight years ago. Other roads in this country have attempted to make powerful engines by the use of large cylinders without boilers to correspond, and always with the result of failure.

Another fallacy which has obtained many converts, is the theory that by providing a large firebox, the boiler would make sufficient steam with small tube-heating surface. The firebox surface is certainly very efficient for evaporating water, but it cannot be utilized to advantage unless there is sufficient tube area to carry off the gases freely. When the tube area which constitutes the chimney for the firebox is restricted, restricted nozzles must be employed to intensify the draft. The lessons of the experience learned by expensive experiment are, that ample heating surface must be provided for free steam-making, and that the flue area must be made large enough to permit the fire gases to pass through readily.

This is now the accepted gospel of locomotive designing and its influence is apparent on what may be termed the modern American locomotive. The heretics who attempt to be guided by different articles of faith are not likely to receive much enjoyment from their independent beliefs, especially if they be reduced to practice.

## Better Steps and Handholds for Locomotives.

It always seems ridiculous to hear anybody claim to have accomplished reforms, when it is known that the person doing the talking has only talked and not actually had a hand in the reforms made, and no one can despise more than ourselves the newspapers that head everything "as told exclusively," etc.

But, for all that, we cannot help thinking that, somehow or other, all the kicking we have done for the past five years about bad engine steps and handholds has done some good, for within that time almost every builder in the country has made better steps and better handholds.

Looking at all the sixty-odd locomotives at the World's Fair, there was but one that we could object to, and that was very much like those in general use five years ago.

The railroads, and not the locomotive builders, are to blame for these dangerous traps; the builder generally makes what the specification calls for, and it costs about the same to make a good step as a bad one, and the cost of locating it is the same in any case.

The Brooks Works have recently gotten up a splendid tender-step, large, extended toward the engine and two steps cast in one piece, closed at the ends and back; the only improvement that could be made would be to perforate the step to prevent the accumulation of snow and ice. Their suburban engine has a step and handhold arrangement that cannot be improved on.

The Pittsburgh Works have a good step, but have made some recent improvements in their handholds; they extend the handhold on the cab from a point half way up the window right down past the cab deck and curve it in to the lower lug of the cab bracket. This is the best handhold we now know of on locomotives—handles are an abomination.

Baldwin probably makes the best tank handhold, but there is not so much difference here, the thing to do is to make this handle long enough, it should extend from top to bottom of tank.

Many handholds are put as nearly over the steps as possible, this is a mistake, ample handholds should be provided on the engine and tender, and a large, substantial step located between them. If an engine is standing still a man will usually use both hands in getting on, but if moving in either direction at moderate speed the experienced railroader will grasp the *first* handhold with both hands and let the motion swing his body toward the step, by the time his feet are planted there he has got hold of both handholds and is safe.

Steps strung on a rod below the cab bracket and held by set screws are a delusion and a snare, they are too small to step *at* when the engine is moving, no one knows whether they will turn on the rod or not—they usually do—and they are eternally getting turned or bent by striking ties, rails, or other material, or snow. The only real good they are is to allow men to get into the cab in the shop while the tender is disconnected. It would be better if they were off every engine and a longer step put on the tender. These abominable engine-steps have cost more than one poor fellow his legs or his life.

The engine at the World's Fair, with the bad steps, belongs to the C. & O. Railroad. The tank step is a board on wrought-iron hangers, it is not large enough, and is placed so far under the tender-deck that it is almost impossible to put a foot on it to get *off* the engine. While to get *on*, at any speed, is dangerous—because the step is just about the distance below the deck to let a man's knee under it when his foot is on the step—this makes it almost impossible to straighten out the leg, and, if thrown hard, might of itself cripple a man. This engine has small handholds, and the regulation engine-steps on a rod.

On road engines men usually need to get on when they are going ahead, and as the tender handhold is always larger, longer and *lower down* than the engine handholds, nine out of ten men will mount by that. In swinging on this way the steps are on the wrong side, and experienced men will usually put one foot on them, but put the other on top of the first axle-box of the forward tank-truck, this is safest, as it distributes the work of overcoming the inertia of the body to three points, the hands and each of the feet. If in place of the costly and dangerous engine-step in the shape of a fire-shovel, the master mechanics would put a step on the corner of the truck-frame or box, it would be better, a flat piece of boiler plate would answer well enough.

It will always be necessary for men to get on and off moving engines, orders to the contrary notwithstanding, so the thing to do is to furnish good steps and reliable handholds with as much uniformity as possible. It were far better they be too good than too bad.

## The Handicap in Locomotive Building.

The Grant Locomotive Works, which became insolvent in the beginning of June, are not likely to be put in operation soon. The works had only been in operation a few months, and their success as a manufacturing enterprise was greatly hampered from the start through labor troubles. Competition in the building of locomotives is so keen that there is little profit in the business, and the only chances for a new concern to succeed is by the use of the most approved appliances for cheapening the cost of production operated by men specially skilled in the work. The great bulk of the workmen employed in the successful locomotive works are specialists who perform recurring operations very rapidly. These men are trained to the business by years of practice and they all work on the piece-work system. No new establishment can compete with work done in this way unless the same methods are adopted and adhered to. It would be just as reasonable to expect that a sewing-machine factory could be run successfully in Chicago on the old system of doing all the work by all-round machinists, as it is to expect that locomotive works in Chicago can be carried on with profit to the owners on a day pay system with every workman running one machine

But this was the foundation of the dispute which arose between the Grant Locomotive Works Co. and their workmen. The managers of the works wished to establish a system of piece-work similar to what prevails in all other locomotive building shops, and the workmen would not consent to the arrangement. They would work only by the day, and an agreement was entered into among the men that no one should work more than one machine.

The workmen in the neighborhood of Chicago may be united and powerful enough to prevent the general introduction of piece-work into the Grant Locomotive Works, but if they succeed in doing that, it is certain that the works will never build locomotives and sell them in competition with other locomotive builders.

### A Whistling Abomination.

On most of the railroads of the country, that make any pretentions to keeping up with the times, there is a rule forbidding enginemen from blowing their whistles while passing a passenger train, except to prevent an accident.

No man can say but that the practice of blowing whistles in close proximity to a loaded passenger train is very annoying to all the customers of the road and does direct injury to many whose nerves are sensitive, especially women and children. The writer recently saw an infant frightened almost into spasms by a switch-engine whistling fiend employed in the Hoboken yard of the D. L & W —one of ...oads where whistling is a large part ...e business.

...n the road in question, switch and ...ht engineers are allowed to open their ...ar piercers beside passing trains indeed, there seems to be a disposition to wait until there is a crowd to hear the whistle before it is used.

In years gone by, a good deal of "tooting" was indulged in on all the roads, but nowadays the whistle is used to protect people and warn trainmen, and any road careful of its reputation for comfort prune the whistling all that is possible.

If it seems absolutely necessary for switch engines to whistle twice before moving ahead, and three times before moving back, then the railroad owning said switch engines owe to the public the use of smaller and weaker-lunged whistles; the marrow-stirring fog-horns in use should be choked.

If anyone wants to see the whistling mania in all its original noisiness let him ride a few times between Hoboken and Newark, in the State of New Jersey, and note how patiently the switchers in the coach yard wait for the trains before they screech, and observe the effect on the people in the car when a freight train whistles beside it in the tunnel, or note the second-nature regularity with which the engineer of the incoming local waits until he is beside the outgoing one before he hangs his arm over the whistle cord and rests himself on it for a minute or two.

Whistling beside passenger trains is as offensive to passengers as smoke, cinders, bad lights or cold feet, and any road will spend money to lessen any of these. They could stop the whistling by a bulletin notice and an example, and, as most of them will try to accomplish impossible things by this means, it is all the more surprising to find roads that don't try to stop the noise and annoyance when it would cost nothing but an effort—then think of the cars that steam would haul if put into the cylinder instead of worked up into noise to try men's souls with.

### Why Don't They Pay Promptly?

Railroad business keeps up remarkably well all over the country, but the companies are preparing for a depression in trade and helping to bring it on by declining to purchase anything not absolutely required for immediate use. Bitter complaints are heard among railroad supply men, about railroad companies delaying the payment of bills. A curious thing about this is that the companies best able to settle their obligations promptly are the first to plead stringency of the money market as an excuse for delaying the payment of outstanding accounts. There is no class of people doing business who have less justification than railroad companies for the practice of delaying the settling of bills, for they do a strictly ready money business themselves, and it is only common fairness that they should pay out promptly. Men doing business with them are perfectly aware of this, and they do not spare denunciations of the practice that puts them to so much inconvenience. All this helps to cultivate an anti-railroad sentiment among those who are naturally the best friends of railroad companies.

### The Pratt & Whitney Catalogue.

Those interested in first-class machine tools ought to send for the new illustrated catalogue just issued by the Pratt & Whitney Co., Hartford, Conn. Those who are familiar with this company's goods will readily agree to the claim made in the catalogue that "the reputation of the company's tools for exactness, convenience, elegance and adaptation to the end sought is the result of a well-defined policy as to sentiments of fair dealing Every opportunity for improvement has been accepted, and no device that could add to the usefulness of the tool has been neglected. They have sufficient weight to secure strength and durability without clumsiness, they are simple in design, convenient in arrangement of parts and accurately constructed"

The list of tools has been materially increased since the last catalogue was issued, and contains all the lighter tools used in machine shops and some very powerful ones Among the latter is a double-headed milling machine which is used in some shops to flute side rods, work that it does in half the time taken by a planer. The catalogue contains such a great variety of familiar tools that we cannot go into particulars, but we would strongly recommend master mechanics and others who are in the habit of making their own small tools, to get this catalogue and study over the prices. This will present a strong argument against making small tools in railroad shops

"Some Points on Steel-Tired Wheels," is the title of a pamphlet issued by the National Car-Wheel Company, Depew, N. Y. The pamphlet serves as a notice that the company named is about to begin the manufacture of wheels. They are said to be exceptionally well provided with the best modern appliances used in wheel making If they make their wheels as good as their description of the attributes of a good wheel, they are certain to secure a good business

William Sellers & Co., of Philadelphia, are building two large electric cranes for the Robinson-Rex Manufacturing Company, of Pittsburg. Each of these cranes has a span of 80 feet, one being of 30 tons and the other 80 tons. The cranes are provided with a double trolley, a distinctive feature which enables the cranes to be engaged on two separate pieces of work at the same time, or both trolleys can be used together.

### PERSONAL.

Mr. John S. Funk, master mechanic of the Northern Central Ry., at Marysville, Pa., died last month.

Mr. James Brady has resigned as division master mechanic of the Gulf Colorado & Santa Fe at Temple, Tex.

Mr. Linton Williams has been appointed superintendent of the Abbotsford & Northeastern, with office at Athens, Wis.

Mr. Henry Schacks, late superintendent of motive power of the Illinois Central, has returned from a visit to Europe.

Mr. John A. Willey has been appointed traveling engineer of the Black Hills division of the Fremont, Elkhorn & Missouri Valley R R.

Mr W. A. Walden has been appointed acting master mechanic of the Atlanta & Charlotte division of the Richmond & Danville Railroad.

Mr William Moncure, superintendent of the Carolina Central, has been appointed superintendent of the Raleigh & Gaston and Raleigh & Augusta Air Line.

Mr. L. P. Ligon, foreman of repairs at the Radford, Va., shops of the Norfolk & Western Railroad, has been promoted to the position of master mechanic

Mr W. W. Atwood has been appointed manager of the Middlesex Valley Railroad, with headquarters at Naples, N. Y, in place of Mr. H S. Stebbins, resigned.

Mr. F B. Farmer, for some years instructor on the Westinghouse instruction car, has been appointed local agent of the company at St. Paul in place of John Church, deceased.

Mr. A. A. Braden, master mechanic of the Lake Shore & Michigan Southern shops at Norwalk, O., has been appointed master mechanic of the shops of the same road at Cleveland, O.

Mr. G. W. Offutt has been appointed superintendent of the central division of the New York & New England, with headquarters at Providence, R. I., in place of Mr W S Jones, resigned.

Mr. T. R. Chatham has been appointed road foreman of engines of the Richmond & Danville R R., to succeed Mr. W A. Walden, promoted to the position of master mechanic of the same road.

Mr J. N. Kelley, general foreman of the shops of the Gulf Colorado & Santa Fe at Temple, Tex, has been appointed division master mechanic of the road at Temple to succeed Mr. James Brady, resigned.

Mr. E. E. Elden, who has been connected with the Elkhart shops of the Lake Shore & Michigan Southern, has been appointed master mechanic of that company's shops at Norwalk, O., to succeed Mr. A. A. Braden.

Mr Charles H Hogan, the famous engineer of the New York Central whose portrait appeared in the last issue of LOCOMOTIVE ENGINEERING, has been appointed road foreman of engines of the Buffalo division of that road.

Mr John Forster has been appointed assistant master mechanic of the Atchison, Topeka & Santa Fe, at Argentine, Kansas, in charge of Kansas City terminals, *vice* Mr. W H. Traver, resigned to accept service with another company.

Mr J S Graham, master mechanic of the Lake Shore R R, at Cleveland, resigned lately, but we understand that President Newell insists that he shall remain in the service of the company. He has been with them a great many years.

Mr. M. Hopkins has been appointed general manager of the South Side Rapid Transit Railroad, of Chicago, in place of Dr. Bernard, resigned. Mr. Hopkins rose from the position of brakeman on the Chicago & Northwestern to be superintendent.

Mr. Gus T. Neubert has been appointed division master mechanic of the Panhandle division of the Atchison, Topeka & Santa Fe, with headquarters at Wellington, Kansas, *vice* Mr. John Forster, promoted. Mr. Neubert was formerly general foreman at Nickerson, Kansas.

Mr. C. Thompson, son of Mr. Charles Thompson, superintendent of machinery of the New Jersey Central, has been appointed master mechanic of the Kings County Elevated Railway. Mr. Thompson has been for several years a foreman at the New York Central shops, West Albany

Joseph York, the old engineer, whose life story was told in LOCOMOTIVE ENGINEERING of July, 1892, and who spent May and June at the World's Fair, he having been engineer on some of the old engines there more than half a century ago, went home ailing early in July and died on the 7th.

Mr. Robert Burgess, air-brake expert for the L.& N., at Louisville, Ky., and president of the new educational association of air-brakemen, has accepted a situation as instructor on the Westinghouse Company's air-brake car. The Westinghouse Co. could not have secured the services of a brighter air-brakeman.

Mr. B. Haskell, master mechanic of the Northern Pacific at Missoula, Mont., has accepted the position of superintendent of motive power and rolling stock of the Chicago & West Michigan and Detroit, Lansing & Northern, with headquarters at Grand Rapids, Mich., to succeed Mr W S Morris, who resigned April 1st.

At the late mechanical conventions, Mr F. W Coolbaugh, of New York, interested himself in collecting money for the benefit of the children who receive treatment in the *Daily News* Sanitarium, in Lincoln Park, Chicago. We see, by a note in a Chicago paper, that $87.89 had been received for this noble purpose.

Mr. Charles B. Bush, superintendent of the middle division of the Michigan Central, died last month at Jackson, Mich Mr. Bush rose through various positions to be superintendent, having been on the road forty-four years. He was a remarkably pleasant gentleman and was highly popular with all the men under him.

Mr. A Von Borries, superintendent of machinery of the Hanoverian railroads, is in Chicago, visiting the Exhibition He has been appointed by the Prussian government one of the jurors in the railway department of the Exhibition. Mr. Von Borries is an inventor of several important improvements on compound locomotives

The numerous railway friends of Mr Harvey Middleton will be pleased to learn that he has been appointed manager of the Pullman Works, at Pullman, Ill. He has been for several years superintendent of construction at the works. At different times before that he was superintendent of machinery of several of our most important railroads.

Mr. T. A Lawes, who has been for some time master mechanic, in charge of the Brightwood shops of the Cleveland, Cincinnati, Chicago & St. Louis, has been made mechanical engineer of the road Mr Lawes was for some time chief draughtsman for the late W. F. Turreff, on the

C., C., C. & I., and passed through the position of shop foreman to be master mechanic.

---

We have to acknowledge a pleasant call from Mr. Serge Kareischa, of St. Petersburg, Russia. Mr. Kareischa is engineer of ways of communication, and consulting engineer of the Russia Southwestern Ry. He is also a member of the Imperial Russian Technical Society. He expressed himself as being very much interested in LOCOMOTIVE ENGINEERING, and in the proceedings of the American Railway Master Mechanics' Association.

---

Mr. C. E. Schaff became trainmaster of the Cleveland division of the Big Four after a rapid advancement from a yard position. Nearly two years ago he resigned to accept the position of general superintendent and purchasing agent of the Peoria & Pekin Union, of which Joseph Ramsey, Jr., is president. President Ingalls has now selected Mr. Schaff to go into his office as secretary, with power to act in Mr. Ingalls' absence.—*Cleveland Leader*.

---

All those who attended the late mechanical conventions, will remember how industriously Mrs. George McGuire, of Cleveland, labored to collect money for the Fresh-Air Fund for children. This is a labor of love which Mrs. McGuire undertakes every year, and we are glad to learn that she met with unusual success at Lakewood. She asked for no larger sum than twenty-five cents, and that only from men. A great many must have contributed, for we read in a Cleveland paper that she turned in the sum of one hundred dollars to the Fresh-Air Fund.

---

The employees of the New York & Northern invited their late general manager, Mr. H. H. Vreeland, to have a finishing interview with them as a body one evening last month. They began the proceedings by getting Master Mechanic Millen to present Mr. Vreeland with a handsome cane and a flow of kindly eloquence. Others then took turns in telling how well they enjoyed the treatment given to them by their late general manager, and a delightful evening was spent expressing friendly sentiments and impressing various good things provided for the inner man.

---

We are acquainted with no master mechanic in the country who has made a better record, under difficulties, than Mr. Thomas Millen, of the New York & Northern. With remarkably small facilities for doing work, he kept the rolling stock of the road in wonderfully good order, and was always cheerful and hopeful that better times would come to the company, and money would be forthcoming to stock his shop with much-needed tools. His superior officers must have appreciated his efforts, for, when Mr. Vreeland left, to accept a high appointment, Mr. Millen was promoted to the position of superintendent. He still performs the duties of master mechanic, and we feel certain that he will make an excellent officer for the dual position.

---

A rather pretty story is told in a late issue of the Philadelphia *Times* concerning Mr. S. J. Potts, lately promoted to be trainmaster of the Pennsylvania. Mr. Potts has been in the employ of the company for a good many years, having entered the service as brakeman. When he applied for a position on the Pennsylvania Railroad, he was destitute, having spent all his money seeking employment. But he had good clothes, and hearing one evening that there was a vacancy in the train service, he went to apply for the job dressed in an evening suit. He got the position as brakeman, and was told to go out at once. So he went out and made the round trip, dressed in a claw-hammer coat and no vest to speak of. The boys made fun of him, but he did not mind and hung to his job.

---

The following well-known railroad master mechanics have received the honor of being appointed judges of the transportation exhibits at the World's Fair. Mr. John Hickey, superintendent of motive power of the Northern Pacific, and president of the Railway Master Mechanics' Association, Mr. J. N. Lauder, superintendent of rolling stock of the Old Colony, and past-president of the Railway Master Mechanics' Association, and Mr. L. P. Losee, superintendent and master mechanic of the Pennsylvania at Wellsville, O. Mr. R. C. Blackall, superintendent of machinery of the Delaware & Hudson and 2d Vice-President of the Railway Master Mechanics' Association, was offered the appointment of judge of exhibits, but was compelled to decline owing to the absence of the general manager.

---

Our readers will find on another page an interesting letter from Mr. James Hedley on the invention of the link motion and giving other interesting reminiscences of early railroad engineering. Mr. Hedley is of peculiar interest to engineers himself, for he is a nephew of the famous William Hedley, who was undoubtedly the father of the locomotive. He was the first man to build a practical locomotive that did paying service hauling cars, and it was by examining Hedley's locomotive that George Stephenson obtained the ideas of how to build one. It may interest our readers to know that Mr. James Hedley has two sons master mechanics of American railways. One is Mr. E. M. Hedley, of the Brooklyn Union Elevated; the other is Mr. Frank Hedley, for several years master mechanic of the Kings County Elevated and now of the Lake Street Elevated in Chicago. Both are young men of much promise and both are a credit to the engineering race from whom they sprung.

---

When the owners of rival railroad companies became alarmed at the progress which Mr. A. A. McLeod was making towards regenerating the Reading, and used their combined influence toward taking the financial support from under his feet, they appeared to think that a dangerous power was suppressed. The energies of men like Mr. McLeod are not so easily quenched, although they may be banked for a season. Since retiring from the Reading, Mr. McLeod has been recuperating and devoting a little of his superfluous energy to straightening out the affairs of the New York & New England road. The weakness of that property has always been that one end is bottled up without a natural terminus. It looks now as if Mr. McLeod was going to force it on to New York City. He has taken a leading part in incorporating a road to connect with the New England road and extend to New York. There will be hard times around if he does not push the enterprise through. We have noticed lately that the people of Philadelphia are beginning to acknowledge that their city lost a [illegible]ful friend when Mr. McLeod left the Reading.

---

## Samson Fox.

One of the most interesting strangers in attendance at the railroad mechanical conventions was Mr. Samson Fox, whose name is associated in the minds of railroad men by the pressed-steel truck which bears his name. Mr. Fox is much more familiar to the engineering world at large as patentee and maker of the Fox corrugated furnace.

The life of Mr. Fox is a good illustration of what native energy and ability will do for a man who has had a poor start in the race of life. Mr. Fox entered as an apprentice in a large engineering establishment in Leeds, England, when he was fifteen years old, to learn the business. When he was twenty-one years old he was promoted to be foreman of a department. Two or three years afterwards the superintendent of the works was taken sick and Mr. Fox was appointed temporarily to the position and held it a year. Then he was sent to the Exhibition of 1862, in London, in charge of a large exhibit. As he expressed it himself, this was the first opportunity he had of wearing a black suit of clothes.

When in London he learned about the scientific classes in connection with the South Kensington Museum, and when the Exhibition was over, entered as a student, learning drawing and applied science. After a time he returned to his old employers and worked in various capacities, but finally decided to start business for himself, making boiler-plates, flanged beads, etc. One day, when reading the Government boiler inspector's annual report, he was struck with the number of collapsed furnaces, and got ruminating on the subject. It suddenly struck him that by corrugating the furnace a stronger furnace could be constructed with the thin sheets necessary. He went to work in this line and achieved unparalleled success. There are now 72,000 of his corrugated furnaces in use. This furnace effected a revolution in the steam pressure carried in marine boilers. When it was first introduced the prevailing pressure was 70 pounds to the square inch; it is now 160 pounds. There are 200 triple-expansion engines in use that draw steam from boilers pressed to 200 pounds.

---

The New York, New Haven & Hartford Railroad management have raised the pay of the conductors, brakemen and other employees of the Providence division. When this division was operated under the Boston & Providence Company it paid the largest dividends of any railroad in the country, and the employees were among the worst paid in New England. When the Old Colony got the road the management did not prove any more generous towards the men than the old company had been, but the New Haven Company has displayed a much better feeling of justice. The Old Colony people were noted for the small salaries they paid to foremen, master car builders, master mechanics and others in the responsible positions that preclude the exercise of pressure in asking for justice. We hope the New Haven people will remember this class of men, for New England is greatly in need of the example of a railroad company being willing to pay the men fairly who are responsible for carrying out the details of management.

---

## Pleased with Lakewood.

When the railroad mechanical conventions met last year, instructions were given to the committees having the selection of a place of meeting for this year to arrange for a place as near to Chicago as possible, to make it convenient for those who wished to attend the World's Fair. When the committee met to effect the final arrangements, they found it impracticable to select a suitable place near Chicago, and Lakewood, N. Y., was chosen with considerable misgiving. It was the best that could be done, but those responsible for locating the convention there were afraid that the accommodation would prove unsatisfactory. The conventions are past, and all are happily disappointed in their fears that the place would not be popular. We do not remember hearing fewer complaints with a place of meeting. This has been due to a great extent to the efforts of the hotel keepers to do all in their power to promote the comfort and convenience of their guests. Mr. Brady, proprietor, and Mr. Fox, manager, of the Kent House, deserve all praise for their untiring efforts to please their guests, and Mr. Frisbie, of the Sterlingworth Inn, is equally deserving of credit. The visitors carry away so many pleasant memories of the place that we believe the conventions will go there again.

---

## Some Short Notes of Long Tramps.

[EDITORIAL CORRESPONDENCE.]

I don't know of a harder job than tramping around the World's Fair grounds for a week—firing a hog is child's play to it.

But I want to say right here, that every railroad man who can muster the money, and get the lay-off, ought to take in the Fair. Never before has there been collected at one spot on the earth such an array of the products of human skill; and, no matter how long a railroad man stays, he cannot help going away proud of the fact—for fact it is—that the Transportation Building is the most interesting, and the exhibits the best arranged, of all the great palaces in the White City. Not alone is this building of railroad and other transportation exhibits interesting to those in the business, but to all the visitors, with few exceptions.

In one exhibit alone, that of the B. & O. Ry., there is the whole history of railroad development, not alone in this country, but in the world.

A full-sized model, or an actual machine, of every steam locomotive, of any particular design, from Newton's kettle, that blew a jet of steam back into the air, up to the magnificent compound at the head of the Royal Blue train, is here shown.

Here the men of to-day can see what the fathers of the locomotive had to contend with, the material they used and the results they accomplished.

Here are actual locomotives that have been in the service for fifty and sixty years, and were just taken out to come to the show—grisly old fellows, small and queer, but with an honorable record of a long life of hard work, commenced before most of us were born.

I couldn't help but think that if these old "grasshoppers" and "mud-diggers," and the rest of them, were conscious of passing events, and could remember, they would each feel—as they looked across the aisle at the mammoth engines of 1893—very much as an old ape would feel who had just been convinced that the Darwin theory was correct, and that he, himself, was great-grandfather to some shining example of the human family—myself, for instance.

Besides the forty or fifty models, or actual ancient engines, this company also show 1,700 large pictures, in which there are four series, one shows the development of the locomotive, and is complete, from Genesis to Revelations, another shows the development of the brake, from the ox-cart skid to the latest automatic; still another series shows the development of track, from the old cast-iron fish-belly rails three or four feet long, up to the thirty-foot rail of 100-pound steel on stone ballast, while the fourth traces the car from the oldest to the last.

Besides this, there are here, framed, many old and interesting drawings, some of them from the hands of noted men who long ago went away on ships of air into that unknown and eternal subsequently, leaving behind them monuments of their work.

The "old-timer," who feels unhappy with his modern engine, and is continually sighing for "the good old times," should come here and see some of the good engines in use before the war, Masons', Griggs', Perkins', Winans' and a few more of them—you couldn't hire them to run them now.

It is only seventeen years since the Centennial, but seventeen years ago the Junior Philosopher was young—just a tender young thing—and well he remembers with what awe he gazed upon the B. & O.'s mogul passenger engine "600," that stood beside an old "grasshopper," with the proud words over her, "B. & O. Ry., 1876," while the old walking-beam engine bore, though rather shamefacedly, the legend, "B. & O. Ry., 1831."

Well, only seventeen years have come and gone since then, the Junior Philosopher is not so spry in the legs as he was;

that magnificent mogul is an old engine, with visible signs of palsy, and no slight indication of Bright's disease, or stone in the bladder. She is as small, in comparison to some of the locomotives of '93, as the grasshopper was small to her only seventeen brief summers ago; yet that old grasshopper is here, looking just as chipper as in '76, been sawing wood steady ever since, and has no intention of giving up yet—of course, she don't intend to do any more of the hard work, going to let the children do that, but when it comes to doing chores for her keep, she is worth just as much as a full hand—so, it seemed to me, she was thinking.

The array of modern locomotives is complete, almost every maker in the country being represented, not by one but by many engines. There are French engines, fearfully and wonderfully made, German engines, English engines, old and new, and, ah! what finish of sheet-metal work and paint.

But, going from the fine finish, but complicated parts, on the foreign engines to the simple, massive, easily-repaired and get-at-able American engines, every son of the soil will feel proud of his country and its motive power.

There are four air-brake companies, exhibiting 100 brakes each, and an instructor is constantly in attendance—and the boys keep them busy. This alone is a great educational feature.

The famous old war engine "General" is here, and attracts a great deal of attention.

The "John Bull" came here from New York, under her own steam, and all the boys want to see her. 'Cause she went running in '31.

The "De Witt Clinton" stands outside, alongside of the "999," and men, women and children are asking continually "Where is that '999?'" I confess, I wanted to see her, myself. She is certainly the queen, and Solomon in all his glory was not furbished up as Nat Sawyer insists on the "999" being, if a fly lights on her, Nat sends one of the boys out to get rid of that speck.

If there is anything about a locomotive, any kind of metallic packing, injector, lubricator, oil-cup, headlight, or the like, that you want to know about, you can find their headquarters right here, and a polite attendant to explain anything you don't know.

Are you interested in compound locomotives? Well, here is a French 4-cylinder, a Webb 3-cylinder, Pittsburgh 2-cylinder, Schenectady 2-cylinder, Rhode Island 2-cylinder, Brooks 2-cylinder and 4-cylinder, Baldwin 4-cylinder, not one, but several of a kind.

Here is the largest engine in the world, a whale, and you can't see how the track holds her up and a firebox about the size of a bed-room. I heard a fireman say to his pard, after a long look at her firebox "Say, Jim, they 'ort to back the pay-car right up here and tell the fireman to help hisse'f."

Foreign cars will make the compartment system plain to you—so plain you won't ever want to ride in 'em.

The automatic vacuum brake, used so much abroad, is here shown in section and explained.

Not only railroads, but every means of transportation, from a pack mule to a steamship, is in this building, but there is enough modern railroad equipment from all over the country to keep one interested for a week.

Hotel charges are not so extortionate as pictured. You can stop out near the grounds and get a good room for from $1 per day up, eat where you wish, the restaurants are thick.

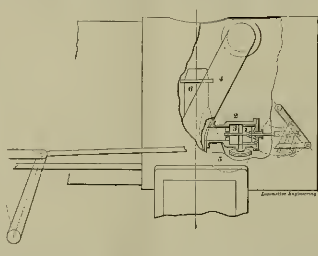
I believe that it would be a good investment for any railroad man to come here, if for only three days.

Of course, if one wants to go up Midway Plaisance and see the elephant, and hear the speaking pig, ride on the big wheel, pinch the leg of the tattooed woman to see if she is real, see the harem of the King of the South Sea Islands (where the summer uniform is to braid the hair in four spikes, instead of two), why, all this will cost you extra money; but the great show itself is dirt cheap, and it's worth 50 cents a day for a week to see the magnificent buildings and the beautiful grounds that have sprung up from the marsh at Jackson Park like a mirage.

J. A. H.

### Starting-Valve for Compound Locomotives.

The annexed engraving illustrates a new form of starting-valve for compound locomotives, invented by Mr. T. W Heintzleman and Mr. C. T Noyes, of Sacramento, Cal., and applied to several Schenectady compound locomotives in use on the Southern Pacific. The valve consists essentially of a valve and casing connecting the receiver and the steam exhaust pipe as shown. This attachment is an addition to the ordinary intercepting-valve and does not interfere with the operation of the latter, its purpose being to enable both cylinders to act independently while starting. When the engine is in full gear back or forward, a connection with the reverse lever throws the valve into the position shown in the engraving. This opens the auxiliary port 3, and permits steam to pass from the receiver 4, by the auxiliary pipe 5, to the exhaust pipe 6. This allows the steam from the high-pressure cylinder to pass into the atmosphere. A separate starting-valve is provided to admit live steam to the low-pressure cylinder, which escapes in the usual way. The notching up of the engine automatically pushes forward the piston 1, closing the auxiliary valve 3, and permitting the engine to work compound. It is a very simple form of apparatus and is said to work very well.



Mr William Buchanan, superintendent of motive power of the New York Central, has got up a very handsome illustrated catalogue containing engravings of the most famous locomotives belonging to the road. There are half-tone cuts of the "999," the "De Witt Clinton," the "Exposition Flyer" on its way, and line engravings of all the leading classes of engines with tables of dimensions. By following back the classes, one can form a good idea of the increase of power required gradually as trains grew heavier and faster. In 1881, the first-class express engine had cylinders 17 x 24 inches, and driving-wheels 70 inches diameter, 1,353 square feet of heating surface, and weight 42 tons in working order. Three years later the cylinders had increased one inch in diameter, the weight of the engine was 49 tons and the heating surface was 1,598 square feet. Then came, in 1889, the 870 class, with cylinders 19 x 24, driving-wheels 78 inches diameter and 1,821 square feet of heating surface. That is the best type of modern passenger engine.

### EQUIPMENT NOTES.

The Kansas City, Pittsburgh & Gulf are about to order 600 cars.

The Nevada Central has ordered some locomotives from Baldwins.

The Waco & Northwestern are about to order two locomotives and one chair car.

The Michigan Central has ordered three locomotives from the Baldwin Locomotive Works.

The Central of Georgia is building, at its shops, at Macon, Ga., several new parlor cars for the "Nancy Hanks" train.

The Seaboard Air Line has just ordered the construction of forty-five patent stock cars at the shops in Portsmouth, Va.

The Beech Creek Railroad people have placed an order with the Lebanon Manufacturing Company for 250 freight cars.

The Soo Line has ordered one heavy consolidation locomotive from the Rhode Island Locomotive Works for special service.

The Portland Company are building three Nevens snow and ice flanges for the Bangor & Aroostook, now building through Maine.

The Pullman Company are building ten vestibuled passenger coaches and four vestibuled smoking cars for the Maine Central.

The Rodger Ballast Car Co. have just finished the construction of 250 of their cars for the Butte, Anaconda & Pacific Railroad.

The Wilkesbarre & Eastern have just received a new lot of box cars, and they have ordered fifteen passenger cars from Jackson & Sharp.

The Wabash Railroad Company have decided to apply the Gould car coupler and the Westinghouse train signal to all passenger rolling stock.

The Merchants' Dispatch Company are in the market for 300 cars. They will be equipped with all the latest improvements, including vertical plane couplers and air-brakes.

Forty new suburban passenger coaches are nearly ready to leave the Pennsylvania shops at Columbus, O. They differ in a number of details from other suburban cars on this system.

The Fitchburg people are building 150 new cars in their own shops and it is expected that the order will be increased to 1,000. They are to be furnished with all the best modern attachments.

The Paris, Lyons & Mediterranean Railway, one of the most enterprising companies in France, have decided to light fifty new passenger carriages by electricity. A storage system will be used.

The P. R. R compound "1515" has been doing good work for some time, on the N. Y. division. She burns as much coal as the simple engines, however, and is at present laying up with a broken frame in splints.

Work is quite brisk in the Roanoke Machine Works. During last month they built 150 freight cars, three consolidation locomotives and one supply car for the Norfolk & Western. The supply car is illustrated in another part of this paper.

The Lackawanna Refrigerator Transit Company are in the market for 1,000 beef refrigerator cars, and they want them at once. They are ready to contract for delivery by September. There are some peculiarities about the construction of cars and trucks that make delivery on six weeks' notice a difficult job.

Forty Pullman sleeping cars and ten Pullman parlor cars have just been added to the equipment of the Pennsylvania. Twenty of these sleepers contain thirty-six berths and twenty more have thirty-two berths. The average sleeping car has but twenty-four berths. The total length of the thirty-six-berth cars is 70 feet. They cost in the neighborhood of $20,000 apiece. With other cars received beforehand, the new additions to the Pennsylvania's Pullman service number seventy cars.

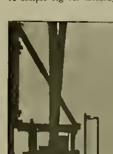
### Home-Made Tool for Grinding Steam-Pipe Joints.

Here is a snap-shot view of a tool got up in the Erie shops at Hornellsville, N. Y., for grinding steam-pipe joints and rings.

It can be seen at a glance that the old drill-press head has a bevel gear on the cone-shaft that meshes into one loose on the spindle that it drives by means of a feather.

The movable arms on the vise allow of the holding of almost any form of steam pipe and bringing the joint face level.

A simple rig for holding the ball joint



rings is fast on the spindle, and when driven at moderate speed with a supply of oil and emery, it is surprising how much sooner a bearing is got than when a man does the soot act in a smoke-box.

The counter weight keeps the spindle up when not in use.

This little tool saves lots of time and trouble, and is shown here solely as a pointer to roundhouse repair men who need something of that kind—and how many of them are there who do not

## Richmond Consolidation Locomotive.

The annexed engravings show two sectional views, of a fine consolidation locomotive built by the Richmond Locomotive Works and exhibited at the World's Fair. The following are the principal dimensions of the engine

CYLINDERS.

Cylinders, 20 in.
Stroke of piston, 24 in.
Piston-rod diameter, $3\frac{1}{2}$ in.
Piston-rod packing, metallic Jerome
Steam ports, 16 x $1\frac{1}{4}$ in.
Exhaust ports, 16 x $2\frac{1}{2}$ in.
Width of bridge, $1\frac{1}{4}$ in.
Slide-valve, Richardson balanced.
Travel of valve (maximum), $5\frac{1}{2}$ in.
Lap of valve (outside), $\frac{3}{4}$ in.
Truck-axle journal, 5 in. dia. x $8\frac{3}{4}$ in. long.
Tank capacity (water), 3,500 gallons.
Tank capacity (coal), 6 tons.
Rigid wheel-base, 14 ft.
Total wheel-base of engine, 21 ft. 8 in.
Total wheel-base of engine and tender, 48 ft. $\frac{1}{2}$ in.
Total weight of engine, in working order, 127,300 lbs.
Weight on drivers, 110,800 lbs.
Weight on truck, 16,500
Weight on tender, loaded, 67,000 lbs.

One of our Western correspondents adds the following postscript to an interesting letter

"Here is something that I think is funny This spring, when business began to get dull, some of the older men on a certain Western road thought it would be advisable to reduce the number of engineers employed. So, as usual, the Grievance Committee waited on the superintendent, and succeeded in having seven of the youngest men laid off. Then the division assessed itself to pay the Grievance Committee, and sent each member, including the seven unfortunates, a bill for \$2.65. Just imagine losing your job, and having also to pay \$2.65 for the pleasure (?)"

## Some Comical Things Seen and Heard at the Fair.

"Jeemses Cripe! pa, look at the spile-driver," said a 10-year-old kid as he caught sight of the great Bethelem steam-hammer, with a hammer-head weighing 125,000 lbs.

There are two German engines in the exhibit, one numbered 1338 and another 1322. The J. P. was tired and he sat down opposite 'em on a Barr contracting chill when two old ladies came along. "1338; dear me, I didn't know they had steam cars so long ago!" said one. "Look here, Mary," said the other, "this one was built in 1322, don't it look funny beside the kind they have now?" Then they both leaned their note-books up against something and made an entry about the "old" engines.

This always attracts attention. One day a little fagged-out man pushed a rolling chair and a 200-pound wife up to the railing and they admired the engine. She was making the notes and the man was doing the sweating.

Nat gave the lady his card and a smile. The lady adjusted her gold-rimmed specs and read the card. "Plug-puller, plug-puller; what's that, James?" "Why, that's what engineers call themselves, dear," said he, "that's the engineer of this engine, he's run 112 miles an hour. Quiet little feller, and I want to call your attention to the fact that he ain't no bigger than me, small men are the real——" "There, there, James," said she, "wheel me away, you're all the time bragging up these little runts to me"

It's always comical to see the inquisitive man "get a shock" at the "999." The draw-bar on her pilot is polished, as is most of the wrought-iron work on the engine, her nose sticks through under the railing, and about one man out of ten wants to heft that bar. This tarnished it, and the cleaners at last daubed the under side with black lead; now when a man lifts it he turns away quickly and hunts his handkerchief, and every half-hour Nat says "Boys, charge that bar again, they've wiped it all off"

The full-sized models in the B. & O. exhibit are such good imitation of iron that most folks feel the necessity of knocking on the sides of the boilers to see if they are iron or wood. R. C. Wright, in charge, is figuring on putting a boy inside each of them with instructions to yell, "Come in!" when they knock. While the J. P. was looking at one of these models, an Illinois Central fireman came along and opened the fire-door, knocked it with his knuckles, and said "Bejazes, that's nothin' but wud, but I suppose it owny timporary like, pwhy the doure on our ingin gets so bloody hot yez can't touch it, but, av coorse, they wurrked these ould pelters aisy to whot we do."

As I went into the Transportation Annex I found a woman and half-a-dozen youngsters in front of a little engine built by H. K. Porter & Co., and numbered 1, and a Brooks eight-wheeler, numbered 210, that stands on the next track. "Now, children," said the lady, "here is where you can see the way things are improved all

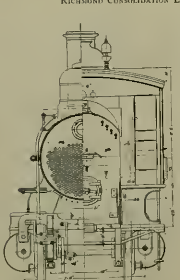
Diameter of driving-wheel, 50 in.
Driving-axle journal, 7 in. dia. x $8\frac{1}{2}$ in.
Engine-truck, two-wheeled pony-truck.
Diameter of truck-wheels, 30 in.



A railroad man was leaning over the railing looking at the great Erie decapod, and wondering if engineers would ever get paid for running engines according to their weight, when a young farmer from Indiana came up the aisle towing his best girl. They stopped before the monster, and the man spoke up: "Say, Sairy, she's some punks, ain't she? Say, mister, how many cogs has she got?" "Ten," said the railroader. "Is she fast?" "Lightnin' on a limb." "Well, a feller back there told us that big wheels was for fast, little ones for slow going. Her'n ain't so all-fired big" "Yes, but she's got ten; she's a multiplier. Supposen she was steamed for ten miles an hour; she's got ten drivers, ten times ten is a hundred—see!" "An' she's got two bilers on a side," observed the rustic, as he noticed the compound cylinders. "Yes, that's another multiplier. The big one catches the water and boils it again, gettin' twict as much power out of it, so, if she was multiplying for 100 miles an hour, that would give her 200" "Do ye mean to say this here engine kin go faster 'n 'lectricity—200 miles in one hour?" "I ain't sure," said the railroader. "We ain't had a chance to try yit, she's new" "Gosh! they air makin' improvements, ain't they, Sairy?" said the boy. Then the railroader went behind the engine and butted his head against the tank and laughed.

Nat Sawyer, in charge of the "999," has a personal card which reads "Nat Sawyer, N. Y. C. & H. R. R. Plug-Puller."

the time. There is the first engine; see the number, Willie? and here is the last—just see the difference in the size." When she got to the engine with the Wootten firebox she stopped. "Now, children, here is a tandem engine—see, one engineer is in one little house and the other one is in the one just behind him, that's tandem, you know."

Some of the locomotives are running by compressed air, and it's comical to see the railroad men feel of the cylinder casing to see if it's hot. One of 'em turned to his companions the other day, after feeling of a head, and remarked "That's the best job of laggin' I ever seen, it's as cold as a ham sandwich; why, my engine cylinder casing gets so cussed hot you could fry eggs on it; that's where half the heat goes to, then they kick about the coal you burn. My engine is a Baldwin, too, and if they'd lag their regular engines like *that* it would pay, pay big."

## BOOK REVIEW.

LOCOMOTIVE CATECHISM. By Robert Grimshaw. Page, $4\frac{1}{2} \times 7$. 362 pages, 178 illustrations and 7 folding plates. Norman W. Henley & Co., publishers, 150 Nassau st., New York. Price, $2.00

This is a new book on the old lines of questions and answers—perhaps the best possible way to instruct the novice. The author here gives some 1,300 questions and answers about locomotives, which are put into attractive book form, and provides a very complete index of subjects. Especial attention is given to compound engines, which are the subject of 18 illustrations and about 40 pages of matter; types being described and illustrated.

While there are probably very few questions in this book that are not asked and answered in other works on the locomotive, there is no doubt that they are well chosen, and make a valuable work for locomotive engineers, firemen, or others interested in the detail of the locomotive. It is, undoubtedly, the best of the series of catechisms written by the same author, and is worth the price asked many times over.

## Biographical Dictionary.

One of the most welcome books which we have received lately is the "Biographical Dictionary of Railway Officials of America," published by the *Railway Age*, of Chicago. The book contains well condensed biographies of all the leading railroad officers in this country and in Canada. The work has been admirably done, the careers of over 4,000 men being outlined. The book will be found very interesting to those who care to reflect on the careers of the men who keep the wheels of railroad progress moving. The student of his fellow-men will here find an amazing record of men whose qualities of self-help have raised them from workmen to leaders. One might read prolonged biographies for a lifetime and not learn about half the men who are mentioned in this single volume as having by their own unaided exertions climbed the ladder that leads from obscurity to celebrity. We heartily commend the book. It can be got for $3.

## A Way Out of the Trouble.

"I remember," said Gleason, thoughtfully, "when I first went running on the Lackawanna. I was stuck on my job, loved my engine, and was twice as jealous of her as I am of my wife. We had a trainmaster that got a notion that we were pulling trains far too light, and he commenced putting on cars. After a hard trip—doubling, running for water and the like—I went to see Bill Halstead.

"'Mr. Halstead,' said I, 'I've come to see you about these heavy trains. They are just pulling the stuffing right out of my engine, I can't take care of her this way. I've got the best engine on the road, and I don't propose to see her overloaded and abused without a kick.'"

"'I'll tell you,' said he, 'the best way to fix that—lemme see, which engine is yours? The 'Anthracite.' Oh, yes. Well, as I was saying, the company want a few engines, supposen you sell her to the road, they'd just as lief pull all the cars with her as not—how much do you want for her?'"

OPERATING AIR-BRAKES ON EQUIPMENT FOR ONE HUNDRED CARS.

WESTINGHOUSE AIR-BRAKE EXHIBIT AT WORLD'S FAIR.

The management of the Erie have announced that they will transport all employés and members of their family dependent upon them, to Chicago and back during the summer, in order that they may have the opportunity of visiting the World's Fair. This road is already doing a heavy passenger business between New York and Chicago.

## Boilers and Furnaces.

By Angus Sinclair.

CONSIDERATIONS OF THE DESIGNER.

Persons who design boilers for supplying steam to engines follow certain well-established rules in order to make the boiler suitable for its purpose. In the first place they have to calculate how great a volume of steam per minute or hour the boiler will be required to generate, and they arrange the proportions to meet the requirements. With a certain velocity of draft the surface of a boiler exposed to the fire may be depended upon to evaporate a certain weight of water per hour when the grate is large enough to burn the fuel freely. The three leading factors in boiler design are therefore the character of the draft to be employed, the amount of heating surface, as the parts exposed to the fire gases are called, and the extent of grate area.

Besides arranging that a boiler shall be equal to the demands of steam making, there are several other important considerations that demand the care of the designer. Among these are strength sufficient to resist the pressure inside, durability, smallness of bulk and weight, free circulation of the water, ease of access for inspection or good provision for cleaning, and economy of fuel.

REQUISITES OF A GOOD BOILER.

In the Manual of Steam Boilers, by Professor Thurston, published by John Wiley

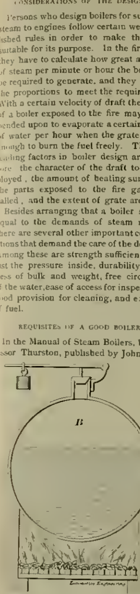

Fig. 1.

& Sons, New York, the following requisites are given as essential in a well designed boiler

1. To secure complete combustion of the fuel, without permitting dilution of the products of combustion by excess of air.

2. To secure as high temperature of furnace as possible.

3. To so arrange heating surfaces, that without checking draft the available heat shall be most completely taken up and utilized.

4. To make the form of boiler such that it shall be constructed without mechanical difficulty or excessive expense.

5. To give it such form that it shall be durable under the action of the hot gases and of the corroding elements of the atmosphere.

6. To make every part accessible for cleaning and repairs.

7. To make every part as nearly as possible uniform in strength and in liability to loss of strength by wear and tear, so that the boiler when old shall not be rendered useless by local defects.

8. To adopt a reasonably high "factor of safety" in proportioning.

9. To provide efficient safety-valves, steam gauges and appurtenances.

10. To secure intelligent and very careful management.

We BOILER EXPLOSIONS.

1845, to.. years after steam boilers came gauge engi..t accidents by rupture and 7-feet gauge. common that a belief by the Railway Com..ysterious agencies engines to be tried," sp.

were at work inside boilers, which no degree of strength could resist. Increase of knowledge concerning boiler construction has eliminated from engineering minds all theories about mysterious causes for boiler explosions. All men familiar with the design, construction and care of steam boilers are unanimous in the belief that explosions happen only when some part of the boiler is too weak to resist the steam pressure within. The weakness may arise from faulty design, deterioration, want of care, or by reckless practices on the part of those in charge. No matter how the weakness may arise, it is agreed that acci-

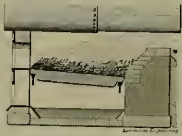

Fig. 2.

dents happen only through *steam* pressure being too great for the plates provided to hold it inside.

SURVIVAL OF THE FITTEST.

There is a great variety of steam boilers in use, and a vast variety of forms have been tried and abandoned as unsuitable. The best known existing forms of steam boilers have held their own through a prolonged process of natural selection, and have been adopted because they were the fittest for their purpose.

GLOBULAR BOILERS.

The globular boiler was the first form employed to generate steam much above atmospheric pressure, and was no doubt chosen because it is the strongest natural form for resisting pressure. With a globular vessel pressure within puts equal strains on the whole of the surface and there is no tendency to distort the contour of the surface. Soap bubbles, toy balloons and numerous other objects supply illustrations of how strong the globular form is to resist inside pressure.

The experiments made with steam engines and boilers during what has been called the "speculative era" of the steam engine, were all carried out by philosophers and scientists, so it was natural that they should cling to the strongest theoretical forms in designing boilers. The globular boiler shown in Fig. 1 was the favorite form in use until the improvement of the steam engine fell into the hands of practical mechanics. The first form of furnace used was a plain hearth made of brick or other refractory material, and the first important improvement effected was the raising of the fire and placing it upon grates, which permitted the air necessary for combustion to enter beneath the fire. This invention was the work of a French scientist.

Although the solid hearth was early abandoned by steam makers, owing to the difficulty of supplying the necessary air to the fuel, its use was several times revived by inventors of smoke preventing furnaces, and it is now employed largely in metallurgical operations.

THE CYLINDRICAL BOILER.

The principal shortcoming that a globular form of steam boiler suffers from is that it provides very little heating surface. When practical mechanics began to work out the necessary appurtenances of a steam engine that would do work more cheaply than other forms of power, they quickly adopted the cylindrical form of boiler, which is strong, of simple shape and provides a large surface for the fire gases to act upon to heat the water within.

In connection with the cylindrical boiler the oblong furnace with a bridge in front came into use. The bridge was not applied for many years after the oblong furnace was introduced, but the combination is nearly as old as the modern steam engine. The arrangement shown in Fig. 2 is that most commonly employed. With slight modifications this furnace is almost universally used except for locomotives, and it was the first furnace applied to the pioneer locomotives. With skillful firing, and with means provided for admitting air over the fire, this furnace can be made to burn coal as economically and as free from smoke as any ever invented. Another good thing about this furnace is, that there is nothing in its construction which a common fireman cannot understand.

THE CORNISH BOILER.

An improvement on the plain cylindrical boiler, which had the furnace outside and had merely the bottom plates for heating surface, was the Cornish boiler, which had a large single flue through the center of the water space and had the furnace at one end of this flue. The next step in boiler development was to put in a return flue, so that the fire gases passed twice through the boiler. The first practical locomotive, or at least the first locomotive to perform everyday work of hauling cars, had a boiler of this kind. It was built by William Hedley in 1813.

An improvement on a single large return flue was two smaller ones, which gave much more heating surface for the space occupied. This line of development gradually led to the modern multitubular boiler. When a boiler flue is smaller than 3 inches diameter it is usually called a "tube." This brings us to the modern locomotive boiler.

DEVELOPMENT OF THE LOCOMOTIVE BOILER.

Those pioneer engineers who gave to the world the high speed locomotive with all the essential parts complete, performed a very difficult problem when they designed a suitable boiler. Before the work was done the difficulties seemed insurmountable. Two conflicting elements had to be harmonized. The problem called for the lightest form of boiler that had ever been used, and at the same time it must generate steam ten times faster than the boilers most commonly in service.

American inventors, whose genius had been stimulated by the demand for fast steaming boilers for river steamers, had made the engineering world familiar with various forms of multitubular and water tube boilers, but neither of these seemed suitable for locomotives, as they required a built-up furnace. To use an internal furnace in a large flue and then small return tubes above, called for a larger boiler than was considered permissible with a locomotive. A firebox seems a simple expedient after we have seen it applied, but it was a tremendously difficult undertaking for those who applied it for the first time.

INVENTION OF THE FIREBOX.

Various inventors and engineers had proposed employing a firebox in combination with the multitubular boiler for locomotives, but there were difficulties of construction to be overcome that the pioneer boiler makers were slow to overcome. The

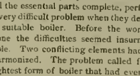

Fig. 3.

first engineer to apply to practical use the combination of a multitubular boiler and firebox was Mr. Marc Seguin, of the St. Etienne Railway of France. In the beginning of 1829, he changed the boilers of two locomotives bought from the Stephensons, and built them in the form shown in Fig. 3. In this the water did not surround the firebox. Referring to the engraving it will be seen that firebox was a detached chamber, so secured that the fire gases passed directly into the boiler tubes. A fatal objection to this form of firebox was that the material soon burned out. When it was lined with brick the rattling of the engine quickly shook the structure apart.

Detached brick fireboxes have been experimented with a great deal at various times during the last sixty years. Not a few modern engineers believe that a firebox made of firebrick would be more economical than the common form, which has plates surrounded by water, because a higher furnace temperature would be maintained. The Verderer boiler, which was tried in Germany some years ago, had a brick-lined firebox. Apart from the tendency of this form of firebox to shake to pieces, a still more serious difficulty arose against its use. The boiler tubes received the fire gases at such a high temperature that no means could be devised to keep them from leaking.

THE MODERN FIREBOX.

Seguin's experiment with the detached firebox with solid sides was a highly important step forward, but the prototype of the modern firebox appeared in Stephenson's "Rocket," which was built in 1829.

Fig. 4

The general arrangement of this firebox is shown in Fig. 4. The furnace is a double box, one inside the other, with a water space separating the two shells. It was secured to the back boiler-head, and had circulating pipes on each side to keep the water moving between the body of the boiler and the firebox. Within two years after this firebox was put into use the locomotive firebox reached its present shape in small forms of engines. Very few locomotives were afterwards built without fireboxes.

No invention connected with improved methods of transportation received such general and cordial adoption as the locomotive firebox. Yet, strange to say, there is no part of the locomotive except the link-motion that has been the object of so much fault-finding. It is reputed to be the worst kind of form to withstand pressure successfully, it does not lend itself conveniently to the putting in of a large enough grate, it is awkward to make and hard to maintain in good order, while its perpendicular sides are a vicious form of heating surface. Substitutes without number have been offered, and the highest engineering indorsements testified that they were likely to be much superior to the firebox, yet somehow this ridiculous paradox on engineering perfection would not be suppressed, and it continues to hold its own, while all its rivals slip one after another into quiet oblivion.

## Invention of the Link Motion.

BY JAMES HEDLEY.

Previous to the link being put in use several valve motions were used, the principal one used by locomotive builders being the gab motion, which was often out of order and required a great deal of repair. About the year 1844, I was at that time serving my time with Stephenson as mechanical engineer. There was also in the shops at that time a young fellow named William Williams, and Mr. William Hutchinson was manager for Stephenson, having charge of the shops at Newcastle. A man named George Howe was foreman in the pattern shop. Williams was the man who invented the link motion. He made the drawings and gave the idea to Howe for him to make a small wood

model from. After Howe had got all the details from Williams he kept Williams at bay, promising daily that the model should be handed over to him; but that time never came. A short time afterwards Mr. Hutchinson called Williams into his office and showed him the model that Howe had made from the drawings that Williams had given him, leading Mr. Hutchinson to believe that it was his own invention.

The result was that Messrs. George and Robert Stephenson were sent for and investigated the matter, the only alteration that Howe had made was—Williams' link was straight, and Howe put the curve to the one that he showed to Mr. Hutchinson. Hence it was that a patent was never obtained for the link.

I took the first engine from the shop that was fitted with the link, and worked the engine for Stephenson during the guarantee mileage, and also put the link motion to several old engines that had been fitted with the gabs and other motions that were used by other engine builders. The year that the link was first put in use, the boiler was loaded 56 pounds pressure. The link was then of little use for expansion, its principal merit being as a reversing gear.

We had an order for several new engines, and the boilers were extra stayed and loaded at 80 pounds; then the link showed what it was capable of doing. We then fixed the catch-plate for the reversing handle, and marked the quadrant plate according to the cut-off.

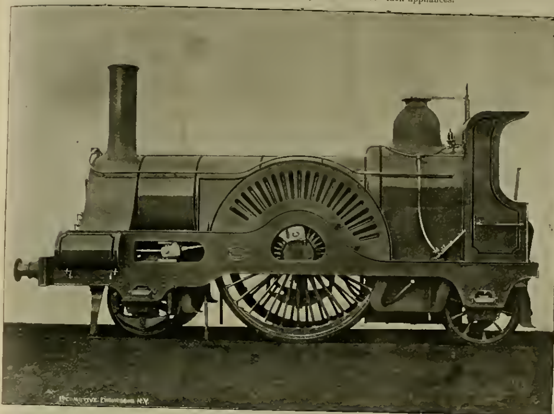
I have given you a correct account of the invention and working of the link motion. Now, what advance has been made in locomotive engineering since the link was first fixed? I cannot see that much has been done. The engines are much larger, stronger boilers and high-pressed steam. "It is the high steam that drives them along." Mr. Webb is the only locomotive engineer that has made a show towards improving the old class of engine, and I am afraid he will have to abandon it. Locomotive engineers are too closely confined to add extra machinery. The gauge is too narrow.

We built an engine, 4 ft. 8½-in. gauge, in 1845, to run against one of the broad-gauge engines, Great Western Railway, 7-feet gauge. It was an order issued by the Railway Commissioners, for the two engines to be tried, "speed, power, and consumption of fuel," for a test to show which of the two gauges, 4 ft. 8½-in. or 7-feet, was best for the service of the country. We had a train loaded with pieces of short rails—coal, coke and water weighed to each engine. The result was the 4 ft. 8½-in. gauge engine showed much better than the Great Western 7-feet gauge, so that all new railways laid down were to be standard gauge, 4 ft. 8½-in.

During my railway experience I have worked engines fitted with all classes of valve-gear, and never saw one that was equal to the link. Some time after the link had become the standard class of slide-gear, the principal locomotive engineers and railway moneyed men presented Williams with a cheque for £1,000 for his invention. About that year I left the shop and engaged with the Southeastern Railway, a road running from the city of London to the port of Dover, the shortest and most direct road to all parts of the Continent.

For eight years I ran the fast mail on that road, the S. E. Company building their own engines for that class of work, fitted with 18-inch cylinders, 24-inch stroke, one pair of drivers 8 feet in diameter. They could make good time, but I had an engine, "Crampton's patent," same dimensions as the company's build, and I could make better time with the Crampton. On some special occasions I have got seventy miles per hour out of that engine with the India overland mail, the weight of train just enough to keep the engine steady. Queen Victoria and many members of the Royal Family have ridden behind me on that road. After eight years, running the express and fast specials, the superintendent of motive power placed me in a better position, giving me charge of two locomotive stations, and a dock fitted with steam cranes for discharging coal from screw steamers for the use of the company's coal station. That position I held for twenty-five years, serving that company thirty-three years.

Now I am an old man, but even now I cannot leave off handling the tools. My locomotive model is getting in a fair way of completion, and should be glad to show it to any gentleman who takes a delight in seeing a nice piece of work. I think you will be able to see that I have had a good sound practical experience in railways and their appliances.



Passenger Locomotive, Egyptian Government Railways. Cylinders 17½ x 24 Inches, 8-Foot Wheel.

Piece of a Clinker Formed in One Trip of 90 Miles on Engine [illegible] Wootten Consolidation, P. & R. R. R. Covered Entire Flue Sheet 1½ Inches Thick [illegible] Buckwheat Coal and Snow.

The locomotives built by the Brooks Locomotive Works for pulling the twenty-hour limited on the Lake Shore & Michigan Central appear to be making a splendid record with those fast trains. In cases where delays have happened that made the train late these engines have demonstrated their capacity to materially reduce the running time. In one case a whole hour was made up between Buffalo and Elkhart, raising the average speed, including stops, to about fifty-four miles an hour. To make up for the delays caused by stopping and reducing speed at water-troughs and crossings, a running speed of sixty-five miles an hour is necessary. There is said to be no difficulty in maintaining this with four cars.

---

California redwood has several characteristics that make it a remarkably good lumber for car building. It is the only wood known which will neither shrink nor swell on exposure to the weather after being thoroughly seasoned. Tests have been repeatedly made by immersing redwood in water for days, and it was in no case perceptibly changed. This makes it an excellent wood for window sashes and other parts which cause inconvenience and annoyance by shrinkage or swelling. Another good point about redwood is that it burns very slowly.

## Good Material a Remedy for Broken Stay-Bolts and Exploded Boilers.

An honored correspondent, on reading an article in Locomotive Engineering on broken stay-bolts, was inspired to write:

"The subject of stay-bolts is certainly a very important one, not only to the master mechanic but also to the managers of railroads. In the earlier days of railroading, 80 to 100 lbs. of steam was considered a high pressure, and the speed attained did not exceed twenty miles an hour. At the present day the finger on the dial of the gauge on a locomotive points to 160 to 180 lbs., and the speed attained would reach the average of forty miles an hour.

"With these facts before us, and the disposition of both builders of locomotives and operators of railroads to use cheap (and consequently inferior) material, it does not seem so remarkable that much annoyance is caused by the breaking of stay-bolts. If we increase the demand on our machinery, we ought certainly to increase the power of the machinery to meet successfully the increased demand upon it.

"When we consider that the firebox is one of the most important parts of an engine and the severe strain put upon the iron which holds the firebox in place, we feel convinced that much of the trouble might be avoided if better material was specified when ordering locomotives, or in ordering iron for repairs on this class of work. There is nothing connected with locomotive construction where a cheap article so thoroughly proves itself to be dear than in the selection of iron for stay-bolts. Purchase the best in the market and there will be no danger of explosions due to broken stay-bolts." We heartily indorse these sentiments.

### Lining Guides.

BY G. K. WENTWORTH.

When a locomotive engine receives general repairs, or from any cause, when the guides are taken down and it is necessary to line them up again, they should be straightened and ground, or filed true on the part that wears on the crosshead lugs.

In the four-bar style of guides, on the upper guides, the bottom part should be square with the part that wears on the crosshead; on the lower guides the top part should be square with the side that wears with the crosshead. The guide-blocks should be planed $\frac{3}{8}$-inch less than thickness of crosshead lugs; if guide-blocks are so thin that it will require over ¼-inch liner on top, and $\frac{1}{8}$-inch on bottom of guide-blocks, to have them the thickness of crosshead lugs, then use thin (tin) liners to the thickness of ⅛-inch on top, and $\frac{1}{8}$-inch on bottom, and one thick solid liner for the balance; make all thin liners larger than guide-blocks, cut them so they can be put in from end of guide-block without taking guide-bolt out, then when liners are trimmed off there will be no open space on side of guide-blocks and it will leave a neat job; heavy liners should be just the size of guide-blocks.

I prefer planing guide-blocks instead of planing off end of guides where they bear on guide-blocks.

As the upper guides and top of crosshead lugs that wear on the upper guides wear faster than the bottom guides and bottom back cylinder-head. Get the center of hole in crosshead where piston-rod fits, place the crosshead on two parallel blocks, the parallel blocks should be set on a level surface. With the guide-gauge get the distance from center of hole where piston-rod fits to bottom of crosshead lugs as shown at Fig. 3, then put the bottom guides up, put a large nut about the thickness of top guides on guide-bolts for a washer. It is very essential in lining guides, that guide-bolt nuts be drawn tight every time a liner is changed. Place the bottom guides in proper position by measuring with guide-gauge from bottom guides to line, and from straight-edge placed across the frames to guides, same as done when setting guide-blocks; have both edges of both guides caliper the same from straight-edge in front, and the four points on back end of guides the same, or any place the straight-edge is placed across the frames, but do not try to have the points at $A$ caliper the same as at $B$ in Fig. 4, try the guides by placing a straight-edge diagonally across them from $A$ to $D$ and $B$ to $C$, as well as lengthwise from $A$ to $B$ and $C$ to $D$. When the bottom guides are in proper position they will measure with the guide-gauge same distance from the line at all points; and from straight-edge across the frames, and a straight-edge bears evenly both lengthwise and diagonally when placed on guides, the bottom guides are correct.

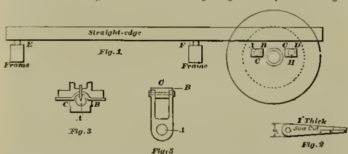
When straight-edge is placed on guide, put a narrow strip of thin paper under the straight-edge at each point on the guides than a linen thread and is much better to caliper from.

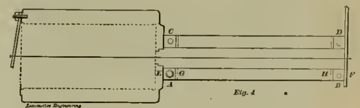
I have got better results from using a straight-edge across the frames and setting guides to it, than with a spirit level.

If the bottom guides are correct on the ends, and low in the middle, they can be sprung by putting narrow strips of paper for a liner at end of guides, between guide-blocks and guides, at points $E$ and $F$, Fig. 4, and tighten the guide-bolt nuts; putting liners at points $G$ and $H$ will spring guides down in the middle. Practice only will tell a person how thick liners to use to get guides correct.

When putting guides up use bolts that fit holes in guide-blocks and end of guides tight; if loose-fitting bolts are used guides move sidewise and are not true to line; it is best to have the bolts that will be used permanently. That cannot always be done, for frequently new bolts are needed. It is best to line guides to proper place, first with temporary bolts, then put clamps across both guides at front and back end, to hold them in position so they cannot move, then take bolts out, ream holes and fit new bolts in holes, then trim all the liners off neatly.

In the two-bar style of guides, the upper one will generally require putting up first, and the bottom of it should be parallel to straight-edge across the frame, and to line through cylinder, and be the same distance from line as distance from center of hole in crosshead where piston-rod fits to top of crosshead, as shown from $A$ to $B$, Fig. 5; put up the crosshead $C$, and close





of crosshead lugs on an engine that runs forward most of the time, the top guides will need closing first, so leave more thin liners on top of guide-block.

Before putting guides up it is best to see that the back cylinder-heads are tight, and all the studs are good, and nuts tight on studs, so cylinder-head joint will not leak. Set the front guide-blocks in the proper place by putting a straight-edge across the frames just back of the cylinder-heads, and caliper from the top of guide-blocks to lower edge of straight-edge, when straight-edge is placed across the frames; if it is below top of guide-blocks, place small parallel blocks on frames as shown at $E$ and $F$, Fig. 1, then place the points $A$ and $B$ on inside of guide-block same distance, and $C$ and $D$ on outside of guide-block same distance from straight-edge across the frames; fasten guide-blocks tight in this position, move straight-edge to back guide-blocks, and place them in proper position same as done by front guide-blocks.

If the guide-blocks are all planed the same thickness from centers $G$ and $H$ the four points $A$ $B$ $C$ and $D$ can all be placed the same distance from straight-edge across the frames, if the holes in the back cylinder-head and guide-yoke are the same distance from straight-edge across the frame. By scribing a circle the same size on each guide-block from the centers $G$ and $H$, will show if the blocks are planed so the two opposite sides will be parallel.

Fasten a board, made as shown on Fig. 2, to one of the top front cylinder-head studs; put a line in the saw-cut at $A$, with end fastened to a small nail or stick placed across saw-cut so line can be moved in saw-cut, fasten the other end of line to board, put tight on guide-yoke; set the line true to center of cylinder by the counter-bore in front end, and stuffing-box in where the straight-edge bears; if the paper is loose that point on the guides is out, and should be changed so straight-edge will bear evenly at all points.

When crosshead is placed on bottom guides, there should be no "rock" in it if crosshead lugs are planed parallel and true; if there is any "rock" in crosshead it should be taken out. It is not necessary that the crosshead lugs be the same thickness, but it is that the bottom of each lug should be the same distance from the center of hole in crosshead where piston-rod fits, when the bottom guides are put up first.

The guides are set true to bore of cylinder sidewise by measuring from center of hole where piston-rod fits to side of crosshead $A$ to $B$ and $A$ to $C$, Fig. 3, then setting side of guides parallel to line through cylinder.

After the bottom guides are in proper position, take the line away, put crosshead on bottom guides, put a block or jack-screw under each end of bottom inside guide, then put upper inside guide in place and close it on crosshead lug; have crosshead move free from end to end of guide, but not so loose that it will shake; put the upper outside guide in place the same way. This is on a four-bar style of guide where the two bottom guides are put up first. On some engines the upper guides will require to be put up first; then it will be necessary to measure from center of hole in crosshead where piston-rod fits to top of crosshead lugs. In these, the top of each crosshead lug should be the same distance from center of hole where piston-rod fits. In these, it will be necessary to fasten straight edge to the lower side of frames, unless there is room for it on top of frames.

I prefer using a small steel wire for a line through cylinder; it is much stronger bottom guide to it, so it will move free from end to end of guide. I have found the four-bar style of guides, when the two upper ones require to be put up first, the most difficult to line up. If guides are put up as they should be, with about $\frac{1}{64}$-inch lateral motion, and free from end to end of guides, and true with the bore of cylinder, they will run cool, and will not need closing for a long time.

I have seen guides put up so a piece of writing-paper could not be put between the crosshead lug and guides, at the same time crosshead moved free from end to end of guide, and engine made about 35,000 miles before guides needed closing, and from the time the machinist began to hang the guides until they were all done, was a little less than ten hours.

This article is not written with the expectation that it will be of any great benefit to all machinists, but for the younger class, as I heard one of them say he would like to see something on this subject in LOCOMOTIVE ENGINEERING.

### Broken Piston-Rods.

There was a most edifying discussion about broken piston-rods at the last Master Mechanics' Convention. We believe there is scarcely a railroad in the country that is not suffering more or less from the breaking of piston-rods, and this element of trouble has been greatly on the increase since the Laird guide came prominently into use. The consensus of opinion, as expressed by the members of the association, was that breakage is due principally to the action that comes from lost motion between guide and crosshead. The true remedy, of course, would be to make sure that no locomotives run with lost motion on the crosshead. The manner in which railroads are operated prevents this remedy from being generally adopted, so it is well to mention the precautions which members had found successful in preventing breakage.

Mr. David Brown, of the Delaware & Lackawanna, considered that a good remedy was to examine the piston-rods occasionally. Then he proceeded to outline a system which he had adopted of examining the piston-rods periodically. This close inspection generally leads to the detection of cracks that would become breakages if not taken in time.

Mr. John Mackenzie attributed breakage to the piston-rod being too much reduced in strength where it fits into the crosshead. He had adopted the practice of using the full thickness of the rod in its crosshead fit, or as much of the thickness as practicable, and it entirely stopped breakage in a class of engine that had been noted for this form of accident.

Mr. Wm. Smith, of the Chicago & Northwestern, believed in long crosshead bearings and in watching to prevent the growth of lost motion. By following this practice he is able to run Laird crossheads very successfully, and has no more breakage with them than he has with the crosshead held by four-bar guides.

Pistons are becoming so heavy, that we think the practice adopted on many foreign railroads of using tail-rods for pistons would be of great benefit in preventing breakage. When a heavy piston-head is carried by one rod, there must always be more or less of a tilting motion which causes breakage in time. The real remedy for this line of weakness seems to be something which will tend to carry the piston from both ends, holding it central in the cylinder. The reduction of wear alone and the prevention of steam leakage would be sufficient, we consider, to pay the expense of applying tail-rods to heavy pistons.

### The Compound a Good Spark-Arrester.

During the discussion on Compound Locomotives at the last Master Mechanics' Convention, Mr. John Medway, of the Pittsburgh, said "One very important matter to me has been omitted—that is, the capacity for throwing sparks. I would say that in our case we have good results from the compound in regard to that.

Thereupon Mr. Mitchell said "In regard to throwing the sparks, I had occasion a few days ago to send my man on the hill, and in talking with the track sub-foreman, he said, that with the consolidation engines formerly used on that hill for pushing trains, it required one or two engines, in the dry season, to watch the sparks and put the fires out. Since the compounds have been used there, a fire was something never known. I think that speaks very well for the compound."

An exceptionally quick run was made between Denver and Pueblo, on the Denver & Rio Grande, on June 6th. One of the express companies desired to take a large sum of money to Pueblo for the use of a national bank that was in jeopardy, and they engaged a special train for the purpose. The run was made in two hours and forty-three minutes, including one stop for orders and two for water. No special arrangements had been made for the train. The engineer was Jakey Brown, and Joe Brandt, fireman.

Write on one side of the paper, state your point plainly and briefly, and then quit. We supply the generalities. No letters noticed unless name and address accompany.

## War Badges and Ironclad Cabs.

*Editors:*

My attention was called to an article in your July issue concerning engineers' badges on the military roads. I have heard that such badges were issued in Virginia, and I have also heard that there were ironclad cabs in that State.

I ran a locomotive about two and a half years for the Government, but in all that time I never saw an ironclad cab nor a military engineer's badge. I was in the Army of Tennessee and the Cumberland, and was for four years in Government service.

Say, Mr. Hill, tell John Alexander to go to the World's Fair and write it up for your subscribers. I spent seven days there, and I saw so much that I got muddled, and can't tell anything about it except I saw the Infanta Eulalie.

I feel sure that if Alexander and Shandy McGuire had been there they would have made eyes at her. I didn't.

There is no value to the engineers' military badges that I know of.

## Theory and Practice.

*Editors:*

It seems to be quite a fad in general among railroad master mechanics and traveling engineers to have examinations in regard to air-brake practice, engine management, repairs, etc. And, of course, every one will admit that it is a good thing for a person to thoroughly understand his business and to pass a satisfactory examination by answering all the questions given him out of the little Sunday-school catechism that the company furnishes. But suppose he does, what of it? Does he understand the practice that is expected of him on the road, or has just an inkling of what other people's theories are? I believe that there are many engineers and firemen who could recite both questions and answers, word for word, without the slightest idea of what it meant. I think this is Darwin's theory reversed (aping after)—that is, the man turning to monkey.

While it is all very well to pass such an examination, yet, it seems to me, to illustrate by actual practice in the shop or roundhouse is of far more importance than answering the little catechism questions.

Don't understand me as having an idea that reading mechanical books and papers are not helpful to one. Far from it. They are as essential in my opinion as the actual practice. Theory by itself is of no importance without being mixed with practice (half of each). I remember a case of a mechanical school graduate who went to work in a railroad shop, and having a head chock full of theory was ready to work out on a piece of paper a broken stud, when an apprentice with ratchet and drill would have accomplished the aim in far less time. It is a fine thing to know theory, but to practice it is more desirable. Seeing is a great aid to the catechism question. Assisted by a steel scale and a look down into the steam-chest and valve-seat of a locomotive, you may perhaps, if the valve is around, find out the inside and outside lap and get ideas that the little catechism won't give. And in leisure time by watching some machinist in the shop, find out the best way to get a dead center and set a valve. You won't catch on so quick in the catechism.

I am glad to learn that the tendency now is to equip the front trucks of the engine with brakes. It looks possible to retard the train as much with front truck as with tender-truck. While writing about front trucks it occurs to me that if you look at it right, the front truck gets a good deal of petting. In some shops the brasses are scraped and fitted, and cells packed after each trip. How about an old box-car truck loaded to its fullest capacity, never properly oiled, traveling thousands of miles and seldom hot? Perhaps the front truck becomes spoilt. The style of putting brakes on drivers between the wheels of eight-wheelers ought to be condemned according to the way one would look at it. The wear is on the shoe in front pair and wedge behind and will eventually cause the rod brasses to stand open. What is the matter with putting both brakes in front of drivers? Mr. Hill has done much to give the readers of LOCOMOTIVE ENGINEERING an insight into the mechanical department of English railroads, and is now showing us the World's Fair in a manner that is quite to our taste. One can almost imagine himself within the Transportation Building gazing with open-eyed wonder at the scenes around.

The wrapper on your paper I think is the only objection to it. It won't come off quick enough.

ERNEST MARTIN.

## Broken Stay-Bolts.

*Editors:*

I read your criticism on hollow stay-bolts in the July number, and coincide with your views in the matter of hollow stay-bolts. I believe some twenty-five years ago, more or less, there was a law passed in the State of Massachusetts, that the four top rows of stay-bolts on all locomotives should be drilled in from outside, a suitable distance, to show if they were broken off. We found quite a number of stay-bolts broken by complying with this law, that we should not have detected in testing them the old way, by sounding them with a hammer. I have all stay-bolts put in our boilers, drilled in 1¼ on outside, $\frac{3}{16}$ hole. I do not consider that this weakens the bolts anything to speak of.

Supt. Machinery.
*Corning, N. Y.*

## A Reliable Draw-Bar Attachment.

*Editors:*

During the existence of this company we have never deemed it necessary or advisable to publish any statistics concerning the use of the Butler draw-bar attachment.

When contracts for cars have been let on which our device was specified, we refrained from making it publicly known. In the face of recent events, however, and in view of the importance given to "attachment of M. C. B. couplers," we will give figures showing our position in the trade. Railroad and car companies using our device represent 28,000 miles and 265,000 cars, all of whom are well satisfied with the service of the device.

In the report of the committee, which was made at the recent Master Car Builders' Convention at Lakewood, the total draft-gear defects were appalling to any who desire to keeping their rolling stock in motion, most of which was caused by old style and inferior attachments, the cost of which, considering repairs, is greater than the device we offer and guarantee to give entire satisfaction. We have numerous customers who report that the total cost of repairs to Butler draw-bar attachments does not exceed 5 per cent. of their cost per annum, and we are prepared to enter into contracts with any of the railroad and car companies to maintain our attachment for $1 per car per year, if manufactured by us and applied as we direct.

Our claims for superiority are based upon simplicity of construction, fewness of parts and absolute protection to draft springs, and our reference to sustain these claims are the users of our device.

In the earlier days of this company some light castings were sent out, which did not stand the required service, but these have been recalled and replaced, and new strengthened castings made, which are now equal to the service required.

With these facts before you, which can be substantiated, we solicit your patronage.

BUTLER DRAW-BAR ATTACHMENT CO.

ONE ENGINEER FORGOT HIS ORDERS.

## An Erratic Triple-Valve.

*Editors:*

The writer recently had a little experience with a plain triple-valve used for tender-brake, in which the aforesaid triple was guilty of conduct entirely unbecoming to a well-ordered and self-respecting triple. As air was turned into the train-pipe the triple did its duty properly until the auxiliary reservoir and train-pipe pressure equalized at, say, 70 pounds, but as soon as such equalization was effected, this erratic triple got in its queer work by immediately applying the tender-brakes, although the train-line pressure was maintained so that no other brakes applied. This triple having been put into a school system with gauges showing pressure in auxiliary reservoir and brake-cylinder, it was found that when the tender-brake was applied as above, the pressure in reservoir and cylinder was not reduced by the application, but, on the contrary, remained at 70 pounds. On taking the triple down the trouble was easily located. As a pointer, I will say that this could not have happened with a quick-action triple.

## Wants a Better Angle-Cock.

*Editors:*

In reading over LOCOMOTIVE ENGINEERING, the last issue, I notice that engine "999" made 112½ miles an hour at one time. I would like to ask if, at some place where that train stopped, some miscreant or bum had shut off angle-cock behind first car; how long, and what distance would train have gone before engineer could have stopped it with only one car and engine?

Westinghouse has a good, reliable and safe brake, and has made many improvements on it, but I think the angle-cock is one of the most important parts of the brake which has not been improved. Any boy knows how to turn an angle-cock, and

in its present form it is unsafe. Engineers who start out on a run, say with a stock train of eighteen cars, all working and good air, after making a few stops, can see about how to handle train and how to depend on brakes; but at some stop, air is cut out on him, and when he goes downhill into some station, he applies brakes, and they do not stop train and probably there is an accident. There have been enough accidents on account of angle-cocks being shut off to equip a road with air-brakes or safety angle-cocks.

I would suggest that some brake company get up a safe angle-cock. If the handles were taken off all of them and only allow car inspectors, conductors and brakemen to carry a handle, so as to turn them off, that would be some safer, because a bum or boy would not hardly go to the trouble of getting a wrench to turn them. There is an instance where a stockman going over train and punching up his cattle, accidentally put his foot against angle-cock to climb up and turned it off, which nearly caused a head-end collision. I say, take all the handles off angle-cocks anyhow, and only put them on when using to open or close. Someone invent a better method, by which engineer can tell when train is all cut in.

When I get ready to start after being stopped at places, I always make a 5-pound application on brakes before I start, and with a train-line of over seven or eight cars I could detect from the amount of air exhausted from train-line if any have been cut out, and several times I have tried this plan, and went back and found the tenth car cut out, and, of course, all cars behind it out, too. But how many engineers do this when they start? Very few. It causes delay to do so sometimes, but I think it prevents accidents sometimes also.

If I was running a fast train, engine like "999," I would want angle-cocks locked open and examined every start. Angle-cocks have cost railway companies more than anything else in accidents, besides good engineers their jobs. Here is a train going out: engine, eighteen cars and caboose; engine and fourteen cars working air, four cars and caboose non-air; it's a dark, rainy night; engineer makes a stop at water-tank where it's down-hill; four cars and caboose crash into rear end of fourteen air ones, turn one over and delay stock trains, fast vestibule trains and everything for several hours. As an experienced man and close observer, I say that this wreck was unavoidable as far as train crews and engine crew are concerned, because they could not discover on either end that train had parted, so bad was the night. Probably some one is discharged for it, but it could not have been avoided by any crew or set of men, but the company has been damaged and had quite a delay and loss, and censure the employees. What could have prevented this accident? A piece of bell-cord four car lengths long, fastened to last angle-cock on air cars and tied to caboose over or around four non-air cars. That accident would have bought enough bell-cord to equip every train. That seems like a better way than having so many break-in-twos and running together, and all railroads have them every week. With a long train, part air and bad nights, are when they happen. Anyone can see how the bell-cord attached to rear angle-cock handle can prevent this.

If triple is out of order on an air-brake, and that brake is cut out, the hose and train-line is valuable in case of train parting.

Young engineers, read LOCOMOTIVE ENGINEERING, and get other men's experience and be prepared for an emergency. The old engineers think some of us young ones are most too smart; but let them think what they please. I, for one, appreciate anything I learn from our old ones. They all have the practical experience, and we get it through LOCOMOTIVE ENGINEERING—which is about the same.

Would like to see something in your paper from our master mechanic at Denison, he is a No. 1 mechanic and all-round engineman, and could give us some puzzles, I think. And for machine shops, roundhouse and sandhouse—well, come to Denison, and take a look around and see the improvements.

W. M. PIRKIN.

*Denison, Tex.*

### Defective Air-Brakes.

*Editors:*

I saw an item in your June issue in regard to defective air-brakes by Fred S. Lee, and think he is right on that question, as I have had three or four trains in the last month with bad, leaky train-pipes and hose, that it was impossible to get over forty pounds train-pipe pressure with twelve to fifteen air-brakes in train, and the trainmen expect you to do all braking just the same as though the air was in good condition.

I understand Mr. J. F. Deems, master mechanic at Ottumwa, has introduced a form or plan which, if adopted, will, no doubt, be a good thing. It is to furnish trainmen with blank cards, so when they find defective brakes they can state the defect on this card and tack it on car or leave with their bills at destination. If this is kept up and air-brakes are repaired, it will not only save some of the sudden stops between stations, with the probability of a rear-end collision, but will save the air-pumps to a great extent and make it more convenient to stop on your own account when desired.

BALDWIN COMPOUND ON A 25 PER CENT GRADE—PIKE'S PEAK RAILROAD.

### On the Criticisms of the Engine "James Toleman."

*Editors:*

In your description (June number) of the "James Toleman" express passenger engine, I respectfully wish to draw your attention to some incorrect measurements which materially affect the comparison you make between various engines.

The outside cylinders are $10\frac{1}{2} \times 24$ inches, not $12\frac{1}{4} \times 24$ inches as stated.

The four cylinders of this engine you give as equal to a single pair of about $20\frac{1}{2} \times 24$ inches. Now, the cubical capacity of the four cylinders of the "James Toleman" are equal to 20,246 inches, whereas the cubical capacity of a pair of cylinders, $20\frac{1}{2} \times 24$ inches, is equal to 15,840 inches.

Now, as to tractive power.

Is it not rather unreasonable to draw up a comparison between such an engine as a six-wheel coupled, having wheels 66 inches in diameter—in other words, a freight engine—and one, such as the English locomotive, having non-coupled wheels of 90 inches in diameter, one specially designed for high speed?

I should certainly look upon the New York Central's "No. 999" engine as a better sample for comparison, both this and the "James Toleman" are designed for the same class of work, namely, express passenger traffic.

Tractive power of "999" engine stands at 111.62 pounds per pound of effective steam pressure.

Tractive power of "James Toleman" engine, 143.24 pounds per pound of effective steam pressure.

Further, the designer of this four-cylinder English locomotive is accused of never having considered that repairs were necessary in a locomotive for express work, and yet your article states that the bearings and connections are large and strong, which is the case, and very much in excess of the usual practice. This was done with the object of keeping the engine out of repairing shops for a long period.

Yours faithfully,

For Westwood & Winby,

ROBT. CHAPLIN.

### Pierce's Pump Governor Puzzle—Difference Between New and Old Equalizing Discharge-Valve.

*Editors:*

The problem sent in by our St. Albans friend is comparatively new, and as there will probably in the near future be a great many questions referring to this valve, perhaps it would be well to endeavor to bring out the points most likely to give trouble to those not familiar with it, and to start the ball rolling I will try to trace the difficulty, and instruct those not posted, as near as possible in writing in the style used here in regular practice, and invite criticism both on process of reasoning and manner of instructing, promising to learn all I can from those not in sympathy with my system, and agreeing to kick back according to what ability and spare time I may be possessed of.

The Westinghouse Instruction Book, page 21, referring to small diagrams, speaks of position of handle for releasing brakes, and shows that air, then, has free passage through supply ports *I* *B* and cavity *C* to train-pipe, and by becoming slightly familiar with this diagram, and tracing the passage of air as per plate No. 2, it will be seen that in release position (if the apparatus is in good working order) the main reservoir and train-pipe pressure must be equal, and that whichever has the governor attached must regulate the other, shows on page 22, after placing handle in running position, that direct communication is interrupted by bridge in rotary-valve covering solid edge of valve-seat, and then main reservoir pressure flows through ports *I* and *F* by feed-valve 21 to train-pipe, and whatever may be the strength of feed-valve spring, just that amount of air will have to accumulate in main reservoir before train-pipe can receive any. It is then evident that it would be a very risky business putting governor on main reservoir and depending on such a valve to furnish a stated quantity of air to train-pipe, consequently the governor is connected to train-pipe, and by backing up to main reservoir from feed-valve the most uncertain feature of reserve pressure is placed where it will do the least harm in case it varies from its predetermined supply. But it should be thoroughly understood that by returning handle to release position this reserve or excess pressure feature is cut out and inert, as ports *I* and *F* do not match, the pressure in main reservoir being then controlled by train-pipe governor direct. And, again, that whenever train-pipe pressure falls below what governor is set at, the pump must keep going, and will (power being sufficient) until this pressure rises again and shuts governor off, no matter what position the handle may be in, because in this style of valve the maximum train-pipe supply controls the air governor.

This settled, let us go to Supplement No. 1, Catalogue 1891, and examine the Plate D 5 valve. By making a transparent tracing of Fig. 4, and after reversing it, working it on the valve-seat Fig. 2, it will be seen that so far as admitting air to train-pipe, the rotary valves are alike, and with the Fig. 5 excess pressure-valve attachment there is practically no difference between the two valves, the reducing-valve attachment is then where the difference is. It will take but a moment to ascertain that this feed-valve No. 63 is held away from its seat by feed-valve piston No. 66 and piston spring No. 65, and will stay open till the pressure in both main reservoir and train-pipe is sufficient to force feed-valve piston down and let feed-valve seat itself, after which the pressure on top of feed-valve and communicating with main reservoir (only when handle is in running position) is not off from train-pipe, and, except when train-pipe pressure is reduced enough to let feed-valve piston lift feed-valve off its

... it has no escape. Therefore, unless there is something on main reservoir controlling the pressure in this now separate apartment, it will rise as far as steam will carry it, hence a demand for a governor for this purpose, which is set at a maximum pressure, and the air is reduced down to train-pipe pressure. Of course, no matter where the brake-valve handle is left, the pressure in main reservoir would not vary provided the pump could keep it up.

This, then, is the difference between the old and the new brake-valve, the old one has its feed-valve closed to train-pipe till ... pressure has accumulated, when it opens. The new one has its feed-valve open to train-pipe until pipe is supplied, then valve closes. When the new valve handle is in release position, the reducing-valve is cut out and train-pipe connected direct to main reservoir, and it having the governor, of course, and set at, say 100 pounds, puts that amount in train-pipe before it stops. Now, the pump in question started all right in running position, the reducing-valve stopped pressure to train-pipe at 70 pounds while the main reservoir pressure rose, and when it came to the 90-pound mark would have stopped the pump had the air got to the governor.

WORK OF DRIFTING SAND

Remember, the reducing-valve then controlled the train-pipe pressure. When handle was in release position the reducing-valve was cut out and did not control train-pipe pressure, but as the pump stopped at 90 pounds, there can be no doubt that the air from main reservoir flowing through to train-pipe charged it to 90 pounds and stopped the pump. It is plain, then, that the governor was connected to train-pipe instead of main reservoir, probably after the style of the Plate D 8 valve. Imagine, then, a train-pipe to which only 70 pounds of air could be admitted while handle was in running position trying to shut down an air governor set at 90 pounds.

These valves will not act like this all the time, as it depends on the manner in which the balance is maintained between the governor and reducing-valve, and when the valve goes crazy, it will pay if there is not evidence in sight sufficient to determine where the fault lies, to examine, first, the feed-valve No. 63, to see if it leaks or has not been turned upside down, then the feed-valve case gasket No. 56, next, examine the lower gasket No. 61, for a rupture between main reservoir and train-pressure.

WALKER'S PUMP GOVERNOR

As for Brother Walker, I wish he had shut off the drain-cock, put a lever against piston in brake-cylinder and tried to push it back I have found a few cases similar to this, except that I could not hear the piston rise when I put my ear to the valve, neither could I see that the exhaust port was cut out. I have taken all down that I found, and in the brake-cylinder the old oil had gummed so bad that the piston stuck and jerked by turns. Cleaning the cylinder and valve in each case overcame the trouble, and I do not think the air between the stop-cock and triple-valve ought to take five seconds to exhaust, while keeping up its proportion of pressure as against an open drain-cock in auxiliary reservoir.

AIR-BRAKE DEFECT CARDS.

I like our friend Lee's plan of reporting air-brake repairs on trains. I keep a lot of tags stamped on the back as follows: "When repairs are made, return this card to George Holmes, Air-brake Inspector, Western Gen'l Div. N. & W. R. R., Roanoke, Va.," and when a defective car is caught, tie on the tag where it may be easily seen, with the defect written on the face of the tag. Why could not train crews be supplied with some such card, only have them finally turned in, say, to general superintendent? Perhaps there was a leak in auxiliary reservoir under that tender, or some obstruction between it and triple-valve; maybe it was in such shape, it took the two-sevenths more air given by straight air to set the brakes.

GEORGE HOLMES.

*Roanoke, Va.*

---

## Straight-Air at One Triple and Automatic at the Other.

*Editors*:

In July number of the LOCOMOTIVE ENGINEERING, C. C. McMullin says he recently took out an engine and when he cut the brakes in to work automatic the driver-brake would work automatic, but the tender-brake would not go on automatic. He says he cleaned tank-triple, but still the tank-brake would not go on automatic. Changed the tank triple-valve with same result, yet worked straight-air all right. What was the matter? I will give my reason why the brake would not apply automatic on tank, and that is, the piston packing leather leaked, the air passed around the piston and through the leakage groove together as fast as it went into the brake-cylinder. I have often had the same experience.

That the leathers will leak when they get worn through, we all know. But often the leather becomes dry and stiff so that it will not expand outward against the cylinder, and when this is the case, the air passes around it and out of the back-head. I often take packing leathers out of both tender and driver-brake cylinders that have been in but a short time and soften them, and chamfer the inside corner off so that the air strikes the leather on the chamfer and presses it outward against the cylinder body. I will state here that cutting this inside corner off the leather does not shorten the life of the leather, as the leather always wears through at the corner where the expander presses it hard on one side and cylinder body on the other.

I often take out leathers that engineers report as being worn out, and find them square on the edge, and, in many cases, drawn in toward the center, allowing the air to pass around them. Where the leather has only been in a short time, and not worn much, I chamfer the edge, put it back, and that will be sufficient for months, until it is worn through in the corner by expanding ring. I would recommend air-brake men to try this, as it only takes a minute or so, and it saves a great deal of work, especially on driver-brakes, where a pull-up brake is used and the cylinder sets in over the engine frame, necessitating the taking down and lifting up the cylinder every time a new leather is put in.

I should have said before, if Brother McMullin had held his hand or a torch at the back-head of tank-brake cylinder when the brake was applied automatic, he would have been very likely to have felt the air leaking through back cylinder-head around the piston-rod, and then he might have tried it with triple-valve handle down straight-air, and if there was no leak then, he would have been satisfied that the leather was dry, and would not expand only with a heavy pressure against it. In the front cylinder-head there is generally a plug, which can be removed and oil put in to soften the leather, which should be done once in a while. I should like to hear from some air-brake men or anyone else what sort of oil or liquid is best to use on leather to keep it soft where it is subject to great heat alongside of fireboxes, as it is in driver-brake cylinders.

I don't see any reason why we should not have more iron packing rings in driver-brake cylinders. It seems to me that leather is a sort of nuisance. Engineers know that. As their brakes give out on them so often, at least they are unable to make an ordinary service stop. Their brake will apply in emergency notch, or straight-air, but on account of a hard, dried-up leather they cannot lift the driver-brake pistons even, only by a rapid discharge of air, as in emergency or straight-air application.

Here is a chance for some one to invent a piston packing that will be more durable and cheaper in the end than leather.

## Recharging the Auxiliary Reservoir with the Brake Applied.

*Editors*:

Every little while some brilliant inventor rises above the air-brake horizon from out of the depths of obscurity and starts out to astonish the world with his wonderful scheme, warranted to absolutely prevent runaways on mountain grades. There is no doubt but all, or nearly all, of them are perfectly honest in their conviction that such a thing has never been tried before, and they are astonished to find when they apply for a patent that the same thing *had* been thought of before, and not only thought of, but *patented* in a number of different forms. In fact, this idea was embodied in some of the first triple-valves ever designed, just about the time that Westinghouse was perfecting his first valve. The general scheme of all the devices is about the same. They are designed so that a more or less sudden increase in train-pipe pressure is necessary to move the triple-valve to release position, a slight gradual increase simply equalizing with the auxiliary reservoir through a small feed-groove or port. This, it will be noticed, is to a certain extent an interference with the release function of the brake, and it is on this account that the scheme is impractical On a long train, after some of the brakes have released the train-pipe, pressure increases very slowly, and a brake which cannot be pumped off cannot be used with satisfaction in such service, as it will have to be bled occasionally by the trainmen. The condition of such valves would be the same as that of a triple-valve in which the main piston was a poor fit and leaked badly. Such a valve placed near the end of a fifty-car train is almost impossible to release without bleeding.

In 1883 Buyden patented a valve embodying something of this idea It had a side passage around the main piston, through which air could feed into the reservoir and cylinder while the brake was applied, provided the increase in train-pipe pressure was not made too suddenly. This is claimed by some to embody the first idea of "quick action," as there was a communication from the train-pipe to the cylinder Not being a lawyer, I do not wish to express any opinion as to this further than to note that there is quite a difference between a valve for holding a train down a long grade and one for making a very rapid application on a long train.

Some of Dixon's valves, patented about 1888 or 1889, were designed so as to accomplish this recharging of the auxiliary reservoir.

One patent was issued about this time to Moore and assigned to Westinghouse, showing the application of the scheme to the Westinghouse standard quick-action valve. It was simply a small feed-groove or by-pass in the main piston bushing, located just at a point where the main piston would stand right over it when in application position. In 1888, Williams, of Lacrosse, secured a patent on a triple-valve embodying still another form of the same idea, and in 1891 Riggs patented still another triple on the same lines. There were a number of other devices of the same general nature, but time and space will not permit a review of them here.

This article is not written to discourage struggling inventors, but to impress upon them the fact that when a new idea is con-

ceived it is a good plan to try to find out what has been done previously by others in the same line, before spending much time and money in pushing an application for a patent. Patent litigation is slow and expensive, and, besides this, extremely discouraging, and anyone embarking on such a sea of difficulties should take good care that their boat is one that will hold water.

PAUL SYNNESTVEDT.

### Why the Pump-Governor Would Not Act.

*Editors:*

In answer to Clark L. Pierce, St. Albans, Vt., why his pump-governor would not work, I would say that the governor was connected up to the train-pipe instead of the reservoir pipe. If it was connected to reservoir, the little stop-cock must have been shut. In the 1892 pattern of brake-valve, main reservoir pressure is regulated by the governor, while train-pipe pressure is regulated by a spring. If the spring was set at 70 pounds, and the governor connected to the train-pipe, the 70-pound pressure would not affect the governor, and it would allow the pump to keep right on working, as he says it did.

The governor being set at 90 pounds, when the handle was thrown to release position it would stop the pump, because the main reservoir pressure rushes in to the train-pipe and thence to governor, and when this takes place the pump stops, because the pressure is equalized. Black and red hands are together.

Mr. Pierce does not state what kind of governor was used, whether it was an improved Westinghouse-Mason, or what style or make. I have often noticed that, with the latest improved valve, when the brake is released, reservoir pressure is admitted to train-pipe, and when the handle is put in running position you will see black hand falling back. I don't like this part of the valve. I recently had an engineer tell me he was not stuck much on the 92-valve for the reason that the governor would only allow 90 or 95 pounds pressure on main air reservoir, and when you stand with the brake on, you don't get any more air to recharge the auxiliary reservoirs under the train; while the old brake-valve would not recharge a train-pipe, until the 20 pounds excess was obtained in main air reservoir to open the feed-valve, and the brake were liable to leak on. With it, you can, while standing with the brake on or with the valve on lap, pump up about as much air as steam, and when you release the brake or throw handle to release position the extra amount of air accumulated in main air-drums will recharge the auxiliary reservoir under a long train much quicker. You can see why this is so, I think. With the new valve, reservoir pressure is limited at all times to what governor is set at, while on the old valve you are not limited, only when the air is feeding into train-pipe and thence to governor.

For the benefit of Clinton B. Conger, I will say that Phelan's "Air-Brake Practice" has a rule for calculating driver-brake power or leverage.

F. B. ARMSTRONG.

*Camden, N. J.*

---

*Editors:*

In regard to pump-governor spoken of by Clark L. Pierce, I would say that it was connected to gauge-pipe indicating train-pipe pressure, instead of the one indicating main-reservoir pressure. Therefore, when valve-handle was in running position, the valve allowed 70 pounds to escape into train-pipe; the governor being connected with train-pipe, and set at 90 pounds, became inoperative while valve-handle was in running position.

When valve-handle was placed in release position, the pressure in train pipe was increased to 90 pounds, and governor then cut off supply of steam to the pump.

WM. N. SHEPHARD.

*Philadelphia, Pa.*

---

*Editors:*

Brother Pierce, on page 317, wants to know why his pump-governor did not act. From his explanation, it would seem the governor did act, but it was not piped right. It was set at 90 pounds and connected to the train-pipe. It could not shut off at 70 pounds, but when the train line was charged up to 90 or more, by placing the brake-valve handle in full release position, the pump would stop and stay stopped till handle was put in running position, and pressure in train line reduced to less than 90 pounds by leak under tender. After the difficulty was corrected, the governor took air from reservoir line.

Here is a puzzle that caught me for a while. Am not quite sure it is right yet, but it works O. K.; that is all I want.

Some weeks ago a new ¾-inch governor would not shut off steam at any pressure of air, even after the screw-plug over coiled spring No. 18 was taken out. It was piped right, piston 5 worked steam-valve 9 O. K.—all holes open for air and steam. It was clean and in good order. After monkeying with it for quite a while got it to work, so it shuts off at the required pressure and goes to work on 2 pounds reduction in three seconds. The remedy applied was a little work with a fine file.

What was the matter with it?

If a ¾-inch governor keeps the steam shut off too long after pressure is reduced 2 or 3 pounds below what it shuts off at, cut a small crease crossways of the threads in No. 12 or air port of governor, where it screws into No. 4, or top of steam port of governor, so a *very little* air will leak out when governor shuts. This can be done with a jack-knife blade with a nick near the point, or a very small half-round file. Do not make the notch too large or very much deeper than the bottom of threads, or too much air will leak out. The new 1-inch Westinghouse governors have a small hole drilled in them for this purpose. A notch made this way does not stop up very easily, as we have some governors in service two years with this "bleeder" in, which start up on 1 pound reduction in two seconds.

CLINTON B. CONGER.

THE ANSWER.

The air-pipe from pump-governor was connected to train line, as in the old style valve, instead of to the T taking pressure from main reservoir.

CLARK L. PIERCE.

*St. Albans, Vt.*

---

### A Whistle Signal Difficulty.

*Editors:*

Much has been said in "our" paper about testing train signal-pipes and valves. Now, I think my way is as good as any that I have read about. I have a whistle hose-coupling, with short piece of pipe attached to the end that goes into the hose. I have a small gauge about 2 inches in diameter, which I screw into the end of the pipe, then I couple this "combination" on to signal-hose at back end of tender and open stop-cock. I note pressure on gauge; if 25 or 30 pounds is indicated, I test the signal by the use of a small air-cock screwed into short air-pipe under gauge, this is done, as you will understand, by opening and closing small air-cock. To find leak in pipe, if any, I close stop-cock, which is located between the pressure reducing-valve and drum, and if there is a leak, the gauge will show it very quick. Now, if the gauge shows the same pressure on signal-pipe that there is in the drum (after stop-cock between pressure reducing-valve and drum is open), I take the cap off of pressure reducing-valve, and with screw-driver turn valve 5 around a few times as if grinding it in, and by pressing the valve, the pressure will blow out all the loose matter and let the valve come to its seat most always; if it don't, I take off the "pesky" thing and grind it in. Right here is where the advantage comes in of placing a stop-cock between pressure reducing-valve and drum, because you can take off the valve without letting the air out of the drum.

A short time ago I tested the whistle signal apparatus on an engine which was coupled on to five coaches. The whistle would blow all right before the hose was coupled to train, but when coupled to train, I could not give a signal by pulling the cord in coaches anywhere throughout the train, but when I put my gauge "combination" on the hose of the last car, I could give a signal perfectly by opening and closing the small air-cock under the gauge. What was the trouble?

W. P. RELYEA.

*Syracuse, N. Y.*

---

### Hamar's Whistle Signal Puzzle.

*Editors:*

Whistle signal that would blow perfectly when engine and train was standing still, but would not sound when train was running. Everything about the engine was examined and found to be in the most perfect condition. Car discharge-valves were perfect; no leaks in any part of the equipment of engine or train.

This is a "corker." Who can tell where the trouble was?

W. T. HAMAR,
Road Foreman Engines.

*Atlanta, Ga.*

---

### That Whistle Signal Puzzle—Hamar's Answer.

*Editors:*

The signal whistle was located on the fireman's side of cab, the signal pipe running up alongside and at the right of front cab window, whistle extending above top of window. The signal pipe when first put up was found to be too short, and in order to save piping was spliced at the top. Later on this splice became bursted, and was taken off and the whistle attached to the original pipe, which was then shorter, which brought the whistle down below the top of cab window, and in such a manner that when the engine was running and with front cab window open, the strong current of air blowing through the window affected the sounding of whistle. When the window was closed and engine running, whistle worked perfectly.

W. T. HAMAR,
Road Foreman.

*Atlanta, Ga.*

### To Calculate the Power of Cam Brakes.

*Editors:*

Mr. Conger asks for a rule in calculating the power of driving-wheel cam brakes. The following is an extract from the New York Air Brake Co.'s instruction book, page 50:

"Where the stems of the cams are attached directly to the brakeheads, the total power on the engine is equal to the pressure developed by the piston multiplied by the distance between the pins that connect the stems to the brakeheads and divided by the height of the point of contact of cams above a line joining the centers of the brakehead pins. As the power is usually connected to the cams by pins three or four inches apart, this distance should be deducted from the distance between the pins used as multiplier.

"Where the stems of the cams are attached to lever below the brakeheads, multiply the power found by the above rule by the length of one lever, and divide the product by the distance from the brake-head pin to the pin on which the lever hangs. The above rules give the total power on both sides of the engine."

I think Mr. Pierce's pump-governor difficulty was the result of connecting the governor air-pipe with train line instead of main reservoir.

With the Westinghouse brake-valve of 1890, an "excess pressure-valve" is used to create the differential pressures of main reservoir and train-pipe, and the pump-governor receives its air from the train-pipe at the union stud in lower case of the brake-valve. The new brake-valve of 1892 has a "feed-valve attachment," instead of an excess pressure-valve, and with it the main reservoir pressure should govern the action of the pump. If desired, the Westinghouse Company will furnish an excess pressure-valve with their latest brake-valve, instead of the feed attachment, and as this would require that the governor's air be supplied from the train-pipe, the lower case of the brake-valve of 1892 has a threaded and plugged hole, in which the governor-pipe union stud may be fitted same as with the old valve. The subject of Mr. Pierce's article was an equipment of the latest brake apparatus, feed-valve attachment, etc., but with the governor-pipe connected at this hole in the lower brake-valve case, instead of with main reservoir connection.

WILL W. WOOD.

*Terre Haute, Ind.*

### Ancient Financial Difficulties of the Reading.

The poor Philadelphia & Reading Railroad seems to have suffered from impecuniousness at brief intervals ever since the first spike was driven, but it never got down to hopeless poverty until that brilliant financier, Franklin B. Gowan, loaded it up with obligations which are not likely to be discharged for several generations to come.

Mr. James W. Holmes, a resident of Reading, now 72 years old, who was many years employed in the Reading Railroad shops, writing to the *Sunday Eagle*, a local paper, has this to say about a financial stringency of long ago:

"The present financial straits of the Philadelphia & Reading Company remind me of the same condition of affairs fifty years ago, last winter. The road having been built and opened to Pottsville in January, 1842, the company was put to great expense to operate it with satisfaction to the public. The consequence was it was unable to pay its employés their regular monthly wages, and in order to pay them up (as some of them had from three to six months' pay to get) the company, about the 1st of January, '43, issued notes (the employés called them 'slow notes'), bearing interest at the rate of 6 per cent. per annum, payable in three, six, twelve and eighteen months.

"The men accepted them with the understanding that thereafter they should receive their pay regularly every month, which promise was kept up for several years afterwards. These notes were the most beautifully engraved that I ever saw. Some were issued for as much as \$50. They were generally accepted by the public as bank notes, but some of the employés retained them until they were redeemed, receiving the interest and all. I saw some of the holders of them long before they were due offered change for 50's, but the answer of the holder was: 'No, it is too pretty to part with.'"

---

An order has been issued by the management of the Missouri Pacific and Iron Mountain system of railroads for the reduction of expenses wherever retrenchment can be made. The order has led to material decrease of the clerical force and the number of workmen employed in the shops and on the track will be reduced as much as possible. This is the season when the working staff in shops and on the track can be used to the best advantage, but considerations of this character have little weight with those who control Wall Street railroads.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates. They are made by BRADLEY & POATES, 251 William Street, New York City.

## Some Figures on the Magnitude of the Engineering Work on the Gothard Railroad.

BY HENRY GRETENER.

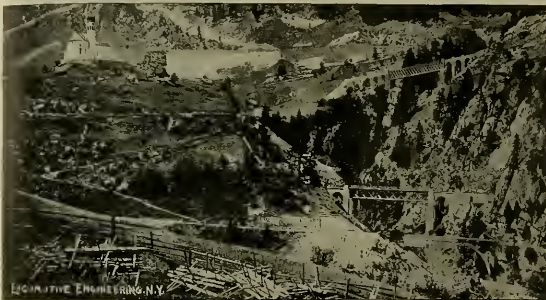
Thinking your readers would be interested in some account of the great Gothard Railroad from the spot, I send you herewith some photographs of the most interesting parts of the line.

The idea of building such a road dates back to between the years 1830–1840. Opinions were divided as to which of the following mountain passes, Simplon, Gothard, Lukmanier or Splugen, would be the most suitable for such a railway. Finally the Gothard was decided upon. The man whose efforts had principally brought about this decision, was Dr. Alfred Escher, of Zurich, who, later on, was elected president of the company.

In 1869, a treaty was signed between Italy and Switzerland, in which the former agreed to pay 45,000,000 francs (or $9,000,000) and the latter 20,000,000 francs (or $4,000,000), à fond perdu. In this treaty it was agreed that the line should be built and the traffic carried on by a private company under control of the Swiss government. In 1871, the then newly created German Empire joined the two other States and promised to pay 20,000,000 francs, à fond perdu. In the same year the company was formed and shares given out, and in 1872 the work on the great tunnel began from both entrances, from Göschenen on the north side and Airolo on the south side. The contractor, who undertook to bore the tunnel, was L. Favre, of Geneva, who had made himself a good reputation for this kind of work in France. He had originally been a simple joiner with hardly any education, and though he committed some grave errors in the construction of the gigantic tunnel, it cannot be denied that a great deal of the final success was due to the restless energy displayed by this man.

A great many unforeseen difficulties, however, arose during the construction of the line. The original calculation of expenses of the international committee proved to be insufficient. Especially the so-called Tessin-Valley lines, from Biasca to Chiassa, cost 33,000,000 francs instead of 14,500,000. There were also troubles with Favre, because the stone formation in the tunnel made it necessary that the latter road be built up with masonry almost throughout its entire length, which was quite an unexpected feature and certainly a very unpleasant one for Mr. Favre. By-and-by, however, this crisis was passed through, the original plans modified, so that the first estimate was exceeded only by the sum of 46,000,000 francs. Of these, 28,000,000 were again paid by the three governments, à fond perdu, Germany and Italy 10,000,000 each, Switzerland 8,000,000 francs, the rest by the company and the shareholders.

During a visit in the tunnel Favre died suddenly, but his heirs were willing to carry the work on, so that Favre's death caused no interruption, and on the 29th of February, 1880, the first drill went through the narrow partition of rocks which was then left.



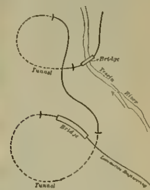
STATION OF WASEN ON THE ST. GOTHARD SPIRAL.

SOUTH SIDE OF ST. GOTHARD, LOOKING UP.

The total length of the tunnel is 9.25 miles, the cost of building it was 65,000,000 francs ($13,000,000). Height above sea level in the center, 1,154.55 m. (3,275 feet); height of north entrance, 1,109 m., south entrance, 1,144.85 m.; incline towards north is 5.8 (30 feet per mile); towards south, 2.

During the construction three high-pressure turbines were used in Göschenen for compressing air to about 12 or 14 atmospheres (180 or 210 lbs. per square inch), which was conducted to the rock drills in the tunnel. Towards the center of the tunnel that pressure diminished to about 7 atmospheres. Similar arrangements had been made on the south side at Airolo. From six to seven rock drills were at work continually from either side. They were mounted on a traveling frame, and each drill made a hole about 1.20 m. long (47 in.) The firing of all six or seven holes was simultaneously, and about 1 m. (39 in.) of rock would be blasted at the time. After that the debris was removed, the track for the drill-frame laid and the latter advanced correspondingly. The average was three shots every 24 hours, equal to an advance of 3 m., or 117 in. a day. Sometimes not more than 2 m., sometimes as much as 5 m., a day would be blasted, according to the quality of the stone. The latter was mostly granite, the formation of it showed vertical layers. This caused many inconveniences, because the water would flow down between the layers, and sometimes submerge almost the whole boring plant. At an average, about 3,400 men were employed daily in building the tunnel.

The total length of the main line from Lucerne to Chiassa is 232 kilometers (144 miles). The mountain line, from Erstfeld to Biasca, 90 kilometers (56 miles), has two tracks. Part of the second track has only been in use for a few months. The cost of the total length of line (not including the cost of the second track) was 238,000,000 francs, or $47,600,000. The average grade is 25 ft. in 1,000, the maximum grade 27 ft. in 1,000. The smallest radii are 280 m., or 910 feet. Photograph No. 12131 shows the bridge across the Kerstelen river, which comes down from the



Maderaner valley, just above the station of Erstfeld, where the mountain line begins on the north side.

Small photograph shows the station of Wasen, twenty-one kilometers from Erstfeld, where height had to be gained with circular turn tunnels, by means of which the line is carried down the valley for some distance, though, of course, always climbing up along the side of the hills. The entrance to the second turn tunnel is shown to the left above the little church. The uppermost portion of this great zig-zag line is shown just where it crosses a little stream on an iron bridge. Lower photograph on page 369, shows the same portion of the line, but looking up to it from the bottom of the valley below the church.

There are, altogether, three circular

tunnels on the north side, two at the station of Wasen and one below, near the station of Gurtnellen. The radius of each is from 280 to 300 m.; grade, 23 feet in 1,000. The length varies from 900 to 1,300 m. The maximum difference of level between the two entrances is 35 m., or 113 feet. On the south side, there are four circular tunnels, two just above the station of Faido and two above Giornico. The latter section of the line is shown in the two photographs, Nos. 12898 and 154, the first number giving a view from up above, the second from down below. The sketch gives you an idea of how tunnels are arranged.

As you see, the photographs have been taken before the second line was started.

The fare for second-class passengers is seven centimes per km., or 2 4 cents per mile, with an addition of 15 per cent. for the mountain section of the line. The rails weigh from 38 to 46 kg. per m., or from 77 to 94 pounds per yard.

The total number of tunnels on the whole line is fifty-six, twenty-seven north of the great tunnel, twenty-eight south of it, total length of tunnels is 41 km., or 25½ miles, which is as much as three-fourths of the length of all tunnels in the German Empire.

The bridge over the Kerstelenbatch at Amstey is 138 m. long (including two stone viaducts). Height is 54 m.

### An Electric Locomotive.

An electric locomotive has recently been built in the Lynn shops of the General Electric Company, and is on its way for exhibition at Chicago. The builders thus describe the engine:

"The locomotive weighs 30 tons, and compactness of machinery is at once apparent in its build. It is 16 feet 6 inches long, 11 feet 6 inches high, and 8 feet 4 inches wide. The draw-bars are set 2 feet 6 inches from the top of the rail, while the whole rests on four 44-inch wheels.

"Two electric motors, one at each axle, provide the power, the motors being gearless and supported upon spiral springs having their base on the side frames of the truck. This arrangement gives the wheels a certain freedom of movement irrespective of each other, which permits them to adjust themselves to any unevenness of the track, making the locomotive ride easier and diminishing the wear and tear upon the tracks and the motors.

"The motor fields are solid iron castings and the hollow field spools are bolted to them. The iron-clad armatures have each separate windings, embedded in a mica-lined slot in the curved surface of the laminated iron armature body.

"The locomotive axles pass through the hollow shafts upon which the armatures are mounted. They rest in bearings of the motor frames, and are connected to the axles by universal couples, which allow of considerable freedom of motion. The commutators are of substantial construction, and each one has four sets of brushes.

"It is claimed that the series parallel controller, which takes the place of the throttle in the ordinary locomotive, makes it possible to start and stop the motor easier and with less straining than is needed for the steam locomotive, while the speed, by this arrangement, can be more readily controlled.

"The truck, suspended from the journal-boxes, is constructed of heavy I-beams, and forms the foundation for the locomotive cab, of sheet iron, of symmetrical design, and so curved off as to diminish the atmospheric resistance as far as possible.

"The interior is finished in hard wood. Two sliding doors are placed at each side of the cab, and the windows are so arranged as to permit of an unobstructed view in all directions. There is ample space in the cab for the motorman's movements, and it affords him considerably better protection than that usually vouchsafed the steam locomotive engineer.

"The use of these locomotives over very long distances is at present limited only by the cost of long lines of electric feeders, and until the problem offered by this condition is solved restriction of its employment must necessarily exist.

"But for places comparatively near each other, and where traffic is dense, the denser the better, the electric locomotive is peculiarly adapted, for here all the advantages of electric propulsion are available, unhampered by the extreme expense involved in long feeder lines."

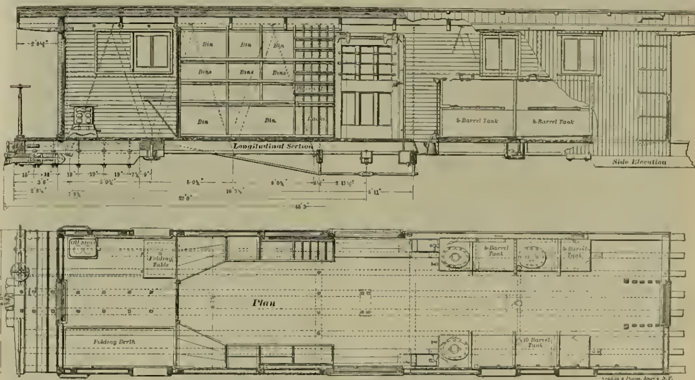
Serve-ribbed tubes are coming into common use on locomotives in France. These tubes are said to increase the evaporative efficiency of the boilers so much that much smaller boilers can be employed for a given size of cylinder.

There is competition between several Canadian cities just now to secure the location of the Grand Trunk shops. General Manager Seargeant has written the corporation of the city of London, Ont., in which he reviews the negotiations in the past between the company and the city of London, Ont., in regard to the shops, points out that Sarnia is willing to give $100,000 for the shops, and that the council of that town will make an agreement free from the many objectionable conditions suggested by London. There are advantages offered by Sarnia and Point Edward as points for location of the shops.

# Car Shops and Car Builders.

## Norfolk & Western Supply Car.

The annexed engravings show a novel form of car used by the Norfolk & Western for conveying stores to the different stations on the line. In fact, it constitutes a traveling store-house and is regarded as a great convenience The details of the car are seen so distinctly in the engraving that no detailed description is necessary



NORFOLK & WESTERN SUPPLY CAR.

## Norfolk & Western Freight-Car Truck.

The truck shown in the annexed engraving has lately been designed by the mechanical department of the Norfolk & Western for use under cars of 60,000 pounds capacity. The principal particulars are

Bolster composed of two steel I beams weighing 21 lbs. to the foot and 9 inches deep, separated by four castings, each taking two horizontal ¾-inch bolts.

Wooden blocks on outside of I beams filling out the space between the web and the column guides, which also give elasticity and prevent the nuts rattling off, and wooden plank on top of I beams under center plate and side bearings to deaden vibration.

Springs consist of six standard coils. (The number of coils may be varied to suit the weight and capacity of car body). The springs rest in pressed-steel plates, but these plates are not bolted together, but simply rest on the springs and spring plank.

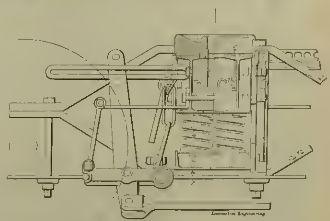
Cast-iron center plates.

Arch-bars Top, 1¼ x 4 inches; bottom, 1 x 4 inches, tie-bar, ⅜ x 4 inches

National hollow brake-beam.

Malleable-iron brake-lever connector and dead-lever guide.

Truck weighs about 5,600 lbs.



NORFOLK & WESTERN CAR TRUCK.

## Danger of Mixed Draw-Bars.

A very desirable change was made in the Rules of Interchange of Cars at last Master Car Builders' Convention, when Rule 16 was made to read "Any company finding a link and pin draw-bar in a car originally equipped with the M. C. B. type, and so marked and carded for wrong material, may replace the link and pin draw-bar with a M. C. B. draw-bar, and bill upon the card to the railroad company carding the car for the wrong draw-bar."

This indicates a disposition to maintain uniformity of draw-bars, which is a move in the interest of safety. Coupling a standard draw-bar with a link and pin coupler is a dangerous operation, and every effort should be made to prevent the practice It is understood that the officers of the Vanderbilt lines are opposed to the practice of substituting a link and pin coupler for one of the M. C. B. type and carding for the defect. They would prefer that the putting in of a standard draw-bar should be absolutely prohibited, and many railroad men sympathize with these inclinations.

Every year will see a large percentage added to the number of standard draw-bars in use, and it seems to be the right practice to prevent the mixing of draw-bars since it greatly increases the danger to trainmen. Should a brakeman or switchman get injured coupling a car that is carded for a wrong draw-bar, he would have a good case against the company for using a dangerous attachment. The fact that the mixed draw-bars are dangerous ought to be sufficient reason to induce railroad companies to oppose the practice. The self-interest, however, that makes them more liable in a suit for damages is likely to have more influence in rooting out the practice than mere humane considerations.

## To Abolish Obsolete Standards.

A circular has been issued by Secretary Cloud, of the Master Car Builders' Association, relating to letter ballots, in which the recommendation of a committee to abolish certain standards is repeated. The standards referred to are

Diameter testing gauge, flange and journal gauge, wheel-bore testing gauge, journal length and diameter gauge, guard-rail gauge, centering and journal shoulder gauge, journal distance gauge boring wheels (the use of six dogs), attachments and dimensions of draw-bars, train-pipe fitting for steam heat

The reasons for the proposed change are thus explained:

"It is proposed to retain the wheel circumference measure as a standard, but it is believed that the form of gauges to be used to produce certain standard dimensions in standard parts is purely a matter of local shop practice which should not properly be legislated upon by the association. Similarly with the question of chuck-jaws or dogs for centering wheels on the table of a wheel-boring machine The standards governing the attachments and dimensions of draw-bars are very old (established in 1876 and 1879), and do not command any respect at the present time, are but seldom observed or conformed to, and have been in part superseded by the present standards governing the proportions of vertical plane couplers The standard train-pipe fitting for steam heat is practically a dead letter, which is our justification for recommending its abolishment

"The present standards of the Master Car Builders' Association are the result of their deliberations through a long period of years. Many of the earlier standards were adopted when the association was in its infancy, and there has been a great deal of legislation under the general heading of standards, which has resulted in the acceptance and promulgation of certain forms of construction or forms of practice, which, in our judgment, ought never to have been classified as standards It is the opinion of the committee, therefore, that what are now comprehended under the general category of standards of the association should be divided into two groups, the first group to be continued and maintained as the standards of the association, the other group to be rescinded as standards, but to be established as recommended practice"

## Weak Draft-Springs.

In a paper on "Draft-Rigging," by Mr. Geo W. Morris, of the French Spring Works, read at the Southern Railroad Club, attention was directed in a striking manner to the weakness of springs used in the draft-gear of cars. He said that English cars carrying 9 tons have about 400 pounds of steel per car for draft-springs, and American cars carrying 30 tons have about 70 pounds of steel for the same purpose

A curious case of ignorance was mentioned Years ago Mr Kirby, of the Lake Shore, designed a draft-gear that had two sets of springs side by side A master car builder of a prominent road hearing of the advantage of Mr. Kirby's plan, sent for blue-prints with the view of adopting the improvement. Like many others, he wanted to put his own improvements upon the improvement, so instead of putting the springs side by side he put one behind the other When the uselessness of putting one spring behind the other was pointed out to him he could not see but what it was all right, and an actual test was necessary to convince him that the two springs so

arranged did not offer more resistance than one.

Mr. Morris agreed very strongly in favor of greatly increasing the strength of draft-rigging springs. The draft now most generally used, he said, by the most ad-

First-Class—Intercommunicating.

vanced officials in their specification is $6\frac{1}{2}$ inches diameter by 8 inches long, two-coil, and $2\frac{1}{8}$ inches hole, made of $1\frac{1}{4}$ and $\frac{3}{4}$-inch steel, and weighing about 35 pounds, with a total action of 2 inches, and with a total capacity of 20,000 pounds. This I consider is not of sufficient capacity for the draft-spring, considering the increased power of the engines now in use. Take the heavy freight engines of to-day, say a 22-inch cylinder by 24-inch stroke, and 50-

First-Class Coach—Intercommunicating.

inch driving wheels, and a boiler pressure of 180 pounds steam, and say we allow 85 per cent. of the boiler pressure, which brings the figures within the power of the engine, we find the traction to be over 35,000 pounds; while on the largest engines formerly used, say 16 x 24 inches, 50-inch driving wheels, and a boiler pressure of 130 pounds steam, and following the figures as before, we have a traction of the engine to be only about 13,000 pounds.

Second-Class—Compartment System.

Therefore, there is not sufficient capacity in the draft-springs, nor sufficient resisting power for the buffer, as the maximum of the blow is enormous, contingent on the velocity, weight of train imparting the blow, etc., and the spring referred to is, in my judgment, the maximum in capacity that can be produced for a durable spring.

### New Policy About Standards.

The Master Car Builders' Association at last convention inaugurated a new policy in regard to standards of the association. They recommended that a number of obsolete standards should be abolished, and adopted the following policy in regard to new standards:

"Those forms, parts, constructions, units, measurements or systems in which it is desirable to secure not only sound construction, good practice and safe operation, but which also promote quick and cheap repairs, and, consequently, free interchange of cars.

"Those forms, parts, constructions, units, measurements or systems which are conducive of sound construction, good practice and safe operation, but which do not affect either interchangeability of parts or interchangeability of cars as a whole."

### Some Spanish Rolling Stock.

The eleven little pictures shown herewith will give the reader some idea of the kind of cars he might expect to see in Spain. Some of them are quite American

Royal Mail Car.

in appearance. These all belong to one road; the odd ones are from several lines, the names of which appalled the writer when he tried to put them into English—but it's just as well for the reader that he don't know.

Some of the cars with the dog-house on top for the "gafter" are odd but not uncommon in all European countries, in Spain this is called some Spanish name that means a "perch"—as if the brakesie were a canary or a poll parrot.

Second-Class—Intercommunicating.

People who have been in New York City are not likely to forget that Broadway is the most crowded street they had ever seen, for there is nothing like it to be seen anywhere else. After a long fight, some years ago, a street railroad company obtained a charter to lay tracks on Broadway. Those familiar with the blocks of vehicles, which were of hourly occurrence, predicted that street cars would be useless on this street, since they would be blocked most of the time. A strange effect came

Freight Car with Brakeman's Box.

from their use. It seemed that they regulated the movement of other vehicles, for the street was never for years so free from blockades as it has been since the cars began running. Lately, they have put cable cars upon the street. One day, shortly after these began running, a wire of the cable got tangled in the grip, and the car could not be stopped. It rushed along the street like a battering ram, overturning wagons, cabs, hucksters' carts and everything that came in the way. The street looked like a lane of wrecks before the cable was stopped.

The J. A. Fay & Egan Co., of Cincinnati, O., have a display of over fifty different wood working machines at the World's Fair. They are all finished in a very perfect manner. They are fine examples of wood-working machinery and attract a great deal of attention. We are informed by the makers that these machines will be sold after the exhibit is finished, at the same price as the ordinary machines. Any concern or individual making a purchase can obtain good free advertising now, for the name of the purchaser, place and style of business will be placed on the machine.

We have received from the Patent Safety Railway Car Co., of Kansas City, illustrations and description of an invention made for the purpose of preventing cars telescoping when passenger trains come in collision. The mechanism employed is very simple, considering what it has got to do. The body of each car is separate from the truck. In fact, it is an arrangement of flat cars for carrying the body of the pas-

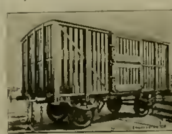
Accommodation Car with Closets and Passenger Accommodation.

senger car. When a collision occurs, mechanism provided on the flat car turns the body of the car round on a pivot, so that, instead of telescoping, the cars slip past each other. The idea is not notable principally for its boldness and freedom from what are regarded as established rules of designing. We have no doubt that it would work all right if put in practice. The great difficulty about making a

Three-Story Fruit and Fish Car.

success of this kind is that railroad companies do not build their rolling stock with a view of preparing for collisions or other accidents. The tendency of to-day is to perfect details of train operating, so that special provision against accidents will not be necessary in the designing of rolling stock.

The Safety Car Heating and Lighting Co. of New York, have sent out a circular cautioning patrons and others against anonymous assaults made upon their

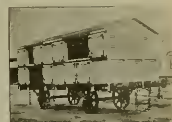


Two-Story Stock Car.

lighting system by unscrupulous rivals. We understand that the company has very good reason for complaint about secret misrepresentations. There is no system of lighting ever tried that has given such thorough satisfaction as the Pintsch, and it is too late in the day to try and injure the system by underhand means. There are now more than 200 gas plants in daily operation supplying this illuminant, and there are more than 100,000 cylinders, an equal number of regulators and over 500,000 lamps applied to 54,000 cars for illumination by this system daily demonstrating its safety, reliability and superiority.

### Value of Water as a Lubricant.

On the car and locomotive journals of a great many railroads and on the heaviest bearings in steamers, water is used as an aid to keep the bearings cool. The fact that bearings can be kept running cool by the use of a stream of water applied to them has lately raised a discussion of the question, "Is water a lubricant?" There is no doubt that water is a lubricant to a limited extent, but as a means of lubricating heavy bearings it is liable to be very unsatisfactory. We are informed that a New England Railroad Company some years ago made a practical experiment with journal boxes for cars in which nothing but water was used to lubricate the journals. The boxes were made watertight and filled with water. They ran cool but the cars were extraordinarily hard to pull and the journals wore very rapidly.



Fruit Wagon—Ventilated.

For this reason it was considered that water as a lubricant was not a success.

In the lubrication of journals there is always more or less friction which causes heating. If the bearing is too small for the weight placed upon it the mechanical work converted into heat is liable to increase so greatly that the bearing will become too hot for safety. If means can be provided to carry away the heat as fast as it is generated the journal will remain

Mineral Wagon with Brakeman's "Perch."

at a safe temperature. The air is not sufficient sometimes to carry away the heat generated, but a stream of cold water will do so, and that is where we consider there is an advantage in using water on bearings. As a lubricant, water is worth very little, but as a means of carrying away the heat from a journal, it is likely to be a decided success.

We have received from Mr. Jew Gathek, Paterson, N. J., an illustrated catalogue of miniature steam locomotives and cars. The little engines are working models and vary in price from \$6.50 to \$18. People wanting to make a present to a boy of mechanical taste will find these locomotives certain to give satisfaction.

Send for our Premium List.

### Brooklyn Elevated Engines.

The annexed engraving represents an improved type of Forney engine, designed by Mr. E. M. Hedley, master mechanic of the Seaside & Brooklyn Elevated Railroad Company, and built by the Rhode Island Locomotive Works. The cylinders are 13 x 18 inches, and the driving-wheels are [illegible] inches diameter. The total weight of the engine, in working order, is about 56,000 pounds, of which 40,000 are in drivers. The engine is remarkably well proportioned throughout, the bearings being unusually large. The parts most liable to give out in this class of engine have been materially strengthened. First-class material is used throughout.

Several important changes have been made in the boiler and firebox. The firebox has been shortened, and the barrel of the boiler lengthened. The boiler is 44 inches diameter, in front. A wagon top is employed, and the firebox is secured by radial stays, the dome being placed in front of the firebox. The length of the firebox, inside, is 50 inches, and the width 42⅛ inches.

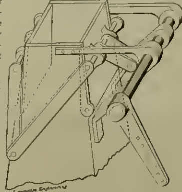
These engines are now in service, and show a decided saving of fuel over those that have longer fireboxes and shorter tubes.

To the many subscribers who have written us asking why planished or Russia iron is almost invariably buckled or kinked, and a remedy therefor, we have to say that diligent inquiry develops the fact that this trouble is well nigh universal. Russia iron is polished by hammering; a number of hammers striking very fast do the business, and it is very likely a hard matter to keep them from stretching the sheet unevenly. It is customary to use the best pieces on the sides and put the worst buckled ones out of sight as much as possible.

### Variable Exhaust Nozzle.

The engraving shown herewith illustrates a form of exhaust nozzle recently patented by two engineers of the C., St. P., M. & O. road, Messrs. Wallace and Kellogg, of Altoona, Wis.

The nozzle is square and the two movable sides are hinged at the bottom, and each time they are moved they shear off any accumulation that has adhered to the sides of the pipe, and its inventors provide for their being moved regularly by connecting the device direct to the reach-rod, so that every time the lever is moved the "variable" is adjusted, being largest when cutting off full stroke and getting smaller as the cut-off becomes shorter, the amount of this adjustment can be changed to more or less by adjusting the connections on the operating lever.



Variable Exhaust Nozzle.

This device has been in use some ten months, and those who have watched it claim that it saves fuel and requires no care more than an ordinary nozzle.

Those interested can learn more of the device by addressing the inventors as above.

Business generally appears to be getting very flat in the Southwest, but the business of train-robbing seems to flourish like a green bay tree. No sooner does one gang of ruffians who follow this line of light industry get exterminated than others are ready to take their place.

For a fibrous packing the brand known as Asphaltum packing has some properties not usually found in rope packings. It keeps soft under steam pressure, and does not bake or harden into an iron ring, as most packings do. For air-pumps, pistons and valve-stems it seems to give excellent results without scoring the rods—the trouble with most packings of the fibrous order.

Brooklyn Elevated New Locomotive.

The Official Railway List for 1893 is out. It is getting thicker every year, but whether because there are more names or more advertising it is hard to tell; in either case there is nothing to complain of. The Official List is the best list of railroad officers, but, appearing but once a year, gets considerably out of date along about the holidays. It is published by the Railway Purchasing Agent Co., Chicago, and is worth $2 of any man's money who wants to know who is purchasing agent or general manager of the Baffin's Bay & Patagonia Ry.—or any other line in North America.

Mr. James Dredge, writing to his paper, *Engineering* (London), from the World's Fair, says of the Pullman train: "* * * As for the internal fittings and arrangements of the cars, they, of course, go far beyond anything that has yet been attempted, and no royal trains of Europe will bear comparison with them. Yet they will no doubt set the standard for the better class of American travel before long * * *."

We are informed by Jenkins Brothers that they have adopted a new form of holding the disc-holder in place, having increased the number of bolts in valve-bonnets, and the thickness of flange has been increased, so that high pressure can be used with safety. It is the intention of the company to manufacture but one grade of valve, so that it will not be necessary for customers to mention "valves for high steam pressure." Mention is made of the wonderful improvement in the manufacture of a rubber compound on high-pressure steam. They have been working on this compound for a long time and now find it entirely satisfactory, and are offering it to the trade without increasing the selling price.

The Falls Hollow Stay-Bolt Co. wish to remind their friends that they have increased their capacity lately and are in a position to fill all orders promptly.

Reeves' American Band, that dispensed music at the last M. M. and M. C. B. conventions, were from Providence, R. I., and their music was so far superior to anything the conventions have ever had that there is a movement on foot to secure their services for every year. They certainly were artists.

A guard on one of the Indian railways has invented a method of cooling cars by means of compressed air. The air is compressed by a pump worked from an axle, the heat generated by compression dissipated by exposure, and then the compressed air is permitted to escape into the car. It cools in expanding, and lowers the temperature of the car. Those attending the Chicago Exposition can see a good illustration of how expanding air cools by watching the exhaust of the locomotives that are run by compressed air. The air in escaping from the smokestack looks like steam, but it is the cooled air converting the moisture of the air into mist.

Times are getting dull in locomotive building. Most of the shops are laying off hands.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(79) J. S. M., Danville, Ill., writes:

Will eccentrics of a Schenectady engine, packed with wool waste within an inch of the top, run fifty-five miles safely with one oiling, pulling five vestibule cars and make eight stops in 100 minutes? *A.*—Yes, easily, if the oil is good and the packing kept fairly clean.

(80) F. W. P., Boone, Ia., asks:

1. Why are the top rows of stay-bolts on the sides most given to breaking? *A.* The upward and downward movement of the inside sheet due to expansion and contraction, appears to be greater there than at other points. This would put greater stress on that row of stay-bolts. 2. Why do stay-bolts invariably break off next the outside sheet? *A.* The inside sheet moves up and down, and the part of the bolt secured to the outside sheet becomes the fulcrum of the stay-bolt movement.

(81) Fireboy, East Grand Forks, Minn., writes:

1. There is a difference of opinion among our engineers, as to the proper way to change the lead on a locomotive. Some say it should be done with the blades, others that it ought to be done by the eccentrics. *A.*—If, in running over the valves, it is found that there is more lead on one end than on the other, that can be equalized by the blades. But the blades cannot be used to change the total lead, the eccentric alone can accomplish that. 2. If an engine is being run on one side, and happens to stop on the lower quarter, would she have the same chance to start herself as if stopped on the upper quarter? *A.*—Yes.

(82) T. J. McD., New York, says:

I find the horse-power of "999" is 419¼, taking 32 circular inches as a H. P. I find the H. P. of the boiler 138, taking 14 square feet of heating surface as a horse-power. Now, I want to know how a boiler of 138 H. P. can supply steam to cylinders of 419¼ H. P.? *A.*—Horse-power of locomotive boilers and engines cannot be found by the rule you use. The proper rule for the engine is, multiply the area of the pistons in inches by twice the stroke in feet, multiply the quotient by the revolutions per minute, and that by the mean effective pressure in the cylinders. With the forced draft employed in locomotives, from 1½ to 2 square feet of heating surface will generate steam for a horse-power.

(83) J. A., Houston, Texas, writes:

1. With an eight-wheel Baldwin engine, I stalled on a hill. Just got the first cut put away and was returning with the engine in back motion when the reach-rod broke. Do you think that the back pressure would keep the links raised in back motion? *A.*—No. Unless the counterbalance spring was stronger than it usually is, the links would drop with forward motion. 2. Suppose I was running an engine that was the only one on a road with a Sellers injector on one side and a pump on the other. Suppose the injector failed, and a main-pin broke on the side the pump was on. How could I bring engine in and keep water in her? Could I use a scantling to pump up by hand? *A.*—This has been done, but is no easy job. You would probably have to let the boiler pressure get low before using the pump.

(84) R. P. M., Bloomington, Ill., says:

Please give me a simple rule for calculating the velocity of steam. For instance, what fraction of time does it take steam to pass from the dome to the cylinder? *A.*—It is not practicable to find any easy rule for this. The theoretical velocity of steam flowing into a vacuum is equal to the velocity a falling body would acquire in falling freely by gravity from the height of a column that would equal the steam pressure. The theoretical velocity of the steam escaping into the atmosphere or into a vessel having some pressure inside would be that equal to the difference in height of the two columns. To find the velocity of steam at, say, 150 pounds gauge pressure, the rule is: From 13 subtract .005 of the gauge pressure. Multiply the remainder by square root of the gauge pressure minus 7. To the product add 1,890. This subject is very clearly treated in "*The Engineer's Epitome*," published by the Mason Regulator Co., Boston, Mass.

(85) G. H., Laurenburg, N. C., writes:

1. Steam gauge when cold shows 15 pounds. Would you call it light or heavy? *A.*—It is light. When it shows 140 pounds pressure, the real pressure would be 125 pounds. 2. What causes the air-pump to flutter when starting? Several things may cause this. Wear of air-pump valves, a bent reversing valve-stem or a broken main steam-valve ring are among the most likely causes. 3. Does the exhaust from right side of cylinder go up right side of stack when double nozzles are used, or does the steam cross over and pass out at the opposite side of the stack? *A.*—If the nozzles are set straight the steam will pass through the stack on the side from which it escapes through the nozzle. If the nozzles lean inward the steam will cross to the other side of the stack. 4. I have seen no answer to the question, What knocked the cylinder-head out when the lower rocker-arm broke? *A.*—We can give no positive answer to this. The valve probably closed the steam in the cylinder and did not rise off the seat quick enough to relieve the pressure caused by the advancing piston.

(86) F. O., Waltham, Mass., writes:

1. What is the idea and advantage of having the piston-rod of the low-pressure cylinder of the Pittsburgh compound locomotive extended through the front cylinder-head, as shown in LOCOMOTIVE ENGINEERING for July? *A.*—It is to act as a guide and support for the heavy piston-head. 2. In one issue of LOCOMOTIVE ENGINEERING I read a statement to the effect that a locomotive could pull a light train with the reverse lever in the center notch. How can you throw such an engine out of gear? *A.*—Putting the lever in the center notch is the best that can be done. 3. What is the greatest distance that the drivers of an eight-wheel engine can be placed apart? *A.*—About nine feet. 4. Do engines with sight-feed lubricators feed oil when the engine is working steam? *A.*—Yes. 5. Two classes of locomotives were tried on fast passenger trains here. One class had driving-wheels 60 inches and the other 69 inches diameter. The engines with the small wheels did not make the time, and some of the engineers say that at high speed the counterbalance of the drivers kept the speed down. I said that it would be the compression and back pressure that would prevent the engines from running faster. Who is right? *A.*—You are likely to be right.

---

The New York Central Railroad Company are not only giving all their employees leave of absence to attend the World's Fair, but they are giving them passes to and fro for the whole distance. The company have also arranged for hotel accommodations for the visitors at rates which are so low that a man may spend a week in Chicago without incurring more expense than he would have to meet in an ordinary boarding-house.

## A Practical Man's Views of Compound Locomotives.

At the last Master Mechanics' Convention a very edifying speech was made on the subject of compound locomotives by Mr. G. R. Joughins, master mechanic of the Norfolk Southern. Mr. Joughins said:

"Last year we commenced to think about compound engines, and in looking over the question we concluded that we might reasonably expect a saving of 15 per cent. at least in freight service. On that conclusion we ordered from the Baldwin Locomotive Works one freight and one passenger compound. Those engines have been running about eight months now. The freight engine is doing work which had previously been done by some simple engines of exactly the same dimensions, received from the Baldwin people also. We find the results with that freight engine to be very satisfactory. The engineers like the engine. It seems to be ample cylinder power. The fireman likes the engine because he has not got so much coal shoveling to do. We have not attempted to make any test of these engines. We keep an elaborate performance sheet, and we determined to rely upon that performance sheet simply. We find that there has been a uniform saving every month amounting to at least 20 per cent. in fuel. We do not find that the oil has been required more copiously. It is apparently about the same for freight work, except, of course, the first month or two in which the engine was put in service. The repairs of that engine we find to be practically the same as the ordinary engine—that is, the running repairs. We cannot see that it is necessary ever to keep that engine in from a trip, or that it has any large repairs required.

"On the passenger engine, however, we have been rather unfortunate. A great many small matters have gone wrong with that engine, partly, perhaps, due to the higher speed at which it is worked, but I think mostly from rather undeveloped designs and a little bad workmanship. The result of these troubles has been that we are not quite satisfied with the passenger engine. We bought that passenger engine with a definite object. We have sometimes, during the truck season especially, very large trains of perishable freight. I mean large trains compared with the speed at which we had to haul them. We take on twelve or fifteen, or even more, 50,000-pound freight cars loaded completely and run them at passenger speed. The engine does this very satisfactorily, so far as speed and power and general performance are concerned, but, as I said before, it has given us trouble in many little details. I do not know whether to conclude that the compound engine is not suitable for passenger service or not. It is rather a small experiment on which to base any conclusion. But I was over in England last winter, and, of course, I went to see the Crewe Works, and also went to Gateshead on the Northeastern Railway. At the Crewe Works I was surprised to find that they had not built a single compound engine for eight months except the engine which was then under construction, and which is now at the Exposition in Chicago.

"That seemed to indicate that the compound was not quite a success on that road. I then went to the Northeastern Railway, to Mr. Worsdell's works, who, we all know, has been long a very strong advocate of the compound engine, and I was still more surprised to find that they were building twenty locomotives for passenger service with simple cylinders, and abandoning the compound for that purpose. I did not quite get at the reason why they abandoned the compound for passenger service. It was a little difficult to get an expression of opinion. But in talking to other people on the railway, they said that they found the compound rather unwieldy for passenger service, considering the slight advantages which they derived from it otherwise. The saving in coal was, perhaps, a little, but there were other things which militated against that, and which destroyed the value of the compound on passenger service. I would say in regard to oil on compound engines, that I think any report which the committee has made about the consumption of oil is utterly valueless. I think we all know that a locomotive very seldom indeed receives the oil which is necessary for lubrication. It receives the amount which in the judgment of the engineer he thinks is needed, and that is often two, three, four and five times the amount actually necessary. I therefore think that the oil question is quite undetermined yet, and the figures given are of no service. In determining whether a compound engine ought to be used in passenger service or not, we must, of course, remember that the engines are still in their infancy, and that if we go along experimenting with those engines in freight service that we shall perhaps eventually obtain an engine which is very desirable for passenger service. Notwithstanding the apparent success of those compound engines on the Reading road and on the Jersey Central, I think that it is still a very undetermined matter about the success of those engines in passenger service.

"In obtaining the results from different people of the test of compound with simple engines, we all notice that they vary very much indeed and a very large factor comes into that question. In determining the relative efficiency of the compound or its relative economy the question is, what is the efficiency or economy of the simple engine against which it is being tried or tested? The compound may be tested against a simple engine which is a very poor machine indeed, or the simple engine may be a good engine, and the compound one or it may be improperly handled. There is therefore, I think, a very important question to determine, what is the factor of efficiency as a machine of the simple locomotive against which the compound may be tested.

"Respecting the way in which a compound engine may be abused, I can give you one very good example. When we received those two engines from the Baldwin Works, I was preparing to go away for some time, and I had only time to receive the engines and see them through a trial trip before I left. On my return ten or eleven weeks after, of course, one of the first questions I asked was what about the compounds, and to look at the figures on the performance sheet showing the fuel consumption. I was very much astonished to find that the compound passenger engine was using 50 per cent. more fuel than the simple engine. I thought that was not right. In the meantime while they were doing this, eating up all this coal, of course, they had no one to instruct them in the use of the compound. I took a few rides on the engine and I talked to the engineer a little, and we have now, instead of the compound using more fuel, she uses somewhat less fuel than the simple engine—a little less, say 10 or 12 per cent. This has been all brought about simply by talking to the engineer and showing him that the engine was a compound engine, and that it was not to be used to its full capacity all the time with the live steam running into the low-pressure cylinder. That was his chief fault. The result, I say of that talk has been a very considerable reduction. I think we reduced the coal per car mile somewhere about 75 or 80 per cent. and I thought that a very good example of how a compound may be abused."

---

The newspapers of Cleveland, O., have been carrying on a crusade against the smoke nuisance, and the lives of steam users and firemen have been made a burden by the threats of smoke inspectors. Railroad people are coming in for their share of the abuse. Care, mixed with a little skill, would greatly reduce the nuisance complained of.

# LOCOMOTIVE ENGINEERING

A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK.

VOL. VI, No. 9. NEW YORK, SEPTEMBER, 1893. 20 Cts. Monthly $2.00 Per Year.

## The Railway Air-Brake Men.

The men who have charge of the air-brakes of railroads, those who test them, keep them in repair, and instruct the engineers and trainmen in their use, recently formed an educational association similar to that of the Traveling Engineers' Association. We publish herewith portraits of the officers and a photographic bird's-eye view of part of the working members—those who stayed in Pittsburgh after the work was done.

Robert Burgess, the president, is one of the bright young mechanics raised by hand under the tutorship of Pulaski Leeds on the L. & N. Since the formation of this society he has been employed by the Westinghouse Company as an expert.

C. C. Farmer, the vice-president, is in charge of the air-brake equipment of the M., K. & T. road and lives at Sedalia, Mo.

P. J. Carney, the secretary, is in charge of the repairs of brakes on the Milwaukee, Lake Shore & Western, at Kaukauna, Wis. It will be noticed that he looks some fifteen years younger in the group than when by his lone self; this is because the boys got him to shave in honor of the organization.

In the group, reading from left to right in the front row, can be found R. N. Martin, Penna. R.R.; L. S. Andrews, N. Y., N. H. & H.; H. P. Shreve, N. Y. Brake Co.; Sam D. Hutchins, Big Four R.R.; Otto Best, N. C. & St. L., and J. B. Swann, of the P. C. & St. L. Reading from right to left in the back row, can be found W. M. Carr, P. C. & St. L.; H. Montgomery, Penna. R.R.; C. C. Farmer, M., K. & T.; F. M. Nellis, Westinghouse Brake Co.; Robert Burgess, L. & N. (now with W. A. B. Co.); A. W. Bragdon, Penna. R.R.; P. J. Carney, M., L. S. & W., and W. C. Walsh, of the L. & N.

---

One of our correspondents sends us the following copy of a recent entry on his work book, and heads it, "Puzzle for Roundhouse Men Only:" "Wash Out Boiler all so See on BallWheel on R. S. the Brake Shone wont Stay in it Place all the Cylner to the steam the hed is goin Look a Rond."

The Chicago & Alton people have begun the reduction of operating expenses by dispensing with the services of several superintendents and trainmasters.

---

Locomotive engineers will recognize an old friend in the solid frame and smiling face of the center-fielder in the group of air-brake men, for it's Sam Hutchins, of the Big Four. Hutchins was recently promoted from the best express run on the road to the position of air-brake instructor, a position he is entirely capable of filling. S. O. Hutchins was promoted to the position of locomotive engineer when scarcely eighteen years of age, and was for some years the youngest engineer in the country. He attended to business strictly, had no trouble, and has been for long years in charge of the throttle of the fastest and most important trains on the road; he has taken a prominent part in Brotherhood affairs, and was chairman of the Ohio Legislative Board—the only board that ever accomplished very much in the way of legislation tending to protect railroad men.

## The Railroads of the United States.

**Their Length, Cost, Debts and Earnings—Number of Locomotives and Cars—Amount of Freight and Passengers Handled—Cost and Profit of Operating—The Facts for the Year 1892.**

The most reliable compilers of railroad statistics in the world are the editors of *Poor's Manual of Railroads*, and from advance sheets of their work on the railroads for this country we are able to concisely place before our readers a few interesting and reliable facts from the records of the year 1892.

### TRACK.

There were, on December 31, 1892, 175,223.44 miles of track laid, but there were only complete and in actual operation when the companies reported 171,866.29 miles; leaving out the elevated lines, this leaves 171,804.72 miles of main line. There are 49,823.81 miles of second track, sidings, etc.—a total trackage of 221,628.53 miles. Of this, 182,710.76 miles

OFFICERS AND MEMBERS OF THE RAILWAY AIR-BRAKE MEN.

are laid with steel rails and 38,917.77 miles laid with iron rails.

LOCOMOTIVES AND CARS.

There were in service, on the last day of 1892, 35,281 locomotives, 24,881 passenger coaches, 7,900 mail express and baggage cars and 1,168,849 freight cars

COST OF ROADS AND EQUIPMENTS.

These 171,804.72 miles of road and the equipment on them cost the enormous sum of $9,293,052,143. Besides this, the roads own in real estate, stocks, bonds and other investments, $1,600,493,849, and have other assets to the value of $253,089,497, and the current accounts outstanding are reported as $212,925,530—a grand total of assets of $11,359,561,019. This is a sum so vast in proportion that no man can form any idea of its magnitude.

THEIR LIABILITIES.

These roads have outstanding a capital stock of $4,863,119,073, a bonded debt of $5,405,049,960, an unfunded debt of $285,455,207 and current accounts of $417,466,957, making a total of liabilities of $10,971,091,286. Therefore, the excess of assets over liabilities is given as $388,469,733.

TRAIN MILES RUN.

During the year the trains on the roads in the United States ran 864,910,463 miles, of which 323,930,550 were run by passenger trains and 523,831,458 by freight trains and 17,148,455 by mixed trains.

PASSENGERS AND FREIGHT CARRIED.

During the year there were carried 575,769,678 passengers. The average ride of each passenger was 23.79 miles, if all the traveling had been done by one passenger he would have traveled 13,697,343,804 miles. There were 749,331,860 tons of freight hauled. the average haul for each ton being 112.70 miles; if one ton of freight had constituted the freight train load it would have traveled 84,448,197,130 miles.

WHAT WAS EARNED ON PASSENGER BUSINESS.

The total passenger earnings were $293,557,476. The average fare per passenger was only 50.99 cents. The average receipts per passenger per mile, 2.143 cents. The average receipts per passenger train mile were 90.62 cents. The average passenger receipts per mile of railroad were $1,721. There were carried 3,375 passengers per mile of road.

WHAT WAS EARNED ON FREIGHT BUSINESS.

The total receipts for hauling freight were $816,716,759, an average of only 0.967 cents per ton per mile. The average receipts per ton were 108.99 cents. The average receipts per freight train mile were 155.9 cents, and the average receipts for freight per mile of road were $4,787. The average number of tons per mile of road was 4,392.

WHAT WAS EARNED IN OTHER WAYS.

Beside the freight and passenger earnings there were received from other sources the sum of $81,582,864, and the elevated railroads (whose earnings are not included in figures given above) earned $13,414,924, exclusively from passenger business.

TOTAL EARNINGS AND OPERATING EXPENSES.

From all sources it will be seen that the roads earned from the traffic the enormous amount of $1,205,272,023. The operating expenses were $846,633,503, leaving net earnings to the amount of $358,638,530. Then from receipts, rents received by lesser companies, etc., there were received $114,619,545, leaving a total available revenue of $473,258,065.

PAYMENTS FROM AVAILABLE REVENUE.

Interest on bonds called for the payment of $232,659,089; other interest, $6,600,799; dividends, $83,336,811, rents, tolls, etc., $62,553,445; miscellaneous expenses, $32,711,558—a total of $417,861,702. This leaves a balance of $58,396,363 excess of available revenue over actual payments for the year.

WHAT RAILROADS ARE WORTH PER MILE.

Our railroads have a capital stock of $28,080 per mile of completed road and a bonded debt of $31,845 per mile, while the cost of each mile equipped ready for business is given as $54,644.

RECEIPTS AND COST OF OPERATING PER MILE.

For each completed mile of road there was earned $1,721 from passenger business, $4,787 from freights, the gross earnings being $6,986 per mile. The cost of operating was 70.40 per cent. of the earnings.

PERCENTAGE OF EARNINGS.

Of the gross earnings of the roads the passenger business was 24.63 per cent., freight earnings 68.52 per cent, while from other sources 6.85 per cent. was received.

PERCENTAGE OF INTEREST AND DIVIDENDS.

The average interest paid on bonds was 4.25 per cent, the average for bonds and debt, 4.38 per cent. Dividends averaged only 1.68 per cent. of the stock, while the total interest and dividends on bonds, debts and stock were 3.01 per cent.

ROBERT BURGESS,
President Air-Brake Men

P. J. CARNEY,
Secretary Air-Brake Men.

C. C. FARMER,
Vice-President Air-Brake Men.

### Demands for the Metric System.

It is wonderful how extensive the volumes of hope are in the breasts of the people who make it their mission in life to advocate the general adoption of the metric system of weights and measures. A writer, ventilating his pet theories in London *Engineering*, expresses the belief that the United States will soon adopt the metric system. For this reason he wants his British friends to begin the introduction of the metric system by forcing it upon India, and thinks the railroads there are the best field to begin upon. Great Britain and the United States are the two largest manufacturing countries in the world, and they contain 80 per cent. of all the railways in the world. To change their system of measurement alone would be more costly for these nations than the greatest war the world has ever seen. The impractical students who are weeping because the English-speaking nations will not adopt the French metric system have no idea that its introduction would cause the least inconvenience in shops, factories and on railroads. It would take tons of printer's ink annually to print the extra figures necessary in giving dimensions according to the metric scale.

---

The enginemen of the Wisconsin division of the C. & N. W. Ry. have formed a club known as the "Engineer's and Fireman's Mutual Improvement Company." The railroad company furnished a room and the men are collecting models, books, etc. W. H. Whalen is a moving spirit in the enterprise and is making strong efforts to work up an interest among the men. These little self-education societies are among the most promising signs of the times and should be encouraged.

In a report on timber physics, published by the Agricultural Department of the U. S. Government, a statement is made to the effect that a few years ago a large amount of valuable chestnut and oak timber was felled along the line of the Louisville & Nashville for its bark. The timber itself was allowed to rot because those interested did not know that it was valuable timber for ties. The object of the publication referred to is to spread information relating to timber.

### Railroad Coppersmithing.*

BY JOHN FULLER, SR.

My attention has been called to your invitation to coppersmiths to discuss matter and things appertaining to their trade or calling. You appear to have noticed the absence of information in this line of the metal trade, as well as your correspondent who doubtless, like thousands of others before him, has searched in vain for a trustworthy guide to assist in exploring this interesting field of operative labor.

The art of coppersmithing takes in such an extensive field of labor, that one must of necessity confine himself to a particular section of the trade and be content if he would become efficient, because only here and there a man can be found with the natural ability to become proficient in more than one or two of the many branches of the copper trade. Usually the copper workers are divided into three classes, which may almost be designated as three separate trades. The first and most ancient have been known for centuries as braziers. These men were, and are now, employed in the manufacture of all kinds of kitchen utensils, transmitting their craft from father to son for many generations, and they have guarded their patrimony with a jealous eye. The next division turned their attention in the direction of larger and heavier vessels, such as brewing coppers, tallow coppers, dyer's coppers, sugar tieches, stills of various kinds, and vacuum pans and boilers for refining sugar, worms and coils, and many other heavy articles and vessels. These men are called coppersmiths, and properly so, because a majority of their work has no need of soldering, and therefore from these circumstances as a rule they are poor braziers. With the invention of the steam-engine another and third branch was called into existence. These men are employed about locomotive and marine engines, and seldom seek employment in any other line. Their work principally consists in making pipe of various sizes, forming bends, T-pieces, cross-pieces, expansion joints, and, in fact, twisting a copper pipe into any conceivable shape required to fit the position it is intended to occupy.

Now, before a man can work to advantage in any of the metal trades, it is necessary that a comfortable shop be provided, and that it be equipped with suitable appli-

*Copyrighted by John Fuller, Sr., Seneca, Kan.

ances to execute the work required to be done. This is more often than not overlooked or totally disregarded; hence there are only a few coppersmiths' shops on American railways where a good job could be done expeditiously and in a workman-

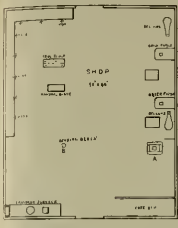

FIG. 1.—PLAN OF SHOP.

like manner, as evidenced by my own observation. As we are about to engage the attention of the reader to this class of coppersmith's work, we will endeavor to describe a well-appointed shop wherein to do

On the opposite side of the shop three forges may be placed, two made of brick, and one, *A*, of iron. The two brick, Fig. 2, should be about 3 feet high, and 3 feet 6 inches wide, and reach 5 or 6 feet from the wall. In the center of the top is the fire-hole, which is about 10 inches wide and 12 long and from 8 to 10 inches deep. The blast can be supplied in the most convenient way, either from a fan or a large bellows; if from bellows, they should be hung overhead out of the way so as to be convenient for the two outside forges, pipes being laid so the blast can be carried from one fire to the other, and to all of them if necessary. The iron forge, Fig. 3, should be made of ¼-inch boiler iron, and so constructed that the two side leaves of the top can be taken off easily when necessary to get the fire closer to work in hand. In the spaces between the fires there should be two pits of convenient depth to receive from 8 to 10 feet of pipe.

These pits are about 3 x 4 feet and 6 feet deep, and covered with a lid made of 2-inch oak plank; one plank of the lid, or cover, is left loose, to give access to the pit, when the whole opening is not necessary. In one of the outer corners of the pits a blast-pipe is fixed for work which must be done over or near a pit. On the same side of the shop is a bin to hold coke, Figs. 1 and 3, which is placed near or close to the door for convenience in keeping it stocked. On the opposite side, and in the

caught in the links. These chains are used to hoist and sling work, that it may be easily manipulated over the fire, at the bench and mandrel-block. To the wall is fixed a cleat or hitching-hook, for the pur-

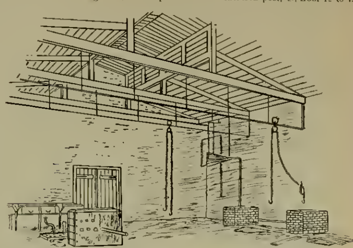

FIG. 2.—INTERIOR VIEW OF FRONT END OF SHOP.

pose of tying the fall end of the chain when work is slung over the fire.

The tramways are conveniently placed so that work may be easily carried from one place to another and to and from the

go through both plates, so that the mandrels may be securely wedged and held fast in their places. Some 20 feet from the back or furnace end of the shop floor is fixed a cast-iron post, *B*, from 12 to 14 inches square. This post is for the purpose of bending pipe, and is called a bending-block. It should be placed as near the middle of the shop as convenient, and must be firmly set in the ground with a

FIG. 4.—A RAILROAD COPPERSMITH SHOP IN LONDON.

FIG. 5.—A RAILROAD COPPERSMITH SHOP IN LONDON.

it. The most essential thing for a healthy coppersmith's shop is a lofty, spacious room; if possible, not less than twenty feet high, with a floor 50 x 60 feet; the light should, if practicable, come from the roof through opaque glass; the roof should be furnished with dormers having movable slats, which may be raised and lowered as occasion requires to let out the fumes and gases that arise from the fuel in the forges and from the metal being worked, for they are often of the most repugnant nature.

The room having been provided and proper provision made for the exit of the poisonous gases, benches for the accommodation of from four to six men may be erected and firmly fixed against the wall, as shown in the accompanying sketch. The bench should not be less than three feet wide and three inches thick, of some hard wood, preferably beechwood. They should be provided with capacious drawers for the tools of each man, with a vise at each drawer, the vises being not less than eight feet apart. The bench may reach as far as necessary along the side of the shop, and may turn at the end as far as the door. The doors should be in the middle of each end, and large enough to allow such work to pass through as is likely to be done, and admit a current of air readily when necessary.

space from door to wall, a furnace is erected having a cast-iron caldron for the purpose of melting lead, also a fire to melt resin used to fill pipes for bending. Above

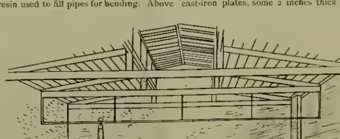

FIG. 3.—INTERIOR VIEW OF BACK END OF SHOP.

each of these fires and forges is a kind of tramway for wheels to run on, the lower wheel carrying a chain, as shown in cuts. The chain should be large enough so that a hook at each end of it can be readily

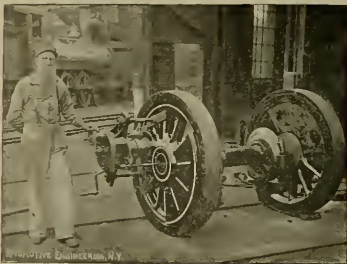
fire, also to hold the work balanced while being operated on at the bench and mandrel-block. The mandrel-block is made of cast-iron plates, some 2 inches thick and about 6 feet long and 3 feet wide, stood on edge and 2 feet apart. The plates, which are firmly fixed opposite each other, have holes in them, both round and square, to receive round and square mandrels, which

good broad foot at the bottom (similar to the stump of a tree), as it requires considerable power to bend 5-inch pipe filled with lead, and if the block is not made solid the power used in bending would loosen it and make it useless.

The top of the block has a ledge four inches down for a strap to rest upon, the strap is of iron an inch thick and three inches wide, made like a square staple with the ends drawn down so that a 1¼-inch thread can be cut on them. Another piece of iron with holes at each end is made to go over the threaded ends of the strap. This strap is to hold a thick lead-piece on top of the block, the lead having a hole in it large enough to take the pipe in easily which may be required to be bent.

For the benefit of the reader, and to make more clear what has gone before, I herewith present two photographs of a railway coppersmith's shop in London, taken from different positions, so that as much of the interior as possible may be seen. The first object in the picture, Fig. 4, is the floor block, with a brazier's bottom stake standing in it; a little to the right of this is a coppersmith's anvil, used to work down the saddles of bends, which are made in two halves (one of these bends is lying on the right-hand end of the mandrel-block in picture, Fig. 5).

In a table near are two brass safety-valve covers, the crowns of which have just been brazed in. The next thing beyond these covers is a forge, in which there was a fire when the picture was taken. Other prominent objects are three brass dome covers, the making of which may described in a future article



Streiber's Crank-Pin Turning Machine.

The next thing we notice is a coping, which is made of sheet-iron, and when it is fitted to its place makes a necessary and neat finish to the lagging at the back end of the firebox. Under the left hand end of this coping is a pit with a blast-pipe in the southeast corner of it, convenient for work which must be performed over a pit. Hanging on the wall is another kind of a coping for the front end of the firebox and which connects the lagging of the fire box with that of the boiler

The traveler chains used for slinging work are all clearly shown hanging at different parts of the shop. In the other picture (Fig 5) taken from another point the benches are all shown. The principal object on the bench is another coping finished ready for fitting, and in the corner are two long boiler steam pipes, 6 inches in diameter, which are the largest pipes usually made in a locomotive shop. The next thing is the mandrel-block, upon which are lying four cods, six small heads of different shapes and three large long heads, in the end hole at the left hand of the mandrel-block is a wooden bar shoed with an iron strap to keep the head in and form the hole for the head shank

In the north left-hand corner, and securely fastened to it, is a 3-inch round iron bar about 7 feet long, upon which are two cast-iron blocks that slide up and down the bar as required. These blocks have holes in them to receive a round or square mandrel, and are made fast to the bar by a suitable set-screw at the back, which holds the block and mandrel at any required height when the main block is too low for the work in hand. A little to the left of this bar is a screw jack, used to hold up one end of a pipe at the fire or for other purposes On the wall may be seen various wire templates of delivery and other pipes. The shop, it will be noticed, is illuminated by electric light, two lamps being shown. Altogether, these pictures afford an interesting peep into a London railway coppersmith's shop.

## Master Mechanics' Investigation Committees.

The following is a list of the subjects selected by the Master Mechanics' Association for investigation and report at the next Convention, with the committees appointed on the various subjects by President Hickey. The first name on each list of committees is that of the chairman.

The subjects are unusually good, and will no doubt provide matter for a very interesting and valuable meeting

*1. Cracking of Back Tube-Sheets.*—What method of construction can be devised to prevent the cracking of tube-sheets?

T B. Purves, Jr., J. M. Boon, R. C. Blackall, David Brown, John Mackenzie, L. R Pomeroy, Committee.

*2. Oiling Devices for Long Runs.*—What devices can be provided for locomotives to supply lubrication on long runs?

J. Davis Barnett, J D. Campbell, Geo W Stevens, George W. West, C. E. Smart, W A Smith, Committee.

*3. Locomotive Fire-Kindlers.* — Best methods of starting fires in locomotives and their relation to insurance risks.

John Hickey, J. O Pattee. Geo B Brooke, Wm. McIntosh, W. T Reed, John A. Hill, Committee

*4. Exhaust Nozzles and Steam Passages.*

Robert Quayle, William Forsyth, James McNaughton, James W. Hill, W. S. Morris, D L. Barnes, Committee.

*5. Boiler and Firebox Steel.* To report on standard specifications and tests for boiler and firebox steel for adoption by the association.

A. W Gibbs, G. R Henderson, J. A. Lawes, J. W Luttrell, E M. Roberts, W D. Crosman, Committee.

*6 Sanding Devices*

O. Stewart, F M. Twombly, L M. Butler, C E. Fuller, John Medway, H. P. Robinson, Committee.

*7 Special Shop Tools.*—To report on new or improved appliances, either hand, power, pneumatic, hydraulic or electric, applied or applicable to locomotive manufacture and repair

T W Gentry, George L. Potter, H D. Gordon, G. R Joughins, William Swanston, F. B. Miles, Committee.

Foster's "Handy Man" Unloading Lumber with Air. Fall Brook Railway.

*8 Standard Tests of Locomotives.*—(Continued from last year)

J. N. Lauder, George Gibbs, P. Leeds, R. H Soule, Angus Sinclair, F. W Dean, Committee.

*9. Tire Treatment.* — What is the amount of shrinkage to be allowed for large driving-wheels? Is there any necessity for retaining-rings or clips? What is the limit of thickness tires should be worn down to? What is the greatest permissible depth of groove on the tread before turning?

A. E. Mitchell, W. C. Ennis, Thos. Millen, J. H. McConnell, A. J. Cromwell, John Y. Smith, Committee.

*10. Cost of Maintaining Locomotives* —Report on the comparative cost for repairs of locomotives built in contract shops and those built in railroad shops.

G. W Rhodes, Jacob Johann, W Smith, J. N. Barr, Wm. Garstang, W H Marshall, Committee

## Streiber's Crank-Pin Trueing Machine.

The photographic reproduction herewith shows a new crank-pin trueing device and its application to its work.

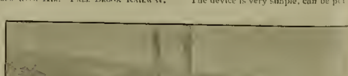
As can be seen, a large shell is used to carry the cutter and act as a frame and guide for the tool.

The two large lugs on the shell are used to clamp it solidly to wheel, the two smaller lugs carry set-screws that merely true it up and act as feel for it to stand on, a large center-point screws through the center of the shell to bring the machine true by entering the drilled center on the pin, and there are three jaws on the back of the shell that center the collar or flange of the pin.

Inside the shell there is a second shell that revolves, carrying a tool-post with it, this tool-post being fed out and in by a screw, operated either by hand or the small belt shown.

With this device, not only the bearing but the faces of the collars, can be trued up. When it is desired to turn the inside bearing of a main pin, an extension to the tool-post is screwed into place, as shown in the engraving The machine will true up all pins from 4 to 7¾ inches in diameter

This machine was designed and built by Mr. H. Streiber, a machinist in the tool room of the W. N. Y & P. shops, at Oil City, Pa.



There is More than one Way to get them in. The Way it was Once Done on the Canadian Pacific.

## A Speed-Figuring Watch Dial.

Will McCarroll, one of the traveling engineers for the Baldwin Locomotive Works, has invented a watch dial that tells the speed a train is running at by looking at it.

He accomplishes this result with the fewest possible figures, and figuring that the need of such a dial is for high speeds, the miles per hour figures range only from 25 to 120 miles per hour.

Our illustration shows the arrangement there is an extra circle on the dial and outside of it a row of figures in red, these are the distance figures.

For instance, if you have made a mile in 34 seconds, looking at the row of outside figures you will see that this is at the rate of 105 miles per hour (nearly, the lines don't quite coincide). If you have run a mile in 57 seconds you see that this is at the rate of 63 miles per hour. If you are a minute and, say, 7 seconds, the speed is shown 54 miles an hour.

The mile circle is figured in five-mile jumps, and the distance these lines are apart will vary as the speed varies.

The device is very simple, can be put on any watch in place of the present dial, and would be a neat, handy thing for any railroad man. We hope some concern will put these on the market—we want a couple anyway.

The Traveling Engineers' Association will meet at the Hotel Hayes, corner Sixty-fourth street and Lexington avenue Chicago, on September 12th.

## What the Finished Parts of a Standard 18 x 24-inch American Locomotive Weigh.

Some months ago the Schenectady Locomotive Works took the pains and trouble to weigh the parts of one of their standard eight-wheelers, of course where there were more than one piece of a kind only weighing one.

The engine weighed is shown in our engraving. She has a boiler 54 inches in diameter at smallest ring, tubes 12 feet long, cylinders 18 x 24-inch, driving-wheel base 9 feet, total wheel-base 24 ft. 1 in.

| 1 | Driving-box saddle | 120 |

## The Wreck on the Big Four, Aug. 5th

One of the most disastrous freight wrecks of the summer was that suffered by the Big Four road at Danville, Ill., on August 5th. Our engraving gives a fair idea of the appearance of the wreck on the day after its occurrence.

A valued correspondent on the ground writes as follows.

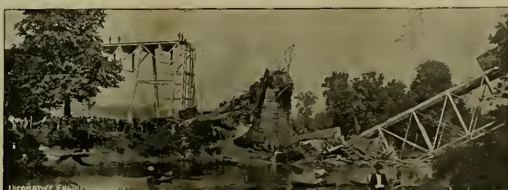
"At about 10 o'clock on the evening of the 5th inst., two freights were started out of Urbana for Indianapolis, over the Peoria division of the Big Four Railway; the first one arrived here (Danville, Ill.) about 11.30 P M. The bridge where the accident occurred is situated at the northwest edge of the city, and approaching it from the west is a heavy down grade of between two and three miles in length, and leaving the east end of the bridge is a heavy up grade for about a half mile to the depot.

"The first train broke in two pieces in going up the grade east of the bridge, and on the crew attempting to couple up the detached portion, started back and was not stopped until on the bridge, which is about seventy feet high at the channel span.

"Before a flagman could get back far enough, the second train, consisting of twenty-eight cars of merchandise, grain, flour, and one car of hogs, came down the grade at the west end of the bridge and ran into train on bridge, tearing the bridge down and precipitating the whole of the last train, engine and caboose and all, and six cars and caboose from the head train, to the ground and river below.

"The engineer jumped before he got on the bridge and was slightly bruised, as also did the hind brakeman, but the fireman, head brakeman and conductor went down with the wreck. The fireman was thrown into the water below, a distance of seventy feet, and clear of all wreckage, with only a few bruises to show for his startling adventure. The body of the brakeman was found under the debris two days later. The conductor was taken from the caboose with a mashed foot. There were wild rumors about there being seventeen tramps in the wreck, but, so far as known, there has been but four bodies found as yet.

"The bridge was a structure of steel and wood, the approaches at the east and west ends being composed of wooden trestles; the channel span was steel and rested on stone piers, one on each side of the stream, just west of the west pier there was another steel under-truss span, the east end of which rested on the west abutment, and the west end rested on a heavy steel pier, as shown in the illustration. It seems that the engine left the bridge immediately above the stone pier seen standing alone in the wreckage, and fell into the water below with the head end to the west.



Three Lives, a Locomotive, Two Cabin Cars and Thirty-four Loaded Freight Cars and a Bridge Lost in one Wreck for the Want of Brakes.

"There are six cars, one caboose and engine in the river, and piled around the stone pier are twenty-eight cars and two cabooses. There were several thousand bushels of oats and shelled corn in the train

"The loss is variously estimated at from $100,000 to $110,000—which would have come very near equipping the entire road with air-brakes. As it was, at least ten cars had air-brakes on, *but the engine was not equipped.*"

Those who wish unfolded copies of our inset, printed on heavy plate paper, can secure same by remitting one dollar.

## Compound Express Locomotive for the N. Y., N. H. & H., for Heavy and Fast Trains.

The "Consolidated" road has recently put into service some new Rhode Island compound locomotives that are doing remarkably well on their heavy and fast expresses

The elevation and cross-section drawings shown herewith will give a good idea of the plan and arrangement of these modern American engines.

The general dimensions are as follows

Fuel—anthracite coal.

Gauge of track, 4' 8½".

Cylinders, 21" and 31"x26".

Driving-wheel diam., 78".

Driving wheel base, 8' 6".

Rigid-wheel base, 19' 8".

Total wheel-base of engine, 22' 9.

Total wheel-base of engine and tender, 47' 6¼".

Weight on engine-truck, 41,000 pounds.

Weight on drivers, 84,000 pounds.

Total weight of engine, 125,000 pounds.

Weight of tender, 75,000 pounds.

Capacity of tender, 4,000 gallons

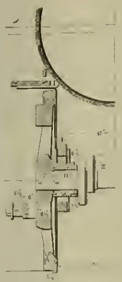
Boiler, radial-stayed, extended wagon-top.

Boiler, diameter at smoke-box, 60.

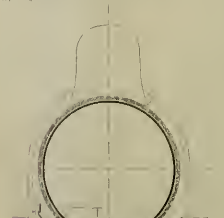
Boiler, diameter at rear, 69½.

Material, ⅝ steel

Firebox, 120 long, 41¼ wide, of ⅜ steel



Cross Section Through Main Driver



Cross Section Through Guides—Looking Back

250 tubes, each 2" diameter and 10' 9" long.

Water-tube grates, with cleaning-bars.

Heating surface of tubes, 1,229.00 sq. ft.

Heating surface of firebox, 166.50 sq. ft.

Heating surface, total, 1,395.50 sq. ft.

Grate area, 34.50 sq. ft

Steam ports, H. P. cylinder, 20" x 1½".

Steam ports, L. P. cylinder, 25" x 1½".

Exhaust port, H. P., 20" x 3".

Exhaust port, L. P., 25" x 3".

Travel of valves, 6⅛".

Tires under engine and tender are Krupp's crucible steel.

Driving-box bearings of Damascus bronze

Every wheel under the engine and tender has an air-brake on it.

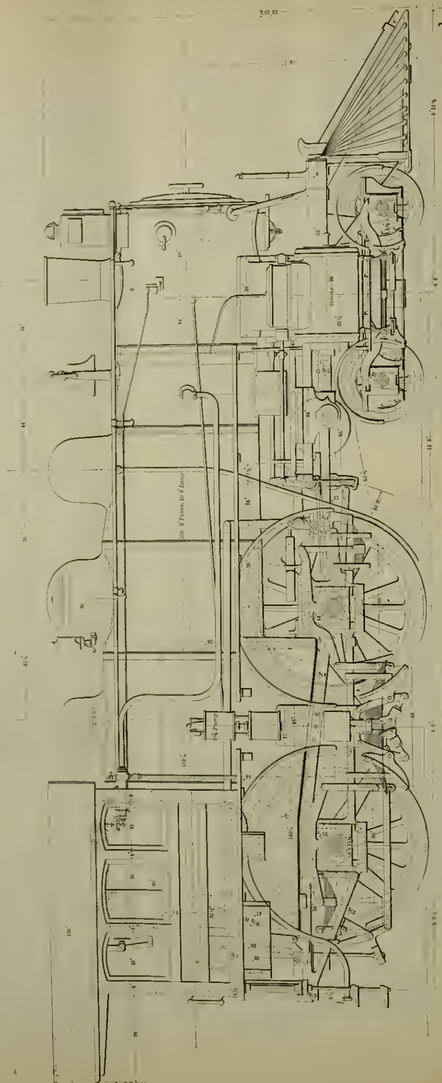
Valves are balanced.

Metallic piston and valve-stem packing.

Tender fitted with Miller coupler

Steam-heating apparatus.

Other principal dimensions are shown on engravings.



Compound Locomotive for Heavy Fast Passenger Service. N. Y., N. H. & H. R. R.

Built by Rhode Island Locomotive Works, Providence, R. I.

Designed by John Henney, Jr., Supt. M. P.

## The Traveling Engineers.

### Souvenir of the First Annual Meeting—Personnel of the Inset.

The Traveling Engineers of the American Railroads is destined to be one of the most useful of the many educational associations of railroad men. Organized for mutual advancement in their particular calling, with the aims of their association condensed into the motto "To improve the Locomotive Engine Service on American Railroads," they have, since the formal organization perfected in the office of this paper only last January, secured a working membership of over 100. On the 12th of September they meet in Chicago to discuss live subjects pertaining to their line of work. A prominent railroad manager, writing to this paper on the subject of this association and its possibilities, said "It is my opinion that a good, honest, earnest, *fair* man in the position of traveling engineer can save more money for a railroad company than any other officer."

We only collected fifty chromos of the boys in time to include in the collection, and you would go a long way before you would find a finer looking lot of men, but truth compels us to say that from the samples of "lates" coming in we are led to believe that the other fifty are the best looking of the lot.

The central figure, as can be seen, is the president of the association, Clinton B. Conger, traveling engineer of the Chicago & West Michigan and the Detroit, Lansing & Northern roads. Mr. Conger was mechanical engineer of the Railway Commission of Michigan until the politics of the State went "'agin' the government," he is well known to our readers as a bright correspondent of this paper.

John W. Sheldon, the first vice-president, is the well-known hustler on the Philadelphia & Erie divisions of Pennsylvania Lines, located at Renovo, Pa.

R. D. Davis, second vice-president, is traveling engineer of the Illinois Central road of Chicago.

W O. Thompson, secretary, until last month has been traveling engineer of the Western division of the Lake Shore; he has been promoted to the position of foreman and dispatcher. He has been one of the men who worked to make the association a success

W E. Miller, the treasurer, is traveling engineer of the Vandalia Line and lives at Terre Haute, Ind.

The rank and file are numbered and can be found by reference to the plate; unless otherwise stated the subject occupies the position of traveling engineer or road foreman of engines.

No. 1. J. W. Brant, Wabash, Decatur, Ill.
2. J. S. Seeley, Wis. Central, Waukesha, Wis.

## Schemes for Reducing Compression.

A correspondent writes us that, "in view of the high railroad speeds becoming common it is of the greatest importance that the capacity of the locomotive should be increased in every possible manner consistent with keeping down the total weight of the machine, and that the most practical way to do this is to reduce the loss of power and loss of steam due to compression." Particulars are then given of a method for reducing compression by means of a supplementary release pipe.

This subject has been discussed so often that it is a stale and unprofitable theme for many of us, but there are so many of our readers who are just beginning to study the action of steam that we feel inclined to go over well-trodden ground once more. This seems to be necessary, since those who will see only one side of the question keep lamenting about the imperfections of the link motion because it increases compression as the cut-off is shortened and so reduces the capacity of the cylinders as the speed augments. All locomotives have what may be called excessive compression at high speed, but it is not, as a rule, more than the nature of the forces to be controlled requires. What can be said in favor of or against high compression are not mere theories based on mathematical calculation, they are the teachings of experience over a long period of years.

As soon as the peculiarities of the link motion in the distribution of steam were properly understood, attempts were begun to protract the periods of release and of valve closure. It was argued that by preventing the steam from escaping as soon as it does when a link-motion engine is notched up, that more work would be taken from the expanding steam, and that by holding the port longer open during the return stroke, less piston resistance would result, and more work would be done with a given volume of steam. Some of the ablest engineers the world has ever seen devoted their energies to improving the locomotive on these lines. Numerous forms of special mechanism were applied to secure the desired end, and in every case failure ensued. Keeping the steam longer in the cylinder caused increase of back pressure that neutralized any gain due to greater expansion of the steam. In connection with the attempts to reduce compression, it was found that the smooth working of the engine demanded that compression should be of sufficient intensity to fill the clearance spaces and raise the cylinder pressure to that of the steam-chest when the valve opened. If this was not done, the engine did not work smoothly nor steam well. There is tremendous force stored in the moving connections of the piston which have to be brought to a state of rest at the end of each stroke. The most practical way to stop these parts smoothly is by using the steam confined in the cylinder as a cushion. When this is done skillfully, several advantages are obtained. The parts are brought smoothly to rest without having to draw on the boiler for steam to cushion with, and the mechanical heat generated in the compressed steam heats the cylinder at the beginning of the stroke, so that the heat loss, due to steam condensation at the beginning of the stroke, is reduced and economy of heat increased.

The forces in the reciprocating parts that have to be controlled at the end of each stroke are of much greater magnitude than the average railroad man realizes. The piston, with its connections, weighs, say, 650 pounds. When the speed is very high there are two difficulties in controlling this projectile that is flying towards the cylinder-head. The mass has a force in proportion to the velocity, and this velocity shortens the time in which it has to be stopped. An engine, with drivers 72 inches diameter and 24 inches stroke, running at sixty miles per hour, makes 280 revolutions per minute and has a piston speed of 1,120 feet per minute. As the piston has to be stopped twice during each stroke, cushioning must take place 560 times a minute or over nine times each second. Only very positive forces will perform this work in the brief time available, and nothing has been found equal for this purpose to the steam that the returning piston compresses after the valve is closed.

It may be edifying to our studious readers to follow the calculations of the mechanical energy in the reciprocating parts of the engine taken as an example at the speed mentioned. The piston speed is 1,120 feet per minute, and the reciprocating parts weigh 650 pounds. The total energy in foot-pounds is calculated as $E = \frac{W v^2}{2g}$, when $W$ weight in pounds, $v$ velocity in feet per second, and $g = 32.2$, the velocity in feet per second acquired by a body falling by gravity at the end of one second. Putting the formula in figures, we have $E = \frac{650 \times 18.66^2}{64.2} = 3{,}514$ foot-pounds of a blow that has to be brought quietly to rest at the end of each stroke.

In some kinds of engines it has been found practicable to control the reciprocating parts principally by means of steam admitted by opening the valve before the piston reaches the end of the stroke; that is, by giving lead sufficient. The practice is, however, out of the question for locomotives. The piston speed varies so much that it is impracticable to provide for pre-admission of steam to do the work of cushioning at all velocities. The amount of cushion obtained from lead that would be sufficient to make a smooth working engine at 50 revolutions per minute would be entirely inadequate to control the moving parts at 300 revolutions per minute, and the action of the link motion of increasing the lead as the engine is hooked up does not provide the necessary port opening for very high speed. A decided advantage obtained from cushioning by compression is that the supply is to a great extent automatic. When the piston speed is very high an increased volume of steam is left in the cylinder because it has not time to escape through the ports. This increases the intensity of compression when the greatest amount of cushion is wanted.

Those who object to the use of compression say that at best it causes a waste of power, reducing the capacity of an engine for doing work. With certain kinds of engines this may be a serious objection, but not with the locomotive. The cylinders of locomotives are generally too large for the work to be done after a train is forced well into speed, and the natural effect of cylinders too large for the work to be done is the wasting of steam. As compression reduces the capacity of the cylinders it lessens the probabilities of wasting steam in a remarkably simple and efficient manner. There are many locomotives in use with viciously designed valve motion which causes excessive compression that keeps the engine working against itself. In such cases compression is carried to an injurious extent, but that does not prove the principle to be wrong. Yet it is cases of this kind that set men to the inventing of methods for relieving the disorders due to excessive compression. A simple form of remedy is adjusting the valve motion. Any effort beyond that is certain to end in disappointment.

## Hot Boxes.

There is no minor trouble connected with the operating of railroad trains that gives so much annoyance as hot oil-boxes. Some roads are chronically afflicted with this malady, which is an extremely expensive disturbing element in the movement of traffic. No end of exhaustive investigations have been carried out to ascertain the exact cause of hot boxes, and we are familiar with no question in mechanics where the truth has been so sedulously withheld. It looks as if many of the reports on the subject have been framed with a view of finding fanciful causes for hot boxes when the true cause was staring all concerned in the face. It is very amusing to read some of these reports. There will be learned disquisitions on the reasons why rubbing surfaces generate heat and on the action of lubricants as a preventative of friction. A great deal will be said about the safe pressure per square inch of surface, and concerning the composition of the metal best adapted for journal bearings. In rare cases the party making the report will venture on the slippery subject of lubricants, and will generally fail to give information of interest, yet this is the real heart of the subject. Almost every road in the country that is suffering from hot boxes is using inferior oil that will not keep the rubbing surfaces apart.

This is one of the worst phases of dear cheapness that we are familiar with. It eats away the revenues of railroad companies, showing nothing in return but bitterness and contention among the men responsible for operating trains and those whose duties it is to see that the machinery is kept in good running order. The hard times which have come upon us so suddenly have furnished us with a good object lesson on the cause of hot boxes. The A. & B. railroad trains have been noted for the few detentions caused by hot boxes. For the last five years a hot box on a passenger train was practically unknown, and there was very little annoyance from hot boxes on freight cars. The company used a good quality of oil and paid fair prices for it. The details of the mechanical department were so well attended to that oil-boxes seldom got hot through becoming dry, and a good quality of packing was used to supply the oil to the journals. When the money stringency arose the management became panic-stricken, although there was no cause whatever for alarm, and orders were given for retrenchment in every department.

In addition to this, inferior quality of supplies was resorted to as a method of reducing operating expenses. Among the changes made was the purchasing of an inferior quality of oil and cheap bearing metal. Before the new bearings got in their inevitable trouble, the change of oil put the road in an uproar. The road is carrying an unusually heavy passenger business, and, being a single track, the successful movement of trains requires that they should be run nearly on time. Hot boxes were so numerous soon after the change of oil was introduced that the train dispatchers were harassed in arranging meeting points. As usual, the management alleged that the trouble was worked up by those who objected to a change of oil, and there has been very badly strained relations between various offices, but hard words or misrepresentations between the men in authority do not help the trains over the road. Meanwhile it seems seasonable to remark that a manager who ventures to demoralize the train service of a railroad for the sake of the small saving that might be effected by cheap oil is an idiot unworthy of holding a position higher than that of galvanizer.

## Can Car-Couplers Be Too Strong?

Before the existing depression of business knocked everything out of railroad men's heads to make place for the cogitation of schemes for keeping things running on the least outlay of money, there was considerable interest developing concerning the relative merits of steel castings and malleable iron for car-couplers. Several makers of couplers are employing steel, and, naturally, claims are made that this renders the coupler more reliable; but those who are using malleable iron are by no means ready to allow that steel is the better material for couplers. The experience with good malleable iron couplers certainly indicates that the material is well suited for the purpose. It is doubtful if mere increase of strength is an unmixed advantage in a coupler. A remark made by Mr. G. W. Rhodes on this subject is worthy of earnest attention. He said "The engineer who makes a device stronger than necessary may be more politic but not any more skillful than the one who makes them too weak. Those who have the coupler problem to solve will have to steer through the channel of the two extremes."

The point evidently implied is that it is better to make a coupler which will break under an irresistible shock than have the draft timbers and sills torn off. A coupler that is strong enough to withstand ordinary shocks and weak enough to yield before its attachments are torn away would seem to be the kind likely to keep down the cost of repairs. The breakage of attachments of couplers causes the most numerous and most expensive repairs to cars, and it seems desirable not to render the case worse by employing couplers that will act as battering-rams upon the weaker parts. The number of blows that a coupler will stand in a drop test is a very indifferent way of demonstrating its utility.

## New Method of Testing Steel.

At the International Engineering Congress held at Chicago, last month, Mr. Alfred E. Hunt read a paper in which he proposed a new method of testing structural steel. It consists in punching, cutting, shearing or drifting pieces of a given thickness, and comparing the force required in this work with that required to treat standard pieces in a similar manner. The comparison can be made also with the work done at different stages of the punching, etc., with results obtained in treating standard pieces in a similar manner. He uses the term "work" to express the force necessary to punch a given hole or cut a given notch or drift a given hole, multiplied by the space through which the force moves, and by the time during which the force acts. In practice a combination of the first of these factors with the second or third is often used, and it is the combination of force and space that the author has so far found to be the best and most accurate way of using the method.

### Emergency During Service Application.

A man used to the handling of air-brakes cannot help noticing the interest taken by enginemen who visit the Fair and the air-brake exhibits, and, if he is observant, will not fail to notice that six out of ten of them want information on two points, *i. e.*, the "kicking-off" of brakes and how much can be gained, if, while there is a slight service application on, to recharge and then go to emergency, in case of dire necessity, rather than to put the engineer's valve into emergency at once.

Some harm has been done by too fine-spun theorizing on this subject, and too many chances are being taken when the recharging plan is used, or attempted to be used.

With a short train a quick throw to full release might increase the auxiliary pressure some, but the time is too short to get much past the feed-port, and beside this, the distance between the train and obstacle is lessened very much. It would have been far more effective to have had a lower braking pressure for the longer time.

In an emergency, time is everything. If you recharge you lose what air you have in your cylinders; release your brake entirely and lose valuable time in the uncertain hope of getting a better hold when you do apply.

Every man cannot calmly sit in front of an emergency and figure this out—*don't fool with it, but go to emergency at once.* You may have reduced your pressure in service application so much as to prevent the quick-action valve from working, but rest assured that the brake is full on *from the start.*

We want this lesson impressed on all young runners who are so interested in every detail of the brake and who are striving to be experts with it. You may try to be "too fine" with it in a case of this kind. An emergency stop should call for the engineer to slam his valve-handle into the emergency notch *and leave it there.* You might save some of the train-line pressure, if the brake was fully charged, by causing the quick-action valves to act by a quick reduction of 20 or 30 pounds, and then bringing the valve to lap. This would be advisable in making a water-tank stop or where emergency has to be used to prevent running by a station, where failure would simply mean inconvenience, but where there is a real emergency, no matter what you are doing with the brake, don't take any chances; go to the emergency stop instantly. It's sure, safe and correct.

---

The Report of the Proceedings of the Twenty-sixth Annual Convention of the American Railway Master Mechanics' Association has just been issued. This book contains 275 pages, twenty more than the report of 1892, and is the best job of printing yet done on the work. This work contains a mass of information at first hands, experience related by railroad men to each other, and is far different from the ordinary book that is apt to take one side of a question only. It is distributed to members of the association and railroads and sold to outsiders. Anyone interested can secure a copy by addressing Angus Sinclair, secretary, 5 Beekman st., New York.

### Reducing Wages.

The existing financial stringency came upon the country like rain out of a cloudless sky and many people think it will pass away as quickly as it came on, but many railroad companies seem determined to turn the tide of depression to the purpose of pulling down the pay of their employés. From all directions come intimations that railroad companies are reducing the hours of labor, reducing the force of men, and that not a few have given notice of a reduction of wages, while others are reported to be contemplating similar action. In some cases the reduction of working force and of hours of labor is a necessary result of decreasing business, but in many cases action of this kind merely anticipates decrease of business and helps to bring it about. The notices of reduction of wages tell of panic-stricken managers who are courting worse evils than a slight depression of business.

The relations between the railroad companies and their employés have been remarkably friendly and cordial for the last few years, and both sides have benefited by this condition of affairs. Those who invite a change by inconsiderate interference with men's pay are not acting wisely, to say the least of it. The process of pulling down wages is harassing to every person who suffers and the balance secured does not represent saving. There is no line of employment where economy is so much dependent on cordial heart service as in railroad work, and reduction of wages nearly always brings reduction in results that more than raise the cost of work to its old figure. There are thousands of railroad men who take as much pride in doing work at the least possible cost as if they were working for themselves. The proper way to take the heart out of this kind of zeal is to intimate that the pay will be reduced. Railroad men are generally well organized for self-protection, but they have made little use of their power. The reckless movement to reduce pay as soon as the smallest excuse is presented will arouse animosities that are difficult to root out. A few thousand dollars saved by reduction of pay is a miserably small profit on which to face years of hatred that thinks not of moderation when the opportunity for retaliation offers.

### Curious Economy.

We were recently shown a letter of recommendation given by the general manager of a Western road to a large manufacturing firm, asking them to put his late traveling engineer on the road for them.

He said the applicant was a first-class man, had done good service and his work had resulted in *great economy in supplies used on the engines*; but that in the present financial distress the cutting down of expenses required the abolishment of his office.

A foreman, traveling engineer or other man in charge of men who can show by his management of the work in hand that ten men will do, under him, as well as twelve men without a leader, is well worth his hire, and he becomes more valuable just in proportion to the number of men he has any influence over.

You can scarcely find an official in the country that won't acknowledge that the traveling engineer causes a saving of supplies, better handling of brakes, better inspection of engines, raises the standard of intelligence by examination of enginemen, insures more accurate information about accidents, locates and remedies more petty troubles on the road, and has a good influence in keeping up running repairs—any one of them worth more than the man's wages to the company—yet how often we see short-sighted managers who cut off this official's head at the first order for economy (?), because the trains can actually be run over the road without him.

For every dollar the railroad saves now by this kind of economy, they will lose two in the service and have to pay two more to get it back where it was.

*Esprit de corps* is like a house—when left vacant it goes back into the elements with surprising rapidity—keeping it up and occupying it, from cellar to garret, is the only way to make it valuable.

### Criticism of the Erie Engineers' Locomotive.

On another page will be found a scrap of discussion at the last Master Mechanics' Convention, which mentions the engine designed by the Erie engineers.

There are several things about the Erie engine that we cannot approve of, but we believe that in its cab can be found as handy an arrangement of manipulating devices as can be found anywhere for this class of engine.

The hand-brake on tender *is* a bad scheme, the ratchet is too high, and any tank-brake located on the left side of tank is a nuisance, and not a brake; it is always in the fireman's way, and he will take the wheel off to prevent butting his brains out; in this particular the Erie engine is not far different from 90 per cent. of the locomotives in the country, and the sand-pipes are about four feet too far away from the wheel.

The boys must not take to heart what was said by one member about engineers designing tank-handles and sand-levers, "things that they knew something about" and letting alone "boilers, cylinders and things about which they knew nothing." The man that made that remark came up from the foot-plate of a locomotive, and is proud of it, and nine out of ten men that heard him came to the positions they now hold, at the head of motive power departments, from the same place—and came up because they did know something about "boilers, cylinders, etc."

The fact of the matter is, that the Erie boys did very little *designing*. They were anxious to demonstrate to the officers of their road that a very heavy eight-wheeled hard-coal locomotive could be built that would handle the trains now hauled by the big ten-wheelers, and they voted on the weight, size of boiler, cylinders, etc., and asked the Cooke Locomotive Works to build the machine, and it is a very creditable one, too.

It may be big and clumsy and uncomfortable-looking to Western men used to soft coal and a big cab, but hard coal means a very long firebox, a boiler through the cab and all the crowding that this entails.

---

Our railroad system requires annually 80,000,000 ties, costing the railroad companies about $30,000,000. Their life in the average may be computed at six and one-half years. There are means of doubling their life easily by using only the more durable kinds, paying proper attention to the handling of the ties and by impregnation with fungus-resisting materials or by other processes. Such increase of durability may be obtained by an expenditure of say $20,000,000, by which an annual saving of more than $5,000,000 would be effected, or 25 per cent. on the additional outlay.

### BOOK REVIEW.

LOCOMOTIVE RUNNING REPAIRS. By L. C. Hitchcock, late General Foreman of the "Soo" shops. Debs Publishing Co., Terre Haute, Ind. Price, 50 cents.

This little book, of 110 pages, is gotten up in the same style as "Progressive Examinations of Locomotive Engineers and Firemen." Small, but neatly bound in cloth and printed on good paper, almost every chapter is illustrated.

The regular readers of this paper are more or less familiar with the subject matter, as most of the articles appeared in this paper.

It is the only book published on the running repairs of locomotives, and every machinist and shop apprentice ought to have one of them, as the right way to care for cocks and valves, line up rods, shoes, wedges, driving-boxes and guides, how to change flange wear, adjust spring rigging, move eccentrics, set valves, etc., is told in plain language and illustrated by sketches. This little book deserves to sell like the proverbial "hot cakes."

---

The Rogers Locomotive Co., of Paterson, N. J., have just issued a very neat little book, giving photo reproductions and outline drawings of the locomotives exhibited by them at the World's Fair. Copies can probably be secured at their exhibit at the Fair, or at the works.

### PERSONAL.

Mr. Lucius Tuttle, general manager of the N. Y., N. H. & H., has been elected president of the Boston & Maine.

Mr. J. E. Rose, for several years with the Big Four, has been appointed superintendent of the Iron Mountain road.

Mr. George W. Jenkins has been promoted from conductor to be train-master of the Decatur division of the Wabash.

Mr. James Cunningham has been appointed master mechanic of the Choctaw Coal & Iron Co., with headquarters at South McAlester, I. T.

Mr. T. D. Kline has been appointed general superintendent of the Central Railroad of Georgia. He was formerly general manager of the Mexican National.

Mr. H. F. Houghton, train-master of the Wabash, has been appointed assistant superintendent of the Big Four, with headquarters at Indianapolis, Ind.

Mr. M. D. Campbell, general foreman of the Lehigh Valley shops at Delano, Pa., has been appointed master mechanic of the Buffalo division in place of Mr. A. Dolbeer, resigned.

Mr. J. B. Boone has been appointed master mechanic of the Kansas City, Osceola & Southern, with office at Coburg shops, Mo., in place of Mr. I. E. McCracken, resigned.

Mr. W. E. Guerin, of Columbus, Ohio, has been chosen president of the Sandusky & Columbus Short Line. He is also secretary and general solicitor of the Columbus, Shawnee & Hocking.

Mr. R. E. French, general foreman of the Southern Pacific shops at Oakland, has been promoted to be master mechanic of the Bakersfield division of the same road, with headquarters at Bakersfield, Cal.

Mr. James E. Palmer, engineer of maintenance of way of Peoria & Pekin Union, has been appointed general superintendent of that road, with headquarters at Peoria, Ill., in place of Mr. C. E. Schaff, resigned.

Mr. A. G. Wells has been promoted from the position of train-master to that of superintendent of the Atlantic & Pacific, with headquarters at Albuquerque, N. M. He was formerly a superintendent on the Big Four.

Mr. George F. Copeland has been appointed superintendent of the Butte, Anaconda & Pacific, with headquarters at Anaconda, Mont. He is a railroad man of mature experience, and has risen through the engineering department.

Mr. G. W. Butcher has been appointed superintendent of motive power of the San Antonio & Aransas Pass, with headquarters at San Antonio, Tex. He was formerly general foreman of the Southern Pacific shops at Houston, Tex.

Mr. W. E. Knox has been appointed superintendent of the Alabama Mineral division of the Louisville & Nashville, with headquarters at Anniston, Ala., in place of Mr. T. K. Scott, resigned. He has heretofore been chief train despatcher.

Mr. Henry Tregelles, a member of the Railway Master Mechanics' Association, who has been agent for the Westinghouse Air-Brake Company for several years in Brazil, has returned to Pittsburg. Mr. Tregelles was formerly a division master mechanic on the Erie.

Mr. W. O. Thompson, road-foreman of engines of the Lake Shore & Michigan Southern, has been made foreman of engine-house and engine despatcher at Elkhart, Ind. He has been given charge of the movement of all the engines on the southern division of the main line.

Mr Alonzo Dolbeer, master mechanic of the Lehigh Valley, at Buffalo, has resigned. A few days after he gave up the position, a number of the employés of the mechanical department presented to him a gold watch and charm as a manifestation of their warm feelings towards their old superintendent

Mr William M Greene has been appointed general manager of the Cincinnati, Hamilton & Dayton. Mr. Greene was for several years assistant to President Ingalls of the Big Four, and was for a short time general manager of that road He has been out of railroad service for several years.

Mr J W Fowle has been appointed master mechanic of the Cincinnati, New Orleans & Texas, with charge of the shops at Ludlow, Ky Mr Fowle has been for several years on the Colorado Midland, with charge of the Leadville division. He went there from the Cincinnati Southern, and was one of the bright young mechanics who graduated upwards under the inspiring influence of Mr James Meehan.

We have to acknowledge several pleasant calls from Mr David G. Watson, of Dundee Scotland, who was sent by the *Weekly News* to visit the World's Fair, and report on matters of interest to Scotch railway men Mr Watson is an engine driver on the North British Railway, and is remarkably well informed concerning railway appliances He found much to admire on our railways, and the comfort and convenience of our locomotives impressed him very greatly

Mr George D Wadley, who has been for some time general superintendent of the Central of Georgia, has resigned under peculiar circumstances He is very much of a disciplinarian, and men with a strong leaning in that direction generally consider it necessary to discharge men frequently The road is in the hands of a receiver, and some of the discharged men applied to the United States Court for justice and were reinstated, which caused Mr Wadley so much chagrin that he resigned

Mr John W Kendrick, chief engineer of the Northern Pacific, has been appointed acting general manager in place of Mr Mellen, who died suddenly last month. Mr. Kendrick is a New England man and is a graduate of the Worcester Polytechnic Institute. Shortly after graduating he went into the engineering corps of the Northern Pacific, then engaged surveying the line up the Yellowstone Valley. He remained in the employ of the company ever since, and gradually rose step by step and was made chief engineer in 1888

Mr. Alexander Mitchell, the well-known Lehigh Valley master mechanic was made superintendent of machinery of that system under the Reading's lease. The Lehigh Valley never had a chief of motive power under its old management, every division master mechanic was a law unto himself, and many thought that when the lease was annulled that things would go back into the old way. This, however, is not to be, as Acting General Manager Voorhees has appointed Mr. Mitchell superintendent of motive power of the entire system

Mr. J. E Morrison has been appointed superintendent of the Chicago and South Side Elevated road, vice A J. McBlair, resigned. F E Colgrove takes Mr Morrison's place as trainmaster This is the first time a trained elevated railroad man has been in a position of responsibility on the alley road. Mr. Morrison was raised on the Manhattan, and the best thing the management of the road can do is to let him handle the business and give him power to rip off some of the red tape and operate the line as a railroad—and not as a side show.

Among our foreign callers last month was Mr A Brunner, of Munich, who has been in this country for four months attending the World's Fair and investigating American railway machinery and shop methods Mr Brunner is manager of locomotive works in Munich and is looking up the American system of manufacture with a view of adopting the parts suitable for a German shop He worked for years in Glasgow, Scotland, and is a most progressive engineer. He is extremely well pleased with what he saw at the Fair and elsewhere, and is very free in expressions of admiration. Engine "999" he considers the finest piece of locomotive work he has ever seen

Mr T F Oakes, president of the Northern Pacific, puts himself nearer to the hearts of many men on that system through his warm-hearted and kindly notice issued on the death of the general manager, William S Mellen In the circular on this subject he speaks of Mr. Mellen as a man of strong physique, a tireless worker, he was devoted to the interests of the company, which he served with conspicuous faithfulness and ability, while by mingled firmness and consideration he won the regard of all employés. He had mastered the business of management. His death removes a valuable and useful officer, whose services to this company will long be held in grateful remembrance.

Some of the most substantial work ever done in connection with street railway cable lines has just been completed at the terminal of the Third avenue, New York The work has been done under the close supervision of Major R B Tomassek, a well-known engineer, who has done a great deal of difficult surface railroad work since the war. The personal history of the Major is more varied and interesting than the pages of most romances He is a Hungarian nobleman and was educated as a military engineer. When the French expedition to Mexico was organized, Major Tomassek joined the staff of Maximilian and took an active part in all the military operations He was taken prisoner with Maximilian and would have shared the fate of his chief had he not escaped and made his way to the United States He has been engaged on bridge and railroad work ever since.

The *St Louis Republic* of July 28th contained the following General Manager W B Doddridge, of the Missouri Pacific Railway, was yesterday presented with a team of high-bred Kentucky horses by R M Galbraith, general master mechanic of the Cotton Belt, in behalf of the officials and employés of the latter road. Mrs. Doddridge received at the same time a beautiful pair of diamond earrings as a token of esteem from the Cotton Belt employés Mr. Doddridge is not a man of ceremony, and the gifts were presented and received informally. It was a sort of family affair Mr. Doddridge was general manager of the Cotton Belt before he became general manager of the Missouri Pacific, and to know, by the present to him, how much he was liked by the men who worked under him made yesterday one of the happiest in Mr. Doddridge's life.

It seemed only a few days since we enjoyed a pleasant visit from our old friend W S. Mellen, general manager of the Northern Pacific, who was in New York for a couple of weeks getting treatment for rheumatism. He was then greatly encouraged about the improvement in his health and was full of schemes of future useful work. Mr. Mellen's mind ran greatly towards plans for making the life of the men under him more comfortable. Now comes the announcement of his death from paralysis of the heart Mr. Mellen was an Illinois man, and he entered railway service in December, 1865, when nineteen years old, as telegraph operator on the Chicago & Northwestern at Milton Junction, Wis , and remained in the employ of that road as agent and operator at different points until 1872, in which year he accepted the position of general freight and passenger agent of the Green Bay & Lake Pepin, now the Green Bay, Winona & St. Paul In 1874 he returned to the Chicago & Northwestern as general agent at Winona, Minn., and one year later was promoted to be assistant general freight agent at Chicago He held this position until 1881, when he went to the Atchison, Topeka & Santa Fé as assistant general superintendent, but in October, 1882, he again returned to the Chicago & Northwestern as general freight agent. He held this position until February, 1885, when he received the appointment of assistant general superintendent. He resigned in October, 1885, to become general manager of the Wisconsin Central, and on July 1, 1889, was appointed general manager of the Northern Pacific.

### Sheet-Iron Jackets.

There is not much danger that the locomotives from England, France and Germany, now on exhibition at the World's Fair, will be very extensively copied in this country. There is nothing about any of them that is really worth copying, except the material and workmanship, which are both very fine, and one other item, and that is the jacketing. All the European engines have sheet-iron jackets, nicely painted and varnished. It presents a nice appearance, is serviceable and easily kept clean.

It seems strange that this style of jacketing is not used more extensively on American locomotives Sheet-iron is fully as durable as planished iron, and when painted is not as liable to rust

If an accurate account was kept of the amount of waste, oil, and polishing material used on a planished-iron jacket in the course of a year, it would surprise many a master mechanic who is studying continually how he can best keep down expenses The sheet-iron jacket, with a good coat of paint and varnished, will look fully as well No cleaning material required, only a little waste and an occasional washing off with soap and water.

This idea of the sheet-iron jacket may be copied with good results by American builders, both for economy and neatness. Where iron or steel of about a sixteenth of an inch in thickness is used, it never becomes dented or bent up, and lasts as long as the rest of the engine does, simply requiring paint with the rest of the machine. A Russia iron jacket only lasts for a few years at best

We are anxious to secure two back numbers of the Railway Master Mechanics' Reports, those for 1870 and 1873. We will give $3 00 each for them Any party having these reports to spare will confer a favor by sending them to this office

The extremely uniform covering of foreign passenger cars, which many visitors to the World's Fair notice as being remarkable, is due to the siding being of steel about ⅛-inch thick This practice of using steel for covering is followed because the material is cheaper than good wood siding, and the claim is made that it takes a better polish than wood and wears longer without revarnishing. Those who have had experience with iron cars in this country agree that the outside finish is more easily maintained, as there are no nails to work out and no cracking to damage the paint and varnish.

### Kansas City, Memphis & Birmingham Shops.

(EDITORIAL CORRESPONDENCE )

In Memphis, on the top of a high bluff overlooking the Mississippi river, stand the repair shops of the Kansas City, Memphis & Birmingham Railroad. A curious interest attaches to these shops. The river when in flood is rapidly eating away the bank, and it is only the question of a few years when the shops and a big slice of Memphis real estate will fall upon the bosom of the Father of Waters, unless heroic measures are taken to turn off the hydraulic action of the fast-flowing stream.

During a brief visit to the shops I was surprised to see the small establishment provided to maintain the rolling stock that has to be kept in running order here There are about fifty heavy engines to be looked after, and all the tools to do the work are grouped in a small brick building about 40 x 80 feet. The tools consist of one wheel lathe, one engine lathe, two small lathes, one heavy planer, one shaper, one bolt-cutter, two emery wheels and a few minor tools. This small supply is all Pond tools, nearly new and capable of taking deep cuts, otherwise the work put through could never be done Mr. R. H. Briggs, the energetic master mechanic in charge, helps the work wonderfully by good management, but with all that it is surprising to find the rolling stock in such good order. The place is clean and orderly, and everywhere there are evidences of close attention to every detail.

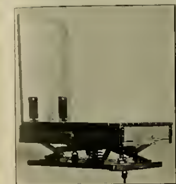
Mr. Briggs is proud of the small amount of boiler work required by the engines, which is to a great extent brought about by the care taken to prevent the formation of scale and mud. The engine-house is provided with a hot-water system for boiler-washing operated by a Rue instrument The water on the line is not very bad, but the boilers are washed out regularly after every second trip. Three years ago Mr Briggs began a practice of putting a gallon of kerosene in the boiler at every washing-out and the results have been wonderfully successful. Before this was done, the frequent washings did not prevent the flues from getting so badly coated with scale that they had to be removed through the dry-pipe hole. Since the kerosene came into regular use the tubes could be removed through their own holes This ought to be good testimony in favor of the kerosene habit. I have heard of several roads that tried kerosene and declared it no good, but I suspect those trying the experiment were not persistent enough. Regularity and persistency are highly important factors in the success of any system of boiler treatment

The performance sheets of the engines on this road testify strongly in favor of enlightened management. Repairs, wages, fuel and oil only cost 14.8 cents per mile run during the past year, and this, too, with mostly heavy ten-wheel engines. Included in this was the cost of six sets of air-brakes and the rebuilding of an engine whose boiler exploded. Part of the credit for the fine showing is no doubt due to a highly intelligent class of enginemen. I met several parties of engineers and firemen, and have seldom seen such bright men It goes without saying that a large percentage of them are readers of LOCOMOTIVE ENGINEERING Several of them spoke enthusiastically about the pleasure and benefit derived from reading the paper.

The ten-wheel engines on this road all have rigid leading trucks, and a blind driving-wheel tire in front. On careful inspection of all the engines in the roundhouse, I found all the tires in good order, and no sign of flange cutting. Several driving boxes on the floor that were getting the lateral motion taken up by Babbitting indicated that there might be considerable wear of the boxes. They have just applied a set of malleable iron driving-boxes and they are watching with much interest to see how they stand. All the engines have the globular form of exhaust-pipe introduced by Mr. McCrum, and it is highly spoken of. A 5-inch nozzle is used on the large engines, and steam is made very freely with that large opening. The men say that the engines work with very little indication of back pressure. The coal account shows that the engines are light on fuel! A. S.

### Drop Cab-Seat for Small Cabs.

A new form of drop-seat for the cabs of "Hogs" and other big engines with the boiler coming through the cab, has been put on the market by Stannard & White, of Appleton, Wis. The platform spring arrangement is the same in this as in their other seats, but the cushion is dispensed with, and a seat of sheet metal covered with horsehide takes its place. This admits of a good drop-seat in a space of six



inches. The back, when wanted, is simply an inch board. This whole seat is arranged on a rod, and can be shoved ahead out of the way when down and not wanted.

Stannard & White are making their well-known seats now in the best possible manner, the latest kink being the building up of the cushion so that any spring can be taken out of the seat by hand and replaced in case of breakage or weakening of the spring.

### Scooping Too Much Water.

When scoops for dipping up water for locomotive tenders while the train is in motion were first brought into use in England, the enginemen using these useful aids to long runs were often embarrassed and put into ludicrous plights by the apparatus sticking after it was dropped into the trough. The washing of nearly all the fuel off the tender by the flood of water that could not be stopped caused many an express engine to stop for coal before the journey was over.

The scoop mechanism on American locomotives appears to be so well designed and built that accidents are very rare, but they occur at rare intervals even on the best regulated railroads. The New York *Sun* lately contained the following account of a miscalculation in scooping water

"One of the Pennsylvania fast trains that do good by bringing Philadelphia within suburban time of New York is known to the railroad people as the '7.30,' because it leaves Philadelphia at that hour in the morning. It runs through without a stop, and takes water on the run out of a long trough between the rails near Edgley. A scoop is let down from beneath the tender into the trough. Yesterday morning the first coach of the train contained about thirty passengers Some of them were women. * * * Well, no one was thinking about the water-trough or the water, until suddenly the front door of the coach next to the engine was burst in by a broad stream of water, like that thrown from a water-tower at a fire. In just one second every man and woman was standing, and in another they were all sitting, sittin on the backs of their seats to keep their feet out of the stream of water that rushed along the car floor with such force as to roll the aisle carpet up into a wet wad which landed against the rear door and dammed the flood there, and also prevented the door from being opened.

"No one had the remotest idea of what was going on. The passengers were all getting a shower-bath, and the car was rapidly being converted into a pond. There were a great many cries of alarm, but for once no one offered any advice, for a huge stream of water pouring into the front door of a lightning train on a cloudless day offered no suggestion to even the most expert advice-giver. It was very lively while it lasted, but it was all over in twenty seconds. Then the water drained out of the car and the passengers began making investigations. The water-tender had been filled before the end of the trough was reached, and while the scoop was still down. The force of the water had knocked off the cover of the manhole in the center of the rear end of the tender, and the speed of the engine directed the stream from the manhole against the front door, and the force was so great as to knock in the door. When the scoop was lifted up the shower ceased. Then the people began mopping themselves with handkerchiefs, and some said they thought it was funny. They were the ones who sat in the rear seats."

### An Inventive Engineer.

Mr Merrit Turner, road foreman of engines of the Erie, writes us

"It has been my observation that an inventor's mind is so rapt in his studies of invention that he never accomplishes much beyond the useful things he invents, but the monotony is broken by an engineer on the Delaware division of the New York, Lake Erie & Western Railroad, by the name of Arthur O'Hara, who has made several useful inventions and is not second to the best engineer in the country.

"His first was a device for the purpose of turning a switch when approaching it toward the points, where the switch might have been left wrong, and the approaching train would set it right for the main track on approaching it and before passing it.

"His next was a dump-car to be used on construction trains. to dump by air or steam taken from the engine which hauled the train. There are several of his cars in use on the Long Island Railroad, and have proven a great success in labor-saving.

"His third is a device for pumping air in the pneumatic tire of a bicycle, while in motion, in the event of the tire becoming punctured and causing a leak, which would disable the machine and leave its occupant to walk home without the use of Mr. O'Hara's pump, which requires no pains or discomfort to the bicycle riders, but is brought into use by the ordinary motion of the machine."

---

The Nathan Manufacturing Company have an elegant pavilion and fine display of their goods at the World's Fair, but the management of Machinery Hall stuck their beautiful job of cabinet work behind an immense iron column in a side aisle, while a chicken wire fence surrounds a public telegraph office on the main aisle corner just opposite.

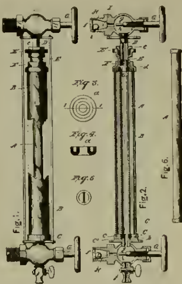
---

The boilers of the steamship Campania have 102 furnaces.

### A New Design Safety Water-Glass.

In the Hausman safety water-glass, just being put on the market by F. McLewee & Son, of 25 Waverly place, New York, we have an invention that seems a step in the right direction.

The trouble with the ordinary water-gauge glass has been its fragile nature



and liability at any moment, as a Scotch engineer put it, to "gang awah."

Hausman uses two glasses, the large outer one protecting the inside glass from atmospheric changes, snow, water or other substances that suddenly contract and break the glass, he uses the old and well-know ball-valve to effect automatic closing in case of breakage.

His main invention is in packing the glass *on the end* and in making the tension of this packing always adjustable by the hand of the engineer.

This is accomplished by making a "steam-pin" from the upper cock to the top of the glass, on this screw is a packed nut carrying flanges at the bottom for the glasses, this nut has a movement up and down of about half an inch, there are no nuts, glands or packing around the glass.

When it is desired to put in a glass the engineer screws up the gland *E*, Fig. 1, this lifts the sleeve at the bottom and the glasses can be set in place, the inner one having its end gaskets of vulcabeston, Fig. 4, in place, the nut is then screwed down until there is a joint on the end of the glass. The outer glass fits into a loose sleeve on the main one and there is no tension or compression on it, the space between it and the gauge-glass proper being open top and bottom by small holes, its sole duty is to protect the inner glass.

Cleaning blades extend from the valve, so that when screwed home the hole through to the boiler is thoroughly cleaned out.

The makers of this gauge are using the best of material, especially imported glasses, and there is no doubt of their success.

### Jigs for Drilling.

The Americans often use what is termed a jig for drilling. Will anyone kindly give a sketch, together with drill?

The above is from an English mechanical paper and shows what our cousins across the fish hatchery know about American shop methods—they evidently think a jig is some kind of a machine with a drill attached, or something that runs a drill. A jig is merely a device for holding work so that machine work can be done on a number of the same kind of pieces in precisely the same way—a device that insures accuracy and interchangeability without "setting" or measuring each piece of work.

### The P. R. R. Standard Registers of Locomotives and Cars.

The Pennsylvania Company issue every few months a corrected "register" of locomotives and cars, that are small, cheap, paper thumb books, and are given freely to the men.

We have taken a page at random from each of these little books and reproduced them, full size, in order to show how much information can be gotten into a small space.

Each page has 100 squares and each square represents a locomotive or car. The first page is headed "0 Hundred" and has a description of the stock numbered below 100, the next page is "1 Hundred" and so on.

We have reproduced page 8 of the locomotive register and it contains information of all engines numbered from 800 to 899. If you wanted to know what engine 855 was you look in the column headed by the figure five and follow down to the five in the side column, and you find that the 855 is a Class M engine carrying 160 pounds of steam (some Class M's carry less), that she was built at the Juniata shops in 1892. Any car can be traced in the same way.

P. R. R. Standard Coach Register.

---

The fine and complete set of models of early locomotives exhibited at Chicago, should be made the nucleus of a national railway museum, where all the valuable relics and records of our old and historic roads could be kept and cared for.

### Brooks Two-Cylinder Compound Ten-Wheel Locomotive.

Gauge—4 ft. 8½ in.
Fuel—Bituminous coal.
Weight in working order—102,000 lbs.
Weight on drivers in working order, 76,-500 lbs.
Rigid wheel base—8 ft.
Driving-wheel base—13 ft. 3 in.
Total wheel base—23 ft. 1½ in.
Diameter and stroke of cylinders—18 x 24, 28½ x 24.
Diameter of driving wheels—56 in.
Diameter of boiler—52 in.
Length and width of firebox—96 x 54½ in.

TENDER.

Coal capacity—6 tons.
Capacity of tank—3,700 gals.

ENGINE AND TENDER.

Total wheel base—45 ft. 6½ in.

### Brooks Eight-Wheel Passenger Locomotive.

Gauge—4 ft. 8½ in.
Fuel—Bituminous coal.
Weight in working order—112,000 lbs.
Weight on drivers in working order—74,-000 lbs.
Driving-wheel base—8 ft.
Total wheel base—22 ft. 8 in.
Diameter and stroke of cylinders—18 x 26.
Diameter of driving-wheels—73 in.
Diameter of boiler—58 in.
Length and width of firebox—102 x 32 in.

TENDER.

Coal capacity—8 tons.
Capacity of tank—4,200 gals.

ENGINE AND TENDER.

Total wheel base—46 ft. 8 in.

Brooks Compound Ten-Wheeler—Now at World's Fair.

### An Encouragement.

From the Creston, Ia., *Advertiser* we quote the following item of interest:

"Engineer Chas. McClellan is the owner of a very fine brass oil-can of improved pattern, valued at $8, and his fireman, John Miller, sports a new patent engine seat, of splendid design. These were presented to Messrs. McClellan and Miller, this morning, by Master Mechanic Jones and Traveling Engineer Button for making the best three months coal record on the west Iowa division. This record is for the months of May, June and July, when they handled mogul engines 436 and 439 on trains 76 and 77 between Lincoln and Creston. In May they made 28 miles to the ton, in June 28½ and in July 29 miles. This is certainly a remarkable record when it is taken into consideration that they pulled heavy freight trains and made fast time, and the presents they received were well merited. Engineer McClellan and Fireman Miller have done work that they can well be proud of."

Brooks American Passenger Engine—Now at World's Fair.

### Need of More Secure Couplings Between Engine and Tender.

At the last Master Mechanics Convention a very valuable report was submitted on "Attachments between Engine and Tender," by a committee, of which Mr. J. Davis Barnett was chairman. After reading the report, Mr. Barnett said:

"In the matter of draw-bars there is some very bad practice on this continent, if one were to accept the blue-prints as representing the actual shop and road practice. In bent coupling-bars there are cases where the double set put in the bar is put in a distance equal to twice the thickness of the bar, and where no reason could be seen why a gentle curve could not have been used, making that bar stronger for its service without increasing its weight.

"There is another case where the bar is set downward almost at an angle of 45°, a very great depth, the sharpest possible corners are shown, and even the hubs on the ends of the bar are not so put on as to lessen that bend. The hubs are so put on as to increase the amount of angle. That has been sent to the committee as being good practice, which they recommend to this association. There are cases of very light safety couplings, and I noticed in one engine at the Columbian Exposition, a powerful engine at that, where the safety chains are ⅞ of an inch in diameter—just one-third the cross-section area of that which the committee recommends. It seems to me, personally, that if it is worth while putting on the safety chains at all, it is worth while putting on something that will do the work on the rare occasions they are called upon to come into play.

"May I say, too, that if the blue-prints are to be believed, the hook usually fastened to the tender, securing the free end of the coupling-chains, is in many cases shown with the sharpest possible corner where it bends around the wood—a right-angled turn—the most favorable condition for breakage at that point when a sudden pull comes on, and in many cases it is bolted with but a single bolt. It seems to me no earthly use if you are running and the coupling-bar should break; you might as well have left all such fixings off."

Mr. W. H. Lewis, of the Chicago, Burlington & Northern, considered the subject of very great importance, owing to its bearing on the safety of trainmen. Any subject, he said, "that involves the injury or loss of life of the employés of railroads is a more important subject than the proportions of a locomotive, and I do not believe that too much importance can be placed upon the suggestions of the committee about this, as regards the safety of employés. We can readily correct any defects in the locomotive in other respects, but we never can recall the injury or death of an employé, and I hope that the suggestions that have been thrown out by the committee will be taken by the members, and that they will profit by those suggestions in the line of improving the appliances to the better protection of the employés."

---

All the Brooks engines at the Fair have cabs that are at least half open across. Even in the largest consolidations the boiler comes but half way through the cab. This has its advantages, but also its disadvantages, especially where the engineer's seat is in the back corner of the cab. To see well at night the engineer should be as close as possible to the front windows of his cab, this being especially true in stormy weather. When beside the boiler and well ahead, the light from the open fire-door does not blind him. For seeing well the farther ahead on the boiler the engineer is the better; there are other conveniences that have to be given up for this advantage, however.

### Smoke: Its Cause, Effect and Cure.

At the meeting of the Engineering Association of the South, Nashville, Tenn., July 13th, the subject of "Smoke Prevention" was presented by Prof. Olin H. Landreth, of Vanderbilt University. The paper discussed successively the causes, the effects of smoke and the remedies for it. Objectionable smoke comes mostly from bituminous coal, other fuels producing very little smoke. When fresh coal is thrown on incandescent coal there at once begins the distillation of the more volatile hydro-carbons, which distilled matter is burned if sufficient oxygen is present and the temperature is sufficiently high, but which otherwise passes up the chimney as yellowish fumes. As the fresh coal becomes more highly heated the less volatile hydro-carbons are distilled, and are decomposed at a temperature much below that necessary for the combustion of the carbon liberated, about 2,000 degrees Fah., a temperature so high as to give considerable margin of opportunity for this portion of the carbon to escape unburned. It is this free unburned carbon in a finely divided state that, while incandescent, produces the luminous flame and, when cooled, the clouds of smoke that issue from the chimney and afterwards settle as soot.

After the volatile matter is driven off the fixed carbon remains, and in burning produces but little flame and no smoke, since the particles of carbon are not detached from the solid mass till combustion takes place. As to the effects of smoke production, the fuel loss in the smoke itself is but small, estimated at one-sixth of 1 per cent.; but the causes of smoke are also the causes of imperfect combustion and consequent waste of fuel in the form of invisible gases, carbonic oxide and light hydro-carbons, and the presence of smoke indicates this parallel waste.

Aside from the fuel waste, the effects of smoke outside the furnace make its abatement of public interest. It is authoritatively stated that the residuum of smoke in the lungs induces consumption of an incurable character; and that, in the city of Pittsburg, Penn., the death-rate was 1.62 per 1,000 lower during the eight years in which the use of natural gas almost freed the city from smoke, as compared with the preceding eight years; and that, since the partial return of smoke, the rate has increased 2.57 per 1,000. Carbon, in a finely divided state, is an easy vehicle both for noxious gases and organic impurities. The insidious soot pervades and defaces public and private buildings, and calls for fruitless efforts for cleanliness, when cleanliness is impossible. Smoke is objectionable, from the loss of light and increased cost of artificial light; also from the repression of æsthetic tendencies and consequent mental and moral discouragement. Consideration of the causes suggests the agencies and the mechanical devices for the prevention of smoke; these latter, so far as pertains to steam boilers, are classed as mechanical stokers, air-flues in the walls and grate-bars, coking-arches, dead-plates, down-draft furnaces, steam-jets for injecting air and mixing the gases, baffle-plates and double furnaces. Smoke prevention must be accomplished by educating the public to consider smoke a nuisance, that unquestionably can and should be abated, for the smoke-producers are very slow to be convinced that this abatement is to their interest. Following the influence of public sentiment, laws are to be enacted and provision made for their enforcement, and for furnishing to smoke-producers, when desired, professional advice regarding the means and appliances for smoke prevention. The paper gives the statutes passed in Chicago, Cincinnati, Cleveland, Pittsburg, New York, Rochester, Boston, Denver, the State of Ohio and the city of Birmingham, England, with statements of the success attained in preventing smoke in these localities, success in each case being proportional to the vigor of action taken. The paper also contains descriptions of various mechanical devices for smoke consumption, and closes with a list of literature on the subject.

The report is published by the society, Walter G. Kirkpatrick, secretary, Nashville, Tenn.

### Volume of Receiver of Compound Engines.

There is great diversity of opinion among all engineers having to do with the designing of two-cylinder compound locomotives as to the proper size of the receiver that receives the steam from the high-pressure cylinder and delivers it to the low-pressure side. When the experiments to be made with locomotives in the testing department of the Purdue University are carried out, it may be possible to settle the best size of a receiver; but in the meantime the matter is a question largely of speculation. An English authority on compound engines, writing on this subject some years ago, said:

"The average pressure in the receiver, and therefore the 'drop' at high-pressure exhaust, depends wholly on the volume of the low-pressure cylinder open to the receiver at the point of cut-off, compared with the total volume of the high-pressure cylinder. The high-pressure cylinder full of steam at the terminal pressure, expands into the low-pressure cylinder, and the initial pressure in the low-pressure cylinder will be less than the terminal pressure in the high-pressure cylinder in the inverse ratio of the total volume of the high-pressure cylinder to the volume of low-pressure cylinder at point of cut-off. And this pressure will be quite unaffected by the size of receiver the steam may have gone through on its way to the low-pressure cylinder. Theoretically, the bigger the receiver the better, for the variations in pressure caused by the varying volume between the high-pressure and low-pressure pistons will be proportionately smaller.

"The angle between the cranks will affect the variations in receiver pressure, if the receiver is small compared with the high-pressure cylinder, but the *mean* receiver pressure will be quite independent of this angle.

"In practice it is impossible to avoid a material drop in the receiver, because, in the first place, the terminal pressure in the high-pressure cylinder must be something above the receiver pressure, which is the back pressure on the high piston, to give a steady running engine.

"Then, with ordinary two-cylinder compound engines it is not desirable to arrange the low-pressure cut-off so as to avoid any drop, because in this way the balance of power on the cranks will be altogether destroyed (the low-pressure doing more than its share) and this balance of power, though not absolutely essential, is generally aimed at."

### A Growing Superstition.

That staid old newspaper, the Providence *Journal*, got rid of the following editorial notice a few days ago:

"It is an appalling fact that cheap novels can be turned out at the rate of 5,000 an hour and at a total cost of three cents apiece. The book is printed, folded and trimmed, all by a single revolution of a great cylinder. Then it is distributed all over the country and sold for ten cents, and the masses buy and read, often with the most direful, not to say fatal, results."

Just to see what *fatal* kind of books were sold so cheap, we went out on to the street and purchased for 25 cents the first four paper novels on a stand—6¼ cents each. They were: "The Scarlet Letter," by Nathaniel Hawthorne; "A Marriage at Sea," by Clark Russell; "The Other Man's Wife," by John Strange Winter, and "Very Hard Cash," by Charles Reade. That cheap machines can turn out good novels just as easy as bad seems to have been forgotten by the *Journal*. The fact of the matter is that the howl about pernicious books being printed because they can be printed cheap is as thin as the mother-in-law joke. The machine that can turn out books at a revolution, enabling them to be sold at a profit for ten cents a copy, will put a million good books in the hands of those who can't afford better ones, for every hundred bad books turned out. The quality of printing is not the *fatal* part of the book—it's the quality of the reading matter. Here's more power to the printing press that cheapens literature—and, God bless the mother-in-law!

### How Sentiments Change.

When a railroad is first opened to a country town in a Western State, there are no bounds to the courtesy displayed by the people, and even by the local editors, towards those who have given the district new transportation connections. After the thing gets old, and it is plainly understood that the railroad company is not likely to tear up the tracks, then the period of squaring up comes. Few granger communities fail in the long run to express their contempt for and independence of railroad companies. But when the only road is first opened, anything will be endured.

A new railroad was opened a few months ago to a Kansas town, and an excursion was run for fifty miles out into the prairies to show the wonderful resources of what was really a barren country. The track had not been surfaced up, and the road was as rough as a corduroy trail. The local editor lost his footing as he was passing from one car to another and fell off. He walked to the next station, and was kicked out of the place by the station agent, who said that they would not tolerate tramps or loafers about that depot.

He walked on to the next station, where there was a water-tank, and waited for the return train. The conductor refused to carry him, saying that no suspicious persons would be carried on that road unless they paid their fare. The editor had to walk home.

Those who knew what had happened expected a roasting for the road in the next issue of the *Western Eagle*, but the general passenger agent had agreed to give passes for the weekly publication of the company's time table, and the aggrieved editor vented his chagrin thusly:

"We cannot too cordially congratulate our readers on their good fortune in seeing our city connected with the great A., T. & S. F. system. The finely ballasted track leading to our city makes the cars ride like wafting balloons, and the employés of the company make traveling a round of pleasure. The courtesy of conductors and station agents leaves nothing to be desired, unless it be that the company should insist on their wearing slippers."

There is great mystery in the district as to the true significance of the last sentence.

### An Aluminium House.

Engineers and others interested in metals who visit the World's Fair will find a metallic curiosity there in the shape of a house built of aluminium which is well worthy of examination. This metal, although hardly fulfilling the predictions of zealous advocates, is coming steadily into use. The present cost of aluminium, though still higher than any of the cheap metals, has brought it within the range of everyday life; and its present uses, limited as they are, necessarily bear some relation to the great question of the future of the new metal, and the possibility of realizing the hopes of the metal worker and the engineer. For all personal equipment which must be carried by the owner, aluminium is rapidly taking the place of every other metal. Its lightness is its obvious recommendation in this case. In the German cavalry, even the stirrup "irons" are now made of aluminium. The men's water-bottles are also of the same light and strong material. In binoculars for field use, and all kinds of scientific instruments for distant and toilsome expeditions, such as Dr. Nansen's Arctic journeys, or observations on high mountains, the same metal takes the place of the heavier brass, when the saving in weight so secured may often make the difference between scientific success or failure. Nearly all the small articles of luxury and ornament usually made in silver or brass are now produced in aluminium, though where weight is not a drawback, the gain is rather one in appearance than construction. But aluminium thimbles, pen-holders, paper-knives, flasks or cups are so far superior to those made of the ordinary materials that no one who has once made use of them in the new metal will readily return to the old.

## A Failure of an Apprenticeship Experiment.

BY SAM SHORT.

Some railroad men are destined to be in trouble all the time and their endeavors to keep things right and straight appear to result in working up kinks where a smooth rope ought always to be. My friend Greatsam, of the Twin Threes, is one of these men. With the best intentions in the world, with energy and no end of industry, he is constantly in hot water through faults of omission and commission. When he decides through good nature to permit breaches of discipline to pass unheeded he gets into disgrace with the management; and when he displays energy enforcing orders he raises a tumult among the men. He has the name on one side of the social circle of being a tyrant without a heart to feel for those who have difficult and trying duties to perform. On the other side he is looked upon with suspicion as an officer who spares his men in preference to acting strictly in the interests of his employers. The real weakness of Greatsam is that he is deficient in tact. That is a very valuable attribute for a man who has to keep contending interests in harmony.

Greatsam is in hot water now over a curious thing that many men would have managed without a hitch. When the money stringency began pressing the credit of corporations, the management of the Twin Threes was very prompt in ordering a reduction of the shop force. The road is doing a good business, and the outlook for heavy traffic was never better, but that does not matter. The management called for a reduction in the pay-roll, and the shopmen were considered the most convenient victims. Greatsam made a reduction in the force below what he considered necessary to do the work; but that was not enough to satisfy those above him. They demanded the discharge of more men. Greatsam presented figures to show that he had not enough good men left to keep up the running repairs, and the manager told him to run the shop with the apprentices and laborers. This matter of apprentices has been a stumbling-block and a cause of much disappointment and heart-burning.

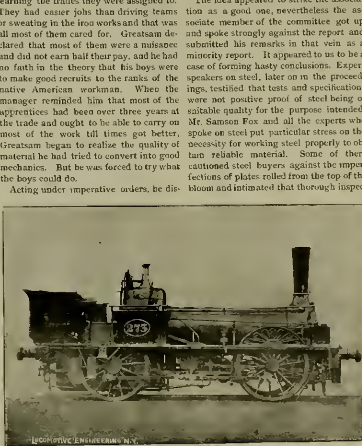
Some years ago there was a social reformer lecturing in the town where the headquarters of the Twin Threes are, and he made an eloquent appeal to the employers of skilled labor to foster and encourage the apprentice system He drew pathetic pictures of the thousands of American youths who are hungering after the opportunity to learn a trade, and appealed to the patriotism of the people to encourage this laudable desire. The wife of the general manager attended this lecture, and went home soturated with the subject. Next week, Greatsam received an order to employ all the apprentices that could be worked to advantage in the shops.

An order of this kind is not long a secret in a country town and Greatsam was immediately besieged with applicants for employment as apprentices. He could not accommodate half the applicants, so he determined to move slowly in the matter. To escape the persistent appeals of the father he first took in young Tom Sullivan, son of the night watchman; and widow Green next forced in her boy Joe by the same means that a similar person used many years before to worry out the patience of an unjust judge. These two boys were known to be the hardest cases in the town and they set the standard of the class of boys who could fill the apprentice list in the shops. A few bright ambitious boys got in, but the roughs soon made the place too disagreeable for them. In an effective and persistent way the rowdy boys obtained possession of all the apprentice openings. No test of fitness was made. If a boy looked sturdy enough to pull on a jack-lever he was considered eligible, no matter what his previous training or form of servitude had been. There had been talk of requiring candidates for the places to be able to read and write, but older sympathizers had asked if reading helped a man to push a file straight and if writing would make a man more skillful in calking a seam. That was considered good argument.

As time went on even the best friends of the apprentice system had small reason to gush over the success of the apprentice experiment in the Twin Threes shops. The boys, themselves, displayed no interest in learning the trades they were assigned to. They had easier jobs than driving teams or sweating in the iron works and that was all most of them cared for. Greatsam declared that most of them were a nuisance and did not earn half their pay, and he had no faith in the theory that his boys were to make good recruits to the ranks of the native American workman. When the manager reminded him that most of the apprentices had been over three years at the trade and ought to be able to carry on most of the work till times got better, Greatsam began to realize the quality of material he had tried to convert into good mechanics. But he was forced to try what the boys could do.

Acting under imperative orders, he discharged all but a few leading mechanics, and attempted to run the shop with the boys. Never was there a more dismal failure. There was not one of them who could line a set of guides or put in a set of flues, and none of them tried very hard to do the work right. Greatsam stood over the boys day and night trying to encourage them to get the work out, he helped, and praised, and flattered, but all could not make workmen out of the youths who had not learned the business. Then he lost patience and tried abuse and invective, with the result that all the boys went on strike. The terms of settlement they wanted were full mechanics' pay and proper treatment. When the stoppage of work began to tell on the train service, some of the old men were hired and more have been taken on.

There is now a sore subject between Greatsam and the G. M. in connection with the failure of the apprentice system. Greatsam says that apprenticeship is a humbug, since boys are not sufficiently under control to make them learn the trade properly. The G. M alleges that neither the system nor the boys is entirely to blame for the failure, and he is looking up facts bearing on the case. Meanwhile the workmen are perfectly satisfied that apprentices cannot be trained properly in a railroad shop.



AN OLD CRAMPTON CENTER CRANK ENGINE.

## Tests of Steel and Iron.

One of the best reports submitted to the Master Mechanics' Convention, was that of the Committee on Tests of Steel and Iron, of which Mr. William Smith, of the Chicago & Northwestern, was chairman. The report presented the subject in a thoroughly digested shape and read like a good article by an expert on steel and iron. As the ordinary methods of testing steel and iron are presumed to be familiar to the members of the association, little was said on the subject and the well-known forms of specification of steel were not discussed. The committee, however, urged that a system of expert inspection ought to be introduced because steel was often found to pass the required tests and to fulfill the specifications and yet failed prematurely in service.

The idea appeared to strike the association as a good one, nevertheless the associate member of the committee got up and spoke strongly against the report and submitted his remarks in that vein as a minority report. It appeared to us to be a case of forming hasty conclusions. Expert speakers on steel, later on in the proceedings, testified that tests and specifications were not positive proof of steel being of suitable quality for the purpose intended Mr. Samson Fox and all the experts who spoke on steel put particular stress on the necessity for working steel properly to obtain reliable material. Some of them cautioned steel buyers against the imperfections of plates rolled from the top of the bloom and intimated that thorough inspection was the only means for detecting the defects common to steel taken from that part of the pouring.

The Committee's report merely emphasized the necessity for more expert inspection. There is good reason for believing that the additional safeguard proposed by Mr. Smith for detecting the presence of poor material would work for the benefit of railroad companies.

## Curious Shop Nomenclature.

It is curious to notice the difference in railway and in shop nomenclature in American and in British shops. Both sets of men talking the same language, it seems natural to expect that the names of things should be the same, but in a great many cases they are different. "Chordal" writing years ago in the *American Machinist* on this subject, gives some amusing examples, and time has tended to diversify expressions instead of bringing uniformity He says

"With the English, our steady rest is a catch-plate and our follow rest a back-stay. Our engine lathe is their self-acting lathe Our 24-inch swing lathe is, in mother English, a 12-inch center lathe. Our belt is with them a strap, our stripper, a strap-shifting apparatus, and air counter-shaft, an overhead driving apparatus."

Special trades in our country vary about as much. Men brought up in railroad shops call a shaper a compound plane, and engine-slides of any description guide bars. But the worst thing the railroad machinist is guilty of is bringing into shops such words as "six square nuts, three square files," etc He has often sent cubs running among roundhouse men after circular squares and straight hooks, and wondered at the greenness of the boy in supposing for an instant that there are such things, when he himself uses daily such outrageous expressions as bevel square, four square file, etc

We have in this country four names for a connecting-rod. It is main-rod, connecting-rod, pitman and rod. Eccentric-rods are often cam-rods, crossheads and tee-rods, and safety-valve weights are often called Pees, from P weight in the equation, I suppose. The crank-pin with some becomes a wrist.

## Workmen Reporters.

The proprietors of the *Daily News*, of Dundee, Scotland, have displayed remarkable enterprise to obtain news of interest to all classes of industrial readers concerning the Columbian Exposition. They sent twelve workmen belonging to the principal trades to take notes of what was to be seen at the World's Fair, and to collect information of value from all sources where it could be obtained. Besides descriptive matter of their several interests the delegates were required to collect information regarding the conditions of the American wage-earners, how they live, what kind of houses they have, what hours they work, what leisure they enjoy, what kind of food they get, and anything else concerning workmen likely to interest their own class in Scotland.

## The Clang of the Bells.

BY L. R. ANDREWS.

Where railroads are found, the world around,
The "Baldwin's" bell is known,
And as it rings, the song it sings
Is a very familiar one

From Tehachapi's heights to Dakota's plain,
From Maine to Mexico;
With a deep harsh note from it's brazen throat
The "McQueen's" alarm doth go.

There are bells and bells, no two the same,
On lowlands or on highlands,
They count their friends to the world's ends,
The bells on the "Rhode Island's."

In lands of sun, 'mid tropic climes,
Thro' wintry ice and snow,
The "Brooks'" bells rhyme their varied chimes,
As o'er their course they go.

The "Pittsburg" bell has a curious clang,
As it echoes thro' the vale,
'Tis easy to tell the sound of this bell,
Rumbling o'er the rail.

With a shrill "ding! ding!" and a short, sharp ring
The "Rogers'" bell peals loud,
You may always know that they're ready to go
When its clapper warns the crowd

Oh! the "Mason's" bell is balanced well,
But its voice is not for me;
As to and fro it sways so slow,
Like the bell-buoy of the sea.

"Cooke," "Richmond," "Dickson,"
"Rome" and the rest
Have their champions who love them true,
Each thinks well of his fav'rite bell,
Tho' it suits but one man in the crew

But the "Blood" bell's tone is all its own,
Sonorous, mellow and clear,
It's rhythmic ring in measured swing
Is music I love to hear.

### Quartering Driving-Wheels.

BY GEO. K. WENTWORTH.

As there has not been anything in LOCOMOTIVE ENGINEERING for some time in regard to quartering driving-wheels, I will try to explain how it is done in shops where there is no quartering machine.

Will take any pair of driving-wheels that require a new axle or a driving-axle that requires new wheel-centers. The keyway in axle or wheels is already cut; if new wheel-centers, the hole for the crank pin has been bored out, after axle and wheel-center have been fitted, place axle on two wood V-blocks, high enough so wheels will be clear from floor; then put each wheel on axle about ½ inch, or just enough so keyway can be marked on axle, or if it is a new wheel-center, keyway can be marked from axle onto wheel.

When putting wheel-centers on axle put them on so crank-pins will be as near right angle to each other as can be done with the eye; be sure the leading crank-pin is put on the proper side; on all locomotive engines that I have seen, the crank-pin on the right side was the leading one, when running forward. After the wheels are on axle get the centers of the wheel fit on a small piece of tin, fastened to a small piece of wood that is tight in hole where axle fits in wheel-centers as shown at *A*, Fig. 1, or better, use a tool made as shown at Fig. 3—as all sizes are given it can be easily made.

Take a straight-edge, put one edge against collar on crank-pin, or hole for crank-pin, at *B*, Fig. 1, and the other end of the straight-edge at edge of hole where axle fits at *C*, draw a straight line from *B* to *C*; put straight-edge at *P* and *E* and draw another straight line, where these lines bisect at *F* make a small center punch mark; then put one point of a pair of dividers at *F*, and the other point a little distance below points *C* and *E*, and make the lines *G* and *H*; make small center punch marks at the points where the lines *G* and *H* bisect the lines *D E* and *B C*, then with dividers from the points *G* and *H* make the two lines at *I*, make a small center punch mark at this point; draw a straight line from *F* to *A* and to *I*—this line could be got without the point *I* by drawing the straight line from *F* to *A* and continuing it to the point *I*—when the point *I* is got from the points *G* and *H* and coincides with the points *F* and *A*, it proves that the points *F*, *A* and *I* are correct. From the center of wheel *A*, with a radius *A* to *I*, draw the arc of a circle *M*; where this bisects the line *F A* make a small center punch mark, draw a line at *A* right angle to the line *F I* by using the points *I* and *M* and drawing the arc of a circle at *K* and *L*, make a small center punch mark at these points *K* and *L*, draw a straight line from *K* to *A* and *L*; this line should be at right angles to line *F A I*. From the center *A* draw a circle with a diameter equal the diameter of collar on crank-pin next to wheel, as shown at *O* and *P*; get all these lines on both wheels.

With a square made as shown at Fig. 2, the small holes at *C C* are for a plumb-line to be put in—draw a line on square from *C* to *E* and *C* to *A*, have these lines parallel with the edge so when using this tool you can see if plumb-line hangs parallel to edge and line; place the edge *A B* of the square on the collar of crank-pin at *D* and edge of circle of same diameter as crank-pin collar *P*, Fig. 1, on left side, put a plumb-line in small hole *C*, Fig. 2, then move this wheel until plumb-line hangs true with square; then place the edge *E F* of the square on the collar of crank-pin at *B* and edge of circle of same diameter as crank-pin collar at *O*, Fig. 1, on right side, then move the wheel on axle until plumb-line hangs true with square.

Be careful that in moving one wheel on axle the other doesn't move. It is best to try the first wheel again after the second wheel is in place to be sure that it has not moved. The first wheel, or the one on left side, can be proved by placing plumb-line over collar on crank-pin next to wheel, and having lines coincide with circle same diameter as collar on crank-pin, as shown at *O P*, Fig. 1.

After both wheels are true with the square and plumb-lines, then keyways in wheels can be marked off from keyway on axle, or, if new axle, mark off keyways on axle from wheels; then wheels can be taken off and keyways marked off on axle with a key-seat rule, or keyway in wheel fit with a T-square, then keyways can be cut in axle or wheel-centers. Before wheels are pressed on axle, have false keys fitted to keyways in axle and wheels, have them a good fit sidewise so wheel can not move on axle. When putting the wheels on axle to mark off keyways, have them go on axle same distance all around, have them stand parallel with each other; they can be held together, and on axle, by three ⅞-inch rods and clamps bolting the two wheels together.

After the driving-wheels are pressed on the driving-axle they can be tried to see if they are correct by scribing from center of axle with a ball-center on one point of a pair of dividers, a circle on each end of axle, of same diameter as collar on crank-pin next to wheel; then place the wheels with one crank-pin on the top, so when plumb-lines are placed over collar on crank, pin will coincide with circle on end of axle of same diameter as collar on crank-pin; then place square, shown in Fig. 2, on crank-pin collar of wheel on opposite side, and edge of circle on end of axle of same diameter as collar on crank-pin; if plumb-line hangs true with square, then wheels are correct; if not true, press one wheel nearly off and take false key out and file enough off from false key on side that fits next to wheel, so wheel can be moved around on axle so crank-pins will stand at right angles to each other, then put false key back in keyway and press wheel on axle a little so pressure will hold it, then set a jack under one spoke of the wheel on the side so wheel can be moved around on axle; set another jack under one spoke of the wheel on opposite side; have the two jacks set so they will be on opposite sides of each wheel, so the jacks will "lift" against each other when screwed up tight; then press the wheel on axle and the wheel will turn around on the axle until it comes against the false key, then the jacks can be taken away and the wheel pressed on as far as needed.

A handy and useful tool for getting the center of hole in wheel where axle fits, is shown in Fig. 3. it is made of 1-inch square steel; in one end is a ⅜-inch screw with a square head, turned to a sharp point so it can be screwed into hole in wheel to hold it rigid. The piece *B* is fastened to the 1-inch square piece by the screw *D* so it can be set at edge of circle of same diameter as collar on crank-pin, and edge of square can be set against it and collar on crank-pin. This little tool makes the work much easier than when a piece of wood is used for a center. A piece of brass can be fitted in slot *C* for a center, and as center punch marks for a center get worn large the piece of brass can be removed and a new piece fitted in.

I am opposed to using a spirit level on a locomotive engine whenever a plumb-line or square can be used instead. In this way of quartering wheels no spirit level is used; all that is necessary is that the two sides *A B* and *E F* of the tool shown in Fig. 2 are on an angle of 90 degrees, and be careful about drawing the lines and making center punch marks.

### Handling the Air-Brake.

BY GEO. ELLIS.

I have just finished reading an article, "Handling the Brake-Valve," which appeared in the July number of LOCOMOTIVE ENGINEERING, by Mr. Will W. Wood, and I think a few remarks upon the same are in order. The first part of his subject is given to discussing the propriety—after having attempted a service application and wishing to make an emergency one—of quickly throwing brake-handle to full release position for a second or so, thereby throwing a volume of air into train-pipe, and immediately returning same to emergency position. Mr. Wood gives a very graphic account of what takes place under this method, and in this I fully agree with him.

But what strikes me as strange—considering the number of times this argument has come forth—is that some recognized air expert, or even the Westinghouse people, do not come forward and put a damper on this method, or if it should be the proper way to handle the emergency feature of the Westinghouse brake-valve (which I candidly admit I would not attempt even as an experiment), let them say so.

There are lots of engineers in this country who would like to see this quickly brought to an end. Meantime, I shouldn't advise any one to shoot any air into train-pipe in making emergency stop, until this method is approved by unquestionable authority, as it is just possible they might not stop, at least not where they want to. Some people speak of pressures as others do of weights and solids, and appear to think they can be drawn and pushed from place to place in the same way, never considering it takes volume—compressed volume—to make pressure, and that placement or displacement of pressure can take place only upon the compression and release of volume.

It is a disregard of this rule, it appears to me, that leads some to think, that by shooting a "solid mass or embankment of air" into train-pipe and against triple pistons, and "suddenly" withdrawing it, gives the "cushion" or pressure on the other side of the triple-piston a better "hold," "fulcrum," or "grip," to sort of slam it along toward the emergency feature of the valve, which, if the volume could be handled quickly enough, might to a certain extent fill the bill, providing he had the original pressure in auxiliary—which, of course, he has not. Mr. Wood goes on in his essay to state that the Westinghouse people have perfected and produced a brake-valve that can be handled successfully by those unfamiliar with the finer points of the brake mechanism, if the engineman will only follow the directions in their instruction book, and that "younger runners do a great deal of reading nowadays and that naturally enough many will believe the statements of those air-brake experts, printed in technical publications, and handle their brakes accordingly."

Also that "there are five indicated points for the brake-valve, and the instruction books explain clearly when and how to use those different points." Now, this would have excited no comment, but further on Mr. Wood undertakes to set forth a set of instructions, just like an expert, that sounds to me just like "Skeever's Fourth Vice Mahogany Desk Affair." I do not wish to hurt Mr. Wood's feelings, but I must say I cannot believe he has ever handled a freight train for a living, with and since the introduction of the Westinghouse "Engineer's Equalizing and Discharge-Valve."

Some of Mr. Wood's statements are not consistent. He seems to infer that by following the instruction book to the letter, it is impossible to make a mistake. All railroad companies publish a book of rules that is supposed to be absolutely correct. If followed to the letter in every instance, how many of us would railroad for a living? Westinghouse instruction book, page 16, paragraph 3, says: "To apply the brakes with full force, a quick reduction of the pressure in the train-pipe of ten to twelve pounds is made," etc. And Mr. Wood tells us to move our brake-handle to emergency position and leave it there until we have stopped. Zounds! How can we take his advice and follow the instruction book and his instructions, too? Isn't a young runner liable to get "rattled" with such advice?

And again, he says: "To apply the brakes gradually, move the handle to service stop position, and watch the black pointer of the gauge; it will show how much air you are letting out of your train-pipe, and you can graduate your stop by the distance it falls back. When you have exhausted twenty or twenty-five pounds of air, your brake is fully applied. [This is official—Westinghouse says so.] Don't let out any more air; save it to release the brakes and recharge the auxiliaries. *You may run by—you will sometimes—but don't get 'rattled.'*"

The above italics are used by me, not Mr. Wood. Any young runner coming into a meeting point, and the opposing train not into clear, or what is more to the point, not in at all, will, of course, make the usual reduction of 20 to 25 pounds of air, and if the locomotion or headway continues about the same, it will be very unbecoming of him to get "rattled." No

matter if he does run by, there is no help for it but to haul her over, a little sand, and when matters get too close, calmly step off.

Away down in your gizzard you feel the satisfaction of knowing your brakes were fully applied. If, by any good fortune, you are able to attend the following investigation, you might tell this to the railroad officials, and also that you know you are right, because your gauge registered a reduction of 20 to 25 pounds, and your brakes were fully applied. Mr. Wood and the instruction books say so. This will readily influence them.

I am inclined to think Mr. Wood's instructions are considerably out of line in regard to some points I have mentioned. I have found it necessary, on numerous occasions, to reduce 40 and even 45 pounds of air, before the brakes would take hold—due to triples being very dirty, dry, etc. Some companies handle so many foreign cars, that very little attention is given to cleaning this part of the service when the business is heavy, and some cars are months and months away from the home road.

I think it foolish to lay down iron-clad instructions, when the service and good judgment make it necessary to deviate from the same. Some people can run a train across a desk or floor, and make all kinds of good stops (as per instruction book), but when they attempt to give some old runners pointers, and instruct young runners how to handle a thirty or fifty-car train, composed of dry triple valves and a prominent leak or two, I notice, they invariably scheme up an excuse to "slide off and take four back to town."

### Brooks Ten-Wheel Passenger Locomotive.

Gauge—4 ft. 8½ in.
Fuel—Bituminous coal
Weight in working order—138,000 lbs.
Weight on drivers in working order—111,000 lbs.
Rigid wheel base—14 ft. 6 in.
Driving-wheel base—14 ft. 6 in.
Total wheel base—25 ft.
Diameter and stroke of cylinders—19 x 26.
Diameter of driving-wheels—72 in.
Diameter of boiler—60 in.
Length and width of firebox—114 x 32 in.

TENDER.

Coal capacity—8 tons.
Capacity of tank—4,000 gals.

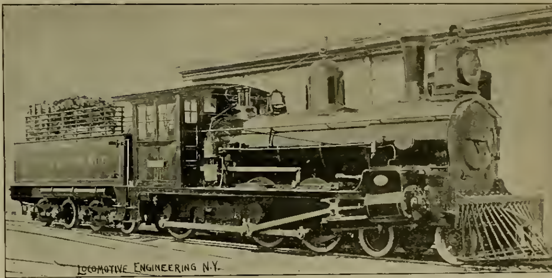
ENGINE AND TENDER.

Total wheel base—52 ft. 3¾ in.

### A Mexican Southern Freighter.

The engraving shown herewith represents a type of locomotive doing good service on the narrow-gauge Mexican del Sur. These engines were built by Kitson & Co., Leeds, England, and rebuilt at Puebla, Mexico; they have 16 x 22-in. cylinders and 48-in. wheels placed inside the frames. They are something like a mule in that they are hybrids—neither American nor English in design.

The men say they are very good mills and serve the purpose for which they were built very well.



ENGINE OF FAST FRUIT TRAINS, MEXICAN SOUTHERN RAILROAD.

### The Erie Engineers' Locomotive Criticised.

The locomotive designed by the Erie engineers, which is exhibited at the World's Fair, received some very severe criticism from the master mechanics at the Lakewood Convention.

Mr. J. D. Barnett said on this subject:

"When walking through the Columbian Exposition, and noticing an engine said to have been designed by men running engines, I thought I would pay some little attention to see if an engine designed by men exclusively handling engines was any safer than an engine designed by a master mechanic. I found, as soon as I stepped upon the foot plate, that I could just get the top of my nose onto the brake-wheel. The ratchet and pawl, to be worked by the foot to hold that brake-staff from slipping back, was 14½ inches above foot-plate level. The depth of the horse-shoe in the tender was the greatest depth in any tender I have seen for several years, there being no slope either at the back or side to throw fuel well forward to the front. The steps were simply secured by a single set-screw, by no means the safest form of securing a step, and the hand-rail and foot-steps in the neighborhood of the head-lamp to be used by the men when lighting up were far from being the safest and most convenient that I have seen.

"Mr. MITCHELL—I wish to say, respecting the engine referred to by Mr. Barnett, which the engineers built, that I think the parts that he referred to were designed by the builder. The railroad company with which these engineers were connected, had nothing whatever to do with the design in any detail, and in talking with some of the committee of the engineers, I inferred from what they said that they only specified the principal parts, like the size of cylinders, size of boiler, journal, and such details as that. I think these minor details referred to are the designs of the builders.

"Mr. GILLIS—I think, in justice to the builder, it should also be said that, as I understand, the engineers who designed this engine had inspectors to overlook the construction and see that it was done as they desired.

"Mr. MACKENZIE—I was very much interested in the remarks made by Mr. Barnett as to the designing of that engine. It would seem to me that if a committee of engineers were to design an engine, they would look particularly after the parts that they were to handle and which they knew something about, and would let other parts, that they knew nothing about, alone. It seems that they lost sight of the fact that they did not know anything about the boiler or cylinder or anything of that kind, and they went to work and designed those parts of the engine, and when they came to the brake-wheel, as Mr. Barnett says, they put it where they could not get to it without a step ladder. I am surprised to hear of the condition of that engine. I thought it would be a model engine as to brake attachments and all that sort of thing. I did not suppose the boiler and cylinders would amount to anything, but the minor attachments I did suppose would be very convenient."

BROOKS TEN-WHEELED PASSENGER ENGINE. NOW AT WORLD'S FAIR

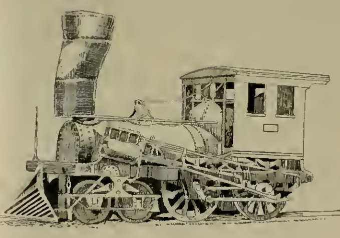
We are in receipt of a neatly bound volume containing fine lithographic pictures of all the locomotives exhibited by the Pittsburgh Locomotive Works at Chicago, as well as descriptions and specifications of each engine. In addition to the general dimensions, there is for each engine a table showing its hauling capacity in tons on grades varying from a dead level to 132 feet per mile, and at several different speeds. The book is well worth a place in the library of any mechanic or railroad officer.

Supt. Thos. Cronin recently left the International & Great Northern to take charge of the Houston, East & West Texas. One Sunday, while "back home" at Palestine, the boys caught him and presented him with some depreciated silver in the shape of a tea-set. Master Mechanic Huffsmith made the speech. Cronin says that silver is worth $400 per ounce.

James W. Holmes, an old-time employé of the Reading Railroad shops, is contributing a series of articles on the men who learned their trades at Reading and afterwards became famous. Col. F. K. Hain, general manager of the Manhattan, was recently "wrote up," with many others whose names are well known in the railroad world.

### Matthews' Improved Spark-Arrester, with Engine Attached.

The engine shown in the annexed engraving is of considerable historical value, having been the first eight-wheeler built for the Mohawk Valley road, now a part of the New York Central. The engine was designed by Mr. David Matthews, and built under his supervision. The smoke stack, which forms such a prominent feature of the locomotive, was Matthews' patent, and was the first departure to making smokestacks rival the boiler in size.



ENGINE "11," N. Y. CENTRAL, AS ORIGINALLY BUILT.

This engine was considered a tremendous, powerful machine in her day, and astonished people by the long trains of cars she would haul. After doing hard work for many years, till the working parts were worn out, the engine was considered worthy of being rebuilt. After going through this process she appeared as shown in the larger engraving. The changes made illustrate very forcibly the line of improvement followed in leading up to the modern locomotive.

An improvement in wrought-iron wheel-making has been patented in this country by Mr. Pierre Arbel, of Paris, inventor of the well-known Arbel wheel. The new invention consists of a process of making a forged wheel by building up a fagot of the rim, then heating this and forging it between dies to produce a spoke-wheel. A heated disk is applied on one side and welded to the spokes, rim and nave. There is talk of the Arbel Wheel Co. establishing works in this country.

---

Mr. George Whaley, a well-known French engineer, who has been in America reporting on engineering appliances at the World's Fair, and in the country generally, visited this office in search of information. He is very much interested in railroad matters and is a most discriminating observer.

### Punching and Drilling Boiler Sheets.

Foreign engineers who visit American railway and locomotive building shops, nearly always express surprise at the prevalence of punching in the construction of boilers. The authorities that control nearly all Government boiler and iron ship work require that all holes shall be drilled, and very decided objections are raised against punching. Although locomotive boilers carry higher steam pressure than any other, and although they are subjected to more trying stresses than any other form of boiler, punching is universally followed in the construction of American locomotive boilers. Cheapness is no doubt the reason why this practice has become general, but there are two sides to the question of punched *v.* drilled holes. The case was very fairly covered by Mr. W. Barnett Le Van in a paper read some years ago before the Franklin Institute, of Philadelphia. The following is an abstract of the points made

Of all tools that take part in the construction of boilers none are more important than the machine for punching holes.

That punching has a more or less injurious effect upon the metal plates surrounding a hole, is a fact admitted by every engineer, and it has often been said that the holes ought to be drilled. But, unfortunately, no drilling appliances can at all compare with punching in rapidity and cheapness of working. A first-class punching-machine will make from forty to fifty holes per minute in a thick sheet. There is no drilling-machine that will approach that with a single drill.

The most important matter in punching plates is the diameter of the opening in the bolster or die relatively to that of the punch. This difference exercises an important influence in respect not only of easy punching, but also in its effect upon the plate punched. If we attempt to punch a perfectly cylindrical hole, the opening in the die-block must be of the same diameter as the point of the punch, or, at least, a very close fit. The point of the punch ought to be slightly larger in diameter than the neck or upper part.

When the hole in the bolster or die-block is of a larger diameter than the punch, the piece of metal thrust out is of larger diameter on the bottom side, and it comes out with an ease proportionate to the difference between the lower and upper diameters; or, in other words, it produces a taper hole in the plate, but allows the punching to be done with less consumption of power, and, it is said, with less strain on the plate

The difference which should exist between the diameter of the punch and die hole varies a little with the thickness of the sheet to be punched, for it is easy to understand that the die which might give a suitable taper in a $\frac{1}{4}$-inch plate would give too great a taper in a $1\frac{1}{4}$-inch plate. There is no fixed rule. Practical experience determines this in a rough-and-ready way, for if a machine has to punch different thicknesses of plate for the same size of rivet, the workman will seldom take the trouble to change the die for every variation of thickness The makers of punches and dies generally allow about $\frac{3}{32}$-inch of clearance.

Punches are generally made flat on their cutting edge, but others are made spiral on the cutting edge. The latter has a gradual shearing action, commencing at the center and traveling round to the circumference. This form of punch is not suitable for thick metal.

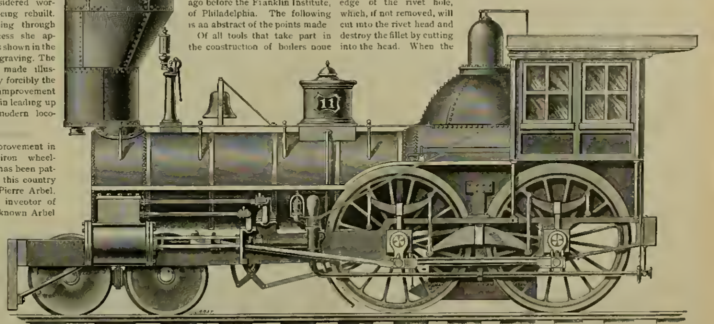
It is of the greatest importance that the punch should be kept sharp and the die in good order. If the punch is allowed to become dull, it will produce a fin on the edge of the rivet hole, which, if not removed, will cut into the rivet head and destroy the fillet by cutting into the head. When the punch is in good condition it will leave a sharp edge, which, if not removed, will also destroy the fillet under the head by cutting it away.

Punching possesses so many advantages over drilling as to render it extremely important that the operation should be reduced to a system so as to be as harmless as possible to the plate. In fact, no plate should be used in the construction of a boiler that does not improve with punching. Experiments made by Hoopes & Townsend show that good material is improved by punching The great objection to drilling rivet holes is the expense, from the fact that it takes more time, and when drilled of full rivet size we are met with the difficulty of getting the rivet holes to correspond, as they are when punched of full rivet diameter. When two plates are drilled in place together, the drill will produce a burr between the two plates—on account of their uneven surfaces—which prevents them being brought together, so as to be water and steam tight, unless the plates are afterwards separated and the burr removed, which, of course, adds greatly to the expense.

The difference in strength between boiler plates punched or drilled of full rivet size may be either greater or less than the difference in strength between unperforated plates of equal areas of fracture section. When the metal plates are very soft and ductile, the operation of punching does no appreciable injury. Prof. Thurston says he has sometimes found it actually productive of increased strength; the flow of particles from the rivet hole into the surrounding parts causing stiffening and strengthening. With most steel and hard iron plates the effect of punching is often to produce serious weakening and a tendency to crack, which in some cases has resulted seriously. With first-class steel or iron plates, punching is perfectly allowable, and the cost is twenty-five per cent. less than drilling, in fact, none but first-class metal plates should be used in the construction of steam boilers.

In the original punching machines the die was made much larger than the punch, and the result was a conical taper hole to receive the rivet. With the advanced state of the arts the punch and die are accurately fitted; that is to say, the ordinary clearance for a rivet of $\frac{3}{4}$-inch diameter, the dies have about $\frac{3}{64}$-inch, the punch being made of full rivet size, and the clearance allowed in the diameter of the die.

From the points made by Mr. Le Van, who is a practical boiler maker, it will be seen that the principal objection to punching is bad punching.



ENGINE "11," N. Y. CENTRAL, AS REBUILT

A sensible writer discoursing in a painter's paper about apprentices, says that the original trouble with apprentices in American shops is the want of care in selecting the boys. If apprentices were selected as carefully as brushes are, they would give more satisfaction than they do. The point is made that there is no use nowadays in withholding trade secrets from boys, because the current trade publications reveal them all.

---

The first cab applied to a locomotive in New England was put on the "Tartar," belonging to the Boston & Albany, by an engineer named Ellis. It consisted of corner-posts, with canvas stretched between them.

## Close Measurements.

The Pratt & Whitney Co., and other makers of fine measuring instruments, have within a very few years reduced ordinary measurements to accurate quantities which were formerly considered an impossibility. There is nothing more striking about old and new methods of doing mechanical work than the processes of measurement. Ever since men began to use tools there have been artisans noted for the closeness of their work, but they were always the exception, and it is within the memory of men still at work when the subdivisions on a two-foot rule were considered close enough to measure to. This caused great increase of work in fitting. The improvements in machine tools have contributed greatly to the reduction of fitting by file and scraper. The mechanic arts have made immense strides in one century, for it was only about one hundred years ago that James Watt congratulated his men on the accurate boring of a cylinder which was only $\frac{1}{8}$ inch out of round. Probably Watt could imagine improvements being carried out in boring appliances that would succeed in boring a cylinder perfectly round. If he expressed views of this character to his contemporaries they probably considered that he was a visionary.

A peculiarity of early mathematicians and mechanicians was, that they had conceptions of accuracy, but they considered that accuracy was an ideal which could not be approximated in practice. Over 2,000 years ago Euclid had correct views about a straight line and about an accurate plane surface, but he had no idea that they would ever be made by the hand of man. Yet practically plane surfaces are to be found in every first-class machine shop. Every machinist ambitious to do close work has in his tool-chest a micrometer gauge by which he can measure to the $\frac{1}{10000}$ of an inch without the aid of a microscope. This is a modern miracle. The men who worked up this degree of perfection are not popularly considered heroes of industry, but they deserve more honor and praise than nine-tenths of the men whose names are considered worthy of being perpetuated by means of memorials and popular biographies.

## Slow Progress in Improving Tools.

The oldest machine-cutting tool is the lathe. In its most ancient form it was driven in a manner similar to the operation of drilling by means of a bow with the cord encircling a pulley on the drill. In this process the drill cuts during one stroke of the bow and runs back during the other stroke. This was the motion given to the first form of lathe introduced into Europe, and it may still be found in use in its most primitive form in China and Japan.

When the crank was applied to give it continuous rotary motion, a great advance had been made. It is strange that mechanics were so slow to adopt the crank, for it was used in water-raising machinery in Egypt almost since the dawn of history. But mechanics have always been slow to make radical changes on their tools. There may have appeared to be as great difficulties in the way of giving the spindle of a lathe continuous rotary motion as there now appears to be obstacles in the way of making a planer or shaping-machine cut during both strokes. Future mechanics may consider it as strange that machinists of the nineteenth century used planing-machines and shaping-machines that did no work during one-half of the machine's movement, as we consider it short-sighted in our ancient mechanics not to adopt continuous rotary motion for lathes.

Standard Steel Works.—Hammer Shop

Standard Steel Works.—Wheel Boring Mill.

The people of the Australian colony, Victoria, appear to be exceedingly hospitable to strangers, so far as giving free transportation over railroads is concerned. The favors given are not always appreciated, or at least reciprocated. In the course of a speech made in a lawsuit lately, a lawyer said that no less than 1,000 free passes were issued to distinguished visitors last year. These happy "globe trotters," who use the railways free, had not even a kind word to say for their entertainers. "They sleep in our houses," the speaker continued, "eat our dinners, drink our wines and finally shake the dust off their several shoes and return home, to write books about us which are extremely unpleasant reading." That appears to fit the case of many visitors from abroad, who have been handsomely treated by American railroad companies.

## Annual Roundup of the Ananias Club—A Throttle Hero who Suffered the Pangs of Conscience—Election of a Dark Horse.

As the members of the Ananias Club gathered under the awning, for the annual meeting, there was a slight delay—the president had called the meeting for 9.30 and it was only 9.18—the president is very punctual.

The Old Colony man remarked that it was fine weather for any road running to the beach, as all the trains were crowded.

The D. & H. man said there were a right smart lot of people going up to the Adirondacks, and the whole party were soon talking of summer resorts and the handling of summer travel with winter power.

The N. Y. Central man sneered at the Ontario & Western man and remarked, That, of course, he supposed they *did* have a little business in summer, but think of the business we do with our *four* track."

The Ontario man retorted that the Jersey Central had four tracks and done a heavy summer business, too. He turned to the representative of the J. C., who had his chin in his hand, a woe-begone look on his face and a tear in his eye.

"Why, old man, what's the matter, brace up—how many trains are you running to Long Branch and Lake Hopatcong, now?"

The Jersey Central man sighed heavily, and, looking around vacantly, asked in a plaintive voice:

"What day o' the month is this?"

"Sixteenth," answered a dozen at once.

The Jersey Central man groaned.

"It's the day his wife died," whispered one.

"Anniversary of the day he run over his own mother," said a second, in a stage whisper.

"What is it, brother?" said the president. "We're all friends, and'l help you stand it."

"It's thirty-four year ago to-day," moaned the Jersey Central man, as he rocked himself back and forth. "Thirty-four year," he repeated, half to himself; "an' I can see it all jist as plain as if it was yisterday—them eyes, them *awful* eyes!" He half screamed, and put up his hand and arm as if to hide a gruesome sight.

The members respected his grief, and let him wear it out. Finally he ceased moaning, and looked from face to face around the circle.

"Boys," he began in a wavery voice; "boys, I hope it won't never be your lot to go through life with a load on your conscience. I hope none of you has never bin guilty of a crime. I hope none of you has ever been placed where you had to choose between death and the deliberate sacrifice of an innocent life—*for I have!*"

"Tell us how it was," said the chorus.

"Well, boys, it was the first summer the Central ran Long Branch trains—that was when I was running and afore I had any official position—I pulled the first train.

"I had a new Grant engine and a boy of a fireman, not over eighteen years old, and we doubled the Branch twict a day.

"Well, one day, nice warm day, just like this sixteenth of August, too, we went into the Branch about 7 o'clock in the evening and lay there for the last train out at 9.30.

"I took several drinks that evening, but thought I was all right, but that was my mistake. I was very drowsy and fell fast asleep at my post just as we passed Elizabethport.

"I was woke up by the fireman yelling, '*Shut her off, for God's sake, the draw is open*!' I woke clean up in a minute, but too late; I just got the air set when the Grant took a fearful plunge into the bay——"

It was a long time before he resumed.

"Boys, the train was all right, the brakes held it, the couplin' back of the tank broke——

"I remember tryin' to get her into the britchin' just as she went over, then all were black——

"When I come to I was layin' on the roof of the cab, and it was being carried out into New York Bay by the tide. I wan't hurt, and set up and looked around——

"I heard a moan, and lookin' behind me seen sompin' white-like; the moon com' out from under a cloud, and I saw it were my fireman's face—it was all bloody.

"'Bill,' sais he, 'give me your hand, my arm's broke.'

"Boys, the cab roof was small and splintered up, and the side he was hangin' to was under water, and I didn't offer to help him.

"He ast me agin, mournful-like, and said he'd drown if I didn't.

"'Willie,' said I, 'this roof won't hold two of us; you're crippled, anyway; let go.'

"But he wouldn't. He ast me to think of his poor old mother, but I told him I had a wife and five children.

"He begged and argued, and tried to climb on the raft himsef.

"Then is when the demon o' self-*pree*servitation possessed me, and I put my foot on his head and shoved him off.

"Oh, them eyes! I can forget him callin' me murderer; but them eyes will keep lookin' into my soul till I die."

He moaned a few minutes and then resumed:

"I were picked up by a tug in a short time and when my story were told I was the hero of the hour, 'the man who fearlessly met death doin' his duty,' 'the man who didn't flinch when he had life to save,' 'the man who grasped the throttle till the engine hit the bottom;' the passengers on that train give me a gold watch, the newspapers had my picture and the gineral supentennent give me the pay car to pull—but, gentlemen, none of these people knowed of the kanker in my heart, none of 'em suspected about the fireman."

After this confession the poor old fellow broke down entirely and there were few dry eyes in the assembly until John Campbell arose, cleared his throat and said:

"In view of the fact that I was raised on the Jersey Central and never heard of this case, I move that the distinguished professional be unani——"

"Gentlemen," said a stranger rising from a back seat and coming forward, "Gentlemen, there is an old saying that all things come to him who waits, for thirty-four long years I have waited for this moment and my revenge. *I am the man this villain tried to kill!* I swore the moment the tide left me high and dry on the mud flats that I would live to get even with my would-be murderer, and at last I have found him; he has fully confessed, and now I propose to whip him within an inch of his life!"

And with one swing of his left hand he knocked the old prevaricator over two chairs and landed him under the table. He made a dive to get on top of his victim, but a dozen hands held him back.

"Leave me git at the old villain!" he yelled, as he threw off his captors and kicked the Jersey Central man in the ribs.

They got him in the corner at last, and as Windy Rogers held him against the wall, the president pounded on the table with a cane and said:

"Gentlemen, this is not the House of Parliament or the Coney Island prize ring. Why this unseemly conduct?"

The Jersey Central man staggered to his feet, and, pointing his finger at his assailant, said:

"Mr. President and gentlemen, that man is evidently a liar, for he ain't thirty-four year old himself."

"No personalities, sir; no personalities," yelled the avenger. "I said I'd git even, and I will. Oh, for just one whack at the old cuss!"

"Why, man," said Brady, "the Newark Bay bridge wasn't built thirty-four years ago; nor twenty-four, neither."

"I don't care when it was built. I jest want to stamp on that old villain's pate—leave me git at him'!"

"Gentlemen," said the Jersey Central man, "a man as went through such an experience would know the number and make of engine he was on; kin he tell that?"

"You said it was a Grant, yourself," said the stranger. "I always fired Grants in them days."

"Mr. President," protested John Campbell, "there seems to have been some mistake here—far be it from me to doubt the word of any brother member—but neither the Long Branch road nor the Newark Bay bridge were built thirty-four years ago. The Grant Locomotive Works had not been established, nor air-brakes invented; one of these gentlemen was not yet born and the other was running a bolt-cutter out at the Hampton shops—I recognize you now, Pete—no engine jumped off the bridge that wasn't built yet, especially a locomotive yet in the ore; there wasn't no brakes to hold the train, no gold watch and no murder. It looks to me as if there was a mistake somewhere."

The stranger had struggled so hard to get to his victim that the crowd had thrown him down and Jim Brady was setting straddle of his chest.

"Mr. President," said Jim, without getting up, "I move that the gentleman from the Jersey Central be made an honorary member for life, and I would further move that this—'er, well, the Dark Horse here, be made president by acclamation; for while he may not be a gifted liar by tongue or pen, he is an actor and a man of some force; I know he could hold his own in a world's congress of liars, and we could all be proud of him."

Prolonged cheering, amid which the president put the regalia on the dark horse and the crowd divided itself each side of him as they faced the barkeeper.

---

### Mistaken Identity.

He was an English railway man, and had run over to see the World's Fair, but he was not greatly fascinated with the attractions of the Exposition, and our great railroad system did not interest him much. Talk about fast trains wearied him.

Mr. John Clayshire had a hobby, and he came here to ride it out as far as his means permitted. A radical among English liberals, he looked upon America as the Mecca of those who loved to see good government, and he embraced the opportunity of cheap rates to witness his ideals.

Besides admiring our political system, he was a diligent student of American literature, and loved to rave about the writings of Emerson and Hawthorne and Longfellow, but more particularly about Emerson.

He landed in New York and took a cab, which jolted him over the dirtiest and worst paved street he had ever seen. The cab driver charged him $2—four times the legal fare—and he could find no means of redress. He proceeded to Niagara Falls and fell into the hands of thieves in the course of his sight-seeing; but fared even worse among those who levy legal blackmail inside and out of the Chicago Exposition.

We met Mr. Clayshire in one of the hotels there, and he was inclined to take a pessimistic view of the world. Freedom, he believed, could be carried a little too far, and he wanted some control mixed with it.

As we talked, Mr. Stott, from Boston, walked up and joined in the conversation. On hearing that Mr. Stott was from Boston, our English friend brightened up wonderfully, and expressed a keen interest in many New England places on account of their literary associations.

"I am a great admirer of Ralph Waldo Emerson, Mr. Stott," he observed. "Nothing would give me so much pleasure as to spend a few days in Concord communing with your great philosopher. Of course, Mr. Stott, as a Boston man, you are an admirer of your immortal Emerson?"

"Emerson! Emerson!" repeated Stott, slightly bewildered. Then a light coming to his memory, he exclaimed, "Oh, yes, you mean Emerson the great rubber man!"

"O ye celestials!" groaned the Englishman, "is this the Boston culture I have crossed the ocean to witness?" A cloud of sadness passed over his brow, and, rising pensively, he remarked, "Gentlemen, I feel as if I could swallow one of your beastly mint juleps!"

---

### Sounded Wrong.

There was a slight misunderstanding at the Market street depot of the Philadelphia & Reading, at Philadelphia, the other morning. Letters have been posted up above the gates admitting passengers to the platforms, and each track is distinguished by some letter. This is a new arrangement.

A lady walked up to a gateman who was busy examining tickets, and asked "Which is the train for Doylestown?"

"Go to L," he exclaimed, pointing in a certain direction, but continuing to examine tickets.

The lady snorted, looked indignantly at the gateman and made a bee-line for the station master's office.

"One of your gatemen has grossly insulted me," she exclaimed, on finding the station-master. "I want him discharged right away."

"Why, you astonish me!" said the official. "What did he say or do?"

"I went and asked him where the Doylestown train was, and he told me to go to hell."

The gateman, on being accused of the serious charge, explained that he had told the lady to go to L, meaning L gate, and he was exonerated from all blame, but the passenger went away decidedly disgusted.

---

### Where He Was Stuck.

When Ike Johnson registered in the roundhouse Saturday night, Gotlieb Schmidt, the new man, was setting on a pilot as glum as though he had buried his father.

"What's up?" asked Ike.

"I'm in a lot o' drouble, mein friendt; I got to made out a repord."

"Well, that's nothin'; make her out."

"I don'd like dot repord pusiness."

"Oh, they don't expect no Spencerian writin'—just say what's the matter, in your own way."

"Yes, I guess I wride goot enough, already, but den—ober, I dunno——"

"Know! why, you know what's the matter; you know whether the trouble is in the valve motion or the tank don't you?"

"Ah, Mister Ike, *dot ish youst vhere I was shtuck!*"

---

G. D. Peters & Co., London, have opened an office in the Metropolitan Building, New York. This is the largest firm in the world that deals in railroad and steamship supplies. Their agent here is Captain J. L. Killmer, well known to railroad men as agent for the Boyer speed recorder. Captain Killmer was for seventeen years an engineer on the New York Central Railroad.

### A Driver-Brake That Had a Pulse.

*Editors:*

Not long ago I was firing an engine and one day noticed that at every exhaust of the pump the driver-brake pistons moved a little and then dropped back. There was no leak in the train-line. What caused it?

R. HILL.

*Sherman, Tex.*

### Softening Leather Packing in Driver-Brakes.

*Editors:*

We can sympathize with Mr. F. B. Armstrong, as we have had considerable trouble with the leathers of a pull-up driver-brake. We have tried several ways, and the best thing we can find to do in warm weather is to soak them about twice a week in water, using very little oil of any kind. This can be done with very little work, by filling the space between the brake-piston and the top cylinder head, through the hole in the cylinder-head, with a small funnel. Cut the brake out, and let it stand over night. In the morning cut the brake in, and the water will work out itself as the brake is used.

Leathers may not last as long this way as they would without soaking, but they do good work while they do last.

M. E. WATTS.

*West Nanticoke, Pa.*

### How the Breaking of a Rocker-Arm Could Cause the Knocking-out of a Cylinder-Head.

*Editors:*

Some one recently asked what knocked out a cylinder-head when lower rocker-arm broke? I would say that when the arm broke it left the valve with front steam-port open. The pressure on valve held it there, the steam forced and followed piston on back stroke, and was forced back into boiler on forward stroke, so long as the throttle was open. *When the throttle was closed*, piston was near back end, cylinder full of steam, and, there being no way of escape (as would have been had the valve covered both ports, and escape made for the one revolution through exhaust port, by lifting valve off its seat), the pressure in cylinder was compressed by forward stroke of piston, and if 80 pounds was cylinder pressure, we have about 1,920 pounds per square inch at completion of forward stroke, and she found the weak point in cylinder-head.

A. A. BROWN.

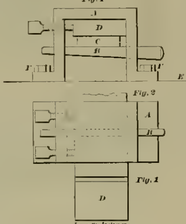
*Waycross, Ga.*

### Some Tool Kinks.

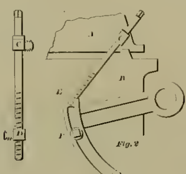
*Editors:*

In planing the ends of guides for closing, there is a great deal of trouble in setting the work in the planer-chuck to prevent the part to be planed being twisted with the wearing surface of the guide. There may be planer-chucks that will not cant the work, but if there are any the writer has never used them. To get rid of this trouble in planing guides I designed the jig shown in Fig. 1. It is a casting *A* of the shape shown, it is planed on the inside square with the bottom bearing, and clamped or bolted to the platen of the planer or shaper. A key, *B*, is put through and a liner, *C*, to suit the variation in thickness of guides. The guide *D* is now slipped through and the key driven, which forces the guide up and against the planed under side of the chuck or jig; the set-screws force the guide over against the planed surface and holding it true in all positions. We can now plane the work, knowing it will not be twisted with the wearing surface. If the guide is run hollow, put a thin liner of paper on low side and key up.

In changing the gears on a large lathe,



the swinging-arm holding the intermediate gears is very heavy and unhandy to handle, to overcome this evil I made a screw (with collar), of ¾ iron, cut thread in bolt-cutter. Made two studs, *C* and *D*, with square heads. The stud *C* is screwed into back head, *A*, of lathe the stud *D* is



screwed into inside of swinging-arm at *E*. The screw slips through the stud *C*—a loose fit, but screws through stud *D*. These studs must not screw snug up to the shoulder, as there is a movement to them as the swinging-arm is moved up or down The end of screw is made square to fit the handle, or crank, of cross-feed. To use the attachment, loose screw *F* (on all lathes), put on gears and draw the whole business into position by the screw. I hope one or both of these kinks will be of use to some brother mechanic.

W. DE SASSO.

*Indianapolis, Ind.*

### Those Air-Brake Questions.

*Editors:*

THAT ERRATIC TRIPLE-VALVE.

If I had been at the roundhouse, working on that St. Albans triple-valve, I should first have filled the packing-ring space in piston No. 5 with polar grease or tallow; if that did not cure it and the port leading to auxiliary was of the correct proportions, should have taken out and examined four-way cock, key No. 13, though I do not understand just what is meant by pressure in cylinder remaining at 70 lbs.; probably a misprint.

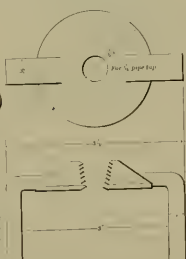
ABOUT ANGLE-COCKS.

Our Texas friend is right as to the necessity of an open train-pipe between each end of a train, but I believe there would be increased difficulties and dangers in the greater number of cars that would be left cut out, because nobody had a handle handy, either in yard or on road. Although I do not get a chance to read the *Engineers' Brotherhood Journal* as much as I would like, I saw in the August number a communication from C. P. R., advocating a hole in angle-cock, drilled in such manner that when the cock was shut the hose end would bleed off.

A few years ago, just after the angle-cock became common, a few were received on this road with these holes in them; hole had been made by leaving handle off and turning angle-cock key No. 2 past where it would be with handle on, and then drilling through side to slot in key. These cocks were hard to keep tight, on account of the short distance between the holes after cock was opened with handle on; I believe, however, that if hole were drilled in the upper part of the angle-cock body No. 1, Fig. 7, Plate D 24, so that it would come in space occupied by slot in key No. 2 when cock was closed, and a hole put in the side of the key itself and near the bottom of the slot so it would come in outer orifice of angle-cock body at the same time, the difficulty experienced in overcoming leaks caused by such holes would be reduced to a minimum; and as for the bell-cord idea, think it is very good.

CARE OF PACKING-LEATHERS IN DRIVER-BRAKE CYLINDERS.

Opinions are divided here in regard to chamfering packing-leathers; some think it helps the matter, some see no difference. I have put packing-leathers in 8-inch driving-brake cylinders, leaving one chamfered and the other square, sometimes one would leak and sometimes the other, and I am of the opinion that the proper plan to keep packing-leathers from leaking in



driving-brake cylinders is to keep them away from where they will get burned, but the greatest demand, that I know of, made for missionaries to overcome the bad effects of the profanity indulged in on account of such a leak, was caused by an 8-inch driving-brake cylinder, that seemed to be sprung in boring, as it was over 1/32-inch out of true. I should think our friend Congers' ¾-inch governor had too long a diaphragm-valve, and if so, after spring-box was tightened, the tension was already on the diaphragm plates, or, perhaps, the valve was too short and did not lift off its seat. The steam would have shut off, if the exhaust No. 10 was clear and the air could get by the diaphragm-valve. In the new 1-inch governor, Plate D 7, the diaphragm plates are about 1/16-inch less in diameter than their seat in diaphragm body No. 37, and when they are renewed, the diaphragm-ring No. 43 is liable to set the plates to one side while being tightened, thus cocking the valve and permitting air to flow through to top of piston; this governor is generally lazy.

RELYEA'S SIGNAL PROBLEM.

As to Brother Relyea's signal problem, there were a number of conditions not noted or stated that, were one present, would present the difficulty in such a light that it might, perhaps, be easily located, but so far, the half-inch stop-cocks might have been closed, the strainers could have been stopped up, the amount of air discharged from the drain-cock mentioned might have served better to locate the trouble. I once had a valve that apparently was all right when tried from the tender with almost any quantity of air, but which would not blow from the stop-cock at rear of first car. In taking the signal-valve apart I found someone had filed about half an inch off the spindle above the three-cornered part. A new spindle was all that was necessary to insure me a good night's sleep. When we wish to test the pressure on air or signal train-pipe we use a yoke, made as per sketch. I got the idea from Mr. Pritchard, of the Eastern Gen. M. D. W., this road. It works on both the old and new style couplings, if there are two inches thread on the thumb-screw, which should be of brass, so that it will unscrew easily. The yoke itself is of steel, and in case half-inch hole is not large enough at the end fitting on the packing ring, a larger one can be drilled and other fittings put in.

*Roanoke, Va.* GEORGE HOLMES.

### Tempering Tools.

*Editors:*

I saw a letter in the July number on tempering tools, in which the writer says taps, hobs, reamers, milling cutters and other tools of that order are subject to warping, cracking and general distortion in tempering, all of which can be overcome to an extent by first simply obtaining an equality of temperature of heat in all parts of the object to be hardened; secondly, the water to be used in hardening should be of the proper temperature. For example, a feather-edge cutter will not bear as much strain as a more bulky tool, hence it will not stand as cold a bath, for the colder the water the quicker the abstraction of heat, which will cause a sodden contraction of the thin edges.

The method of tempering so as to guarantee any desired degree or depth of the hardness of the tool, is to immerse it in water, keeping it there just long enough to harden the surface and cutting parts to the desired depth, then quickly transferring to an oil bath. The object of this method is to overcome the strain and stresses which sudden cooling develops. Now, you claim the water ought to be of suitable temperature for the certain shape cutter you have to harden. Now, Mr. Hinkens, your theory will never be a success, for this reason: "If your steel has been properly heated, it will not crack until it gets to about the same temperature as the water. If your water is of the same temperature as the atmosphere, and you would certainly not have it any warmer."

At any rate, it will not crack until it gets to about the temperature of 75 to 90 degrees, unless you overheat to a great extent, for the cause of your cutter cracking if properly heated is the center shrinking away from the cutting edges after they get to the same temperature as the water.

Now, then, the colder the water the quicker it will cool your cutting edges and the less strain on them, because they get

to their natural condition while the center is of a nice red heat.

Now, it is policy to cool your center gradually, so that the entire strain will not come just to that line where the water could not overcome the heat of the body, and where your cutter generally cracks.

Again, you claim, in order to get the desired depth of hardness, to immerse it in water, keeping it there just long enough to harden the surface and cutting parts to the desired depth, then quickly transferring it to an oil bath.

This may be good practice to prevent some irregular-shape cutters from cracking, but there is absolutely no need of this to get the desired depth of hardness, and I am only longing for an opportunity to prove in your presence that it can be done in a salt brine at a temperature of 32 degrees.

W. G. Lories.

*Rochester, Minn.*

### Curious Brake Action.

*Editors*:

I send you a case of queer air-brake action, for which I have only a theory as to cause, and would like to have it discussed to see if my theory is correct. I left terminal with a freight train partially equipped with air, eleven cars of air. Engine is equipped with latest Westinghouse brake-valve. There were no perceptible leaks in train-pipe. The brake would not creep on even when handle was left five minutes on lap. I had 70 pounds of air in train-line and 90 in main reservoir when I made first application of brake. I reduced air on gauge 5 or 6 pounds in service, when every brake went on emergency. As I was stopping too soon, I threw brake-handle in full release, but it did not release brakes.

Looking at gauge I found I had but 40 pounds of air in train-line and main reservoir. Train came to a full stop and brakes did not release until pumped off, when air pumped up all right. I tried the brakes several times and always with same result. I formed a theory as to cause of quick action from an article in your paper, but I could not account for the great loss of train-pipe pressure until I discovered and stopped the cause of the quick action, when I think I found the cause of loss of train-pipe pressure, but it is only a theory and may not be correct.

It would be proper to state that while trying to locate trouble I cut out behind fourth car of air and brakes worked all right, showing trouble was not in brake-valve.

### Old Times and Old Timers.

*Editors*:

I must say that Locomotive Engineering is the only paper in the country that reaches back a few years and shows up what we had a decade or two ago.

If the letters on the side of one of those old Mason's were erased and No. 11 put on I'd feel like I'd met an old sweetheart—they can all talk about "not owning a bolt in 'em," and all that, but I don't believe a good engineer can help getting stuck on a good locomotive.

Will some of the Philadelphia & Reading's old-timers send a sketch to Locomotive Engineering and tell us about the wood springs that were used on their rolling stock for so many years? And who will send a cut and tell us about some of the old Swinburn's and the John Brandt engines? the latter built at Lancaster, Pa.

W. De Sanno.

*Indianapolis, Ind.*

### Do the Top Guides Wear Most?

*Editors*:

I notice that Mr. Wentworth, in his article on lining guides, in the August number, follows the books in the statement that the top guide and the top of cross-head lug wears faster than the bottom. In an observation of steel crossheads with brass gibs, extending over sufficient time to make it more than superficial, I am led to contest the statement and say that it is not the rule but the exception where the top of the crosshead lug wears the most. It is true that the crosshead is held against the top guide nearly all the time when running ahead, and it would seem reasonable that the greatest wear should come on that guide, yet the fact remains that it is not so. Looking for an explanation, the most plausible reasons I have heard advanced are that the top guide is the best lubricated, and that the crosshead being held against the top guide, any sand or grit that may get on the guide is scraped off, while that on the bottom crowds between guide and crosshead and gets in its grinding work.

*Boone, Ia.*

### A Lame Engine.

*Editors*:

A passenger engine (eight-wheel American) came into relay on one side, with broken rocker-arm; one was wired for, and early next A.M. a man put on the job, completing it about the time she was wanted, and went to breakfast. When she was run on table a slight irregularity in her exhaust was noticeable, but hardly enough to distinguish it from water in ports, pipes, etc., from condensation. When turned and started for train a few revolutions revealed the fact that something was radically wrong; there were three exhausts and almost a fourth.

A second man was called "to lengthen blades and move quick, as time was short." She was put on front center, and the old familiar test method of marking valve-stems, by glands and reversing, and marking again in reverse, were tried. This showed O. K. She was moved to back center with same result.

The eccentrics had not been moved, the blades were put up O. K. as when taken down, the box bolted fast, and all bolts, keys, etc., were in proper place. The trouble was then located; where was it?

A. A. Brown.

*Waycross, Ga.*

### Quick and Slow, New and Old Valve Setting.

*Editors*:

Ever since Mr. Campbell asseverated that he "wouldn't have a machinist who couldn't set an engine's valve in ten minutes," I have been wanting to have a say. My objection is to the limit of time Mr. Campbell allows. Just as I was getting myself "plumed for flight," "Young Whiskers" bobs up with his quick-acting valve setting and fuel-saving method, knocking me out again. If "Y. W." can really do all that he claims he does, I should say it will not be long before the gentle zephyrs will cease their rude meanderings through and beyond his hirsute facial adornments, for he can hie himself to some locality where fuel is dear and talk cheap, and exchange a deal of his stock-in-trade for a small quantity of the article that in combustion converts *aqua pura* (and impura) into the commercial vapor we dub steam, thereby feathering his nest, and making it entirely unnecessary that the wild tempests should ever again circulate through his youthful beard. If this scheme as outlined here should fail, "Y. W." still has another course open to him—he may shave.

Now, as to Mr. Campbell's ten-minute job, I just want to say that I cannot conceive what a man who knows anything at all about setting valves makes such an assertion for, except it be to deceive somebody who doesn't know, and whom he wishes to impress with his capabilities, as testified to by himself. Why, it is an absolute fact that our youngest, most active and energetic machinists can scarcely crawl under one of our modern engines in ten minutes, and narrow gauges are not any more convenient. Then, I would ask, why is it necessary to try to limit a man's time on this operation to ten minutes? When it comes to a job in the office there is no such rush. I have seen a master mechanic's clerk consume ten minutes in sharpening a lead pencil. This fact was indelibly impressed on my memory, for the said clerk kept me waiting for my time-check while he pointed his Faber, and this was in Texas, but not so far south as Houston, nor on a road of such slim proportions as the H. E. & W. T. But here is an operation that a man is doing good work to accomplish in three to five hours, and it may take even longer and all be honest, yet Mr. Campbell says in effect that if he should send a machinist to set a set of valves he would fire the man if he didn't accomplish the feat in ten minutes. I trust I shall never have to strike Mr. C. for a job, for I know I would meet my Waterloo the first case of valves I got.

I worked under a master mechanic once whose method of adjusting valves was practically as described by Mr. F. C. Charles at the close of his article in the June number, and I believe that no man ever had squarer engines. Especial attention was paid to having tumbling shaft-arms proved, and shaft leveled, and lifters proper length, while engine was in shop. When ready to come out, steam was raised to a fair working pressure, then she was slowly run along by steam, and the man in charge walked along by the guides, holding the straight point of his tram in punch-mark in edge of cylinder-casting, just under steam-chest stuffing-box. Just before valve-stem stopped traveling he gave a succession of short, quick strokes on valve-stem; this was repeated for all four points, the extremes of travel being shown by the marks of the tram. The stem, of course, had previously been spaced off for the valve-seat, with the proper lead allowed (at that time they used a piece of Russia iron to give the lead). With a pair of dividers placed in the punch-marks, representing the valve-seat or edges of the ports, and extended to the points of cessation of tr[illegible] it was an easy matter to determin[illegible] he eccentric rods (or blades) neede[illegible] to divide the travel equally over ports. [illegible]ien one dead-center on each side was obtained, and the eccentrics placed in proper position just as is done in every case. No attention was paid to the cut-off matter, for it was not necessary; there was no pinching, scarcely, and all that work and time was saved, the job was much more quickly done than I had been used to seeing it, but yet it took longer than ten minutes.

The advantages claimed for that plan are. The valves are adjusted under the same conditions that the engine does her every-day work under, no trouble from undue or unequal expansion is experienced, all the operations are simpler and more easily understood and more easily performed; greater accuracy in tramming from an immovable point on cylinder, over the use of the short tram, where they tram from the steam-chest stuffing-box flange (as is the general custom). This last I consider as a most reprehensible practice, even if they are supposed to set the steam-chest with a tram mark to always insure the chest being in proper place, and lastly, but by no means of the least importance, much lung power is saved to the valve-setter and his aide in getting the engine on the dead-center eight, twelve, or more times. However, for those who are wedded to the other style, "one of whom even our friend Charles is which," I will say, there is an appliance in use that obviates the last objection in a great measure, but I am not able to give the name of its inventor or discoverer.

The device consists of two sets of rollers operated simultaneously by a lever and ratchet, the rollers are placed under the main wheels of the engine whose valves are to be set, the main wheels are disconnected from the other wheels, the wheels on the rollers are then revolved by the lever and ratchet at the pleasure of the man in charge, and all the pinching and shouting can be entirely dispensed with, to say nothing of the services of three or four laborers with pinch-bars that nine times out of ten won't pinch.

Just why this labor-saving, time-shortening apparatus does not find more favor with the men in charge of motive power, I am at a loss to understand. I never saw but two of them in use, and in one of the places it was very highly thought of; but in the other place it would be safe to say that they have forgotten they ever had it, and have gone back to the primitive old pinch-bar, and the old familiar yells of—"Pinch her ahead!" "Just a little now!" "Easy!!" "J-u-s-t shake her now!!!" "Too much; dammit, pinch her back!" etc.

W. H. Wisley.

*Nashville, Tenn.*

### Air-Brake Questions

*Editors*:

There are a few air-brake questions in the July issue of your paper about which I should like the privilege of saying a few words:

WORKING THE EMERGENCY.

I should like to ask of Mr. Wood if he has any definite figures as to the difference between the auxiliary reservoir pressure and that in the train-pipe when the emergency-valve is brought into action. The statement is frequently made, that to set the quick-action a reduction of 10 pounds must be made rapidly. This is a mistake, as an instant's opening of a large port will secure this result even though that port be closed again immediately.

This movement of the valve can be made so quickly that the gauge will not show as much as 10 pounds reduction, provided the gauge-pointer can be stopped before the quick-action sets, or, to express the idea a little more clearly, perhaps, suppose the triple-valves to be cut out and the handle thrown to emergency position and back on lap again as quickly as it can be done, the gauge will show scarcely any reduction, and yet we all know that such a movement of the valve-handle will actuate the emergency-valve. Careful tests made by Mr. Massey, of the New York Company, with a mercury gauge show that, with a heavy spring, the difference between the reservoir and train-pipe pressure at the moment the emergency-valve opens, is between 2 and 3 pounds, and with a light spring a little over 1 pound.

This can be proven to be approximately correct by a little calculation. The area of the large piston is a little over 9 square inches, which, with a difference in pressures between the reservoir and train-pipe of 2 pounds, makes a total force in movement of 18 pounds

Allowing 2 pounds for loss in moving the slide-valve and piston, or say 4 pounds, to be more generous, we have 14 pounds left with which to compress the graduating spring, and this, it will be seen, is ample for the average weight of spring.

A QUESTION OF SAFETY.

I should like to ask all our air-brake correspondents for their opinion as to whether they consider it good policy to use a plain triple-valve on engine and tender. Does it not increase very materially the liability of breaking the train in two on emergency applications? And if a plain triple-valve must be used, why should it have a large feed-groove when used with a small reservoir? Let us hear many opinions on these points.

PIERCE'S PUMP-GOVERNOR.

It is very evident that the pump-governor mentioned by Mr. Pierce as acting so queerly was not connected properly. It would act exactly as he describes, were

it connected directly to the train-pipe instead of the main drum. The chances are that the governor connection with the old valve was made with a boss on the train-pipe and this was not changed when the new valve was put on.

With Mr. Lee, in his desire to have air-brakes taken care of, I heartily sympathize. There are altogether too many brakes in the country in a useless condition. By all means let us try to find some good systematic way of taking care of them. It seems to me the trainman is the proper one to make the report, and if he were furnished with printed slips or blanks, he would be much more apt to get the facts down in intelligent shape.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

## The Private Car Built for President Lincoln, 1863-1865.

*Editors:*

From time to time, since 1866, the writer has noticed in the press and railway journals different articles in regard to the car which was built during the war for the private use of President Lincoln, and, as this important relic (now the property of the Union Pacific Railway Co.) is likely to attract considerable interest among the exhibits at Chicago, he undertakes to state for the benefit of the reading public what he knows of its history. It may be added, without impropriety, that there is probably no one now living more conversant with this matter than the writer, as will be shown before he is through.

Soon after the beginning of the war the old railroad shops at Alexandria, Va., were enlarged by the Government for the purpose of building and repairing cars. The work was under the immediate supervision of Mr. B. P. Lamason, superintendent in charge of all car work in Virginia, and the writer was one of his foremen.

Some time during the year 1863 Superintendent Lamason either conceived the idea or had received instructions to build a private car for the use of the President. The work was begun in November of that year, and was completed in February, 1865. The car was designed for the general use of the President, and not exclusively for the purpose of conveying him to and from the front, as is generally supposed; neither was the car cased inside with iron, as stated by some writers.

As the car was completed but a short time before the assassination of the President, the first trip it ever made was to bear his lifeless remains, with those of his son, which had been disinterred, from Washington to Springfield, Ill.

After the car had been finished it was photographed by the Government photographer, from a copy of which, now in the possession of the writer, the accompanying cut is produced.

In design the car was similar to those in use on the Pennsylvania Railroad, was 42 feet long inside and had raised roof with circular ends. The inside of car was upholstered on sides and ends from the seat rail to head lining, and was divided into three compartments, viz., drawing-room, parlor and state-room, the latter being in center of car. The drawing-room and parlor were connected by an aisle extending along the wall inside of car, and in the drawing-room end a saloon was placed. The upper deck was painted a zinc white, with coat-of-arms of the different States in the panels.

The car was originally planned to run on two trucks, but after being raised, braced and bolted, Mr. Lamason changed his mind and decided to mount it on four trucks, which necessitated changing the bolsters and considerable other work. The body bolsters were Ambrose Ward's patent, and the ends of the bolster truss-rods projecting through the sides of the car were covered by brass-capped nuts, as shown in cut.

Each two pair of trucks were connected by means of a truss with main center-plate in center, and four guide center-plates with curved slots, one on each truck. There were eight side bearings made of spring steel and rubber.

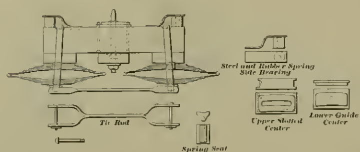
The spread of trucks was 4 feet 10 inches; wheels, 33 inches, cast iron with broad tread. The springs in truck bolsters were hung on old-style long hangers, no sand-board, but bottom of hangers tied with "U"-shaped under-rods.

No equalizing bar was used, the elliptic springs being placed on top of oil boxes. The pedestals were cast iron of a pattern so elaborate as to be difficult to describe, Mr. Lamason having spent weeks in designing them.

The outside of car was painted a rich chocolate brown, and polished with oil and rotten stone with the bare hand. In the oval center, on side of car, was painted the United States coat-of-arms, and in center of panel above the coat-of-arms, in small gold letters placed in a circle, were the words, "United States." Car was ornamented in gold, but had neither number nor name except as described. A very good idea of the hand railings, etc., on ends of car can be obtained from the accompanying cut.

PRIVATE CAR BUILT FOR PRESIDENT LINCOLN IN 1865.

*Truss for Connecting Trucks*



Mr. Lamason had personal charge of the car in the funeral train, and, as the running gear was so different from cars then in use, was attended by one man, with a supply of duplicate parts, tools, etc., to facilitate repairs in case of accident.

When the car was returned to Alexandria it was still draped in black crape, which was removed, carefully boxed and sent to the Treasury Department. The writer had the honor of attending personally to this work, and in spite of orders to the contrary a small portion of the drapery was secured, a small piece of which he still has in his possession, as well as a block of wood from the catafalque on which rested the body of the dead President.

W. H. H. PRICE,
Master Car Builder,
*Atlanta, Ga.* E. T. V. & G. R'y.

## A Defective Engineer's-Valve.

*Editors:*

We have the '92 engineer's brake-valve, with feed-valve attachment, on all engines here.

On one engine we have a valve which has caused considerable talk. The brake-valve handle can be moved to position for service application until the air is heard escaping from preliminary exhaust port from brake-valve reservoir, but not from the equalizing exhaust port, as it should; but, nevertheless, the tank and driver-brakes will be slowly applied, when engine is uncoupled from train.

Upon examination the rotary-valve was found to be in good condition, also the seat, packing good in equalizing discharge-valve piston, gaskets in good condition, and there are no flaws in castings, train-line not leaking. For a pointer, will say that rotary-valve is perforated, *i. e.*, it is drilled full of holes about $\frac{1}{64}$-inch in diameter, and about $\frac{1}{8}$ from center to center in circles around the center of valve.

F. H. GABLE.

*Texarkana, Ark.*

## What Ailed the Engineer's Valve.

*Editors:*

An engineer's valve refused to set the brakes in service application notwithstanding air would flow freely through preliminary exhaust port. The valve was taken off, thoroughly cleaned and piston 17 made to move perfectly free and put on again, but it acted as before. Now, the fault was in the valve, but where?

W. F. RELYEA.

*Syracuse, N. Y.*

## Relyea's Whistle-Signal Difficulty.

*Editors:*

In answer to Mr. W. F. Relyea's whistle-signal question on page 363, would say as the whistle blew all right before the hose was coupled between the engine and train the stop-cock on the whistle-pipe at the rear of the train may have been open, or the whistle-valve on the engine may have worked a little hard and the air discharge-valves been partly choked up with cinders. The air-cock on the gauge "combination" having a larger opening, would reduce the pressure enough to blow the whistle all right.

M. E. WATTS.

*West Nanticoke, Pa.*

THE ANSWER.

*Editors:*

The whistle-signal problem which I gave to the readers of LOCOMOTIVE ENGINEERING last month may be thus explained. There was a crack in rubber diaphragm close to the joint between chambers *A* and *B* and directly under port *d*. Now, my theory as to why the whistle would blow by opening small air-cock at the end of last coach and refused to blow when the conductor's valve was opened, is this. By opening conductor's valve, a considerable amount of air being discharged from whistle-pipe, the pressure in chamber *B*, instead of raising diaphragm, would rush through the crack in diaphragm to chamber *A*. Then port *d*, being so small, would check the flow of air enough to retain a pressure in chamber *A* sufficient to hold diaphragm down and prevent air escaping through seat and enough to blow the whistle; but the hole through the small air-cock, being but a very little larger than port *d*, would allow but a moderate amount of air to escape, or enough so that the pressure in chamber *B* would raise the diaphragm before it could force itself through the crack into chamber *A* and equalize. I have had several cases of this kind, and in every instance it was caused by the rubber diaphragm cracking near the joint.

*Syracuse, N. Y.* W. F. RELYEA.

## Conger's Pump-Governor.

*Editors:*

I had a governor that acted like Congers', and after a great deal of trouble found out that there was a sheet copper gasket put into the cavity of diaphragm nut, 16. This prevented diaphragm valve, 17, from lifting at all. C. B. SMYTH.

*Chicago, Ill.*

THE ANSWER.

*Editors:*

Small air-valve, 17, was a little too long, so diaphragm could not raise it off seat on 12. When it was shortened and plug screwed further up into 16 it worked O. K.

*Grand Rapids, Mich.* C. B. CONGER.

## That Erratic Triple-Valve.

*Editors:*

In answer to Clark L. Pierce, on "An Erratic Triple-Valve," would say that I think the trouble was in the four-way cock which was leaking, as the plain and quick-action triples are the same in other respects. Hoping some one will say something on my question through your paper, I remain as ever,

F. H. GABLE.

*Texarkana, Arkansas.*

## Case-Hardening.

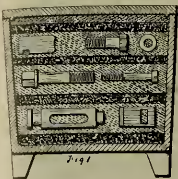
*Editors:*

It seems that certain methods of case-hardening are somewhat of a mystery to a large percentage of blacksmiths; that is, case-hardening and color at the same time, such as you see on gun-locks.

Now, this is something that cannot be explained on paper so that a man can get the same result he would get by having a little practice, but I think I can give any man an idea of how to go at it by furnishing some cuts.

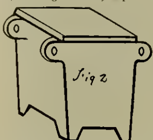
Fig. 1 shows you how to pack your material by first putting about 1 inch of fine-dry charcoal in the bottom, then about $\frac{1}{2}$-inch of fine charred bone-dust, being careful that the oil is all burned out of your

bone-dust and no ashes in it, or, in other words, none of the bones burned to ashes; then lay in your pieces as shown in Fig. 1, and cover up with this fine bone-dust about ½-inch over top; then scatter a little rock-salt over the top, two tablespoonfuls to every 12 inches of surface; then another layer of



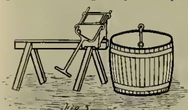
charcoal as you see in Fig. 1, and so on to the top, leaving 1 inch of charcoal on top, then about ½-inch of coarse, dry sand, then put your cover on, and put it in the furnace.

Keep it at a low red heat from 5 to 15 hours, according to size of your pieces and



the depth you want to harden, by keeping it red hot 15 hours you can harden in $\frac{1}{16}$ of an inch, but you get a nicer color by leaving it in the furnace about 6 or 7 hours.

Fig. 2 shows you the box when ready to go in the furnace, Fig. 3 the position to put



it in when dumping it. After getting your box in this position throw off your cover and quickly turn your box, bottom side up, towards your tub, being careful that no air strikes your pieces while going from your box into the tub; also have a screen in the bottom of your tub with two iron rods, as shown in Fig. 3. As soon as your box is dumped take hold of these rods, and keep your screen on an up-and-down motion so as to let your fine charcoal and bones go to the bottom and cool your pieces quicker, thereby preventing soft spots on your case-hardened pieces.

*Rochester, Minn.* W. G. LOTTES.

### A Pinless Pull-Rod for Driver-Brakes.

*Editors:*

I enclose you a sketch of an improvement in pull-rods for American Steam Brake Company's driver-brakes which, if

you think of sufficient interest to your readers, you may publish.

Instead of having the pull come on pins as formerly, the end of the rod is made solid and the rod is slipped over the lever, being held in place by a loose-fitting key-bolt through hole shown. The cost for a set of rods will be slightly more than to ream the holes and renew the pins, but once done there is no necessity for more expense.

F. W. PETERSON.

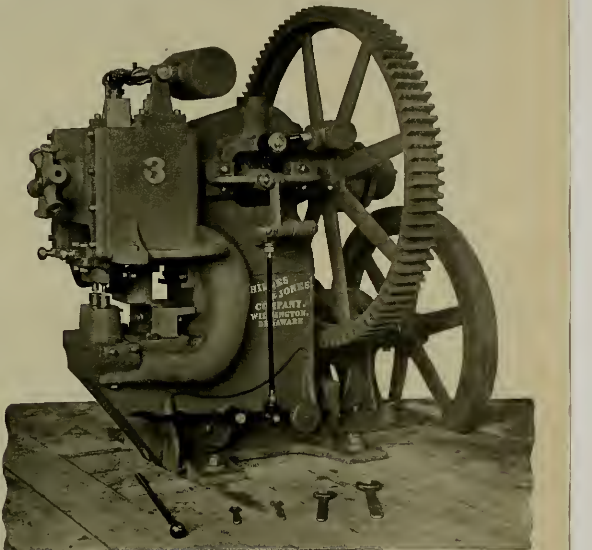
*Boone, Iowa.*

### A New Punch and Shear.

The illustration shows a single punch and shear with both punching and shearing tools attached to the sliding-head at the same time. This machine was designed for special punching and shearing of street rails, but can be adapted to many kinds of work.

Frequently there are a few holes to be punched, then a little shearing and again more punching, each change requiring the removal and substitution of proper tools. The combination illustrated would, in many cases, save the time in changing, and this accomplishes better results.

The construction of this tool has been very carefully looked after, as will be seen on examination of the cut. The sliding-head is of cast-steel, with taper brass shoes for taking up wear. The punching and shearing tools are rigidly held in place by through bolts and tongues, the blocks being also of cast-steel.



NEW PUNCH AND SHEAR FOR REPAIR SHOP.

The general features of our standard single punches and shears have been retained, such as substantial gearing, machine self-contained on one foundation, driving-shaft easily removable, well-designed steel-faced clutch operated by improved adjustable automatic stop which brings the sliding-head to rest at any desired point in the stroke, etc., etc.

This machine is one of the many boiler repair and shop tools made by the well-known works of the Hilles & Jones Co., Wilmington, Del.

### Filing Rod Brasses and Lining Rods.

A correspondent writes us asking for full directions how to file side and main-rod brasses and how to line them up. This is to a great extent a question involving manipulative skill, which can be acquired only by practice. No man need expect to learn to do machinist work by studying directions about how the work is done, any more than he can expect to learn writing by looking over letters written by other people. He must put his hands to the work and learn by practice.

But we will give a few hints on filing brasses and lining rods by one who has been there. As a preliminary to filing side-rod brasses, put up the wedges of the engine and set the cranks on the eighths, where they should be trammed with driving-wheel centers. Should the crank-pin centers be found a little out of true, the difference can be divided by making crank-pin centers a little longer than dividing-axle centers on one side and a little shorter on the other side of the engine. To prevent binding, make the back and side-rod brasses as much larger than the crank-pin as the rod centers are longer or shorter than the axle centers. File the brasses so that when keyed they will bear brass to brass, the joint being square with the body of brass; that is to say, at right angles with the upper surface.

To line up main-rod, move the crosshead until the piston strikes the cylinder-head,

then mark on the guide the point reached by the crosshead *A* in sketch. Then move the crosshead to the back end of guides till the piston strikes the back cylinder-head, and mark the piston on guide, as at *B*. Place the crosshead at one end as shown in cut, and measure distance between end of crosshead and striking point, which, in the case illustrated, is 24¼ inches. As the stroke of crank is 24 inches, there is ¼-inch clearance, which will make the clearance at each end ⅛-inch. Pinch the engine upon the dead-center and line up the rod until the end of crosshead is ⅛-inch from the striking point, and the clearance will be evenly divided.

Apart from the danger of the piston striking the cylinder-head when the clearance is not evenly divided, there are other reasons why the piston should be made to travel to the same distonce from the two cylinder-heads. If in this case there is only $\frac{1}{16}$-inch clearance at one end and $\frac{3}{16}$-inch at the other end, the engine is likely to have excessive compression on one end and too little on the other. The smooth working of the engine and economy in the use of steam require that the clearance space should be evenly divided.

---

The Baldwin Locomotive Works are building a double-ended locomotive for the New York and Brooklyn Bridge. This engine will be about twice as heavy as the little saddle-tank engines used at the bridge terminals to switch the trains. It is not generally known that the cable on the bridge is stopped at 1 o'clock A. M., and for three hours, during the lightest travel, the trains are hauled by locomotives. This has heretofore required a double-header. The bridge is an arch, the grade being 3½ per cent., and the new engine is guaranteed to haul 120 tons over this mile-and-a-quarter of the handsomest bridge in the world.

### A Chance for a Broker.

We are in receipt of the following letter:

DEAR JOHN A. HILL—I thought I would write a few lines asking if you could help me get a job as fireman on the Lake Street Elevated Line of Chicago, Ill., and, if so, let me know. I will send you $25 in return. Yours truly,

---

### New Air-Brake Pressure Regulator.

The Air-Brake Pressure Regulator Company, of Chicago, has lately brought out a device designed to proportion the braking pressure to the load, thus making available for braking purposes a large proportion of the weight of the freight carried, as well as the weight of the car itself, without danger of skidding the wheels.

It has been the aim in designing this device to make no change either in the cars or trucks as now commonly used, in the general design and proportioning of the brake rigging, or in the present automatic air-brake devices; also to make the apparatus as simple as possible and the braking device of each truck of the car independent of those of the other truck.

The apparatus consists of two distinct devices, the first of which accomplishes an increase in the braking pressure without an increase in the train-line pressure or the piston travel. This increase is made by increasing the leverage of the cylinder-lever and introducing between the push-rod *A* and cylinder-lever *G* the combination of levers shown. It will be readily seen that with the combination the first part of the stroke of the piston gives a very rapid motion to the cylinder-lever, but that after the joint between links *D* and *F* drops into the socket on the corner of the triangular lever, the motion of the cylinder-lever is greatly reduced and the leverage correspondingly increased.

The second device is designed to prevent the skidding of wheels, and it consists of a system of levers so arranged that an application of the brakes tends to raise the ends of the car, and so proportioned that the end of the car does rise when the braking pressure amounts to about 70 per cent. of the weight of the car and load. Any further increase in brake-piston travel will only raise the car, and any increase or decrease in load will correspondingly increase or decrease the braking pressure. The arrangement of levers is such that even with a load unequally distributed in the car, the braking pressures at each end will be proportioned to the load above. This is accomplished by relieving the brake-shoe pressure by the introduction between the truck and car body of the lifting-lever *I*' and the bent lever *L* to which latter the brake levers are connected and through the movement of which, by the lifting of the car, the braking pressure is prevented from increasing above a predetermined maximum.

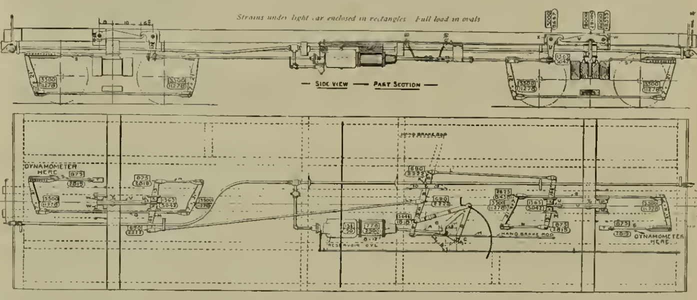
It will be seen that the air-brake reservoir and cylinder remain in their usual position, and that between them and the cylinder-lever are interposed the triangular lever and links, to which previous reference has been made; also, that in order to make the braking pressure on the two ends of the car independent, the cylinder-lever *G* is pivoted at *K*¹, and the lever-rods *L* and *L*¹ connected to it at equal distances each side of the fulcrum. These rods are shortened, and instead of running to the farther brake-lever, they are connected to an equalizing-lever situated between the brake-levers. From the opposite end of the equalizing-lever a short link connects it with the end of the inner brake-lever, and from there on the connections are as commonly used. The equalizing-lever is fulcrumed on the lower end of the bent lever *L*'. The upper end of the bent lever bears on the top of the lifting-lever *I*', the opposite end of which is fixed between the center-sills. The fulcrums of this lever is the top of the kingbolt, which is provided with a heavy collar bearing upon the lower center-plate.

It will be observed that though a number of pieces have been added to the braking equipment in this apparatus, there are several standard parts which have been dispensed with, among which are the elevating-lever with its rod and brackets

This company has in the Transportation Building at the World's Fair two cars equipped with its devices These are a Wisconsin Central freight car of 40,000 pounds capacity and weighing 28,000 pounds, and a freight car of 40,000 pounds capacity, built by the Harvey Steel Car and Repair Works, weighing 25,700 pounds.

Upon a test table near by are eight gauges, divided into sets of four each, one set being connected to each car Two gauges in each set are connected to water dynamometers, of which there is one at each truck so placed and proportioned that the braking pressure applied to the truck-wheels is indicated by the gauge The third gauge is connected with the braking-cylinder, showing the pressure applied there, and fourth gauge to the reservoir, thus indicating the train-line pressure. A Westinghouse engineer's valve furnishes the means of applying brakes

A test made on the Wisconsin Central car gave the following results The car at this time was loaded with four small trucks filled with scrap-iron, each truck with its load weighing 2½ tons, or 10 tons in all, the loads being so arranged that they could be moved from one end to another of the car at will



— PLAN —

| Kind of Brake | Air pressure in lbs per square inch: Train Line. | Final in Cyl'r | Kind of Application | Total braking pressure in pounds: West Truck. | East Truck | Distribution of load in tons: West Truck | East Truck |

### Arbitration Committee Decisions.

It requires careful study of the Rules of Interchange of Cars and clear judgment to decide who is in the right when a dispute arises about damage or repairs done to foreign cars when they are away from home. Cases occasionally arise in which it is exceedingly difficult to do justice between conflicting interests. But these cases are the exception. Nearly all cases that cause contention would be readily settled if both parties to the dispute were properly informed about the rules The rules have been established on a system of mutual concession, and a man cannot tell what his rights are under the rules by mere exercise of common sense. Yet this inclination to use common sense in discussing questions of car interchange leads to many disputes when the common sense is not fortified by a knowledge of the exact wording of the rules. To those who are annoyed with disputes about interchange of cars we would say, study the rules and you will always come out the winner.

The Arbitration Committee's decisions form very valuable reading for those who are interested in avoiding disputes with connecting lines It is surprising how often in these decisions we find the same subject of dispute being referred again and again to the arbitrators. The following are abstracts from a few of the latest decisions.

---

A dispute arose between the Alabama & Vicksburg and the C., B. & Q because the latter company charged their shop cost price for an air-hose The A & V. claimed that the other company's charge was 32½ cents above the market price. The Arbitration Committee held the market price to be the basis of the correct charge

---

An inspector belonging to the Aransas Pass Road issued a defect card for a broken transom on a car belonging to the Cudahy Packing Co. Under the rules of interchange owners of cars are responsible for breakage of transoms and body bolsters unless the damage results from derailment or wrecks, and therefore the carding was not necessary in this case. But the owners of the car claimed cost of the transom on the card, and on payment being refused the case was referred to the Arbitration Committee. They decided that the railroad company was not responsible because an inspector made a mistake, and the charge was not allowed.

---

The Pittsburg & Western put two new truck timbers in a Union Pacific car, and the owners claimed that green timber had been used which shrunk three-quarters of an inch and was still shrinking, so they were removed and a claim made for the involved expense The P & W claimed that the timbers put in were the same size as the old ones, and therefore all had been done which the rules required. On the case going to the Arbitration Committee it was decided that the work was not done with the thorough care enjoined by the rule. Consequently the P. & W were held liable for new timbers.

---

One of the worst-known cases of ignorance of the Rules of Interchange was displayed by the Intercolonial Railway in a dispute with the Canadian Pacific The latter road had an I. C. car which had badly decayed bolsters. A request was sent to the owners for a home card, but it was refused, and the case was referred to arbitration. The decision was a quotation from Rule 11, which says that when a car is unsafe, from age or decay, to run, the owners must provide a home card for the return of the car.

---

A dispute arose between the Newport News & Miss. Valley and the Austin & Northwestern, of a character difficult to settle justly to both parties The former road made a charge against the latter on account of having renewed certain journal bearings. The payment was refused on the ground that the cars were new on their way from the makers and that the journal bearings were not worn out, but that they broke through being permitted to run hot The N N & M V held that the heating was due to bad material or bad workmanship. The Arbitration Committee decided that the latter road was responsible, the inference being that careful attention to oiling would have made the bearings run cool. The decision is probably the fairest that could be given, but it leaves railroad companies to bear the loss, delay and annoyance caused by the car builders who turn out journals as rough as files

---

The Atchison, Topeka & Santa Fe destroyed a car controlled by the American Refrigerator Transit Co , and agreed to return the trucks, but claimed that delivering them at the point on the A. T & S F nearest St. Louis, the headquarters of the A R. T. Co , was performing their part of the agreement. The owners of the car would take nothing short of delivery of the trucks in St Louis and the case

THEIR SUPERIORITY IS PROVEN BY THEIR POPULARITY.

## "AJAX BEARINGS: RECORD 90 MILES AN HOUR."

"EMPIRE STATE EXPRESS N.Y.C. & H.R.R.R."

AJAX METAL CO. INCORPORATED. PHILADELPHIA, PA.

went to arbitration. The decision was that in equity a railroad company destroying the car of a private company was bound to return the trucks to the repair shops of the owner.

In a transaction connected with the changing of wrong draw-bars, the Keokuk & Western would only allow the Atchison, Topeka & Santa Fé credit at the rate of ¼ cent per pound for the value of wrong draw-bars removed. The latter road claimed that according to the rule in effect at the time they were entitled to a credit of two cents a pound for cast iron and four cents a pound for malleable iron. The Arbitration Committee sustained the claim.

The American Refrigerator Transit Co. raised a dispute with the Erie over a case that was very clear under the rules. The Erie people removed a bent axle from a car controlled by the Refrigerator Company, and the owners refused to pay the usual charge, on the grounds that the axle was up to the M. C. B. standard, and must have been bent by derailment, or that the M. C. B. standard size is of no value. There was no evidence of maltreatment, and the Erie people insisted that the bill should be paid. On the case going to the arbitrators, they gave decision according to the clause of rule 9, which says that owners of cars are responsible for charges caused by bent axles.

A considerable portion of the disputes sent to last meeting of the Arbitration Committee were raised by owners of private cars. Some of these companies are very unreasonable in their dealings with railroad companies.

## Reports of Timber Getting Scarce.

A report published by the Forestry department of the Government gives many useful suggestions about the economy and preservation of our timber supply, which ought to receive the attention of those interested. The Forestry department is doing useful work on this question and, although sending out warnings, does not deal in sensational alarm statements. There have been so many sensational fallacies published about the impending disasters from the destruction of forests that the people are getting to consider all such alarms false.

The alleged meteorological results of so-called denudation, as touched upon in the paragraph quoted above, have been time and again exploded by well-known facts. Saying that the destruction of the forests is exerting an "unfavorable influence" as to water and soil conditions is putting the case more mildly than denudatics usually do, since they ascribe to the fact all sorts of climatic extremes.

But to start out with, the denuding of forests has not resulted to the extent usually implied. While white pine has disappeared rapidly, and continues to so disappear, from the forests of the Northwest, large amounts of untouched hardwoods remain, and important hardwood growths have followed the removal of pine in many localities. Thus the forests have not in all cases been denuded at all, nor deprived of trees sufficiently to have any potent influence on rainfall, soil moisture, drouths, cyclones, floods, earthquakes, volcanic eruptions and various other nightmares of the denudatic intellect. It may be accepted as a fact that the actual and complete denuding of forests is seen in clearings made for agricultural purposes, and not through the domain of saw-mill timber cut over for the available pine, where a rank undergrowth often flourishes. If forests are necessary to rainfall and proper soil conditions, it does not follow that a particular kind of tree is any more essential than another kind. An oak or ash belt is likely as good as a pine grove for that purpose.

## War Time Reminiscences—Captured by Confederate Cavalry.

BY JAMES H. HEVES.

The exact date of this incident in my experience while running an engine for the Federal Government has slipped my memory. My recollection is that it was extremely hot and the year 1864. I left Chattanooga with a full train (fourteen cars) of horses for the use of the line officers of Sherman's army. Nothing occurred until we stopped at a water-tank between Tilden and Resaca, where a lieutenant and several private Confederate soldiers mounted the engine, at the same time informing myself and fireman that we were their prisoners. They immediately proceeded to tie us in such a manner that escape was impossible. While the little party were securing us, the balance of the command were busy securing conductor Kelly (died in insane hospital at Nashville of patent smokestack on the brain), and his crew. After securing the crew and driving to the bush the train-guard, they opened the doors of the cars and jumped the horses out.

I was ordered to fill the engine's furnace full of wood and leave her to her fate. Now, the damper shut very tight, and the wood, green pine, luckily did no damage to the flues, and the next train south pushed engine and train into Resaca. I asked Captain Jim O'Niel why he did not burn the train, and was informed that it was too near a d—d Yankee post, and that a big smoke would have Captain Callahan and his Third Indiana Cavalry in his rear in twenty minutes, and the good haul of horses he had made was enough for him if he succeeded in getting them into General Forrest's camp.

For some reason which I never learned the command divided; one company in command of Captain Martin, came down the west bank of the Oostanaula River. This is the one with which myself and fireman were destined to eventually have a rather exciting experience. It was several months before we again saw Kelly or any of his crew; how long they remained prisoners I never learned, as Kelly always refused to speak of it. From the tank we marched through the woods, perhaps five miles, where we struck the old Georgia dirt road; here they sent out scouts, and we had a lunch of "corn pone" and fat bacon. By this time "Old Sol" was pouring his effulgent rays down with a pressure of about 95 degrees. I think eggs buried in the dust of the road would have roasted. In these days I think North Georgia is blessed with more pure spring water than any other State in the South, but that day it was hours between springs. Then the party escorting us were bent on putting as many miles as possible between the scene of their good fortune and Dan Callahan's cavalry as possible. After making about twenty-two miles and being within three miles of Rome we went into camp for the night, the spot chosen was on the bank of the river, in a fine grove, where Sherman's men had left several good chimneys to build houses around.

After a supper of what we lunched on at noon our entertainers for fear we would in our extreme modesty at being so royally entertained, in the hours of the "stilly" night fold our tents and stealthily scout back to the "Yanks," proceeded to very securely secure us to a large oak tree, our hands were tied behind us and a rope passed through the cords on our wrist, which was passed around the tree and made fast so it would not slip. I was soon in the land of dreams, not so with Burnett. It seems that he in some manner got one hand loose and made his way around the tree so that he could awaken me by pinching my arm. As soon as I realized who he was I whispered and asked if he was loose. "No, but have you got a knife?" I told him where it was and he got it, opened it with his teeth and cut me loose. Being free we proceeded to reconnoiter. Everything was still; we could hear no tread of any sentinel and commenced rolling toward the river, at the foot of the hill.

A roll and a look and listen, then another roll, etc., until we reached the water edge. A quiet sneak along the bank soon brought us to a drift; here we found a slab from a saw-mill; this we launched, proceeded to strip and bundle our clothes, which we secured to the slab with our suspenders. Hearing no noise in the camp of our captors we quietly took to the water and headed for the other shore, which we reached after being carried down the stream—which had a very rapid current—some distance. Safely landed on the other side we took a star for a guide and started eastward, destination Kingston.

Traveling a few miles, we crossed the grade of a railroad that had some ties piled along it—this was the Selma, Rome & Dalton, now a part of the Georgia Div. E. T. V. & G. We must have crossed it near Harper's Station, three miles north of Rome; I know we traveled in a ravine a long time, until we came to a small creek (branch); this we followed to the mouth, where it emptied into a river. This we concluded was the same stream we had crossed when making our escape from the "Johnnies." We finally concluded to travel up it a ways, and see if we could find the Rebel camp we had just left. After a time, we noticed such a difference in the lay of the country, we made up our minds to crawl in the bush, and await for daylight before we tried going further.

In the bush, we got some sleep, in spite of the mosquitoes and ants. Morning came at last, when we took a survey of our surroundings. We found ourselves on the banks of the Etowah River, and close to the Rome Railroad. This road we knew would take us to Kingston, if we could succeed in keeping out of the way of the Rebs. There were several houses and many negro cabins on the bluff, about a quarter of a mile from the river, there was also quite a number of men circulating about the houses; also a few saddled horses, which were soon mounted and ridden away.

Now was our opportunity to skirmish for a breakfast, as we saw nothing but women. Burnett said he would take the chances of getting a bite of something to eat. From the river to near one of the cabins there ran a deep, dry ditch—I have learned since, to drain a low spot back of the houses after an overflow—up which Burnett made his way to nearly opposite the house, where he succeeded in attracting the attention of a good old negro woman, who for one of Uncle Sam's greenback promises to pay, gave him a bountiful supply of good pone and bacon; also informed him "Dat dar want no trouble 'bout gettin' to Kingston except at Mars Wooley's, but dat Mars Wooley's two boys war mighty bad after de Yanks."

We breakfasted and proceeded on our way, keeping well under cover of the river bank until we arrived at Dike's Creek, where there is a house very near the bank of the river and close to the track. In front of this house two horses were hitched, ready saddled and bridled. It would be impossible to pass them on that side of the river, so we crossed to the other side, which was densely covered with cane. After proceeding about a mile up the south bank we crossed back to the north side, which brought us out on the Hargrove plantation, where we met a negro who had been a slave on the Johnstone place, who agreed to pilot us around the Eve and Wooley places, but while talking to the negro we heard the rumble of wheels of an engine, and very soon one came in sight, it was "U. S. 134," Sam Laird engineer.

I stepped on the track and with my hat gave him a stop signal, as soon as he saw us he reversed and went back to Kingston, where he reported the woods full of guerillas. Great excitement prevailed, the iron-clad car was got out and put in front of the engine and about forty men detailed to go out on the road and annihilate the bushwhackers, at the same time three companies of cavalry were mustered to scour the countries for Johnnies. All this time our little party were patiently toiling up the road, keeping well under cover of the river bank and near the railroad. It was well for us I suppose that we did, for about three o'clock P.M. we again heard the rumble of wheels; our party crouched low in the cane-brake. This time the engine passed before we made any sign of our presence.

Perhaps, before concluding, I had better, for the benefit of your readers, describe this iron-clad car. It was an ordinary long flat car, with rounded ends, the sides and ends were built of heavy oak timber, plated with boiler iron, in which, at convenient intervals, loop-holes were placed, only large enough to conveniently let a musket work freely.

After the car and engine had passed, I again jumped onto the track and signaled them to stop, which they did. When I informed the captain that there were no Rebs in the vicinity, he said a few cuss words about the man who would get up such a scare on such a hot day. It was a long time before Laird heard the last of the woods full of Johnnies.

On our arrival at Kingston, I found the "U. S. 126" O. K., except the tool-box, which was empty, the most highly-prized tool taken being my Smith & Wesson.

## The Beneficent Railroad.

The *Weekly News*, of Dundee, Scotland, makes the following comment on railways in connection with the sending of a railway engine-driver to Chicago to make notes about American railroads:

"The swift appliances of modern civilization—the locomotive, the telegraph and the steam printing-press—have effected a transformation of the face of the earth. New territories have been opened up, and an abundance of cheap land has in consequence relieved the pressure that existed in congested countries, and done not a little to promote the general welfare of the people. Barbarism has disappeared before their advance, and they have been able to impress their stamp upon the character of communities.

"The railway in our time has done more in one generation than the slow evolutions of many centuries had brought about, and in the Western States of America we have this illustrated. There was first the railroad, then the town, then the farm.

"Chicago itself owes more than any other city in the world to the locomotive, for it was the railway companies which chiefly helped to build it up. Fully one-third of the railway systems of the United States centers there, and, with its branches, comprises over 60,000 miles of permanent way. Here, then, is afforded an opportunity for investigating the methods of railway labor unequaled in the whole world. Such inquiry is of interest to the general public as having a direct bearing on its safety and its comfort. Public opinion claims a right to express itself regarding the hours of railway men, the fitness of appliances, and the facilities for rapid and comfortable traveling. These are matters that require looking into, for nobody pretends that there is not ample room for improvements and reforms, and it may be sufficient to mention that the systems of machinery in use in mines and private works are in many cases far more effective than those on our railways.

"Another matter of universal interest connected with this department is the working of insurance against death, accident, etc., something of which nature in a general way has been recently advocated in Parliament. The insurance of workmen by their employers is certainly worth knowing something about. It is also worthy of mention that the engine-drivers have one of the most successful organizations in America, and their society has, during its thirty years' existence, evolved many difficult labor problems, and settled not a few.

DO YOU WANT TO KEEP YOUR PAPER CLEAN ?

WE will deliver free to any part of the United States a Patent Binder that will hold twelve papers in book form for a little, old one-dollar bill.

LOCOMOTIVE ENGINEERING,
5 BEEKMAN STREET,
NEW YORK.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa.

SINCLAIR & HILL.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates. They are made by BRADLEY & POATES, 251 William Street, New York City.

### Brooks Suburban Locomotive.

Gauge—4 ft. 9 in.
Fuel—Bituminous coal.
Weight in working order—166,000 lbs.
Weight on drivers in working order—102,-000 lbs.
Weight on forward truck—16,000 lbs.
Weight on rear truck—48,000 lbs.
Driving wheel base—15 ft.
Total wheel base—35 ft. 9 in.
Diameter and stroke of cylinders—18 x 24.
Diameter of driving-wheels—63 in.
Diameter of boiler—58 in.
Number of tubes—250.
Length and width of firebox—102 x 32 in.
Coal capacity—4½ tons.
Capacity of tank—2,600 gals.

We would especially recommend the ample and substantial hand holds and steps on this locomotive. It also has a large, comfortable and handy cab, set up so high that the engineer can see as he ought to.

### Brooks Consolidation Freight Locomotive.

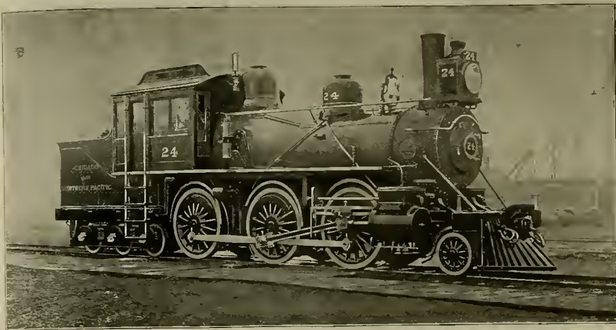
Gauge—4 ft. 8½ in.
Fuel—Bituminous coal.
Weight in working order—147,000 lbs.
Weight on drivers in working order—130,-000 lbs.
Rigid wheel base—15 ft. 6 in.
Total wheel base—23 ft.
Diameter and stroke of cylinders—13 x 26, 22 x 26 in.
Diameter of driving-wheels—55 in.
Diameter of boiler—63 in.
Length and width of firebox—114 x 32 in.

TENDER.

Coal capacity—8 tons.
Capacity of tank—4,000 gals.

ENGINE AND TENDER.

Total wheel base—49 ft. 11¾ in.



Brooks Heavy Suburban Locomotive. Now at World's Fair.

Brooks Tandem-Compound Consolidation. Now at World's Fair.

The National Machinery Co., of Tiffin, Ohio, has issued an illustrated circular showing a new rock-crusher which the company has put upon the market. The machine embodies the Lowry patents, and is of the gyratory type, which is conceded to be the best for stone-crushing where uniformity of product is desired. The ball-bearing or fulcrum is below the head, thereby giving maximum power and leaving the concave entirely open. A variety of other superior features are claimed for the machine. It is made in a remarkably substantial manner, and is likely to prove durable under the severe strains and shocks of service on hard rock.

---

James Murray, a noted mechanic of Baltimore, who in 1848 built the curious old freight engine "Mt. Clare" for the B. & O., was the first man to design and build a roundhouse, having radial stalls arranged around a central turntable. He went to Russia with Winans and spent many years in the service of the Czar as master mechanic.

### Motors Taking the Place of Locomotives.

The cities of Louisville, Ky. and New Albany, Ind., are divided by the Ohio river and they are connected for purposes of intercommunication by certain bridges and railroads. The principal means of transit between the two cities has been by a suburban steam railroad, operated by the Kentucky and Indiana Bridge Co., which is a controlled interest of the Louisville, New Albany & Chicago Railroad. Trains over this company's lines and bridge were run about every half hour, pulled by dilapidated Forney locomotives, that looked as if their day of cleaning came only once a year. We do not know how it was that the transportation company got tired of locomotives, whether it was the general slovenliness displayed by the men in charge or the limping discords made by the exhausts, or the smoke, or the rattle of the loose machinery. Certain it is that the company got tired of locomotives and determined to try electric motors.

The resolution in this direction was quickly put into practice and the locomotives have been pushed for good into the back stalls of the engine-house and neat electric cars put into their place. All told there are fourteen new electric motors put upon the service, and each propels a car which seats forty-eight persons and gives standing room to others in proportion to their clinging characteristics.

The novelty of this change is principally notable because steam locomotives and trains continue to be run over the bridge and part of the track used by the electric motors. The latter receive power through a trolley connection with an overhead wire, which is raised high enough to allow common trains to pass. The only radical difference between these electric cars and those generally found on street-car service is that they have large wheels like an ordinary railroad car and flanges made on the M. C. B. pattern.

The men who operate these cars are not so fortunate as the enginemen and conductors of the steam locomotive and train. There is one motorman and one conductor employed in the new service, and they are paid 16½ cents and 15 cents an hour respectively. The motorman appears to have about as responsible a position as the engineer of a suburban steam train, and we do not see the fairness of paying him half the other man's wages.

---

We often see, says the *Tradesman*, a boy drilling cast iron for the first time, and when the drill squeals a little he naturally treats it the same as any other metal he has drilled, and squirts a little oil into the hole to stop the squeak, and nearly always stops the drill from cutting also, as the oil on the cast iron forms a glaze, which the drill slips over instead of cutting through. Sometimes clean water will stop the squeak and not glaze the iron, and then sometimes it will act almost as bad as oil, so the best thing to do is to keep the drill sharp enough to cut in good shape and also to relieve the gliding sides so as to take off as much friction against the sides of the hole as possible. Of course, this must not be overdone, and enough must be left to give the drill stability, so as to drill a round hole instead of a polygonal one, which is usually three or five sided.

---

The Boyer speed-recorder is making its way slowly into popularity in this country, but its merits seem to be more thoroughly recognized abroad than they are here. The company has just received an order from Russia for a number of instruments, and there are good prospects of its being adopted as a standard attachment for locomotives. About 300 recorders are now in use on English railways, and several have recently been ordered by the New York Central.

# ? A. What You Want to Know. ? A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(87) English, Chicago, Ill., asks

Please tell me the weight of the train of the Lake Shore "Exposition Flyer," there is a dispute about it here. *A.*—The cars of this train weigh 80,000 pounds each; there being four of them, the weight of the train is 320,000 pounds when running without the dining-car; when this is attached the train weighs 400,000 pounds, or 200 net tons.

(88) C. B. W., Savannah, Ill., asks:

What is meant by cylinder condensation? *A.*—The steam that enters the cylinder contains only sufficient heat to keep it in a gaseous condition. The least abstraction of heat causes part of the steam to turn into water. The metal of the cylinder being cooler than the steam causes some of the latter to fall to water, and this is called cylinder condensation.

(89) Gobo, Helensville, Auckland, New Zealand, writes

I am running a six-wheel coupled saddle-tank engine without a bogie, and we'll suppose we have a leading tire broken. If I jack up the leading wheels clear of the rails can I run home with a light train after having taken down leading coupling-rods? *A.*—It would hardly be safe, especially if the main or center wheels had no flanges; if they had flanges it would be.

(90) D. O'Brien, Mancelona, Mich., asks

1. How can a person find the speed a train is running at by sight? Have heard it was possible, but never learned how. *A.* There is no way. Engineers and other trainmen of long experience learn from daily practice to know by looking at the ground very nearly how fast they are running. 2. What keeps one of those velocipedes on the track when the rider sets over the two larger wheels? The wheels are conical and the flanges do not touch the rail. *A.*—The cone of the wheel keeps the machine centered on straight track.

(91) John S. Clemons, Albany, N. Y., asks

1. Is there any book published on accidents and remedies to W. air brakes? If so, what is the price and whom can I get it from? *A.*—The best work on this subject is "Air-Brake Practice," by J. E. Phelan, or the Westinghouse Instruction Book. The first can be obtained from the Debs Pub. Co., Terre Haute, Ind.; the second from the W. A. Brake Co., Pittsburg, Pa. 2. In beaking a main tire on an American or mogul engine must the spring of the driver be taken out to block it clear of rail? *A.*—Yes. 3. Must engine be jacked up off of wheel and wheel then be jacked clear of rail to block, or can the wheel be run on a wedge and blocked after spring is taken out? *A.*—It is not necessary to jack up at all; run the wheel on blocks. 4. If the engine D wheel have to be jacked, where would you place jack? *A.*—Don't jack. 5. When conductor's valve is open on train or hose blows off while running at high speed, should engineer's valve handle be thrown full on (fifth stop), or should it be placed immediately on lap (third stop)? *A.*—On lap, as this saves the air in main reservoir to release brakes when repairs are made. 6. When an engine's spring-hangers are cutting into boiler, how can it be remedied? *A.*—Change them. 7. When an engine is too low on one side, how can that side be raised? *A.*—By putting shims on the spring-hangers or packing up under driving-box saddles. 8. What is best way to fix an engine's driving-box when it is broken vertically through center, so as to get engine to shops without cutting bearing? *A.*—Relieve that bearing of most of its load. 9. If a spring to a pony-truck breaks and you have not got another, can it be blocked over top of box like a driving-spring was broke? *A.*—Yes. 10. In jacking a mogul engine to put a spring in back driver, which is best, to cut engine loose from tender and put jacks to rear (one on each side), or leave engine and tender coupled together and put both jacks on same side (one front and one back)? *A.*—If you have surplus energy and muscle that must be used, it might do to leave the tank on and lift it. If you want to get the spring in, jack up the engine square; if you want to tip her over, jack on one side only. 11. When double-headers are being run and head engine handling brakes, and from some accident the head engine's brakes fail and engineer wants to signal rear engine to handle brakes (air, I mean), what whistle-signal does he blow, and how should rear engine answer? *A.*—A special rule is used on each road where double-headers are run. Usually a call for brakes from the head engine puts the second man on guard. 12. If you started on a trip at 12.00 o'clock at night, in making out your report what would you put after 12.00 to designate it? If it was 12.00 at night you could not put 12.00 A. M. or 12.00 P. M.? *A.*—12 night or 12 midnight.

(92) R. L. V., Columbus, Ga., writes

1. What is the best way to get an exact dead-center on the road without a tram? *A.*—A dead-center close enough for all practical purposes on the road may be found by watching when the crosshead is at the end of its travel. Here is a more elaborate and more accurate method: Pinch engine until crosshead is near end of travel. Place two-foot rule on end of crosshead, and with a pencil draw line on guide at that point. Then open rule to make a right angle, and put one side flat on wheel cover and push other end as flat as possible on tire. Draw lines at the edge of rule on wheel cover and tire. Pinch engine till the crosshead comes back to the mark made on guide. Then place foot-rule exactly in position it was in before on wheel cover, and make a mark on tire where other end of rule comes. There will now be two marks on the tire. Bisect them—that is, make a mark half-way between. Lay rule on wheel cover again and pinch the engine. When the half-way mark on tire comes to edge of foot-rule the engine will be on dead-center. This is making a rule take the place of trams. 2. Why is it that machinists file rods and brasses without finding out striking point of piston? *A.*—Some machinists are like some other careless people, and will take chances to save work. Men with an interest in their work never put up a main-rod without finding the striking points of the piston. 3. In jacking up one pair of wheels of a tender-truck to chain them clear of the rails for a broken flange, where would you place the jack? *A.*—Take some weight off by jacking up tender, then put jack under axle. It is better practice to take wheels from under a box car and change the tender-wheels. 4. In jacking a pair of driving-wheels up for broken flange or axle, where would you put the jacks? If they were put under the axle, how would the top of jack be fixed to prevent axle from slipping off? *A.*—Run the engine on wedges, or frogs, and avoid jacking. In jacking up an axle, put piece of wood on top of jack to form seat for axle, as may be seen done in nearly all engine-houses daily. Keeping your eyes open when visiting the roundhouse is not a bad way to obtain information of value. 5. If the front springs of mogul engine broke and you had none to replace them, is there any other resort than blocking on top of front boxes? *A.*—No. 6. Suppose you broke the radius bar-bolt of a mogul engine and had no chain, what would you do? *A.*—Block the bar in position, or run slow till a chance could be got. The answers to the other questions ought to be obvious.

### To the Foremen Blacksmiths of the United States.

Your committee appointed to ascertain the number of foremen blacksmiths favoring the establishment of a national organization for mutual benefit have received such a large number of favorable replies that we are decidedly of the opinion that we are justified in calling a meeting for that purpose, to be held at Chicago, on the 5th of September, at 10 o'clock A. M., at 901 Rookery Building.

We hope to have a large attendance, and respectfully solicit the hearty co-operation of our friends, the master mechanics and other railroad officials, who have heretofore been alive to our interests, and who, so far as we have been able to communicate with them, have expressed themselves as favorably inclined to our laudable undertaking, and we feel confident that we can rely on their advice and assistance.

We cordially invite representatives from the mechanical press, and iron and steel houses, who may be interested in our better education as to the manipulation of their products.

Hoping that those who are eligible will make strenuous efforts to be present with proper credentials, we remain,

Very truly yours,
J. J. Thornton,
C. H. Williams,
W. G. Lories,
Geo. F. Hinkens,
Committee.

### Could Not Break Him.

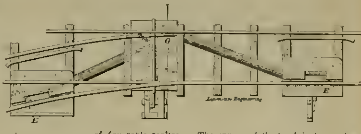
The telegraph operator at X. had a reputation for never "breaking." The boys at Bu. had tried it over and over again. Finally Charlie H., who had recently come to Bu., and who was considered a rapid sender, concluded he would try it on X., and accordingly gathered up a batch of thirty-five or forty messages for the occasion. X. answered with his usual promptness, and was informed that he might expect them to come red hot. Charlie took off his coat and sailed in. Ten messages off and not a break, twenty, and no signs of being hurried at the X. end, although Bu. was sweating at every pore; later on, the whole batch had been sent without a break. This was wonderful, and Charles was crestfallen. Half an hour later the manager at X. called Bu. on another wire and asked that office as a special favor to let them know any time they had such a heavy business for X., as the operator had about 4,000 yards of paper strung out on his instrument, and the instrument itself was not in very good fix. This "fly" operator had an old-fashioned Morse register that done its own "taking."

No further efforts were ever made in Bu. to break a register.

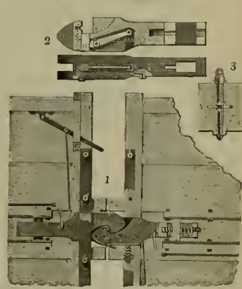
### A Safety Switch Lock.

O. W. Tew, of Rome, Ga., an engineer on the E. T. V. & G., has recently patented a switch lock that prevents the turning of the switch except in the presence of a train—thus preventing malicious persons from tampering with switches away from stations.

He accomplishes this end by putting a lock under the throw-rails, which can only be opened by pushing down the spring of a track instrument, one of which is located fifty feet or so in front of the switch on the main line, and the other the same distance on the siding.



The spring of the track instrument can only be compressed by the flange of a car or locomotive. The sketch makes the device plain; if the track instrument is compressed it releases the lock by moving the piece *G*, when the switch is moved to the main line again it locks itself automatically. This device has been tried on one of the steam tram-roads of Rome, Georgia.



### A New Combination Car and Air-Hose Coupler.

Mr. Robert N. Ervin, an engineer on the G. C. & S. F., at Temple, Texas, has recently taken out a patent on an improved form of Miller coupler.

He has special arrangements for attaching his device to the car, but the most radical departure from general practice is in the formation of an air connection through the coupler and the doing away with air-hose.

The drawheads are made of malleable iron and have interlocking tongues and grooves to prevent vertical movement. The air connection is made through the center of the casting to the face of the hooks, where an adjustable plug forms the joint. Provision is made for coupling an ordinary hose to this draw-bar.

The best device in the combination is the means for uncoupling the hooks. Instead of jerking the drawheads apart by moving them bodily, there is provided inside each head a push piece operated by a lever, as shown in Fig. 2. When these are forced in they unlock the hooks. This might stop some of the jerking and profanity now employed to uncouple Miller hooks.

### Historical Locomotive.

**The First Locomotive Built in New Jersey, Now Famous for their Manufacture.**

One of the most ingenious men who ever lived in America was Seth Boyden, of Newark, N. J. Mr. Boyden made many inventions in textile machinery, invented the governor that controlled by handling the valve instead of throttling the steam, invented malleable iron, invented patent leather and devices for its manufacture, and built the first locomotive turned out in the State.

He only built two locomotives, the "Orange" and the "Essex," both used on the Morris & Essex road, now the D., L. & W. His first locomotive was unlike anything before built, and modern writers have given him credit for making the first outside cylinder locomotive; this, of course, is a mistake, for the "Rocket" herself was an outside cylinder machine. Boyden's locomotive was the first outside cylinder engine that had her cylinders fast to the frame instead of the boiler or smokebox, and the cylinder-chest and guide arrangement was closely followed for years.

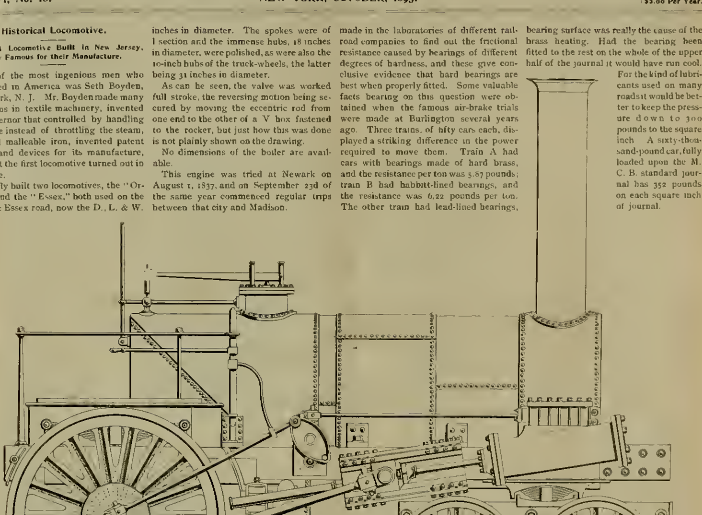
The original drawing from which our engraving was made, is the work of Mr. P. I. Perrin, still living, who at that time, 1837, worked for Seth Boyden as draughtsman and machinist, and was for forty years connected with the Taunton Locomotive Works.

The cylinders were 8¼-inch bore and 26-inch stroke. The driving-wheels were solid cast-iron, flanges and all, no tire, 53½ inches in diameter. The spokes were of I section and the immense hubs, 18 inches in diameter, were polished, as were also the 10-inch hubs of the truck-wheels, the latter being 31 inches in diameter.

As can be seen, the valve was worked full stroke, the reversing motion being secured by moving the eccentric rod from one end to the other of a V box fastened to the rocker, but just how this was done is not plainly shown on the drawing.

No dimensions of the boiler are available.

This engine was tried at Newark on August 1, 1837, and on September 23d of the same year commenced regular trips between that city and Madison.



First Locomotive Built in New Jersey. Seth Boyden, 1837.—From the Original Drawing.

### Soft Bearings Cause Hot Boxes.

There is a mistaken belief among many railroad men that a soft bearing causes less friction than a hard one, and that on this account a mixture that produces a soft bearing is best to use, since there will be less annoyances from hot boxes. This belief is largely due to the success with lead-lined bearings, but it ought to be understood that a soft lining does not reduce the friction, it merely presents a surface which quickly conforms to the journal or pin. When a journal has to grind down a brass bearing to make it a good fit, the resulting friction is likely to cause a hot box. When the brass is made a perfect fit before being put into service, it runs with less friction than a lead-lined bearing.

Very exhaustive experiments have been made in the laboratories of different railroad companies to find out the frictional resistance caused by bearings of different degrees of hardness, and these give conclusive evidence that hard bearings are best when properly fitted. Some valuable facts bearing on this question were obtained when the famous air-brake trials were made at Burlington several years ago. Three trains, of fifty cars each, displayed a striking difference in the power required to move them. Train A had cars with bearings made of hard brass, and the resistance per ton was 5.87 pounds; train B had babbitt-lined bearings, and the resistance was 6.22 pounds per ton. The other train had lead-lined bearings, and the resistance per ton was 7.51 pounds. This makes a material difference in the power required to move trains with hard bearings, and those with lead-lined bearings considered by many people the ideal bearing for cars. Between the axial resistance of the hardest bearing and that of the softest there is a difference of 28 per cent. in favor of the former. This means that when well-fitted hard bearings are employed, an engine will pull several cars more to the train than it will do with soft bearings.

Trainmen will not readily believe this, because very hard brasses frequently cause heating and have to be removed on the road. When these are examined it is found that the journal has made very small impression upon the brass, and that the bearing was confined entirely to a narrow strip across the top. This limited amount of bearing surface was really the cause of the brass heating. Had the bearing been fitted to the rest on the whole of the upper half of the journal it would have run cool.

For the kind of lubricants used on many roads it would be better to keep the pressure down to 300 pounds to the square inch. A sixty-thousand-pound car, fully loaded upon the M. C. B. standard journal has 352 pounds on each square inch of journal.

The secretary of the Traveling Engineers' Association sent out a letter in August asking forty-eight general managers to grant leave of absence to traveling engineers and furnish transportation to the fraternity to the meeting in Chicago. All answered, forty-seven of them granting what was asked and writing encouragingly about the new educational association. One, I. A. Sweigard, of the Reading, wrote a regular Reading letter, refusing to let his traveling engineers take part or to grant any favors to the men who, at their own expense, are trying to increase the engine economy on railroads by a systematic education of the men. The Reading management are opposed to education for men who work, or direct work, they want wooden-headed men with dry rot, and they have one—he's general manager.

## *Railroad Coppersmithing—II.

By John Fuller, Sr.

MAKING COPPER AND BRASS PIPE.

Copper and brass pipes are made when it is necessary to do so, in lengths of from 10 to 12 feet, and from ½ inch in diameter to any required size. With the invention of the steam engine the demand for copper pipes and brass tubes increased so rapidly that it created a contingent trade, and many men were employed exclusively making copper pipes and brass tubes, who were called by the trade pipe-makers. Their apparatus, however, is not adapted to a locomotive shop, and so will not be treated of here. Locomotive and marine coppersmiths are now supplied with all the smaller sizes of straight pipes, both copper and brass, ready to their hand; but formerly we made them all. There have been rapid strides made in this line, and like all other arts, that of the coppersmith has had to succumb to the advance of scientific and practical investigation. Copper pipes and brass tubes are now drawn solid, that is, made without a seam, yet it often happens, either from choice or an emergency, that the coppersmith is called on to make a few lengths of pipe, and the most efficient method of doing this work by hand will now be described. We must first have the circumference of the pipe wanted. If the sheet of which the pipe is to be made is heavy—that is to say, an eighth of an inch in thickness—then the diameter with the thickness of the metal added multiplied by 3.1416 gives the circumference, thus. Let the pipes required be 4 inches in diameter inside, and ⅛ inch in thickness; then $4 + .125 \times 3.1416 = 12.9591$, or 13 inches. Now to begin, we cut out the strip 13 inches wide and the length wanted, then with a thinning hammer, Fig. 5, thin the edges to a feather edge on the opposite sides of the strip, it is then turned and lapped only. If, on the other hand, the sheet is light, the edges must be cramped before thinning. If the pipe is less than 5 feet long and 2 inches in diameter we use a forming board 6 feet long and 12 inches wide and 2 inches thick, reinforced on each side with pieces 5 inches wide and 2 inches thick; the inside edges are then beveled off so as to form a trough 5 inches wide at the top and 2 inches at the bottom. Fig. 6 is intended to show this trough.

Fig 5

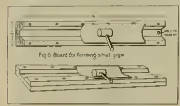


Fig 6 Board for forming small pipe

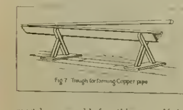

Fig 7 Trough for forming Copper pipe

The sheet, after being annealed and scoured, is laid on the trough and sunk in it with the mallet used in the manner shown in the illustration. This gives the first form. If the pipe is more than 5 feet long and 4 inches in diameter, then we use a trough (Fig. 7) made of two long 2-inch oak planks, placed in crossed pieces similar to a saw-buck, and laying at right angles to each other. The sheet of metal, after being properly prepared as before described, is laid in the trough, and a straight iron bar of sufficient weight is let fall on the metal in the middle, which yields to the falling bar, and thus the first move is made in forming large pipe. It is then placed the other side up over one of the edges of the trough and brought further together with a mallet, then closed in the trough. When it has been brought together sufficiently, the joint is laid even on a steel bar, fastened at the end in the mandrel block as in Fig. 2, Chap. 1. If the pipe is made of thin sheet-metal—say,

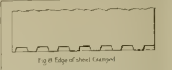

Fig 8 Edge of sheet Cramped

16 to 18 gauge—then the joint should be cramped together. This is done by cutting one edge about every two or three inches with a sharp chisel held slantingly, so that the cramp will form a lap where it is cut, as shown in Fig 8. The edge is now suitably thinned, after which the sheet is turned round. The outside cramps are to be lifted with a tweezer (Fig. 9), so as to admit the other edge that is not cut, and which is put between the cramps, one going inside and the other outside. The pipe (Fig. 10) is then bound together with binding wire, placed about two feet apart and pulled up tight. The cramps are now closed down and the joints laid even with a hammer or a mallet to suit the joint required. The joint must now be made to chatter—that is, jarred to loosen it enough so that the solder may have room to flow freely through the joint when it is being brazed.

All the foregoing directions having been followed successively, we now proceed to charge the joint with spelter. The spelter is first washed clean, then mixed with clean water and borax, equal parts by measure of spelter and borax being used. It will be found that the best results are obtained if the mixture is made ready a few days before it is wanted for use. To charge the seam with solder, take a strip of metal a foot longer than the pipe and form it into a V-shaped reed (Fig. 11), large enough to hold a sufficient quantity of spelter to fill the joint. Fill the reed evenly with the mixed spelter, and then slide it through the pipe, laying it evenly on one side of the seam. Then turn the reed over on the seam, jar the solder out of it and carefully remove the reed, being watchful that none of the solder is dragged from the seam while it is being removed. The pipe is then ready for the fire. The fire must be clean and made of clean coke, care being taken that no lead or soft solder is laying about on the forge nor in the fire. The pipe is now taken to the fire and the solder gradually dried, being laid on the supports (Fig. 12), which are made of suitable angle-iron and bolted to a heavy broad foot so as to stand firm. The angle-irons have holes punched in them about 1 inch apart, and a 1½-inch rod is run through with a wheel between the standards, having a groove in it large enough to carry the pipe in, so that as the joint is being brazed or soldered down it can easily be drawn through the fire without any unnecessary friction. During the process of soldering, a pan of finely powdered borax must be at hand in case at some point the spelter should need more to flux it. After the pipe has cooled it is taken to the mandrel for rounding, and the seam laid up for filing, after which the seam is cleaned off by a sharp file, and if there be any faulty places in the seam they are made good. The work now being perfect, the pipe is finally smoothed up true with a bright top swage ready for use.

TAKING TEMPLATES.

Taking templates for bends is one of the most important features as an adjunct to the successful performance of the operation of bending, for if the template be taken without the necessary knowledge, trouble often ensues. Many a good piece of work in other ways has been mutilated and spoiled by ignorance on the part of the maker of the bend, or the maker of the template, or perhaps it would be said from the want of a mutual understanding between them, when it happens that the coppersmith does not take the template himself, nor sees the position the pipe is to occupy. Templates for use at the bending-block should be made from an iron rod which is stiff enough to retain its form without fear of alteration while being handled at the bending-block. It should be formed so that it will run through the center of the pipe after being bent, as shown in Fig. 13. Templates for large work are better and more safe and satisfactory when made of wood by a pattern-maker, showing the exact curve by cutting boards and nailing the flanges to them in the position desired. Three of these templates are here shown. Fig. 14 represents a single bend, Fig. 15 a double or S bend, and Fig. 16 a double bend, one end of which is made to stand at right angles with the other, and shows clearly how these templates are made. When the position the pipe is to occupy affords sufficient space, due regard, care and attention should be exercised so that the pipe, when finished, will hang perpendicular and lie horizontal, and the bends occupy as near as practicable the center of the space through which the bends run, that is to say, neither cramped nor straggling, but filling the space with a flowing ease. Having the templates now all in proper shape, we will proceed to filling and bending.

Locomotive Engineering N.Y.

FILLING AND BENDING.

All copper pipes and brass tubes should be carefully annealed before bending, that is, that part which is to be bent. The other ought to be left hard. The part to be softened should, when hot, be cherry red, in a clear north light (not sunshine); when cold, the part to be bent is filled with lead or resin, whichever is the most suitable to the particular bend it is required to make. We usually put the end not to be bent in the pit for convenience in filling, if a long end. (There are a great many different kinds of compositions used in as many different shops, but after using them all I have concluded, for general work, lead or resin answers for all purposes.) If the bend required is short, that is, part of a small circle, lead is the best for the purpose; new, soft lead, without any foreign substance mingled with it. If, on the other hand, an easy flowing bend is desired, then resin is best adapted to the purpose. It is necessary here to say, for the benefit of the learner, that, after continual heating and cooling, resin loses its rigidity and becomes soft, therefore it should be kept fresh by renewing occasionally as it may be necessary. If the bend is to be made on the end of a long pipe it is not necessary to fill it the whole length. We usually roll up a hard ball of paper or cotton waste, and ram it in tight as far as it has been annealed for the bend, and then pour in the resin or lead as the case may be. When the work is done, and the lead is all taken out, heat the pipe a blood red and the wadding will fall out, or it may be blown out by applying the blast pipe to the cool end. We will now proceed to the bending-block. The block is used with the center-pin, when, from the nature of the work, nothing else will answer in its place. It will be found especially adapted to a great many forms of bending which practice and close attention alone can teach the learner. It will be noticed, Fig. 17, that the back plate is a piece of iron, usually about 1½ inches thick, with two legs, the top of the bending-block having four holes an equal distance apart to receive the two legs on any side, so that with either the lead-piece or the center-pin the bending may be done on whatever side of the block is most convenient to the operator. Fig. 18 shows the block ready for bend-

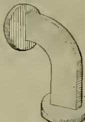

Fig. 14

ing. *A*, loop; *B*, packing; *C*, lever; *D*, pipe to be bent; *E*, center-pin; and *F*, back plate in position for work. The pipe is first marked by laying the straight part of the template on the pipe and running the curved part along until the straight part of the other end of the template lies level on the pipe again, and marking with chalk where the bend begins and terminates on the pipe. It is then laid between the pin and back plate (Fig. 18), or put through the hole in the lead-piece, as shown in Fig. 19. Between the back plate and pipe is put a soft piece of wood or lead; these are to save the pipe from being marked by the pressure exerted against the pin and back plate in the operation of bending. (It is always necessary to have a helper at the block when bending.) Now put the loop *A* on the pipe and slip the lever *C* through it, which may be of iron or wood—in some cases a wooden lever is best, in others an iron one. Then put a block of soft wood, *B*, between the lever and pipe. After the loop is on one mark and the other behind the pin, or just inside the hole in the lead-piece, apply the necessary pressure to bend it to the required curve, giving it attention as it goes round that the curve is going evenly and not one place more than another. The rope loop *A*, Fig. 18, is made of one strand of rope, and is formed like a sailor's grummet. The copper loop shown at the side of Fig. 19 is made of a strong piece of sheet copper. Sometimes the rope is best adapted to the job in hand, at other times the copper loop; experience must dictate this. With the apparatus described, pipes as large as 5 inches may be easily bent. If anything larger is needed, a hydraulic press must be provided.

BENDING IRON PIPE.

In a locomotive shop it often happens the coppersmith is called on to bend iron pipe which is used for sand pipes, or when iron is preferred for hand rails in place of brass. I have seen unpleasant things occur when the workman was deficient in the requisite knowledge to perform the work without filling the pipe. Iron pipe may easily be bent without filling if the proper precaution is used while the work is being performed, upon which a few hints are here offered. In the bending of pipe it should be observed by the operator that as the bending proceeds the outside of the bend must be stretched (and in the case of copper pipe, the inside is correspondingly upset), but in bending iron pipe we contrive to get all the stretching out of the back of the pipe, thus. Lay the template on the pipe in the center, as before described, and mark the length of the bend. Now warm the pipe and flatten it a little with a mallet, making it an oval along the portion to be bent; then have a soft wooden block like a two-pronged fork, of sufficient strength, screwed fast in the vise, and make the pipe hot at the back, a bright cherry red, and the front or inside of the bend keep as cold as possible. If the inside should get hot, cool it with water, always having a pailful at hand. Now having the pipe hot, put it between the prongs of the wooden fork and apply sufficient pressure until the pipe has a tendency to flatten the other way; then make it a little oval again, and repeat the process until the bend is made the curve required. Iron pipe may also be filled and bent in the same manner as copper pipe, or by putting it through a hole in a block of soft wood.

---

## What the Vice-President's Chief Clerk Does, While He Is Resting.

Expressing a longing for a "soft snap," such as our friend, the chief clerk to the Vice-President had, he shocked us by affirming that he had more business to attend to than a lone dude at a watering place. We asked him to take a memorandum of his routine work for one day, and the result is given below.

"At the desk at 8.40 A.M.; open mail and handle ordinary current business; examine morning reports showing work of the Traffic and Transportation Departments of the previous day; submit these reports, together with such correspondence as requires his action, to the chief; comply with his instructions in reference thereto and reply to mail. During the day much time is spent in approving vouchers, examining reports and requisitions, taking necessary action thereon, countersigning passes, answering telegrams, etc.

The first caller is the chief clerk of the Passenger Department, with one of the soliciting passenger agents, to discuss the securing of a large party of World's Fair excursionists.

Then comes a general agent of the Passenger Department, who wants to know how we are getting along in convicting the "other fellow" of manipulating rates.

Then comes our old standby, the railroad man hunting a job, who is easily gotten rid of with a promise to bear him in mind when a "suitable" vacancy is heard of.

The head of the Operating Department now strolls in for a little general talk.

He is closely followed by his chief clerk who comes to answer an inquiry, and to explain how he overlooked doing something that he should have done.

He is followed by the President's secretary, who brings a complaint from the Board of Railroad Commissioners, requesting us to abolish a grade crossing because a man was injured who tried to cross the track at the same time the locomotive was crossing the county road.

Now comes the President's stenographer, who wants the chief to say what character of reply should be sent to a communication he submits.

He has not received his answer before a car builder turns up with a statement that he has lost all of his original papers relating to a recent purchase of equipment, and would like to have duplicates executed.

The next fellow to turn up is an old friend, who is running the "best" railroad paper published. He wants a pass for one of his assistants to attend the Lakewood Convention. This case is not a difficult one to handle, and he is soon disposed of.

Next comes the auditor, with some passes which have been honored after expiration.

Then we have the porter of the private car which is going to the World's Fair with one of the high muck-a-mucks. He gets his instructions and goes.

Then we have an engine-builder, who drops in to explain why he is behindhand with his deliveries, and to make promises.

The next is the coal freight agent, who thinks the general situation is bad, and wants to know how "the other feller" gets so much coal to haul.

Then comes the grain agent, who discusses the situation generally, and tells us why the grain is not coming to the seaboard in as large quantities as it did last year.

The general freight agent then comes in to tell us about a request he has had for a special rate.

Next we have a pass fiend who wants his pass made good on the Limited.

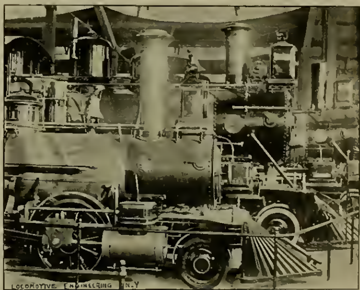
He is followed by a man who says he would like to get his bill paid, and who is respectfully referred to the treasurer.

The head of the Operating Department again turns up to impart a little information, and to invite us to look at a new car-float he is having built.

The next is the coal sales agent, who drops in for his daily chat.

Then we have a member of the legal profession, who wants us to give him the record of an ex-employé.

He is followed by one of the company's tenants, who wants permission to assign his lease, and while we are discussing real-estate matters with him in comes a man to sell the chief a country place.



A CORNER IN THE TRANSPORTATION BUILDING AT WORLD'S FAIR.

The chief clerk of the Operating Department again turns up to tell us why some empties were not gotten around as quickly as they might have been.

The company's attorney now drops in to get some facts which are, of course, made to fit the law.

Then comes the purchasing agent, who wants to explain why he doesn't buy everything from everybody, and he is followed by the superintendent of motive power, who comes to report upon a new mechanical device and discuss the advisability of making a test. Then comes the real estate agent, who wishes to confer about the sale of some of the company's land.

Then the treasurer walks in and comments upon the tight money market.

He is followed by an ex-officer, who simply drops in to say howdy-do.

Next is one of the executive officers, who wants to talk over the best method of handling a particular matter.

The chief clerk of the general manager's office again turns up with information, and he is followed by an insurance man, who comes to tell us why rates are not lower, etc.

The superintendent of motive power again turns up to talk over Convention matters.

Another railroad man now comes in, of course, "the best" paper also, with a request for two passes to the Convention.

The superintendent of telegraph then drops in and tells me I am wearing a pretty cravat. He gets the cravat the next morning.

The day is wound up with a call from a supply man, who expects us to express the usual admiration and astonishment at his new suit of clothes and his diamonds.

As the clock is now quite close to 5 P.M., we sign the mail and close up for the day.

## Promotion of Traveling Engineers.

The rapid upward movement of the men who hold the position of traveling engineer on our railroads may be judged from an item in the address of President Conger at the Traveling Engineers' Convention. He mentioned that since the organization of the association the following members have been promoted: Geo. H. Brown, master mechanic of the Chicago, Milwaukee & St. Paul; J. H. Burns, assistant master mechanic of the Burlington, Cedar Rapids & Northern; James Fitzmaurice, master mechanic Chicago Terminal & Transfer Co.; T. J. Hennessy, master mechanic, Michigan Central; Theodore P. Jacobs and James Tobin, master mechanics, Mexican National. Secretary Thompson has also been promoted to be engine dispatcher at Elkhart, on the Lake Shore road.

## Noticing Things.

A roundhouse foreman who has to perform the functions of a physician in diagnosing all the maladies that locomotives are heir to requires to be of exceedingly observing habits, or he is likely to fail in detecting disorders. The habit of noticing things can be greatly developed by practice. Some men will walk through a shop and take a mental note of everything to be seen, while others with equally good eyesight and equally interested in the place will merely have a vague idea of the kind of tools and material that were seen. People have practiced, as an amusement competition, in trying how many articles they could enumerate in a shop window after a passing glance, and it is wonderful how expert they became. If an enginehouse foreman practices going quickly around his buildings and training himself to note as many things as possible about the engines, he will soon come to perceive at a glance everything that requires attention.

Mr. R. W. Bushnell, master mechanic of the Burlington, Cedar Rapids & Northern, has a wonderful faculty for noticing things out of order about an engine or in a shop. The writer was foreman under Mr. Bushnell for some years, and it was amusing, and sometimes unpleasant, to find how certainly he would find out everything that was wrong in his daily tours through the shop. He would come striding in as if time was of the utmost importance. If there was something you did not wish him to see, you would walk with him and try to divert his attention in the other direction from where your weak point was, and just when you thought he was steered safely past he would glance back and find out what you had been trying to hide.

The advantage to an enginehouse foreman of this capacity for noticing things was lately brought freshly to my attention while visiting a large enginehouse near New York. As I was walking round with the foreman, an engineer came up and began complaining about his tender riding so hard that it shook the coal off. The fireman had to ride the greater part of the time on the tender, and he complained that the rough riding was shaking his teeth loose. The foreman remarked that there had been a great deal of trouble lately with rough riding tenders. There had been complaints of this kind ever since they began using springs from a maker whom he named. He believed that the springs were too stiff. By this time we had got to the engine, and the springs were examined. They did not look too heavy for the load carried, but the foreman concluded that he would put in a lighter set. I noticed that the springs reached almost to the edge of the end pockets, and suggested that the ckets were cramping the springs and preventing free movement. Close examination proved that this was the cause of the rough riding and the proper remedy was applied. It seemed strange that several tenders were being shaken to pieces from this defect, without the trouble being detected at once. A new make of springs had been introduced, and a mistake had been made in specifying the length with the result stated. A. S.

## Organization of the Traveling Engineers' Association.

In his address at the First Annual Convention of the Traveling Engineers' Association, President Conger said:

"For two years past the preliminary work for our organization as a society was being done in a very thorough manner by our energetic secretary, who corresponded with all the traveling engineers he knew or heard of, with a view to getting them in line for the first start. Some took hold enthusiastically, others were a little backward, and some thought they would see about it later, after it was shown it would be a success. Thanks to his executive ability as well as persistency in sticking to it for so long a time, enough were interested to promise him their support and attendance to make a fair start.

"In October, 1892, he called a preliminary meeting for November 12th, at the L. S. & M. S. engine-house in Chicago, in which fifteen took an active part. A committee to draft a constitution and by-laws was appointed, also a committee to arrange for the meeting to be held in New York, shortly after which a call was issued to meet in the office of LOCOMOTIVE ENGINEERING in New York to perfect the organization. On January 9, 1893, eighteen members were there in person and thirty others by written application. The present constitution was adopted, officers elected, subjects for investigation selected, and committees appointed to attend to the questions, and all hands went to work with a will, the result of which you see to-day.

"In this work we were very ably assisted by Messrs. John A. Hill and Angus Sinclair, who gave us the use of their office to meet in and helped us in various ways. Mr. Hill kept the question alive in the columns of LOCOMOTIVE ENGINEERING, and sent out our circular calls everywhere. On the first night of our meeting they gave us a banquet, which was enjoyed by all present. Ever since the first start these gentlemen have helped us along, and we are proud to have them with us as members. The thanks of the association are due them."

"We are now on a good foundation, have money enough in the treasury for our moderate expenses, 109 members on the roll hailing from all sections of the country, all of them bright, active go-ahead men, who believe in being progressive in their vocation and keeping up with the procession of improvement. To be successful as an association we must keep up this gait, interest ourselves in the joint work we meet to do, exchange ideas on the best methods of doing the work of the traveling engineer, keep our hands off the work that properly belongs to others in charge of different branches of the locomotive department, and strive to make ourselves useful to our superior officers. Our motto, 'To improve the locomotive engine service of American railroads,' shows what we mean to do; the next thing is to show each other, and railroad men generally, that we can do it.

"This association expects to give opportunities to all its members, by interchange of opinions and reports of results of different methods, to profit by each other's experience whether success or failure. If all take the proper interest and are prompt in showing it we can, as an association, do a good work, which will be appreciated both by officials and employés."

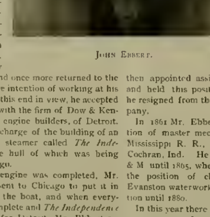
## Sketch of the Life of John Ebbert.

BY LEWIS GLEASON.

The man whose photograph appears in connection with this article is one of the oldest, if not the very oldest, locomotive engineers in the country.

John Ebbert was born in Westmoreland County, Pa., June 19, 1815. His father, who kept a tavern on the Philadelphia and Pittsburg turnpike, was also the keeper of the toll-gate, and when not busy at either one of these avocations he worked at his trade of harness making.

At the early age of fifteen years John Ebbert was apprenticed to McClurg & Wade, machinists, of Pittsburg, and served five years' apprenticeship. At the expiration of that time he left Pittsburg and went to work for the Alleghany Portage R. R. as a journeyman machinist in the company's shop at Johnstown, Pa. He remained in the shop but a few months, and was then transferred to the road as engineer of an engine running between Plane 1 and Plane 2. This was in 1835, and from this time dates his career as an engineer, now fifty-eight years ago. Mr. Ebbert remained for two years in the service of the Alleghany Portage road. He left the company in 1837 to accept a similar position on the Michigan Central R. R., and ran an engine between Detroit and Ypsilanti. He remained with the Michigan Central for five years.



JOHN EBBERT.

In 1842 he entered the service of the Boston & Albany road and had a run between Springfield and Worcester. He remained with the B. & A. Company only six months, and once more returned to the West, with the intention of working at his trade. With this end in view, he accepted employment with the firm of Dow & Kendrick, marine engine builders, of Detroit. Here he had charge of the building of an engine for a steamer called *The Independence*, the hull of which was being built in Chicago.

When the engine was completed, Mr. Ebbert was sent to Chicago to put it in place aboard the boat, and when everything was complete and *The Independence* left Chicago for Detroit, Mr. Ebbert returned aboard of her as a passenger. After his arrival in Detroit he was engaged to take a steamer called *Porter* from that city to Chicago, where the boat was to remain over winter.

Immediately after his arrival in Chicago he made arrangements to enter the employ of Hollister Bros., of Buffalo, who were the owners of a fleet of lake steamers. After a long and weary journey by stage coach, he arrived in Buffalo and entered upon his new duties.

His first work for the Hollister Bros. was to overhaul the engines of steamer *Hercules*.

On the opening of navigation in the spring of 1844, Mr. Ebbert was placed on steamer *St. Louis* as chief engineer, and remained on that boat during one season. In 1845, when navigation was resumed, he was appointed chief engineer of the steamer *St. Joe*, and remained on that boat for four years.

On the last trip for the season of the *St. Joe*, from Buffalo to Chicago, there was aboard the boat as freight a small, quaint-looking locomotive, intended for use in the construction of the Galena & Chicago Union R. R., the first railroad built out of Chicago. At the time of which we write this railroad had four miles of track laid, and from this germ, planted in 1848, has sprung the magnificent system of railroads now known as the Chicago & Northwestern Railway!

On the arrival of the steamer at Chicago, the locomotive was unladen and placed on the track, and duly and appropriately named "Pioneer."

The position of engineer was offered to Mr. Ebbert, by the then president of the road, Mr. William B. Ogden, and was accepted. Once more we find John Ebbert as a locomotive engineer and the first man to open the throttle-valve of a locomotive in Chicago, which city was destined to be (and through the agency of the little machine) the forerunner of its numerous kind.

The Chicago of 1848 and the Chicago of 1893 very aptly illustrate the push and energy of the American character: with a population then of 25,000 inhabitants, four miles of railroad with one little locomotive, the Chicago of to-day with its 2,000,000 of inhabitants, the greatest railroad center in the world, the railroads centering here counting their locomotives by the thousand; and all this accomplished in forty-three years. Well may the World's Fair visitor from other countries gaze with wonder on all the marvels that Chicago presents to his view.

Mr. Ebbert, after one year's service as engineer, was appointed master mechanic, which position he retained four years. He was then appointed assistant superintendent, and held this position until 1860, when he resigned from the service of the company.

In 1861 Mr. Ebbert accepted the position of master mechanic of the Ohio & Mississippi R. R., with headquarters at Cochran, Ind. He remained with the O. & M. until 1865, when he resigned to take the position of chief engineer of the Evanston waterworks and held that position until 1880.

In this year there was organized a company composed principally of Western capitalists known as the Rockaway Beach Improvement Company. The object of this company was to make Rockaway Beach, L. I., the finest summer resort in the world.

The largest hotel ever constructed up to that date was built, and a railroad was constructed to connect the beach with New York and Brooklyn. Gas and water plant was put in, and to superintend and operate the waterworks the company secured the services of Mr. Ebbert, who put in the plant and operated it for eight years.

The company got into financial difficulties, their magnificent hotel was never opened, the Long Island R.R. Co. got their railroad; the gas-house went to ruin. The water-works remained longest of all, but finally they had to go; and, consequently, Mr. Ebbert was out of employment in 1888, after having lost much money through the failure of the company.

In the death of Mr. Ebbert's wife, which took place in 1889, he sustained the heaviest affliction of his long and busy life. Since that event he has not engaged in any active service. He makes his home in Chicago with his children, of whom he has six, four sons and two daughters. All of his children are married, and vie with each other as to who can make happiest the declining years of their honored father.

A few months previous to the opening of the World's Columbian Exposition at Chicago, the officers of the Chicago & Northwestern Ry. thought they could send no more interesting object to the Fair than the old "Pioneer." Accordingly, the dust of years was brushed off, the old boiler, long empty, was filled up once more; fire was started in the quaint old firebox, and in due time steam was generated, and the old engine started for Jackson Park. Mr. Smith, superintendent of motive power of the Chicago & Northwestern Ry., acting as engineer.

General Manager Whitman, of the Chicago & Northwestern, requested Mr. Ebbert to look after the old "Pioneer" at the Fair, and tell the many people who look with admiring gaze on the old engine of the part it played in the development of Chicago, the Northwest, and the Chicago & Northwestern Ry.

At the World's Fair the writer renewed his acquaintance with Mr. Ebbert, having previously known him at Rockaway Beach, and was glad to find this grand old man in vigorous health and in the possession of all his faculties. He has now passed the seventy-eighth milestone of his life's journey. During his long and useful life he has seen—and also has in no small manner contributed to—the grand and glorious upbuilding of our country. In his youthful days the little engines which are brought to the Fair as curiosities for his grandchildren to look at, were considered powerful machines and gazed upon with awe by the populace.

Truly he has seen the evolution and development of the locomotive. What a contrast to his "Pioneer" of 1848 are the monster locomotives of the Brooks works and other builders with which the "Pioneer" is in company.

The poet T. Buchanan Reade, in his verses of "Sheridan's Ride," expressed the wish that when a monument would be raised in Sheridan's honor the horse should not be forgotten; so might we express the wish that, if the Chicago & Northwestern Ry. Co. should erect a pedestal on which to place the "Pioneer," the name of John Ebbert be also emblazoned thereon.

In conclusion, it is the wish of the writer, and this wish will no doubt be voiced by all readers of LOCOMOTIVE ENGINEERING, that John Ebbert may live many years yet to enjoy the fruits of his long life of usefulness to his fellow-men.

---

The Jacksonville, St. Augustine and Indian River management have a way of their own, and it is a quiet, unassuming way of accomplishing their ends. The great changes wrought are noticed on each visit. An additional 100 miles or more of road constructed, ditched, bridged and trestled in a first-class manner; stations of a style and cost which would do credit to any pioneer road. First-class train service instituted; new equipment, both engines and cars, luminous with gold and varnish, all looking new, is the result of each summer's work. The excellent condition of the equipment has given this road the title of "Gilt Edge," and it is well bestowed. Crawford, general superintendent, and Silvius, the master mechanic, deserve abundant praise for their success.

Watch dials of a form invented by Mr. A. G. Leonard, of the New York Central Railroad, are now manufactured and sold by Mr. C. K. Colby, 11 John street, New York. The dial is arranged with figures which show very plainly how many miles an hour a train is running according to the number of seconds required to pass between mile-posts. The dial can be applied to any watch, and is a great convenience to engineers, conductors and others interested in the speed of trains.

### List of Engineers Present at the Engineers' Convention, Baltimore, Md., November 6, 1855.

Mr. E. N. Underwood, one of the engineers who met to form an association in Baltimore, Md . in 1855, recently came East from his home in California, and, while here showed us a list, printed at the time, of the men who attended the first engineers' convention. An association was formed there, but it lasted only a few years, and little interest was taken in it In 1863 W. D. Robinson formed the Brotherhood from which grew the present great organization Very few of these old-timers are alive to-day, still a few of them are doing business at the old stand. John Brunton is librarian of the railroad reading room at Pueblo, Col. W. T. Osborn is foreman at the Hoboken shops of the D., L. & W. E. N. Underwood is M. M of the Colusa & Lake road in California Jas. R. Smith is roadmaster of the P. R.R. out of Jersey City, and John Sexton is foreman of the P. R.R. shops at South Amboy, N. J. There are probably others alive, but we do not know them.

Martin R. Alley, Richmond, Va ; Isaac A Morse, No. 429 Fourth avenue, New York , Charles McKean, No. 572 Third avenue, New York , Levi Huston, Harrisburg, Pa.; Joseph Miller, Chambersburg, Pa , Thomas B. Askew, Baltimore. Md.; A. M. Brown, Dayton, O.; R. M. Gregg. Northfield, Vt., Otis Freeman, Keene, N. H , Earl Hawley, Jamaica, L. I.; John M. Whitney. Springfield, Mass ; Richard B. Duncan, Kensington, Philadelphia, Pa.; Edward Prentiss, Sandusky City, O., William H Thompson, Fitchburg, Mass.; Austin Matson, Jr., Greenbush, N Y.; William P. Furnold, Great Falls, N. H.; H. L Garrett, Portsmouth, N. H., Ormand Butler, Jr., Martinsburg, Va , Robert T. Walker, Watertown, N. Y , W H. Green, Buffalo. N. Y.; U. B. Williams, Baltimore, Md.; John Donahue. Susquehanna, Pa ; John Sexton, South Amboy, N. J., Thomas Kenley, Baltimore, Md., James M. Simmons, Fall River, Mass ; Ed. Hawley, Erie, Pa.; Volney Tyrell, Chicago, Ill ; J. R Smith, Baltimore, Md , William D. Robinson, Rochester, N Y, Benjamin Hoxie, Port Jervis, N. Y ; William Hoyt. Syracuse, N. Y., S. S. Cheney, Laport, Ind.; John Quinc, Buffalo. N. Y.; A H. Felton, Baltimore, Md. ; D. P. Carter, Adrian, Mich.; Wm. Bryan, Baltimore. Md. ; Henry Brown, New Haven, Conn. ; J. D. Bradford, Wilmington, Md. ; A. H. Somers, Ohio & Penn. R. Y. , Sherman Bates, Hartford, Conn. ; James R. Smith, Newark, N. J. ; W. T. Osborn, Hackettstown, N. J. ; L. G. Patterson, Northfield, Vt. ; W. Sterling, Bridgeport, Conn. ; Joseph Blanchard, East Cambridge, Mass. , George Vandanker, Baltimore, Md. ; C. Smith, Harper's Ferry, Va., William D. Winters, Harper's Ferry, Va. ; Henry Milliken, New York , Nelson Underwood, Greenbush, N. Y. ; Daniel N. Anderson, Cameron, Va., David H. Derrick, Portsmouth. Ohio ; William Hayden, Rochester, N. Y. ; Joseph Hoffman, Rochester. N Y

### Chief Arthur and Others Sued.

A press dispatch from Pittsburg says that Attorney Carney has filed the papers in a suit for $20,000 damages for libel in the United States Circuit Court against P. M. Arthur, of Cleveland, Grand Chief Engineer of the Brotherhood of Locomotive Engineers , A. B. Youngson, Grand Assistant Chief , T. S. & D Everett, publishers of the *Journal*, the official organ of the order ; J. G. Owston, Chief Engineer, and R. M. Rhodes and H. B. Schafer, officers of the Keystone Lodge of the Brotherhood of Locomotive Engineers of Allegheny. The plaintiff is Jeremiah Evans, who is now employed as foreman in Elba Iron Works.

Evans was formerly employed on the Pittsburg, Fort Wayne and Chicago Railroad as an engineer, and was a member of the Keystone Lodge, Brotherhood of Locomotive Engineers. He withdrew from the organization to accept a position of foreman.

When a strike was declared at the Elba Works it was declared closed to union men by the Amalgamated Association. Because Evans went there to work, the officers of Keystone Lodge caused to be published in the *Journal* a notice that Evans had been expelled for "scabbing." Evans claims that as he had withdrawn from the lodge he could not be expelled, and for the reason that no labor organization makes a pretence of controlling the position or regulating wages of foremen, he could not be guilty of "scabbing." The case will likely be tried at the next term of the Circuit Court, and is of great importance to unions, nearly all of which publish notices of expulsions.

### A Fine Bridge in Danger.

One of the most handsome railroad bridges in the country spans the Mississippi at Memphis, Tenn., and is used by the tracks of the Kansas City, Memphis & Birmingham Railroad. A thoughtful visitor standing on the bluffs at Memphis, looking critically at the scene below, is likely to be struck with a potential danger which may leave the bridge standing over an abandoned sand bed. Owing to a freak which the Father of Waters is notorious for, it deserted its old channel above Memphis some years ago and took a long sweep inland, returning to its old channel just above the city. All along the new bend it keeps threatening to cut out a short cut, which would leave Memphis several miles away. The engineering authorities who have charge of such matters have been spending hundreds of thousands of dollars in rip-rapping with rock the threatened bank, and still the danger grows. Half the money expended in opening up the old channel would prove an effectual remedy. but the engineers (?) cannot accept such a simple means of solving the difficulty When the river comes down in a big flood some day, and leaves the bridge which connects Arkansas and Tennessee a useless highway, the people concerned will have something strong to say about the engineering imbecility responsible for the disaster

### The Poor Flagman.

The absolute block system, rigidly applied, will absolutely preserve a stated interval between following trains, but the great cost of its construction and maintenance precludes its use on by far the largest part of the railroad mileage in this country. Where this consideration prevents, reliance is placed upon the watchfulness of the flagman, who is expected, when in his judgment it becomes his duty to secure this interval of safety, to leap from the rear of the moving train and, armed with red lantern and torpedoes, to plunge boldly into the darkness of night, perhaps facing rain, snow or sleet, hastening toward the headlight of the following train, which glares at him as he feels for his footing on the cross-ties upon some lofty bridge or long trestle. At length he reaches the prescribed distance of twenty-six telegraph poles, or about one mile, plants his torpedoes and listens with eager ear for the signal of recall. If, through haste to depart or inadvertence, the signal is not given and his train moves off without him, that flagman may pass the night in solitude, perhaps wet, cold and hungry, or until some train stops at his signal and picks him up. Such are the duties required of a flagman, and it takes pluck and endurance to fulfil them.

### Ingenious Cut-Off Motion Designed by W. A. Foster.

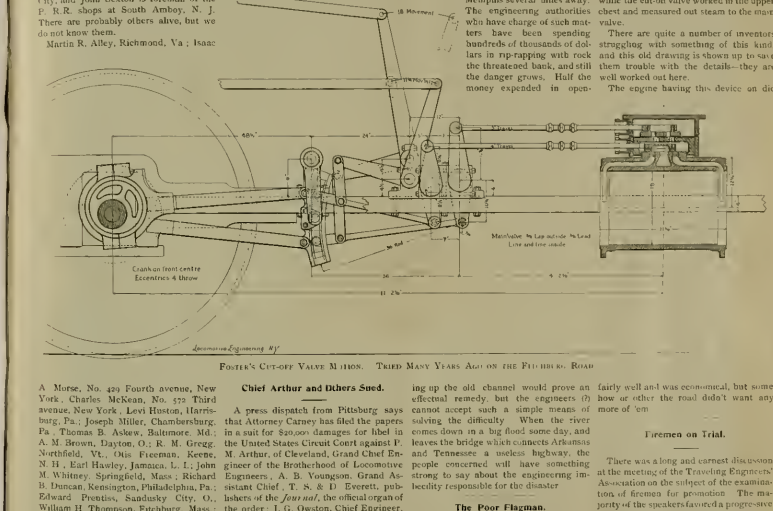
The valve motion shown herewith was designed some twenty years ago and tried on the Fitchburg road by William A. Foster, now superintendent of motive power of the Fall Brook Coal Co.

As can be seen, he used what is called a stationary link, the hanger being pivoted to the frame. In this link were two blocks—one moving the cut-off valve, the other the main valve , each having its own rocker and its own reverse lever, so that one could be varied without the other.

The chest was double, the main valve working in what might be termed the lower chest, this chest being very small, while the cut-off valve worked in the upper chest and measured out steam to the main valve.

There are quite a number of inventors struggling with something of this kind, and this old drawing is shown up to save them trouble with the details—they are well worked out here.

The engine having this device on did fairly well and was economical, but some how or other the road didn't want any more of 'em



FOSTER'S CUT-OFF VALVE MOTION. TRIED MANY YEARS AGO ON THE FITCHBURG ROAD

### Firemen on Trial.

There was a long and earnest discussion at the meeting of the Traveling Engineers' Association on the subject of the examination of firemen for promotion The majority of the speakers favored a progressive form of examination, but were opposed to any set of stock questions, and all were in favor of asking *Why?* after each question. This, of course, to prove that the candidate understands the subject, rather than the answer to a question. The whole body agreed that the great point to be made was to secure the right kind of material to start with, and that examinations on color-blindness, education, etc., should take place before the fireman is employed at all — you can't examine brains into numskulls

The following resolution, offered by Geo. H Brown, of the C . M. & St. P , was adopted, and if carried out by railroads would give a splendid chance to sort out the no-goods early in their career

*Resolved*, It is the opinion of this association that firemen should be hired on probation for the first six months, they being given to understand when entering the service that, for cause, they are subject to be discharged without question before or at the end of six months.

A committee was appointed to offer a plan of standard examination questions at the next meeting.

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK

Address all communications and make all orders payable to

LOCOMOTIVE ENGINEERING,
5 Beekman Street, New York.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } *Editors and Props.*
JOHN A. HILL, }
GEO. W WOLLASTON, *Mgr. Adv'g Dept*
FRED. S HILL, *Mgr. Subscription Dept.*

## Subscription Price.

$2.00 per year, $1.00 for six months, postage paid to any part of the world. Single copies, 20 cents.

## Special Notice.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary—always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly*

## Cutting Wages and Working Hours.

The present depression of business gives a very striking proof of the patience and tolerance of the great body of men who constitute the working forces of railroads. A year ago the country was stirred with wild rumors of war and strife that the wage-earners of railroads were about to engage in against their employers to compel a large increase of pay as soon as railroads were busy with World's Fair business. These reports were without foundation and originated with those who were likely to profit from a conflict between railroad companies and their employés and with those who feared that the temptation to strike railroad companies when a good opportunity for victory came would prove too strong to be resisted. The employés, however, without exception discountenanced the counsel of those who recommended that they avail themselves of the opportunity to compel an increase of wages, and there was not the least indication that labor troubles would have come had business come up to the promise at the beginning of the year.

The unexpected money stringency and prostration of business, however, turned the tables, and instead of the employés having an opportunity to force an increase of wages the railroad managers were in a position to reduce the same. Have they displayed the forbearance manifested by the employés? No fair-minded man will say that they have. There are some exceptions, but on most railroads wages have been reduced either directly or by decrease in the working hours in the most savage and inconsiderate manner. The loss of business has compelled many railroad companies to discharge men and reduce the working hours, but this has been done absolutely without cause on not a few roads. Some managers have been influenced by a panicy feeling, and contributed to the making of hard times by buying nothing and stopping all work where it was possible to do so. Others were guided by different motives, but the result was the same. They perceived the opportunity to strike a blow at their employés and have availed themselves of it. The president of one road, which is doing a better business than it did a year ago, gave orders that the employés' time should be cut until the men began to feel the steel of hard times, and then he said squeeze again until they scream. It is needless to say that they are screaming. The man responsible for this action poses as a philanthropic friend of workingmen. Others are following a similar policy to punish their men for previous independence.

The fact is that several railroad companies are using the general depression of business to increase the net earnings of the roads. They seldom have the opportunity to cut wages, and they are making the best of the chance. It matters not to them what suffering may be inflicted upon the families of faithful employés. They gamble with human lives with the expectation of gaining a few points on Wall Street. A representative case is that of the Manhattan Elevated Railroad Company This company is carrying as many passengers as it did last year, and the entire business is done on a ready-money basis, but the talk of money stringency was no sooner heard than the working hours of the shops were reduced to nearly half the regular hours. Some of the larger passenger-carrying roilroads are receiving heavy earnings from the extra travel to the World's Fair, but that does not prevent them from laying off every man not absolutely essential to keep the trains running. Some of them are purchasing nothing but coal, oil, waste and wheels. The temporary saving effected in this way will have to be paid for eventually in increased expenses. Business wisdom would require the work on rolling stock and track to be kept up, and the dictates of humanity demand that employés dependent on the companies for a livelihood should be kept at work, but sentiment and good sense have little consideration with those who are under the influence of the stock market

Trainmen have been more fortunate than other classes of railway men, for it was impossible to dispense with their services or to reduce their hours on roads that are doing a good business; but shopmen and all others have suffered shamefully. Railroad mechanics are worse paid, as a rule, than skilled men in other employment. The pay at the best is too low for the skill required. When the hours of labor are reduced, the pay earned is scarcely sufficient to keep a family alive. Manufacturers and others employing mechanics have, in very few instances, made reductions of wages, but railroads have nearly all done so. In some cases the reduction has been made in a novel form by the discharge of all the higher-paid men. In most shops there are exceptionally skilled men who receive more than the current wages, because their work is of greater value. In private shops, men of this character receive about a third more than a common hand, but in railroad shops only from ten to fifteen per cent. more is given. This is now leveled down by the discharge of the high-class men with the expectation that they will return to work at the wages of common hands.

Railroad men are very ready to bear their share of the privations that result from hard times, but it is too much to expect that they will tamely submit to reductions where they are not necessary. This class of men are too intelligent not to understand the true condition of affairs when reductions are made without cause. They read the newspapers which publish railroad earnings, and they know how many trains are running and the amount of passengers and freight handled. In too many instances the men have obtained convincing evidence from the decreasing traffic that business was prostrated, and they cheerfully bowed to the necessary reduction or suspension of employment; but on other roads they have been compelled to accept loss of income when all indications said that the cut came without cause. Managers talk glibly about loyalty of their employés and of the superior service obtained from loyal men, but many of them are following methods which are certain to kill the cultivation of a loyal spirit, and to root out any that exists. Men engaged in this business are not wise in their generation. They are sowing seed that after not many days may be reaped in great tribulation.

## Prospects of Electric Locomotives.

The exhibition of an electric locomotive at the World's Fair has been the cause of a new flood of articles giving obituary notices of the steam locomotive, which is soon to be superseded by one driven by electricity. If our railroads could be operated more cheaply with electric locomotives than they are by steam, the change would be made very quickly. Commercial considerations would bring about the change with as much certainty as they are putting in electric apparatus to displace horses in the hauling of street cars. But there is nothing yet in sight to indicate that electric motors would not cost twice the expense incurred in moving passengers and freight by direct steam locomotion. There may be cases like the Niagara Falls Canal, which is going to supply immense power, where electricity could be generated and transmitted for the moving of railroad trains so cheaply that its use would be economical. Waterfalls and rivers may in this way be used to supply power for railroad purposes, but there are comparatively few places where such sources of power are available. So long as the dynamo that generates electricity has to be driven by a steam-engine, there is small likelihood of an electric locomotive taking the place of the steam locomotive unless under exceptional circumstances.

It appears to us that an electric locomotive is a mistake, anyhow. Those who work on this line of invention attempt to perpetuate the worst feature of a steam locomotive, which is the big percentage of dead weight added to the train. To exert a starting power of 20,000 pounds on the draw-bar a locomotive must weigh over fifty tons. A steam locomotive has a heavy boiler to carry, which does much to give the necessary adhesion. A boiler is not required in an electric motor, so the weight necessary for adhesion would have to be carried on the form of useless metal. An ideal railway train would be one in which the vehicles would be utilized to give adhesion to the driving power, but this is impracticable with steam. When electricity is employed the case is different, and the wheels of the cars can easily be made the drivers as in the case of street cars. A train operated in this way would not have a heavy locomotive to be lifted up every hill and to add nearly as much weight as the remainer of the vehicles. If ever electricity should come into use for the operating of surface roads, we anticipate that every car will carry its own means of applying power. The prospects of seeing electric locomotives in the front of trains are not good

## Slipped Eccentrics.

A correspondent from California mentions a rather novel way he followed in setting a slipped eccentric. The engine was put on the dead center and the eccentric set as near to its proper position as the engineer could get it. Then he removed a set-screw, and putting his finger through the hole kept moving the eccentric until his finger found the impression that the set-screw had made in the driving-axle. The set-screws were then fastened and no more adjustment was necessary, for the eccentric was set in its old position.

It is surprising that at this period of advanced practice and prevalence of common sense how many particulars we receive of difficulties occurring on the road through the slipping of eccentrics. The roads that depend upon set-screws alone to hold eccentrics are tempting the annoyance and delay which inevitably occur when an eccentric slips while an engine is hauling a train. The men who are wedded to the ancient practice of securing eccentrics by set-screws insist that the set-screw is much more convenient than a key when any change has to be made on the valves, and they cannot understand why set-screws should not be as efficient and reliable now as they formerly were. This is very lame reasoning. It is all very well to have locomotives in such shape that repairs can be made readily, but the convenience of the shop should not be considered for a moment in comparison with security on the road.

It is simply criminal to send out locomotives of modern size and steam pressure with merely set-screws to hold the eccentrics. Over and over again the story has been told of how a train was speeding safely toward its destination, everything favorable to its arrival on time Without the least warning, an eccentric slips and the train suddenly stops. What is the matter no one knows to a certainty, but it is expected that the delay will be short, and all the trainmen have their attention directed to the engineer, who is under the engine trying to locate the trouble. No one has gone back to protect the rear end, and suddenly wild whistling is heard, then a crash, and a slipped eccentric is again responsible for the blotting-out of human lives and the destruction of much property.

Some day the authorities will learn enough to trace backward to the person who is really responsible for this kind of accident. It will then be a black day for the man who prefers set-screws because they are handy in case of changes being made on the valves.

## Charging Oil to Engines.

One of the most interesting discussions at the late meeting of the Traveling Engineers' Association was on the subject of economy in oil. A great diversity in practice soon pointed out that any comparison between roads as to miles run per pint or quart was unfair. One member stated that shop men packed cellars and driving-boxes and that the oil so used was *not charged to the engine*; another did not charge oil used on tender, while a third issued oil to wipe the engine with and charged oil used in wiper's torches to the engine.

The amount of oil used by the engineer must vary with the weather, trains, country and service. It was generally agreed that the best way to check extravagant men was to limit the supply, but not to judge of the amount necessary by what they did on another road with altogether different conditions.

The following resolution, proposed by John A. Hill and adopted by the Association, seems to be a fair and honest way to regulate the standard of consumption. It puts every engineer on his mettle and interests him in proving that he has some judgment, if allowed to use it, for he has no means of knowing what the average of the best half of the men will be, and an engineer who would not *want* to be one of the best half wouldn't be much of an engineer:

*Resolved*, That, in the opinion of this association, there is no reliable comparison between roads as to the use of oil per mile run. Each engineer must make his time and be allowed some judgment in the use of supplies. We believe that the standard should be the monthly average of the best half of the engineers. This makes allowance for local differences in the roads, climate and experiments in oil.

## Measurements in Brazil.

We have lately seen a statement published to the effect that the makers of American and English machinery are placed at a disadvantage in the markets of Brazil because the workmen in that country are accustomed to metric measurement and therefore prefer machinery made in France and Belgium where metric measurements are followed. This seems a very reasonable thing, but there is nothing in it, nevertheless. The principal article about a machine that a workman will get confused with if he has to apply a strange measurement, is a screw. It is easily seen how a workman measuring after the meter standard would be puzzled by having to figure on the number of threads to an inch. But this is what he has got to do even with French and Belgian screw-threads, for they are made after the Whitworth standard and the threads are reckoned by the inch. It is a little hard on the metric system followers that the world's standard of screw-threads is based on inch measurement, but they must put up with the inconvenience or adopt a new standard for themselves. There is no cause, however, for American and English makers of machinery becoming panic-stricken and changing their standards of measurement to suit Brazilian workmen.

### The Machinist.

A highly interesting article on "The Machinist," by Mr. Fred J. Miller, one of the editors of the *American Machinist*, was published in the September issue of *Scribner's Magazine*. The article is profusely illustrated by sketches made by Otto H. Bacher, who evidently has an eye more for striking pictures than for portraying the real work done by machinists. There are picturesque scenes of operations in blacksmith shops and foundries, but very few pictures of what one sees in a machine shop proper.

Mr. Miller tells in a very attractive fashion how the machinist trade has grown up, till now the man engaged in this business not only performs the most important functions in the peaceful arts, but actually does more than the soldier to render warfare destructive. Details of the machinists' work, as performed under a great variety of circumstances, are given. The article contains so many readable paragraphs that we should like to quote pages of it, but want of space compels us to be satisfied with the following extracts that relate to railroad work:

"In the railroad town the machinist performs much the same office with respect to locomotive and train service, a great deal depending upon his knowledge what to do and how and when to do it. Here the character of his duties usually requires that he be in readiness to be called upon at any time. In the roundhouse there is always employed the regular 'night gang,' which includes a number of machinists whose duties consist of making such slight repairs as may readily be made during a few hours of darkness, made visible by a brace of kerosene-burning torches, remarkable much more for their smoking than for their illuminating powers. But the other men employed in the roundhouse and in the 'back shops' by day, may be called out in emergencies from bed, from church, or even from a visit to their sweethearts; for railroad trains, like Tennyson's brook, must go on forever, and locomotives must be ever ready to pull them. If a rod-brass heats during a run, or if anything else about the engine goes wrong, the engineer very properly sacrifices every other consideration to making his time, and leaves the defects to be permanently remedied at the end of the run by the machinists. Usually the defects are real enough, but it is a regular article of faith with the machinist to charge that many of the complaints entered against engines by their runners are founded upon imaginary defects, and many of the jobs of repairing are accordingly equally imaginary; experience showing that the imaginary repairs often completely cure the imaginary defects—a simple case of adapting the remedy to the disease—something which all true machinists make a specialty of.

"Another effect of the circumstance that the machinist is not so much in evidence as other men, is seen in his connection with railroad work. We see the locomotive engineer, for instance, and understand something of the important duties he has to perform; there is a far less adequate conception of the importance of the work of the machinist in making and keeping in repair the locomotive and its appurtenances. To the traveling public it is as important that the engineer should have an engine ready to respond to his guidance as that the engineer himself should be ready to perform his duty; but the highly skilled and exacting work of the machinist, executed perhaps at night, and often under the most disadvantageous and discouraging conditions, yet necessary to be performed in order that the resplendent machine may be able to take out its early morning express, is little thought of, because unseen."

### Care of Air-Brakes on Freight Cars.

The New York Central people are putting in a plant at Buffalo, to be used for the testing of freight-car brakes. The necessity for plants of this character is every day becoming so urgent that a general movement must soon be made to provide means for making certain that brakes are in operative condition when the cars leave terminal points. So many freight trains are now handled with the air-brake that their safe movement requires the brakes to be in good working order. As the exact condition of a brake cannot be ascertained until air has been applied, hundred of cars pass ordinary inspection when the brakes are not in working order. Many railroads pay no attention to the brakes of freight cars till they are found useless, a careless practice which causes great annoyance to trainmen and danger in handling trains.

The whole question of care of air-brakes on freight cars is badly in want of thorough investigation. Under existing rules of interchange, the careless companies impose the maintenance of brakes upon those that strive to keep in good order the rolling stock passing over their lines. Rules ought to be adopted which will help to spread the expense of brake maintenance more evenly among those deriving the benefits.

### A Law to Punish Train Robbers.

A bill has been introduced into Congress which proposes to make the growing business of train robbing and wrecking more perilous to those who engage in it than it is to-day. The act provides that any person who does or causes to be done any act whereby any car is stopped, obstructed or injured with intent to rob or injure any one passing over any railroad engaged in interstate commerce, and where in consequence of such acts any person is killed, shall be guilty of murder. If the attempt does not result in murder, the guilty person, on conviction, shall be imprisoned at hard labor for from ten to twenty years. Circuit and District Courts of the United States are given jurisdiction of all cases arising under the act. The bill has been referred to the Committee on Interstate Commerce.

Train robbing and wrecking have been so outrageously common of late that vigorous suppressive measures are necessary, and Congress will not act fairly towards the traveling public if the bill does not promptly become the law of the land. The train robber is the successor of the old highway robber, with the difference that murder or violence nearly always accompanies his thieving attempts. Under existing laws train robbers who commit murder generally escape the supreme punishment on the plea that murder was not premeditated. It is high time that strong laws were enacted to meet existing conditions of transportation, for most of the State laws appear to protect rather than punish this class of criminal. Many scoundrels who are now ready to shoot trainmen who interfere with their raids would be less inclined to kill people if they understood that it would lead them to the gallows.

### Colenour Disaster.

The handling of trains on single tracks is so skilfully and carefully done that collisions due to mistakes in orders are now happily rare, but they happen at times, and always will happen while a mile of single track remains. One of the worst accidents of this kind that has occurred in recent years happened on the Western lines of the Pennsylvania at Colenour, Ind., on September 6th. Two south-bound trains had the right of way, and it was determined to hold them for a north-bound milk train. The train-dispatcher gave orders to hold one of the trains, but evidently forgot about the other one. He gave the milk train an order to proceed, and a disastrous collision was the result, twelve persons having been instantly killed and many injured. The railroad company intimated that a searching inquiry would be made into the cause of the accident. It looks as if very little investigation was necessary. The train-dispatcher acknowledged that he alone was responsible, and left for parts unknown.

### Notice.

Owing to failing health Mr. Jos. W. Curran has resigned the position of advertising agent of this paper and will remove to a milder climate; his future home will be at Prescott, Arizona.

Mr. Geo. W. Wollaston will hereafter have charge of the advertising pages of LOCOMOTIVE ENGINEERING. Mr. Wollaston is not without experience in this line, as he was "raised in the business," his last newspaper connection being with the *Railroad Gazette*. For the past three years Mr. Wollaston has been on the road selling machine tools for Pedrick & Ayer, of Philadelphia.

We are flooded with communications, *pro* and *con*, on the subject of seniority. To open this door will let in a flood of uninteresting argument that will do no good; neither side will be convinced. The seniority men argue that seniority is right, *merit and efficiency* being equal, forgetting that this equalism is very seldom, if ever, balanced, and also forgetting that some one must be the judge as to whether they are equal or not. And who will be this judge but the responsible officer? On the other hand, the opponents of the seniority rule are apt to think that the absence of their bugbear will cure all the ills of the great body of working railroaders. If the railroad officials who have the making of engineers would only select with greater care the material of which they make firemen, and do their heavy examination act *before* they want them for engineers, there would be no objection to the promotions being made on a seniority basis. As the matter stands, it's a choice on many roads between seniority and nepotism—both undesirable. Any way you fix it, it's not the place of a mechanical paper to quarrel about it.

It costs less than $1 to mine a ton of anthracite coal. The selling price of this material varies from $5 to $6 a ton within a range of 100 miles of the mines. The prevailing money stringency has not resulted in any reduction in the price of coal, but the mine owners appear to be worried lest something should happen to make their profits less than 300 or 400 per cent. Recent press dispatches intimate that "the coal operators of the Wyoming and Lehigh region met at Glen Summit and talked of forming a pool of $2,000,000 for the purpose of protecting themselves during the depression in the coal trade. Each operator will contribute a pro rata share, according to his output, to form the pool, and the money will be used to store the coal at tidewater until such time as the trade will take it." This means that an unlawful combination has been formed to maintain the existing scandalously high price of a prime necessary of life.

During the year ending with June, 1891, 531,183,998 passengers were carried by the railroads in the United States, on which 784,285 persons were employed in their operation. In the same year 293 passengers were killed, and 2,972 passengers injured, or one passenger was killed for every 1,811,042 carried, and one passenger injured for every 178,604 carried, while for the same period 2,660 employés were killed and 26,140 were injured, or one was killed for every 296 employed, and one injured for every 30 employed.

### PERSONAL.

Mr. John Mackenzie, superintendent of the New York, Chicago & St. Louis, celebrated his silver wedding on Sept. 22.

Mr. C. W. Hedges has been appointed road foreman of engines of the Northern division of the Burlington & Missouri River.

Mr. W. P. Raidler has been appointed master mechanic of the St. Louis & Hannibal Railway. His headquarters are at Hannibal, Mo.

Mr. T. W. Younger has been appointed master mechanic of the Oregon lines of the Southern Pacific, in place of Mr. A. Brandt, resigned.

Mr. E. C. Hiser, who has been master mechanic of the Adirondacks & St. Lawrence division of the New York Central, has been transferred to Utica, N. Y.

Mr. D. A. Fleming has been promoted from the cab to be traveling engineer of the Lake Shore & Michigan Southern in place of Mr. W. O. Thompson, promoted.

Mr. George P. Wilson, who is well known to railroad men as agent for the U. S. Packing Co., has become agent for the Columbia Metallic Packing Co., of Philadelphia.

Mr. J. C. Morrison has been appointed chief clerk of the motive power department of the Northern Pacific. He was for some time purchasing agent of the Great Northern.

Mr. C. W. Walker, master mechanic of the Seaboard & Roanoke, has been appointed master mechanic of the Raleigh & Gaston road, which belongs to the same system of roads.

Mr. Frank Hernandez has been appointed general foreman of the shops of the Florida Central & Peninsular at Fernandina, Fla., to succeed Mr. M. M. Adams, who has resigned.

Mr. E. M. Luckett has been appointed master mechanic of the Salt Lake division of the Southern Pacific in charge of work and employés, locomotive and car departments, with headquarters at Terrace, Utah.

Mr. T. Freeman, who has been for several years with the National Tube Works, has accepted the position of sales agent of the Detroit Lubricator Co. Mr. Freeman is chairman of the Railroad Supply Men's Association.

Mr. John T. McBride has been appointed manager of the Everett & Monte Cristo railroad with headquarters at Everett, Wash. Mr. McBride was for several years superintendent of terminals of the Illinois Central at Chicago.

Mr. J. S. Seeley, traveling engineer of the Wisconsin Central road, has been appointed to a good position with the Galena Oil Co. Mr. Seeley is the third traveling engineer from this road who has been captured by the Galena.

Mr. G. W. Evans, one of the able foremen whom Mr. T. W. Gentry, master mechanic of the Richmond & Danville, developed in his shops at Manchester, has gone to the Richmond Locomotive Works to take charge of one of their departments.

Mr. W. W. Monroe, who was recently appointed superintendent and traffic manager of the Beattyville & Cumberland Gap road in Kentucky, with headquarters at Versailles, was formerly secretary of the New Orleans Freight Traffic Association.

Grand Chief Arthur, of the Brotherhood of Locomotive Engineers, has settled for $2,500 and costs the suit brought against

...m by the Toledo & Ann Arbor Co., on account of the strike. The suit was for 100,000. The Brotherhood will pay the bill.

Mr. Daniel Coxe, superintendent of motive power of the Delaware, Susquehanna & Schuylkill, has been appointed superintendent of that road with headquarters at Hazelton, Pa. Mr. H. J. Davis has been appointed assistant superintendent.

Mr. C. W. Card, trainmaster of the Chicago division of the Chicago, Burlington & Quincy at Aurora, Ill., has been appointed superintendent of the St. Joseph & Grand Island, with office at St. Joseph, Mo., in place of Mr A M. Morey, transferred

Mr. R. B. Fowler has been appointed superintendent of the White & Black River Valley road, with headquarters at Newport Ark. Mr. Fowler rose through a variety of positions on the St. Louis & Iron Mountain and is spoken of as a man of decided ability.

Mr H. L. S Bean has been appointed secretary to General Manager Doddridge of the Missouri Pacific. He was formerly with President Fordyce of the St. Louis Southwestern, and was selected for the decided abilities he displayed for promptly handling the world of business referred to a general manager.

Mr W. C. Pennock, master mechanic and road foreman of engines of the Cincinnati division of the Pennsylvania lines, has been appointed master mechanic of the Chicago division of the Pittsburg, Cincinnati, Chicago & St. Louis, with headquarters at Logansport, Ind., in place of Mr. W. W. Reynolds, transferred.

Mr S L Bean has been promoted to be master mechanic of the Minnesota and Lake Superior divisions and branches of the Northern Pacific, with headquarters at Brainerd, Minn, vice Mr. A Bardsley, resigned. Mr. Bean's jurisdiction is extended over the car department at all points on above divisions, except St. Paul and Minneapolis.

Mr. W W. Reynolds, for eleven years master mechanic of the Pennsylvania lines at different points, has been removed to the office of the superintendent of motive power at Columbus, O., where he will be assigned to special duties. Mr. Reynolds has been a regular attendant at the Master Mechanics' Conventions, and has numerous friends among the members.

Mr. L. H. Palmer, traveling engineer of the C., St. P., M & O., has been appointed traveling engineer for the Galena Oil Co., in charge of the Alton road—his old home. The Galena people are picking up a lot of good traveling engineers and are getting live, intelligent men. The "Omaha" is one of the roads that practice economy at the wrong end, and have abolished the office of traveling engineer

Mr H. C Ives, assistant to Vice-President Robinson, of the Santa Fé, was among the unfortunates killed in the Boston & Albany bridge accident. Mr. Ives was long associated with the late President Manvel, of the Santa Fé, and was highly popular among a large circle of railroad and railroad supply men. As president's secretary and as purchasing agent he was always ready with a kind word. If he had to disappoint people sometimes he treated them like a true gentleman.

It is reported that Mr. Charles Neilson, late general superintendent of the Cincinnati, Hamilton & Dayton, is striving to be appointed superintendent of mails under the government. Mr. Neilson is an excellent railroad man, but his inclination to monopolize authority is so decided that we should not be surprised if, on being appointed superintendent of mails, he took charge of the White House and all its authority as a department over which he had the right to wield sway.

Mr. A. Brandt, who has just resigned the position of master mechanic of the Oregon lines of the Southern Pacific, on account of failing health, is one of the oldest railroad men in the country. He had been closely associated in railroad work with an elder brother, who was in 1855 superintendent of the Lancaster Locomotive Works, and before that was assistant superintendent of motive power of the Erie, having risen from the position of engineer on the same road. Both brothers were on the Erie, and both were known as remarkably able mechanics.

Mr. Alexander Mitchell, who was superintendent of motive power and rolling stock of the eastern and northern divisions of the Lehigh Valley under the lease to the Philadelphia & Reading, has been appointed superintendent of motive power and rolling stock of the entire Lehigh Valley system under the independent management. From 1864 to 1871 Mr. Mitchell was master mechanic of the Mahanoy division of Lehigh Valley and from 1871 to 1892 superintendent of the Wyoming division. Of course, all our readers known that Mr. Mitchell was the designer of the first consolidation locomotive.

Division Superintendent J. C. Sanborn, Roadmaster Emory Bryant and Detective Christopher Bailey, of the New York, New Haven & Hartford Railway, have each been sentenced to one month's imprisonment in the House of Correction by the judge of the District Court at Abington, Mass., on the charge of inciting a riot. This was the outcome of a bitter crossing

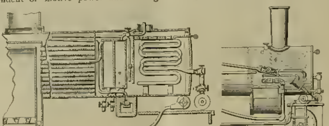
PORTER'S "MIDGET," NOW AT WORLD'S FAIR.

fight at North Abington between the New Haven road and the Electric railroad. The case was summarily disposed of and no appeal was taken. This seem hard, but it is an emphatic intimation that the barbarous practice of trials of physical strength in establishing a grade crossing are contrary to law and justice.

Mr. Lucius Tuttle, who has been vice-president of the New York, New Haven and Hartford, and is one of the most energetic railroad managers in the country, has been elected president of the Boston & Maine. Mr. Tuttle was for several years on the Eastern Railway, now part of the Boston & Maine, first as general passenger agent and subsequently as assistant to the general manager. The greater part of his railroad life has been spent on New England roads, and in every position held he has displayed commanding abilities The opportunity of his life has come now, for he has become the chief executive officer of a railroad with splendid resources, that have been dwarfed by miserly narrow-minded management.

### The Latest Thing in Car Heating.

The appliances illustrated in the annexed engraving embrace the very latest invention for heating railroad cars. A superficial observer might conclude that it was some engineering invention with a locomotive attachment as a side issue, but the locomotive is really intended to be the controlling element in the machine shown. The apparatus is declared to contain new and useful improvements in car heating and ventilating. It relates to that class of car-heaters and ventilators in which the air used for the purpose is taken from the front of the locomotive and is heated by the stream of hot gases produced therein. The object of the invention is said to be

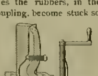


the producin' of simple and inexpensive means for utilizing the wasted heat and gases received in the smokebox of a locomotive, and also the caloric power of the exhaust steam. The purpose of the invention is to take air in through the smokebox, where it will be heated and pass it throughout the cars. This is accomplished by the use of the rotary pump seen at the side of the smokebox. The steam from the cylinders is exhausted into a water-heater shown in front of the tube-plate, and from thence passed throughout the train in a pipe placed inside the air-pipe. Appliances are provided for conveying the cinders out of the smokebox into the firebox. The invention comprises a car-heater and ventilator, a spark-conveyor and a feed-water heater. It might do all these things, but our conclusion is that the locomotive would have very little steam to move trains with.

### Device for Cleaning Air-Brake Couplings.

In the course of a ramble through one of the large railroad shops, recently, says Paul Synnestvedt, I ran across a device which may be of interest to other air-brake men. As Mr. Fred. Meyer, of West Chicago, the man who showed it to me, had no drawings of it, I have made the accompanying sketches from memory, and think they will serve to show the construction and method of operation with sufficient clearness to be understood by most of our readers.

Sometimes the rubbers, in the latest form of coupling, become stuck so tightly



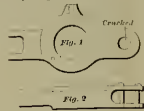
in the groove that they have to be dug out in pieces, and without some kind of a special tool it is very hard to get the groove clean enough to make a tight joint with the new rubber. This tool does the work quite easily and satisfactorily, but in making it great care must be taken that the cutter is of such a shape that it will not do any damage to the shape of the groove or the coupling will be spoiled.

Another method of fixing these couplings is to burn out the old rubber, a very low heat being all that is necessary. If they are put in a hot fire it will spoil them. I know of one place where this method has been tried with considerable success.

The next meeting of the Traveling Engineers' Association will be held at Denver, Col., September 12, 1894.

### Repairing Broken Rod-Knuckle.

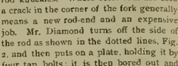
The sketch shown herewith illustrates a trick used by General Foreman W. A. Diamond, of the Lake shops at Cleveland, O., in repairing broken fork ends for side-



rod knuckles. Where steel rods are used a crack in the corner of the fork generally means a new rod-end and an expensive job. Mr. Diamond turns off the side of the rod as shown in the dotted lines, Fig. 2, and then puts on a plate, holding it by four tap bolts; it is then bored out and bushed. This makes a good job and is done quickly without heating the rod.

### McNaughton's Nut-Lock.

The bolt, with nuts applied, shown herewith, is the invention of Mr. James McNaughton, of the Wisconsin Central, and forms a most secure nut-lock. This form of bolt is used on eccentric-straps, pedestal-binders and other places where the loss

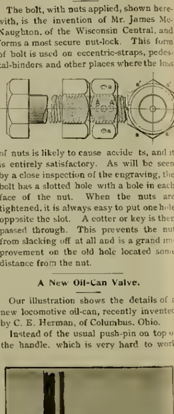


of nuts is likely to cause accidents, and it is entirely satisfactory. As will be seen by a close inspection of the engraving, the bolt has a slotted hole with a hole in each face of the nut. When the nuts are tightened, it is always easy to put one hole opposite the slot. A cotter or key is then passed through. This prevents the nut from slacking off at all and is a grand improvement on the old hole located some distance from the nut.

### A New Oil-Can Valve.

Our illustration shows the details of a new locomotive oil-can, recently invented by C. E. Herman, of Columbus, Ohio.

Instead of the usual push-pin on top of the handle, which is very hard to work



when the can is tipped up, the valve of this can is opened by pushing to one side the small lever on the back of the handle.

The valve itself is larger than usual and is located in the lower end of the spout; it has side openings that prevent foreign substances from clogging the valve; the valve will close even when there are a great many cinders in the can.

The economy of oil from using a valve-can is undisputed; the trouble has been to get a valve-can that would keep in order.

## Stupendous Stone Breaking.

Away in Southern Illinois, when the weary stretches of level prairie are left behind, a traveler going south on the Illinois Central reaches a varied upland country with bold knolls and low hills that mark an irregular upheaval of sub-car-

boniferous rock. There are finely wooded hillsides, with many a grassy vale, clear running brooks and ponds gay with water lilies and suspicions of malaria. This is the land that is contemptuously spoken of as Egypt. It borders the Ohio river and dips down to Cairo, that semi aquatic town where Dickens in his novel led Martin Chuzzlewit and Mark Tapley to be poisoned with malaria, and to give excuse for picturing America as a good place to stay away from, which thousands have done on account of that story.

While still among the uplands, the line passes the high perpendicular quarry and plant shown in the annexed view. This is a rock-crushing plant used by the Sinclair Construction Company, of Chicago, in preparing ballast for the Illinois Central Railroad Company. The plant was established three years ago, and has a capacity for crushing about 600 yards a day of stone fine enough for ballasting. The railroad company has been in a position to take the product of the crusher only for a few months each year, but during the three years it has been in operation a little over 260,000 cubic yards of rock has been placed under the track. It makes a splendid roadbed, and some of it has borne the heavy main line traffic for three years with next to no attention.

The quarry, whose face is seen in one of the views, is very systematically worked under the direction of Mr. Donald Sinclair, a member of the construction company, who has enjoyed extensive experience in quarrying and tunneling. Beginning at the top, a layer of the rock is drilled with Ingersoll 3½-inch steam drills, and the holes charged with forcite powder, a compound of dynamite. The charge is fired with electricity, and an immense volume of the quartzite rock, of which this quarry is composed, is torn into fragments. Next layer is worked in the same way until the bottom is reached. It is greatly to the credit of the superintendent, Mr. William More, that accidents from the handling of the large quantity of explosives employed in this work are almost unknown. Constant vigilance is necessary to keep the men handling the powder from becoming reckless. Familiarity with dangerous material always breeds contempt. When a man in charge of the explosives begins to manifest the least carelessness he is sent to other work.

After the explosives have done their work on the rock, it is broken by hand and loaded into narrow gauge ballast cars, which are drawn by horses to the inclined plane leading to the crusher, up which they are drawn by cable and dumped beside the mouth of the crusher. This is a Gates No. 7, which crushes the stone by a revolving serrated cone. The work is done very expeditiously, for this machine crushes about a yard and a quarter a minute. As a yard of stone weighs about 2,700 pounds, the stone-chewing capacity of the machine is very great. On passing through the crusher the rock falls over a screen through which the sand and dirt passes, while the clean ballast slides into a Rogers ballast car, which can be seen receiving its load in one of the views.

A small village has sprung up round the quarry, for about 150 men are employed in doing the work. Besides the men doing manual labor, there are ten horses, the boiler and steam engine for driving the crusher, a boiler on the top of the quarry for supplying steam to the boring drills, and a great deal of miscellaneous machinery.

The Rogers ballast car carries about 20 yards of rock, and is admirably adapted for this kind of work. Its use has cut nearly in two the expense of putting ballast under a track. On a train of these cars being loaded, an engine is ready to haul it to the place where the ballast is to be distributed. While the train is slowly moving the car drops the stone in a ridge between the rails, and a plow attached beneath the last car on the train spreads the ballast in the state where it is right for track-raising. No hand work is required. The trainmen become wonderfully expert in unloading the correct quantity of ballast, and they say that it can be spread out at a speed of ten miles an hour, but half that speed is preferred, because it does not scatter the material. About ten inches of the rock is put under the track, and at this depth it takes about 3,000 cubic yards to the mile. About ninety miles of the southern lines have been ballasted with this rock, and the railroad company expect to finish the greater part of their main line in this way. The railroad company employs about 100 men, raising track and changing ties, when they are receiving 600 yards a day. This quantity of ballast supplies about 1,000 feet of track.

The Sinclair Construction Co. have another rock-crushing plant near Dubuque, Ia., which has been used to supply ballast for the northern lines of the Illinois Central Railroad. It is similar to that shown. Three years ago thirteen miles of double track between Portage Junction and East Dubuque, which is used jointly by the Illinois Central, the Chicago, Burlington & Northern and the Chicago & Great Western trains, were ballasted. A very heavy traffic has hammered over this track in wet and dry weather—mostly wet, yet the track has received very little repair and is still in excellent order.

There is very little rock-ballasted track west of Chicago, but the enterprise displayed by the Illinois Central in doing this work is convincing many railroad men that stone ballast is the cheapest and best. The indications are that when business revives the prairie country will soon be dotted with stone-crushing plants preparing ballast that may be depended upon to keep the rails out of the mud.

---

In another column we publish a communication from Mr. John H. Cooper, a well-known mechanical engineer, on "A New Unit of Measure." Mr. Cooper argues that the decimal system of graduating rules and scales should be maintained. He also holds that the basis of the existing inch is better adapted than the millimetre for a new unit of measurement, and he proposes to make a new unit 1½ inches long, to be divided into 100

equal parts. The arguments given are very good, and the proposal is well worthy of consideration. We should be glad to received the views on this subject of other readers interested in standard measurements.

---

The progress being made by the Cambria Iron Co. in the introduction of their high-class quality of Open Hearth steel, reenforced by the Coffin process of toughening, must be most gratifying to them. While the temptation during the last few years to meet the market price and quality—which meant just what the railroads offered to pay—has been great, they seem to have adhered to quality and price evidently from a conscientious motive that it would win and be recognized in the end. This material, we note from a recent circular, has found its way to about 125 roads in the shape of axles, crank-pins and piston-rods.

---

The Order of Railway Train Dispatchers, at its annual convention, recently held in Chicago, propose to adopt measures which will lead to the enforcement by the roads of a requirement that each train-dispatcher shall pass a competitive examination and hold a certificate of competency before he becomes eligible to the position of train-dispatcher.

## EQUIPMENT NOTES.

The Beech Creek Railroad have ordered 200 cars from the Buffalo Car Co.

A chattel mortgage for over half a million of dollars has been given by the Baltimore and Ohio to the Baldwin Locomotive Works on fifty locomotives purchased.

On the C. & N. P. engine, shown last month, there is a Golmar bell-ringer, worked by air; when the whistle is blown the bell is automatically set to ringing and keeps it up until shut off by hand.

The Jacksonville, St. Augustine & Indian River have ordered seven additional engines, making ten in all, from the Schenectady Works. The axles, crank-pins and piston-rods are of the Coffin toughened steel.

The Boston & Albany are receiving steadily from the South Baltimore Car Works between fifty and sixty box cars per week on their order for 700 cars, with which they express themselves as very much pleased.

The Buffalo Car Co. are building 200 gondola cars of 60,000 pounds capacity for the Goodyear Lumber Co. for use on the Sinnemahoning Valley Railroad. They will all have M. C. B. couplers and Westinghouse air-brakes.

The Rogers Locomotive Co. are building two 14 x 20 moguls for the Ferro-Carril Santafecino, Argentine Republic. The engines are entirely American but the tanks are the regulation European six-wheel, plate-frames, horn-blocks, etc.

The Fitchburg have called a halt on the construction of the 1,000 cars in their own shops, but it is stated that the check is only temporary, that they will, in all probability proceed with them as soon as they can work off some cars needing repairs.

The Ramapo Iron Works, of Hilburn, N. Y., are building 250 narrow-gauge freight cars for a number of plantations in Cuba. Mr. Snow has a great reputation in Cuba for car building—he cuts all his wood in the decline of the moon, it never will rot—so the Cubans say.

The Mt. Vernon Car Mfg. Co., Mt. Vernon, Ill., have secured the order for 300 fruit cars for the Florida Central & Peninsula. This concern have been running their shops full time during the dull season, and have orders enough to keep them busy until Jan. 1st.

The Brooklyn, Bath & West End Railroad, a suburban line that has been doing a good passenger business, are about to begin operating with trolley electric cars. All the steam-operated rolling-stock is offered for sale, including seven locomotives and forty passenger cars.

The prosperity of the Florida roads is most gratifying, and is indicated by the fact that in addition to the ten engines ordered by the J., St. A. & I. River, they are about to order fifteen first-class passenger cars. The Plant System is also considering additional equipment.

A neat illustrated catalogue has been published by the Brake Pressure Regulator Company, Chicago. It gives a very clear description of the working of the brake pressure regulator and illustrates how the power transmitted varies according to the weight on the trucks.

It is surprising to find how many roads there are, especially in New England, that fail to have a first-class lens lamp carried in a uniform position at the rear end of train. The use of lamps, with the same colors and classification as rear end signals, is a measure of safety, and ought to be generally adopted.

Dixon's graphite is making steady progress into favor as a lubricant for air-brakes, and is much less objectionable than oil. The Joseph Dixon Crucible Co., Jersey City, N. J., have issued a pamphlet on the subject, which all men interested in the lubrication of brakes ought to read. It will be sent free on application.

The Central Railroad of New Jersey, the Erie and several other railroads in the East are using the Smith exhaust-pipe on several of their locomotives. The officers of the mechanical department and the engineers running the engines speak very favorably about this exhaust-pipe. It reduces the coal consumption and gives a soft exhaust that makes remarkably little noise.

### To Build Raub Locomotives.

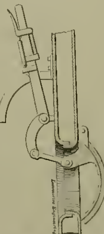
A press dispatch from Elwood, Ind., says: "The papers have been signed for the location of the Raub Locomotive Works in this city. The buildings will cover sixty acres, and employment will be furnished 2,500 or more workmen. A free college with $500,000 endowment for the benefit of citizens of Elwood is in the contract."

This looks like an ambitious scheme for these times. If the promoters succeed in building one Raub locomotive it will probably keep 2,500 men busy trying to make it work.

As most of our readers may know nothing about the Raub locomotive we reproduce a description of the engine which appeared in the *Locomotive Engineer* several years ago.

"Out back of the Erie shops, at Jersey City, stands a monument to the memory of the wasted dollars of a man who thought he could improve the American locomotive. The monument consists of one complete 'Raub Central Power Locomotive.' Just what the inventor of this miscarriage of ingenuity was trying to do it is very difficult to understand—what he actually made is very plain. At a glance, end on, the engine looks like a pile of air-drums, tankboxes and ashpans around a boiler front. There are two separate and distinct small boilers of the regular pattern mounted on four drivers each, making eight in all; the boilers have a door on each side of both fireboxes, and none in the ends. The frame is continuous, mounting both boilers. Between the firebox ends of the boilers there is a round iron dome or tower, and on each side of this dome there are mounted vertical cylinders; these are in the cab, the heads being taken off through the roof. The main rods are coupled to disk cranks on a master shaft running in boxes on the frame, and rods run from this pin to the crank-pins on the wheels, the links are inside the central dome. From the top of each smoke arch a large square pipe leads back to the central dome, and one smoke-stack answers for both boilers. The water tanks are hopper-shaped affairs, located on the four corners of the engine, and there are also four coal bins, holding about a ton each. The air-pump and other rig is all in the cab, and the fireman can dodge around over the engine and use any of the four doors; he has to go out doors to go from one to the other. There is no tender. The water tanks are connected across the frame by 6-inch pipes running within a few inches of the track—sure to break off and cause a drought if the engine drops off a switch. Last summer they had this contraption out, and, as might have been expected, she suffered from chills from the start, and was something like five days getting ten cars over a division. But then, she is 'different.' The inventor, we believe, is a physician. As an improver of railway motive power he is a failure—not an ordinary, every-day failure—but a ripping, howling, sizzling failure."

COOKE TEN-WHEELER NOW AT WORLD'S FAIR



INSIDE OPENING FIRE DOOR, F. & P. M. RY.

We are glad to state, upon reliable information, that the recent report in one of the trade papers, to the effect that the Latrobe Steel Works had shut down for an indefinite period, and had discharged its hands, is without the slightest foundation, as they have been running continuously since their works were first started, and are prepared to execute all orders with promptness.

In addition to the 1,000 freight cars to be built by the Fitchburg, orders have been given for fifteen first-class coaches to be worked through their shops this winter. The ability of the Fitchburg car department to build this equipment as advantageously as contract shops could build it, becomes self evident on a visit to their works at Fitchburg. They seem to have every possible facility, both for repairs and construction, possessed by the average contract shop, with the additional advantage of intelligent high-class labor at perhaps a trifle less cost.

A new air-brake company is in the field. It was recently incorporated under the laws of New Jersey under the title of the Bothwell Compressed Air Improvement and Construction Co. The company propose to make air-brakes, steering apparatus, hoists, and other air-brake devices. Many of the incorporators are locomotive engineers from roads around New York. The officers of the concern are as follows: W. T. Bothwell, Jersey City, N. J., president; Geo. W. Waite, Jersey City, vice-president; Fremont Wilson, New York, secretary and treasurer; Jas. R. Naylor, Brooklyn, N. Y., general manager; A. R. Boluss, Jersey City, chief engineer, and J. W. Rosencranse, Brooklyn, N. Y., superintendent of construction.

The Bangor & Aroostook new equipment, consisting of engines from Manchester, passenger coaches from Delaware and freight cars from Berwick, is being rapidly delivered. This road is being pushed forward to completion, and ninety miles of the 209 will be put in operation in November. In our judgment, no more promising enterprise than this has been floated in many years. This county (Aroostook) contains some 60,000 people, and is almost as large as the entire State of Massachusetts. Much of the land is heavily timbered, the soil is rich and wonderfully productive. Charming country interspersed with beautiful lakes, abounding in fish and game, and withal only twenty-nine miles of railroad in the entire county.

The examiners-in-chief of the United States patent office, before whom the appeal of the interference case between the National Hollow Brake Beam Co., of Chicago, and the American Brake Beam Co., owners of the Pungs patent, had been carried, have decided in favor of the American Brake Beam Co., and the concluding paragraph of their opinion reads as follows: "Pungs remains unimpeached and uncontradicted in any important item, and as to matters in which he could be refuted by other testimony, he is as competent as any other witness. We find that Pungs is the first to conceive of this invention, and the first to reduce it to practice, and affirm the decision of the examiner of interferences that he is the prior inventor."

On September 22d our well-known contributor, Mr. Cy. Warman, started from New York on the Exhibition Flyer, and rode on the engine right through to Chicago. This was done for the purpose of collecting material for an article for *McClure's Magazine*. He was accompanied by a special artist, who made a great variety of sketches to illustrate the article. No one is better equipped to write an article of a correct and interesting character on this subject than Mr. Warman, for he is an old engineer, which keeps him straight on the technical part, and his general literary ability is of a high order.

The National Malleable Castings Company's car in the Transportation Building of the World's Fair contains several styles of malleable iron drawheads, center-plates, journal-bearing keys, door-hangers, dead-blocks, oil-box covers, truss-rod saddles, side-bearings, swing-hanger bearings, swing-hanger pivots, truss-rod washers, cup-washers, transom end castings, driving-box castings, door fasteners (old and new), brake-beam castings and other minor castings for car construction.

One of the P. R. R.'s new class "P" engines, with a 78-inch wheel, made a good record the other day, reaching a speed of 90 miles per hour between Stanton and Wilmington. On one run 65½ miles were made in 63 minutes, including six slow-ups. The 10$\frac{1}{10}$ miles between Bay View and Chases was covered in 9 minutes and 40 seconds. The boys call this good work for the P. W. & B., and the new "P's" are voted a success.

The C. W. Hunt Company, of Chicago invite everybody interested in the handling of coal, ore and similar material to examine their exhibit at the World's Fair. It will repay the time taken for a careful inspection. Those who have not got satisfactory means for coaling locomotives should not fail to study the Hunt exhibit.

The Society of Railway Superintendents meets in convention at the Grand Pacific Hotel, Chicago, October 10th. They have a long list of subjects which will be discussed, and there is every prospect of a profitable meeting. Secretary Hammond extends a cordial invitation to all railroad superintendents to attend the meeting.

The *Railway Age* has been investigating the lines through which railroad general managers have risen, and finds that of 125 managers, 31 began as clerks, 29 as civil engineers, 26 as operators or station agents, 23 as officials through financial connections, 12 as trainmen and 7 from the mechanical department.

The Chapman Jack Company continued to receive orders during the late financial disturbance as though nothing was wrong with the market, being a proof of the jack's superior construction and usefulness.

Indictments have been made at Tacoma, Wash., against President Van Horn, of the Canadian Pacific, for violation of the Interstate Commerce Law.

The Pennsylvania Railroad Company have commenced on an order of 100 box cars in their own shops.

### Suggestion for a Simple Device to Warn Engineer that Air Was Shut Off Part of His Train.

*Editors:*

In your August number W. M. Pipkin speaks of the danger of angle-cocks becoming turned while train is in service, thereby cutting out back end of train and making of it a sort of battering-ram to run into the front end when a quick stop is made.

Now, I would like to suggest an instrument that would (on trains equipped with air-signal) indicate to engineer whether all of train was cut in or not.

My plan is to have a valve—operated by a piston—coupled in between air-signal hose and train-pipe hose on end car of train, and so arranged that when a reduction of pressure was made in train-pipe (such as that when brakes are applied) the valve would be opened and let a little air out of signal-pipe, thereby indicating to engineer that the reduction had taken place in train-pipe on rear car, and therefore that all angle-cocks were open. This device, while it would not give its warning at the really proper time—namely, *before* the application of brakes—would be a constant watch on the angle-cock business.

It has the recommendation of simplicity, and one only would be required for each train. Perhaps this device has faults which I do not now see, or, as there is nothing new under the sun, it may have been tried in the forgotten past and proved a failure.

GEO. E. RHOADS.

*Weatherly, Pa.*

### Cases That Require More Than Twenty Pounds Reduction of Air.

*Editors:*

Mr. Ellis finds considerable fault with the requirement that engineers should not reduce over 20 pounds for a full application, and cites a case which I should call an *emergency*, implying that the rules do not permit him to make a full reduction of train-pipe pressure when needed. I know of no direct instructions anywhere which forbid him to use over 20 pounds of air in case of emergency. If he is aware of any such I should like to have him refer us to them, so as to give us an opportunity to attack them until they are corrected.

While Mr. Ellis is certainly correct in his statement that there are trains on which the best stop can be made by more than 20 pounds reduction, the reason which he gives, *i. e.*, dry and dirty triple-valves, comes far from being the correct one. Careful inspection proves that the triple-valve which will not work for 20 pounds reduction is a very rare specimen.

The trouble is more apt to be found in excessive piston travel, leakage in cylinders, or insufficient capacity of auxiliary reservoir, as is the case with many driver-brakes. Any of these defects will require a greater than 20 pound reduction to make the quickest possible stop. Let us take a specific case for illustration

We have a suburban train of three cars and engine, fully equipped with air. Suppose that one car (the first) had the brake in good shape, piston travel 7 inches, and cylinder well oiled and tight. A reduction of 20 pounds from 70 would apply the brake fully on this car.

Suppose the second car had 11 inches of piston travel. A reduction of nearly 25 pounds would be necessary on this one.

Suppose that the third car had a slight leak in the cylinder. A continuous reduction until the train came to a stop would get the most braking force out of this one, as thereby a part of what the cylinder lost could be replenished from the auxiliary reservoir.

Suppose that the driver-brake had only one auxiliary reservoir to supply both the tender and two driver-brake cylinders. The chances are that a reduction of nearly or quite 40 pounds would be necessary to secure full braking power, or more properly the limit of braking power that could be obtained here, because these three cylinders together would contain nearly as much capacity as the auxiliary reservoir itself, or even more in case the piston travel was very long.

A reduction of 20 pounds on this train would only apply one brake fully, and leave the others only two-thirds or half applied.

A reduction of 40 pounds would give, perhaps, one-third more braking power, and a reduction of all the air in the train-pipe would possibly add a little more to this in the case of the leaky cylinder.

Of course, such a heavy reduction would cause some leakage back to the train-pipe from the cylinders of the brakes which were fully applied, but this could hardly be sufficient during the short time of the stop to cause any material loss.

Such a train as this may be said to be a very exceptional case, but I question whether it is not more common than is generally supposed. While the benefits derived from a greater than 20 pound reduction may not compensate for the loss of pressure in the case of ordinary service stops, they are a great consideration in cases of emergency, or what might be called semi-emergency, such as arise sometimes after the service application has been applied to the extent of 20 pounds reduction.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

### How to Apply Brakes—A Question.

*Editors:*

I would like very much to find out, through the columns of your valuable paper, the proper way to handle the engineer's brake and equalizing discharge-valve, used in connection with the Westinghouse standard freight triple-valve having the quick-action attachment, in making an emergency application to apply the brakes in the most effective manner possible. In the Westinghouse instruction book we are told that to apply the brakes with their full force a quick reduction of 10 to 12 pounds should be made and the automatic attachments will do the rest. In another chapter of the same book we are told to make an emergency application, push the valve handle to the extreme right and the brakes are instantly applied with their full force. The statement has been made through the columns of LOCOMOTIVE ENGINEERING, and to the best of my knowledge has not been disputed, that as a general thing the reduction of pressure caused by placing the brake-valve handle in service-stop position was not rapid enough to cause the quick-action attachment to work. If reduction in train-pipe pressure is made in any other way than service application, how are we to know when we have made a reduction of 10 or 12 pounds? An answer and explanation will greatly oblige

MARK PURCELL.

*East Grand Forks, Minn.*

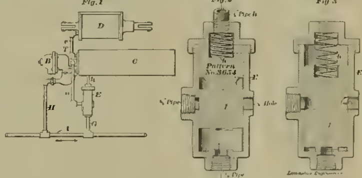
[In making an ordinary stop, of course, a reduction of pressure of six or eight pounds through the service-stop will do the business. When it comes to an emergency, use the emergency-stop, *and don't worry about the amount of air you get out of the train-pipe.* Of course, a ten to twenty pound reduction will cause the quick-action valves to work, and a further reduction of train-line pressure is waste, but if it's a real emergency, don't let that worry you. If, however, you want to stop as quickly as possible, and then go on, you can save much of your train-line pressure, and, consequently, the time it takes to restore it, by making a quick, heavy reduction of pressure and then putting the valve on lap. But you will have to guess at the amount you draw off, if you do so through the emergency port, for after the valve handle passes the service-stop, the passage to the small reservoir and the gauge is blanked, and the gauge doesn't register the fall of pressure in the train-pipe—this has scared many a man who thought the emergency was not taking hold. Rest assured that, if there is a rush of air out of the emergency port there is some heavy wheel-squeezing being done back under the train. Trying to trip the quick-action through the service-stop is an uncertain business.—EDS.]

### An Automatic Pressure-Retaining Valve.

*Editors:*

In reading an article by Paul Synnestvedt, in your August number, page 364, I notice he mentions several patents which were granted for the purpose of recharging the auxiliary reservoirs while brakes were applied, all which patents changed the feed groove or the release groove. Experience has demonstrated that the ports and grooves in the triple-valve are about just what is needful. When the Westinghouse Company improved their triple-valve, they did not alter the grooves or ports, but added thereto the quick action. While many patents have been granted on improving the triple-valve, whereby the train may be recharged while brakes are applied, I wish to call attention to patent No. 416516, issued December 3d, 1889, for an automatic pressure-retaining valve, which accomplishes the same purpose.

Fig. 1 Fig. 2 Fig. 3



When air and vacuum were first used, their chief merit was that the engineer had full power to regulate the speed of his train.

The automatic brake at present is automatic only when on a level road, or when the pressure-valves are not required. If on a mountain road, I would ask has the engineer full control of his train?

On mountain roads few grades are continuous, there being short distances which are almost level, where, if the brakemen fail to turn off the pressure-cocks, brakes will either drag or stop train. Also, at regular or flag stops on down grade, the engine has got to drag brakes when starting, if pressure-valves, as now used, are cut in.

This valve is connected with the discharge passage $T$ from the brake-cylinder. This opening $T$ as ordinarily employed allows the air to escape from the brake-cylinder $D$ when the triple-valve is so moved as to make connection between the train-pipe $A$ and train-reservoir $C$, but in the present case this escape opening $T$ is connected by a pipe $a$ directly with the side of the valve-chamber $E$ and the transverse passage $I$ through the valve $f$.

$V$ is the pipe which connects the brake-cylinder with the triple-valve chamber, and through which, when the triple-valve is in proper position, air passes from the reservoir $C$ to the brake-cylinder $D$ so as to apply the brake.

In the ordinary construction, when the triple-valve is moved so as to admit air from the train-pipe to the reservoir, it also allows air to escape from the brake-cylinder through the pipe $V$ and the opening $T$.

The operation of this device will then be as follows: Air is pumped into the reservoir on the engine to a pressure of say 100 pounds, and by means of the brake-valve it is allowed to pass through the train-pipe $A$ into the train-reservoir $C$, which are beneath each car. The triple-valve, which is already in use, is so arranged that when the pressure from the train-pipe $A$ is admitted into the triple-valve chamber $B$, it moves the valves so as to open communication directly with the reservoir $C$, so that the air may flow into this reservoir to any desired pressure.

This movement of the triple-valve also opens communication between the brake-cylinder $D$ and the opening $T$, which is a discharge passage, but which, in my invention, communicates through the pipe $a$ with the side of the cylinder $E$ (and the transverse passage $J$).

When it is desired to apply the brakes, suppose the air-pressure in the reservoir $C$ to stand at 70 pounds, by means of the engineer's valve the pressure in the train-pipe is reduced to something less than the pressure in the reservoir.

When running down grades the leakage and gradual escape of air will reduce the pressure in the train-reservoir until it is below what is necessary for the proper control of the train. It is then necessary to recharge the train-reservoir from the engine-reservoir, air is allowed to pass through the train-pipe $A$, and acting on the valves in the chamber $B$, communication is opened between the train-pipe $A$ and the reservoir $C$, and at the same time communication is opened through the brake-cylinder $D$ and the discharge opening $T$.

As formerly arranged the air would be allowed to escape from the brake-cylinder and the train would be temporarily out of control, and would be liable to attain a dangerous rate of speed.

In my invention, however, the pressure in the train-pipe, acting through the pipe $G$ upon the bottom of the valve $f$, forces this valve up until the passage $J$ in the valve is out of line with the pipe $a$ and the openings of the valve chamber $f$.

The pressure in the brake-cylinder is thus retained because this valve cuts off its escape.

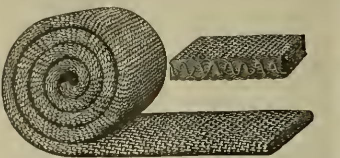
When the pressure in the reservoir $C$ is such as to balance the pressure in the train-pipe $A$ it acts through the pipe $h$ which connects the cylinder $E$ with the reservoir $C$, and pressing on the valve $F$ forces it down until the passage $J$ is on line with the pipe $a$, when air is allowed to pass from the brake-cylinder.

In order to insure the prompt movement of the valve $F$, when the air in train-pipe

### Maddox Cotton and Wire Belting.

The kind of belting illustrated in the annexed engraving is coming rapidly into favor in railroad planing mills and machine shops, and is reported to be stronger, more durable and lasting, more flexible and capable of transmitting more power than the best oak-tanned double leather belting.

This belting is made of cabled soft steel wire and cotton, woven solid together, making it the strongest, most durable and powerful belting made. The cables of wire are each composed of six soft steel wires, twisted together like a cable, giving each separate cable immense strength. The cables are laid lengthwise in the belting, about one-eighth of an inch apart, forming part of the warp, the cables composing about one-half of the warp, the rest of the belt being composed of the strongest, toughest and best cotton yarn, spun especially for this belting. The rough surface given to the belting by the cotton forms an elastic rough face, which prevents any air-cushions from forming between the belt and pulley, causing it to take a tenacious hold and preventing any tendency to slip. The cost of this belting is about the same as for single leather belting. It is handled by H. N. Green, general agent, 254-8 Fulton street, Brooklyn, N. Y.



In examining the higher class of freight cars at the World's Fair, such as refrigerator, live stock and fruit cars, we noticed that no less than ten of them were equipped with the Butler drawbar attachment, which indicates how well the merits of this device are recognized. The simplicity of the attachment forces it into favor. No other expensive castings or forgings have to be made to complete the device.

There will be just sixty volumes for the year 1893 bound up next December. These are for sale at $3 per volume, and no more will be bound, as there are no back numbers. The first applicants will get these volumes. Selah!

Mr. E. W. Baker has been appointed purchasing agent of the Mexican Central in place of Mr. Theo. Nickerson, who resigns to go into private business.

At the recent meeting of Traveling Engineers, C. W. Poole, of the Nickel Plate, asked the pertinent question: "How many of you traveling engineers have passed recent examinations on machinery and time card?" Mr. Poole stated that the practice on his road was to examine traveling engineers as well as the men under them. The tendency of the day is toward rigid examination of all responsible persons.

The "German" engine shown on page 307, of last issue, turns out to be French. A correspondent who "speaks in the Frinch" called our attention to it—we knew it was a foreigner, anyhow.

### Answers to Some of the Questions Received About The Correspondence School of Mechanics, Scranton, Pa.

*Question.* What is The Correspondence School of Mechanics?

*Answer.* It is an educational institution intended to meet the wants of Machinists, Mechanics, Locomotive, Stationary and Marine Engineers, Firemen and others interested in mechanical pursuits, who cannot afford to quit work to attend the regular technical schools in order to obtain the education which they need. It teaches Mechanical Drawing and the theory of Mechanics by correspondence.

*Q.* What are the branches taught?

*A.* Arithmetic, Algebra, Geometry, Trigonometry, Elementary Mechanics, Hydromechanics, Pneumatics, Heat, Mechanical Drawing, Steam and Steam Engine, Strength of Materials, Applied Mechanics, Boilers, Machine Design, Electricity and everything included in a complete mechanical engineering education.

*Q.* Are all these branches taught by mail?

*A.* Yes. There are now over 600 students studying in this school, who are making good progress.

*Q.* What qualifications are required to enroll as a student, and when can students commence?

*A.* The only qualification necessary is to know how to read and write; students can begin at any time.

*Q.* How is instruction given by mail?

*A.* In place of the text-books of the regular schools, the students receive carefully prepared and liberally illustrated Instruction Papers and Mechanical Drawing Plates covering all the subjects embraced in the complete course. These are accompanied by Question Papers containing questions upon the subjects treated of and problems based upon the principles explained. The student studies the first Instruction Paper and writes the answers to the questions and problems in the accompanying Question Paper and sends his work back to the school. This work is carefully examined by competent instructors and if errors have been made, the necessary help is given, and it is returned to be done over. The student is furnished with blanks with which to write for an explanation of anything in the Instruction Paper he may not understand. The student is kept studying each Instruction Paper until he has a thorough knowledge of the subject treated of, when he receives a passing mark on the records of the school and is advanced to the next Instruction Paper.

*Q.* Is it possible to teach Mechanical Drawing by mail?

*A.* Yes. The information given is full and clear, the exercises are practical and instructive and the drawings furnished to be copied are worked out in detail. Persons who will apply themselves can learn not only to draw but to design machinery.

*Q.* What advantage has this method of study over that of the regular schools?

*A.* An education is procured without leaving home or losing time from work. The student can take his own time to study. He has his teacher always at hand. He can advance according to his ability and time without reference to other students. Should sickness prevent him from studying he does not lose standing. The cost of the Scholarships is less than tuition in other schools. The best way to remember a thing is to write it down.

*Q.* What are the Scholarships?

*A.* The branches taught are divided into two so-called Scholarships—the Complete and the Mechanical Drawing Scholarships. Holders of the Complete Scholarship are entitled to instruction in all the branches taught in the school. The Mechanical Drawing Scholarship includes the first nine branches mentioned above.

*Q.* What are the prices of Scholarships?

*A.* The Complete Scholarship costs $35 in advance, or $40 in installments. The Mechanical Drawing Scholarship costs $25 in advance, or $30 in installments.

*Q.* How are the installments paid?

*A.* Ten dollars with the application for admission and the balance in monthly installments of $5 each.

*Q.* If a student is unable to pay his installments promptly, does he lose his Scholarship and the money he has paid?

*A.* No. If on account of sickness or any reasonable cause a student is unable to pay promptly, the time of payment is extended.

*Q.* What are the expenses connected with the course?

*A.* Only those of postage, stationery, and that of instruments and material to do the Mechanical Drawing work. By an arrangement with the Technical Supply Co. of Scranton, we are able to furnish students with these at very reasonable prices.

*Q.* Are students required to purchase text-books?

*A.* No. The Instruction Papers form a complete text-book, and are all that are necessary.

*Q.* Are diplomas given to students completing the course?

*A.* The graduate receives a diploma stating that he has completed the course of study embraced in his Scholarship, and that he has successfully passed an examination in all the branches.

*Q.* For whom is this School intended?

*A.* Machinists, Mechanics, Draughtsmen, Engineers, Firemen, and all connected with the mechanical industries who are anxious to advance. It is an opportunity for them to obtain the technical education necessary to secure better positions and better pay. It is the only way to get an education without leaving home or quitting work.

*Q.* Does it require a long time to complete the course of study?

*A.* No. The Instruction Papers are carefully and concisely written by competent mechanical engineers. Everything unimportant is omitted, and only that retained which is necessary to make clear to the student what he must know. The course is as short as is consistent with thoroughness. The Complete Course requires, for those who can only devote a few hours after work to study, about eighteen months, the Mechanical Drawing Course, about nine months.

*Q.* How can I obtain more information about the School?

*A.* By writing to The Correspondence School of Mechanics, Scranton, Pa. They will gladly send you a free circular of information, which contains all particulars of the course of study, method of instruction, terms, etc.

and reservoir are equalized, a light opening is placed in the valve chamber *E* so as to press on the top of the valve *f*.

The object of this device is to keep the brakes applied while the train-reservoirs are being recharged, without in any way disturbing the triple-valve mechanism now in use.

This pressure-valve is operated from the engine with the engineer's brake-valve. If brakes are applied on train while running, and it is desired to recharge and release the brakes, the valve-handle will be put in full release to get the triple-valve piston up to open charging groove; then place the handle on lap, giving time for air to equalize between auxiliary reservoir and train-pipe, the valve *f* is forced down, allowing air to escape from brake-cylinder; then place valve-handle in full release. There being no air in brake-cylinder the train will be recharged in the usual way.

With this automatic pressure-retaining valve, whenever a train is running steadily with either 10, 20 or 30 pounds pressure in brake-cylinder, having a high pressure in main reservoir, the train can be recharged without allowing air to escape from brake-cylinder.

If an air-gauge was attached to driver-brake reservoir, so that the engineer could see when the pressure in reservoir and train-pipe were about equal, he could then lower the pressure in train-pipe and the air in brake-cylinder would still be held in brake-cylinder by the triple-valve. Trains run on our hill division with straight-air had very few broken, cracked or flat wheels. One reason to account for this is that, with straight air, when brakes were released the brake-shoes were clear of wheels; there being then no 10 or 15 pound pressure-valves used, the brake-shoes and wheels cooled off some before air was again applied. This automatic pressure-retaining valve does this same thing, the engineer having the brakes and pressure-valves under his control.

This valve has been tested on a train on the mountain division of the Southern Pacific and done everything claimed for it. This is written for the information of those who may think of improving the pressure-valve. It may not be what is wanted. Let others keep trying

The triple-valve has proved itself to be almost perfect; the pressure-valve now in use is not. There are many, probably, working and thinking on improving the automatic brake The triple-valve being good, leave it as it is; let them turn their attention to the pressure-valve, for the only way it works good is when cut out.

THOS. P. SWEENEY.

*Sacramento, Cal.*

### That Cylinder Head that was Knocked Out by Compression.

*Editors*:

On page 411, in September number, I noticed an article headed "How the Breaking of a Rocker-Arm Could Cause the Knocking-out of a Cylinder-Head," and signed "A. A. Brown," in which Mr. Brown goes on to explain how it was done. He says, when arm broke it left valve with front port open; pressure on valve held it there; steam followed piston on backward stroke, and was forced back into boiler on forward stroke as long as throttle was open; when throttle was closed piston was at back end of cylinder, which was full of steam at 80-pounds pressure, and there being no way for it to escape it was compressed by forward stroke of piston to a pressure of 1,920 pounds. I should like to have Mr. Brown explain how he kept the steam in that cylinder until it was compressed to 1,920 "pounds." Admitting that throttle was closed when piston was at back end of cylinder, which was full of steam at 80-pounds pressure, when piston has moved half the stroke we have forward half of cylinder full of steam at a pressure of only 160 pounds, without making any allowance for the dry pipe, steam pipes in smoke arch, steam passages in saddles and steam chest, as a receiver of their share of the compressed steam. But, without making any allowance for this, we will suppose we have forward half of cylinder full of steam at 160-pounds pressure. At this point the valve would open port to cylinder on other side, and compression would be stopped, as the advance of piston to front end of cylinder would simply force the steam from that side into the same amount of space in the other cylinder. But if we make due allowance for the pipes, passages and chests, the pressure would be a great deal less.

Now, let us suppose that the dry pipe, steam pipes in smokearch, passages in saddles, and steam-chests are equal to the volume of one cylinder, which I do not think is putting it any too large. When piston has moved half the stroke it has reduced the volume one-fourth instead of one-half, as in the other case, and increased the pressure in proportion, which would be from 80 to about 107 pounds instead of 160. Now, at this point, as I said before, the valve opens the port to the other cylinder, and compression is stopped, and the steam is forced by the advance of piston to front end of cylinder to same space in the other cylinder.

Again, Mr. Brown says, if both ports were covered, the compressed steam would raise the valve, and allow it to escape through exhaust. Here he is mistaken again, in my opinion, as the steam in cylinder would only have about 20 square inches of surface to work on against about 150 inches on top of valve with 80 pounds pressure to hold it down; so it is plain that compression would have to run up to a very high pressure before it would raise the valve, and if there was a weak spot in cylinder-head it might be broken in this way.

### What Sticks These Triples?

*Editors*:

I would like to ask some of the air-brake M.D.'s. who read *our* paper if they ever have brake-valves to stick? I have to take them apart often, grind them in with fine grindstone mud, put tallow on the valve and seat, make them work nice and easy. When a heavy pressure of air is pumped up they will get so tight that a person can hardly move them. These are the valves shown on plate D8, 1890 catalogue. The 1892 valve has not given me any trouble in this direction; probably this is due to the '92 valve having an iron seat. Brass and iron is, I believe, supposed to work together better than brass and brass. I attribute the trouble to the nature of the lubricant so commonly used on air-pumps, and the large amount of it used. Do you know of any railroad company who adhere strictly to the kind of oil prescribed by the Westinghouse Air-Brake Co.? I do not.

FRED B. ARMSTRONG.

*Camden, N. J.*

### Pump Disorders.

*Editors*:

As there seems to be a scarcity of pump problems, I offer the following to those interested

Pump No. 1. A passenger engine was coupled to train and ready to leave, when suddenly air-pump stopped. Enginemen failed to locate the trouble, and it being after night and no one at roundhouse capable of attending to such work, engine was held in, another substituted and another crew called.

The next morning I was told to locate and remedy the trouble. After a few minutes maneuvering I found it, and in twenty minutes engine was ready to go out, as far as pump was concerned. Pump stopped on downward stroke and would not reverse. Trouble was above center-piece. Reversing valve-stem was all right. The above was a 6-inch Westinghouse.

Pump No. 2. A pump was sent in to headquarters to be remedied of an evil which it was said to possess.

As I was then under the tutorship of Mr. Wm. Wright, motive-power air-brake overseer at the point in question, I thought I would "get one on the old man" by solving the mystery connected with this pump; but I was doomed to disappointment, for, after repeated trials on the test rack, William finally bested me.

When steam was given, pump-piston repeatedly persisted in remaining at rest. But when piston was lifted to top of pump and secured by tightening gland-nuts, it would descend in the usual manner when given steam and then stop. There was quite a perceptible blow through exhaust.

All working parts were carefully examined and found to be intact.

All bushings and packing rings, where it was thought the trouble might lie, were thoroughly inspected.

After the—I nearly told it—had lain in the corner a week, it was determined to give the pump a final examination. With this success crowned our efforts, for there, but of Liliputian dimensions, lay the seat of operations of the hitherto cancealed oppressor. What was it?

This was an 8-inch Westinghouse.

### Uncertain Action of Triple-Valve.

*Editors*:

In experimenting with new triple-valves, claimed by the inventors to be the best in the world, etc., I have many times encountered the same difficulty that Mr. Horton describes in the last issue of your paper. Emergency setting when it was not wanted, and then sticking open so as to blow the air out of the train-pipe when the main piston went back to release position. It is not stated in the problem what kind of a brake it was that gave the trouble, so it is hard to ferret out the cause. Supposing it to be a Westinghouse triple-valve, the quick action must have been caused either by a broken pin in the graduating-valve, a large quantity of gum around the graduating-valve or slide, or a weak graduating spring; but the refusal of the quick-action valve to seat again must have been due to some different cause, such as a weak spring under the emergency-valve or a sticking of these parts from dirt. If the offending valve was a New York triple the trouble might have been caused by a weak spring under the emergency piston. The fact that the brakes were afterwards successfully pumped off shows that the emergency-valve finally got back to its seat, for had it not done so it would have been impossible to get the brakes to release at all.

### Caring for Leather Packing in Driver-Brake Cylinders.

*Editors*:

M. Watts says the best thing that he can find is water to soften driver-brake leathers, using very little oil. I have been using water for about six years, and it is the quickest thing to soften a leather that I can find. I will state that one of the road foremen of engineers recently wrote a letter to our master mechanic condemning the use of water, saying it was only a temporary expedient, and that it left the leather worse than it was before. I think a temporary expedient is better than none.

I recently had an engineer take me to his engine when he was starting out on a long trip with a freight train and show me his driver-brake. The air would not lift the piston at all. I said to him, "Put some water in." He replied that it would do no good. I said, we will cool it off, anyway. I put some water in the top of the cylinder and the brakes went on the first time they were applied, and they ran a week and held—if the water had not been put in he would have went over the road without brakes, perhaps killed some one or had an accident of some kind, so a temporary expedient was good in this case. I have done this many times when we have not had time to take down the cylinders and put new leathers in.

We use asbestos in the form of paste-board, in back of the cylinders, and I believe that is a great benefit towards keeping the leathers from burning up. We have it about ⅛ of an inch thick; we cut a piece the size of the back of the cylinder, put four holes in it and put it on the bolts that hold the cylinder on, this prevents the heat from the firebox from burning quite as bad as it would without anything on. Yet it does not keep the leather in good condition.

FRED B. ARMSTRONG.

*Camden, N. J.*

### From Full Release to Emergency.

*Editors*:

I see men are claiming to get increased pressure in brake-cylinder by placing brake-valve in full release quickly and then to the emergency position, when there has been a service application made. I cannot see how it can increase the pressure, for it will certainly throw the triple-valves to full relief position, allowing a per cent. of pressure then in brake-cylinder, and then to get the emergency action to take place the pressure has to be reduced below the auxiliary pressure again (train-pipe pressure I mean), and I think the loss from the pressure in the cylinder would be more than the train-pipe could add, as I believe, from observing the action of cars while trying the experiment, that more air has to be discharged from train-pipe to get the emergency-valves to act under these conditions than by making an emergency application only. And I notice that on a number of cars emergency does not take place, caused by the condition of the strainers, I think, they being so full of dirt and gum that it takes too long for air to pass through them. I am speaking of freight cars; have not experimented with passenger cars yet. Consequently, my advice to engineers is to go from service position to emergency, or from running position to emergency, as the case may be, and leave it there in case of danger. In ordinary stops, you can do a great deal better braking by not using the emergency at all. Judgment will make a better stop with less damage to cars and less time to the stop. If there are no leaks in the train-pipe, there is seldom any call for but a single application of the brakes.

*Covington, Ky.* J. H. BROWN.

### "What Ailed the Engineer's Valve?"

*Editors*:

In answer to W. F. Relyea's question, "What ailed the engineer's valve?" when air flowed freely through preliminary exhaust port, and yet would not set brakes in service application, would say that by some means air was prevented from escaping from train-pipe at service-stop exhaust through ports *M* and *N*, probably by stop-cock being closed; but one would think it must surely be discovered before taking valve apart. It may have been that the hole in the stop-cock plug was drilled transversely to the handle, and on this account might be overlooked in the shop. The difference in sound ought to make it discernible in service.

*Pittsburg, Pa.* JOHN BRUCE.

### Cold Facts About Theory and Practice.

*Editors*:

I would like to preach a short sermon, with Mr. Ernest Martin's letter on "Theory and Practice" as a text. If there was any one who seriously believed that theory was complete without practice, there might be some utility in the repetition of such statements as Mr. M.'s, but as the necessity of practice is universally admitted, even in the

technical schools, I don't quite see the utility The fact of the mechanical school graduate, who Mr. M quotes as going to work in the railroad shop, shows that he appreciates the necessity of practice.

I would like to ask Mr. Martin whether the persons who are examined are not invariably persons who, by a long and successful apprenticeship as firemen, have shown their mastery of the practical part of the work. If he knows of any road where men without a considerable experience as firemen are made engineers on the strength of a theoretical examination, there may be some ground for his complaint, but I do not know of any such.

So far as my observation goes, the oft-repeated platitudes about theory and practice come from men who are too dead intellectually to profit by the experience of others as given in books and periodicals. To support my view, I would refer to the very many splendid engineers who have been made during the last ten years, after making a good record as firemen and successfully passing an examination that the unsuccessful candidates call "theoretical."

### Brown's Lame Engine.

*Editors*:

That lame engine of Mr. Brown's, in the September number, was probably caused by the failure of the artist who put up the job to get the rocker right arm up. In many of our American eight-wheel engines one arm of the rock-shaft is longer than the other, and if their positions are reversed it makes considerable difference in the cut-off when hooked up, while making very little in full gear; so that the engine may have shown everything correct in full gear, and have developed a very cross-legged exhaust when hooked up.

F. W. PETERSON.

*Boone, Ia.*

THE ANSWER.

*Editors*.

A left-hand rocker-arm was put on right side. The effect being, say ¼ inch, threw the valve out 1½ inches by having the set the wrong way.

*Waycross, Ga* A. A. BROWN.

---

### Answer to Driver-Brake Question.

*Editors*:

On examining the three-way cock I found a small crease cut in the plug, and when not left in its proper position it leaked around; but when left in its proper position it did not raise the driver-brake.

*Sherman, Tex.* R. HILL.

---

### Cause of Brake Not Applying in Service Position.

*Editors*:

Mr. Relyea speaks of a brake-valve that would not apply brakes in service position. I am inclined to the opinion that the trouble was caused by a crack in the leather gasket in valve body, and that the crack was located between the direct application and supply passage and chamber *D*. With this defect in the valve an attempt to apply the brakes by a service application would draw pressure from above piston 17, but would not reduce it as the air in the train-pipe would flow through the crack in gasket and into chamber *D*, and assuming that the crack in the gasket was equal in area to the preliminary exhaust port the pressure above and below piston 17 would remain equal, and there would consequently be no movement of piston 17 and no release of pressure from train-pipe except from the preliminary exhaust port. This port being very small the discharge of air through it would not be sufficient in volume to reduce train-pipe pressure enough to cause triples to move the brake-piston over the leakage grooves in brake-cylinders.

Ordinarily these gaskets do not crack, and when they do it is generally caused by the valve being located very near the boiler-head, the heat from which dries and burns them up.

E. P. BISHOP.

*Birmingham, Ala.*

### How to Set Valves in Eight Minutes.

*Editors*:

Some of your correspondents seem to think Mr. Campbell's plan of setting valves in ten minutes not possible. With my own eyes I have seen a "cub" set valves in eight minutes—to a sandbox. Of course, time for drilling holes and putting in pins was not counted.

A. A. BEAVERS.

*Waycross, Ga.*

---

### What Mr. Campbell Said About Quick Valve-Setting.

*Editors*:

At the time I wrote on valve-setting I did expect to hear some comments on it, but I did not expect to have them continue for such a length of time after the article was written.

Now, it seems to have done some little good after all, but, Oh Lord! "L. W." takes the cake, and I must confess it makes me feel proud to see how much he has accomplished through your valuable paper and my article.

I do feel a little sorry that my writing on valve motion was so misconstrued by others.

I did not say anything about a machinist's time of setting a valve.

I said my foreman—and I still say I would not have a foreman that could not tell a machinist what to do in ten minutes to square a valve. The idea of a man pinching an engine all over a roundhouse and keeping the laborers four or five hours pinching an engine! My idea is simply to tell a machinist what to do about lengthening or shortening eccentric-rods.

Now, Mr. W. H. Wesley, you see by this that you misunderstood me about the machinist. Neither I nor any other man living can tell how long it will take a machinist to do his part of the work, as he may have to cut out the holes in eccentric-blades and he may have to offset the keys in eccentrics if they are keyed on. Now, my foreman does not have to crawl under the narrow-gauge engines. He has other duties to attend to.

E. A. CAMPBELL.

*Houston, Tex.*

[This ten-minute valve setting controversy has been going on now for three years and if the readers are not tired of it the J. P is. We will sell the next contribution on the subject for waste paper.]

### What Do You Want to Know About Coppersmithing?

*Editors*:

Let me say a word or two to the boys. I am interested in the boys, and the men, too, for that matter, and the foreman, and while I would like their attention and appreciation of my work, I am far more interested in the boys; because I know what *a boy* had to encounter fifty years ago, and what boys generally have to encounter now when in search of information to assist them in making themselves efficient and competent workmen. Now, I do not presume to know all there is known in the coppersmith's art, but having been a close student of it, and having had fifty years of practical experience in sheet-metal working at the bench, it is to be supposed that I can tell something about it, and if any of my boy readers will write to the Editor of LOCOMOTIVE ENGINEERING, asking an intelligent question concerning the work done in a railroad coppersmith's shop, I will, to my best, answer him or them in the most lucid manner in which I am able, or confess that I am unable to do so.

JOHN FULLER, SR.

*Seneca Kan.*

---

### A New Unit of Measure.

BY JOHN H. COOPER.

Your remarks in September LOCOMOTIVE ENGINEERING reminds me that I once suggested and published the same in February, '88, a new division and organization of our rules and scales. The following will give the data and describe it in a general way:

A rule for measuring and the divisions and subdivisions of it should be suited to the human eye and hands.

The standard inch as we now have it, as a fixed unit, should be preserved and used.

The conclusion is already foregone that the decimal system of graduating rules and scales, the best of all, so far devised, should be employed and maintained.

Whatever standard unit may be adopted, and however it may be divided, the subdivisions of it can be extended and the eye assisted by instrumental means to almost any refinement of reduction by verniers and microscopes, as already done.

The human eye will ever be what it is now, and any scale suited to its present needs will always be right.

The millimetre is too coarse for a smallest division on the scale, and its sub-division into tenths would be entirely too fine for the unassisted eye—much finer than the hundreth of an inch, which is practically invisible to most eyes To sub-divide the millimetre into halves and quarters would mix the fractional with the decimal systems and introduce confusion.

I propose taking for a unit of a new scale a space equal to *one-and-a-half* of the present standard inch, and then divide this new inch into ten equal parts, subdividing each of these parts again into tenths, whence we will find the hundredth part of this new inch a plainly visible and practically usable quantity without the use of instrumental helps to the eye.

A scale is here shown as divided, in order that its least division may be seen in comparison with the standard inch similarly divided.

1½

1

It is neither believed, nor urged here, that all the exact dimensions of the fitting parts of machines can be measured by the eye from this new scale, as they cannot be from any other, nor is the substitution of measures by *sight* for measures by *feeling* here proposed for the extreme niceties of machine fitting.

The superiority of *feeling* over *sight* must ever, as is usual without instrumental aid, remain as a means to be employed for copying minutest dimensions.

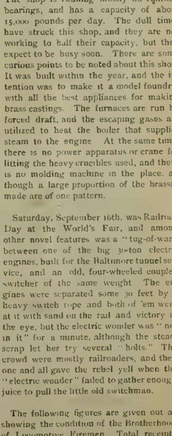
I propose further to use ten of these new inches to make the new foot, which will be equal in length to fifteen of the present standard inches, and the new *two-foot rule* for general use will, therefore, be thirty inches long, which will make a rod in every way equal to the present two-foot rule, and more convenient for eye and hand than the metre, and which can be readily employed for exact continued measuring; a feat not easily accomplished by the metre, by everybody, which any one may prove by taking a rod 3 feet 3 inches and three-eighths of an inch long, and try to see a fine mark at each end of it, while holding it immovable on the surface upon which the measuring is to be done.

But then, any radical change is attended with trouble and expense. The path of least resistance should always be taken.

There can be no reason whatever offered in favor of the metrical measure, other than its decimal division. This we have in the scale here offered, which also preserves the standard inch, a unit already made and preserved at immense cost.

Again, there is not a single tool, machine or device existing, which has been made by the standard inch, that the metre and its subdivisions will measure, while with the 1½-inch unit system a small fraction of the number only would not be measurable.

The system here proposed is based upon the three essentials of a measuring device its smallest division should be the least that is plainly visible to the unassisted eye, it should be graduated on the decimal system, and its two-foot rule should be as handy for general use as is our present two-foot rule.



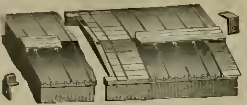
DRAW-HEAD AND REMOVABLE BUFFER FOR TENDERS. SOUTHERN PACIFIC RAILROAD.

One of the tidiest brass-molding shops to be found in the land is now in operation at Depew, N Y., by the Buffalo Brass Co. The shop is running mostly on railroad bearings, and has a capacity of about 15,000 pounds per day. The dull times have struck this shop, and they are not working to half their capacity, but they expect to be busy soon. There are some curious points to be noted about this shop. It was built within the year, and the intention was to make it a model foundry, with all the best appliances for making brass castings. The furnaces are run by forced draft, and the escaping gases are utilized to heat the boiler that supplies steam to the engine At the same time, there is no power apparatus or crane for lifting the heavy crucibles used, and there is no molding machine in the place, although a large proportion of the brasses made are of one pattern.

Saturday, September 16th, was Railroad Day at the World's Fair, and among other novel features was a "tug-of-war" between one of the big 30-ton electric engines, built for the Baltimore tunnel service, and an old, four-wheeled coupled switcher of the same weight The engines were separated some 30 feet by a heavy switch rope and both of 'em went at it with sand on the rail and victory in the eye, but the electric wonder was "not in it" for a minute, although the steam scrap let her try several "holts." The crowd were mostly railroaders, and they one and all gave the rebel yell when the "electric wonder" failed to gather enough juice to pull the little old switchman.

The following figures are given out as showing the condition of the Brotherhood of Locomotive Firemen Total receipts for the year ending July 31, 1893, $624,67? - 25; total disbursements, same period, $56?,-120 45; cash on hand, $56,557 80. This balance forms an excess fund. Protective funds on hand, $52,000. This fund is earning interest at 4 and 5 per cent. Increase of receipts over the present year, $115,000. increase of disbursements, $11,000. The order has now a membership of 29,000.

# THE MURPHY STEEL CAR ROOF.



HAS no surface nail or screw holes. It has no joints where cinders, rain or fine snow can get through. It allows for contraction and expansion, and has ample elasticity to provide for sagging, twisting, buckling and cornering of the car body. It is as solid as the car frame itself. It has no soldered joints. It can be repaired readily, and without taking off more of the roof than is damaged. It is much cheaper than any other metallic roof now in use, and is cheaper than the double board roof, made of good lumber. It is unlike any other metallic roof for the reason that **everything is furnished to make it complete**; so that the parties buying it have no expense other than to apply it.

**This ROOF can be applied on OLD LEAKY BOARD-ROOF CARS without making any changes in the board roof; thereby saving the expense of replacing the old boards with new, and thus utilizing material that must otherwise be thrown away.**

Manufactured by the P. H. MURPHY MFG. CO., East St. Louis, Ill.

# THE BROTHERHOOD SEAT.

Only locomotive cab seat on exhibition at the World's Fair. Perfectly equalized. Adjustable to any weight. Back can be quickly changed to any desired angle. Seats made in any size. We make a specialty of Drop Seats for engines where boiler extends through the cab. Our upholstering is the very best. Both seat and back covered with grained Horsehide Leather. No engineer can afford to be without this seat as it adds comfort and improves health. Over one hundred in use on second division of the U. P. R. R.

**Satisfaction guaranteed or money refunded.**

**Seats sent on one week's trial.**

Send stamp for our twenty page catalogue and price list.

STANNARD & WHITE, Appleton, Wis.

## The Polar Zone.

BY JOHN ALEXANDER.

Very few of my friends know me for a sailor, but I sailed the salt seas, man and boy, for five months and eighteen days, and I know just as much about sailing the hereinbefore mentioned salt seas as I ever want to.

Ever so long ago, when I was young and tender, I used to have fits of wanting to go into business for myself. Along about the front edge of the seventies, pay for "toting people and truck" over the eastern railroads of New England was not of sufficient plenitude to worry a man as to how he would invest his pay check—it was usually invested before he got it—but that's another story, as my friend Rud. Kipling would say.

One of my periodical fits of wanting to go into business for myself came on suddenly one day when I got home and found another baby in the house. I was right in the very worst spasms of it when my brother Enoch, whom I hadn't seen for seventeen years, walked in on me.

Enoch was fool enough to run away to sea when he was twelve years old—I suppose he was afraid he'd get a chance to do something beside whaling. We were born down New Bedford way, where another boy and myself were the only two fellows in the district for over forty years who didn't go hunting whales, icebergs, foul smells and scurvy, up in the Frost King's bailiwick, just south of the pole. Enoch was captain and part owner of a Pacific whaler; she had recently burned at Honolulu, and he was back home now to buy a new ship.

He had heard that his little brother John was the best engineer in the whole world and had come to see me; partly on account of relationship, but more to get my advice about buying a steam whaling ship. Enoch knew more about whales and ships and such things than you could put down in a book, but he had no more idea about *how* steam propelled a ship than I had what the "skivvie tricer" was.

Well, before the week was out Enoch showed me that he was pretty well fixed in a financial way, had no kin but me that he cared about, and offered me an interest in his new steam whaler if I would go as chief engineer with her to the North Pacific.

The terms were liberal and the chance a good one, so it seemed, and after a good many consultations my wife agreed to let me go for *one* cruise. She asked about the stops to be made in going around the Horn and figured a little after each place was named—I believe now she half expected I'd desert and walk home from one of these stops and was figuring on the time it would take me.

When the robins were building their nests the new steam whaler *Champion* left New Bedford for parts unknown (via the Horn) with the seasickest chief engineer that ever smelt fish oil.

The steam plant wasn't very much, two boilers and a plain 28 x 36 double engine and any amount of hoisting rigs, blubber boilers and other paraphernalia.

I'm not going to tell you much about this cruise of the *Champion*, it's not her story I'm telling, she only leads up to another strange, true story.

We refitted in San Francisco, and on a clear summer morning turned the white-painted figure-head of the *Champion* towards the North and stood out for Behring Sea.

I'm here to tell you that your uncle John didn't just relish the idea of three years up in the ice floes, out of reach of mail or wire, with a wife and three babies down in the Old Colony, and the nearer the *Champion* got to big fish the "lonesomer" your Uncle John kept getting.

We'll just pass over the fact that while we lay at the mouth of the Yukon River, up in Alaska, getting ready for a sally into the realm of water above the Straits, a whaler, bound for San Francisco and home, dropped anchor near us, and the homesickness struck in and there was a relapse, and—never mind the details now—your Uncle John came home without any whales, and was mighty glad to get on the extra list of the old road, and don't you forget it, neither.

The story I want to tell is another man's story, and it was while laying in the Yukon that I heard it. I was deeply impressed with it at the time and meant to give it to the world as soon as I got home, for I set it all down plain then, but I lost my diary, and now, after twenty years, my wife turned it up in the garret at this spring house-cleaning. Fred had it and an old Fourth of July cannon put away in an ancient valise, like a boy will treasure up useless things.

Under the head of October 12th I find this entry:

"At anchor in Yukon River, weather fair, recent heavy rains, set out packing and filed main-rod brasses of both engines. Settled with Enoch to go home on first vessel bound South. Demented white man brought on board by Indians, put in my cabin."

In the next day's record there appears the following:

"Watched beside sick man all night; in intervals of sanity he tells a strange story, which I will write down to-day."

The 14th has the following:

"Wrote out story of stranger, see back of this book."

In the back, on paper cut from the blank pages of an old log of the *Champion*, is the story, that now, twenty years after, I tell you here.

On the evening of the 12th I went on deck to smoke and think of home, after a hard day's work getting the engines in shape for a siege. The ship was very quiet, half the crew being ashore and some of the rest having gone in the boat with Captain Enoch to the *Enchantress*, homeward bound, and lying about half a mile below us. I am glad to say that Enoch's principal business aboard the *Enchantress* is to get me passage to San Francisco; I despise this kind of dreariness—rather be in State prison, near the folks.

I sat on the rail just abaft the stack watching some natives handle their big canoes, when a smaller one came alongside. I noticed one of the occupants lay at full length in the frail craft, but paid little attention until the canoe touched our side. Then the bundle of skins and Indian clothes bounded up, almost screamed "At last!" made a spring at the stays, missed them, and fell with a loud splash into the water.

The Indians rescued him at once, and in a few seconds he lay like one dead on our deck. I saw at a glance that the stranger in Indian clothes was a white man and an American.

A pretty stiff dram of liquor brought him to slightly—enough so he opened his eyes, looked up at the rigging, and, closing his eyes, he murmured "Thank God! —Frisco—Polaria!"

I had him undressed and put into my berth. He was shaking as with an ague, and when his clothes were off we plainly saw the reason—he was a skeleton, starving.

I went on deck at once to make some inquiry of the Indians about our strange visitor, but their boat was just disappearing in the twilight.

The man gained strength as we gave him nourishment in small, frequent doses, and talked in a disjointed way of everything under the sun. I sat with him all night.

Towards morning he seemed to sleep longer at a time, and in the afternoon of yesterday fell into a deep slumber, from which he did not waken for nearly twenty hours.

When he did waken he took nourishment in larger quantity, and then went off into another long sleep. The look of pain on his face lessened, a healthy glow appeared on his cheek, and he slept so soundly that I turned in—on the floor.

I was awake along in the small hours of the morning and heard my patient stirring, so I got up and drew the little curtain over the bull's-eye port—it was already daylight.

I gave him a drink and a biscuit, and told him I'd go to the cook's galley and get him some broth; but he begged me to wait until breakfast time, said he felt refreshed, and would just nibble a sea biscuit. Then he ate a dozen in as many minutes.

"Did you take care of my pack?" he said eagerly, throwing his legs out of the berth and looking wildly at me.

"Yes, it's all right; lay down and rest," said I, for I thought to cross him would set him off his head again.

"Do you know that dirty old pack contains more treasures than the mines of Africa?"

"It don't look it," I answered, and laughed to get him in a pleasant frame of mind—for I hadn't seen or heard of his pack.

"Not for the little gold and other valuable things, but the proofs of a discovery as great as Columbus made; the discovery of a new continent, a new people, a new language, a new civilization and riches beyond the dreams of a Solomon —— "

He shut his eyes for a minute, and then continued:

"But, beyond Purgatory, through Death and the other side of Hell ——"

Just here Enoch came in to inquire after his health, and sat down for a moment's chat. Enoch is first, last and all the time captain of a whaler; he knows about whales and whale hunters just as an engineer on the road knows every speck of the scenery along the line, every man and every engine. Enoch couldn't talk ten minutes about anything without being "reminded" about an incident in his whaling life; couldn't meet a whaleman without "yarning" about the whale business. He lit his pipe and asked

"Been whalin' or huntin' North Pole?"

"Well, both."

"What ship?

"The *Duncan McDonald*."

"The devil—the *McDonald!*—why, man, we counted her lost these five years; tell me about her, quick; old Chuck Burrows was a particular friend of mine—where is he?"

EXHIBITED AT WORLD'S FAIR BY H. K. PORTER & CO.

"Captain, Father Burrows and the *Duncan McDonald* have both gone over the unknown ocean to the port of missing ships."

"Sunk?"

"Aye, and crushed to atoms in the bell of ice."

Enoch looked out of the little window for a long time, forgot his pipe and at last wiped a tear out of his eye, saying, as much to himself as us:

"George Burrows made me first mate of the first ship he ever sailed. She was named for his mother, and we left her in the ice away up about the 73d parallel. He was made of the salt of the earth, a sailor and a nobleman. But he was a dare-devil, didn't know fear, always venturing where none of the rest of us would dare go. He bought the *McDonald*, remodeled and fitted her after he got back from the war—she was more than a whaler, and I had a feeling that she would carry Burrows and his crew away forever——"

Eight bells rung just here, and Enoch left us, first ordering breakfast for the stranger and saying he would come back to hear the rest after breakfast.

As I was going out, a sailor came to the door with a flat package, perhaps six inches thick and twelve or fourteen square, covered with a dirty piece of skin made from the intestines of the whale, and used by the natives of these climes because it is light and waterproof.

"We found this in a coil of rope, sir; it must belong to him. Lord, sir; it's mostly lead"

It was heavy, and I set it inside the

door, remarking that here was his precious pack.

"Precious' aye, aye, sir ; precious don't describe it. Sacred, that's the word. That package will cause more excitement in the world than the discovery of gold in California. This is the first time it's been out of my sight or feeling for months and months, put it in the bunk here, please."

I went away, leaving him with his arm around his sacred package.

After breakfast Enoch and I went to the little cabin to hear the stranger's story, and I, for one, confess to a great deal of curiosity. Our visitor was swallowing his last bowl of coffee as we went in.

"So you knew Captain Burrows and the *Duncan McDonald?*" said he.

"Let me see, what is your name?"

"Alexander, captain of the *Champion*, at your service, sir."

"Alexander ; you're not the first mate Enoch Alexander, that sat on a dead whale all night, holding on to a lance staff after losing your boat and crew?"

"The same."

"Why, I've heard Captain Burrows speak of you a thousand times."

"But you was going to tell us about the *McDonald* ; tell us the whole cruise from stem to stern."

"Let's see, where shall I commence?"

"At the very beginning," I put in.

"Well, perhaps you've noticed it, perhaps not, but I'm not a sailor by inclination or experience. I accidentally went out on the *Duncan McDonald*. How old would you take me for?"

"Fifty or fifty-five," said Enoch.

"Thanks, captain, I know I must look all of that; but lemme see, forty-five, fifty-five, sixty-five, seventy, seventy—— what year is this?"

"Seventy-three."

"Seventy-three. Well, I'm only twenty-eight now."

"Impossible' Why, man, you're as gray as I am, and I'm twice that."

"I was born in forty-five, just the same.

"My father was a sea captain in the old clipper ship days and a long time after. He was in the West India trade when the war broke out, and as he had been educated in the navy enlisted at once. It was on one of the gunboats before Vicksburg that he was killed.

"My mother came of a well-to-do family of merchants, the Clarks of Boston—and, to make a long story short—died in sixty-six, leaving me considerable money.

"An itching to travel, plenty of money, my majority, and no ties at home sent me away from college to roam, and so one spring morning in sixty-seven found me sitting lazily in the stern of a little pleasure boat off Fort Point in the Golden Gate, listlessly watching a steam whaler come in from the Pacific.

"My boatman called my attention to her, remarking that she was spick and span new, and the biggest one he ever saw, but I took very little notice of the ship until, in tacking across her wake, I noticed her name in gold letters across her stern, *Duncan McDonald*. Now, that is my own name and was my father's name, and try as I would I could not account for this name as a coincident, common as the name might be in the highlands of the home of my ancestors, and before the stanch little steamer had gotten a mile away I ordered the boat to follow her—I intended to go aboard and learn, if possible, something about where her name originated.

"As she swung at anchor off Goat Island I ran my little boat alongside of her and asked for a rope.

"'Rope?' inquired a Yankee sailor, sticking his nose and a clay pipe overboard, 'might you be wantin' to come aboard?'

"'Yes, I want to see the captain.'

"'Well, the cap'en's just gone ashore, his gig is yonder now, enemost to the landin'. You come out this evenin', the cap'en's particular about strangers, but he's allus to home of an evenin'.'

"'Who's this boat named after?'

"'The Lord knows, stranger, I don't ; but I reckon the cap'en kin tell, he built her.'

"I left word that I would call in the evening, and at eight o'clock was alongside again.

"This time I was assisted on board and shown to the door of the captain's cabin ; the sailor knocked and went away.

"It was a full minute I stood there before the knock was answered, and then from the inside, in a voice like the roar of a bull, came the announcement

"'Well, come in'

"I opened the door on a scene that will never be forgotten. A bright light swung from the beams above, and under it sat a giant of the sea, Captain Burrows. He had the index finger of his right hand resting near the North Pole of an immense globe ; there were many books about, rolls of charts, fire-arms, instruments, clothing and apparent disorder everywhere ; the cabin was large, well furnished and had something striking about it. I looked around in wonder without saying a word.

"Captain Burrows was the finest looking man I ever saw—six foot three, straight, muscular, with a pleasant face ; but the steadiest, keenest blue eye you ever saw. His hair was white, but his long, flowing beard had much of the original yellow. He must have been sixty, but for all the pleasant face and kindly eye you would notice through his beard the broad, square chin that proclaimed the decision and staying qualities of the man."

"That's George Burrows, stranger, to a queen's taste—just as good as a photograf," broke in Enoch.

"Well," continued the stranger, "he let me look for a minute or two, and then said.

"'Was it anything particular?'

"I found my tongue then, and answered:

"'I hope you'll excuse me, sir, but I must confess it is curiosity. I came on board out of curiosity to —'

"'Reporter, hey?' asked the captain.

"'No, sir ; the fact is your ship has an unusual name, one that interests me, and I wish to make so bold as to ask how she came to have it.'

"'Any patent on the name?'

"'Oh, no ; but I——'

"'Well, young man, this ship—by the way the finest whaler ever stuck together—is named for a friend of mine ; just such a man as she is a ship—the best of 'em all.'

"'Was he a sailor?'

"'Aye, aye, sir, and *such* a sailor ; fight' why, man, fighting was meat and drink to him——'

"'Was he a whaler?'

"'No, he wan't , but he was the best man I ever knew who wan't a whaler. He was a navy sailor, he was, and a whole ten-pounder battery by hisself. Why, you just ort to see him waltz his old tin-clad gunboat up agin one of them reb forts jest naturally skeered 'em half to death before he commenced shootin' at all.'

"'Wasn't he killed at the attack on Vicksburg?'

"'Yes, yes ; you knowed him, didn't you? He was a——'

"'He was my father.'

"'The devil, he was!' yelled Captain Burrows, jumping up and grasping both my hands. 'Of course he was ; darn my lubberly wit that I couldn't see that before!' Then he hugged me as if I was a ten-year-old girl, and danced around me like a maniac.

"'By all the gods at once, if this here don't seem like Providence—yes, sir, old man Providence himself! What are you adoin'? When did you come out here? Where be you goin', anyway?'

"I found my breath and told him briefly how I was situated.

"'Old man Providence has got his hand on the tiller of this raft or I'm a grampus' —*say*' do you know I was just wishin' and waitin' for you? Yes, sir ; by thunder' no more than yesterday, says I to myself. Chuck Burrows, sais I, you are a gittin' along too fur to the wind'ard o' sixty fur this here trip all to yourself. You ort to have young blood in this here enterprise ; and then I jist clubbed myself for being a lubber and not gettin' married young and havin' raised a son who I could trust. Yes, sir ; jist naturally cussed myself from stem to stern, and never onct thought as mabee my old messmate, Duncan McDonald, might have adone suthin' for his country afore that day at Vicks——*say*' I want to give you half this ship. Mabee I'll do the square thing and give you the whole of the tub yet. All I want is for you to go along with me on a voyage of discovery—be my helper, secretary, partner, friend—anything. What de you say? *Say!*' he yelled again before I could answer, 'tell you what I'll do—damme if I don't adopt ye , that's what I'll do. Call me *pop* from this out and I'll call you *son*' *Son!*' he shouted, bringing his fist down on the table with a bang. '*Son!* that's the stuff! By the bald-headed Abraham, who says Chuck Burrows ain't got no kin? The *Duncan McDonald*, Burrows & Son, owners, captain, chief cook and blubber cooker, by thunder' And who the hell says they ain't?'

"And the old captain glared around as if he defied anybody and everybody to question the validity of the claims so excitedly made out.

"Well gentlemen, of course there was lots else said and done, but that announcement stood, and was all the adoption proceedings made out, and to the day of his death I always called the captain Father Burrows and he called me son, always addressing me so when alone as well as when in the company of others.

"Gentlemen, to make a long story short, I went every day to the ship or accompanied Father Burrows on some trip into the city, while the boat was being refitted and prepared for a three years' cruise.

"Every day the captain let me more and more into his plans, told me interesting things of the North, and explained his theory of the way to reach the pole and what could be found there that fascinated me.

"Captain Burrows had spent years in the North, noted that particularly open seasons occurred in what appeared cycles of a given number of years, and proposed to go above the 80th parallel and wait for an open season. That, according to his figuring, would occur the following year.

"I was young, vigorous, and of a venturesome spirit and entered into every detail with a zest that captured the heart of the old sailor. My education helped him greatly and new books and instruments were added to our store for use on the trip. The crew knew only that we were going on a three years' cruise, that they had no share in the profits, but were paid extra big wages in gold and were expected to go to out-of-the-way places and further North than usual. Captain Burrows and myself only knew that there was a brand new twenty-foot silk flag rolled up in oil-skin in the cabin and that father Burrows had declared that, 'By the hoary-headed Nebblekenizer I'll put them stars and stripes on new land, and mighty close to the pole, or start a butt atryin'.'

"In due course of time we were all ready and the *Duncan McDonald* passed out of the Golden Gate into the broad Pacific, drew her fires and stopped her engines, reserving this force for a more urgent time, she spread her ample canvas and stood away towards Alaska and the unknown and undiscovered beyond.

"The days were not long to me, for they were full of study and of anticipation. Long chats with the eccentric but masterful man whose friendship and love for my father had brought us together were the entertainment and stimulant of my existence—a man who knew nothing of science except that he was the master of it in his own way, who knew all about navigation, and to whom the Northern seas were as familiar as the contour of Boston common was to me, who had more stories of whaling than you could find in print and better ones than can ever be printed

"I learned first to respect, then to admire and finally to love this old salt. How many times he told me of my father's death and how and when he had risked his life to save the life of Father Burrows or some of the rest of his men. As the days grew into weeks and the weeks into months Captain Burrows and myself became as one man.

"I shall never forget the first Sunday at sea, early in the morning I heard the captain order the boatswain to pipe all hands to prayers. I had noticed nothing of a religious nature in the man, and, full of curiosity, went on deck with the rest. Captain Burrows took off his hat at the foot of the mast and said

"'My men, this is the first Sunday we have all met together, and as some of you are not familiar with the religious service on board the *Duncan McDonald* I will state that, as you may have noticed, I asked no man about his belief when I employed him—I hired you to work this ship, not to worship God—but on Sundays it is our custom to meet here in friendship, man to man, Protestant and Catholic, Mohammedan, Buddhist, Fire Worshiper and Pagan, and look into our own hearts, worshiping God as we know him, each in his own way. If any man has committed an offence against his God let him make such reparation as he thinks will appease that God, but if any man has committed an offence against his fellow man let him settle with that man, now and here, and not worry God with the details. Religion is goodness and justice and honesty ; no man needs a sky-pilot to lay a course for him, for he alone knows where the channel and the rocks and the bar of his own heart is—look into your hearts.'

"Captain Burrows stood with his hat in his hand and bowed as if in prayer, and all the old tars bowed as reverently as if the most eloquent divine was exhorting an unseen power in their behalf , the new men followed the example of the rest. It was just three minutes by the wheel-house clock before the captain straightened up and said 'Amen,' and the men turned away about their tasks.

"'Beats mumblin' your words out of a book, like a Britisher,' said the captain to me , 'can't offend no man's religion and helps everyone on 'em.'

"Long months afterward I attended burial service conducted the same way—in silence.

"In due course of time we anchored in Norton Sound and spent the rest of the winter there, and in the spring of sixty-eight we worked our way north through the ice, we passed the 75th parallel of latitude on July 4th.

"During the summer we took a number of whales, storing away as much oil as the captain thought necessary, as he only wanted it for fuel and our needs, intending to take none home to sell unless we were unsuccessful in the line of discovery—in that event he intended to stay until he had a full cargo."

Here our entertainer gave out and had to rest and while resting went to sleep, so that he did not take up his story until the next day.

In the morning our guest expressed a desire to be taken on deck, and dressed in warm sailor clothes , he rested his hand on my shoulder and slowly crawled on deck and to a sheltered corner beside the captain's cabin. Here he was bundled up and again Enoch and I sat down to listen to the strange story of the wanderer.

"I hope it won't annoy you, gentlemen," said he, "but I can't settle down without my pack, I find myself thinking of its safety ; would you mind sending down for it?"

It was brought up and set down beside him ; he looked at it lovingly, slipped the rude strap loop over his arm, and seemed ready to take up his story where he left off, so he began

"I don't remember if I told you or no,

but one of the objects of Captain Burrows' trip was to settle something definite about the exact location of the magnetic pole, and other magnetic problems, and determine the cause of some of the well-known distortions of the magnetic needle. He had some odd, perhaps crude, instruments of his own design which he had caused to be constructed for this purpose, and we found them very efficient devices in the end.

"Late in July we found much open water, and steamed steadily in a northwesterly course. We would find a great field of icebergs and then miles of floe, and then again open water.

"The Aurora was seen every evening, but it seemed pale and white.

"Captain Burrows brought the *Duncan McDonald's* head around to the west in open water one fine day in early August and cruised slowly, taking a great many observations, and hunting, as he told me, for floating ice—he was hunting for a current.

"For several days we kept in the open water but close to the ice, until one morning the captain ordered the ship to stand due north across the open sea.

"He called me into his cabin, and with a large map of the polar regions on his table, to which he often referred, he said:

"'Son, I've been hunting for a current, there's plenty of 'em in the Arctic Ocean, but the one I want ain't loafing around here. You see, son, it's currents that carries these icebergs and floes south; I didn't tell you, but some days when we were in those floes we lost as much as we gained. We worked our way north through the floe, but not on the surface of the globe; the floe was taking us south with it. Maybe you won't believe it, but there are currents going north in this sea; once or twice in a lifetime a whaler or passage hunter returns with a story of being drifted *north*—now that's what I want, I am hunting for a northern current.'

"'We will go to the northern shore of this open water, be it one mile or one thousand, and there—well, hunt again.'

"Well, it was in September when we at last got what seemed the northern shore of this open sea, we had to proceed very slowly, as there were almost daily fogs and occasional snowstorms; but one morning the ship rounded to almost under the shadow of what seemed to me a giant iceberg. Captain Burrows came on deck, rubbing his hands in glee.

"'Son,' said he, 'that is no iceberg, that's ancient ice, perpetual ice, the great ice ring—palæocrystic ice, you scientific fellows call it. I saw it once before in '37 when a boy, that's it, and, son, beyond that there is something. Take notice that that is ice; clear, glairy ice. You know a so-called iceberg is really a snowberg; it's three-fourths under water. Now, it may be possible that that being ice, which will float more than half out of water, the northern currents may go under it—but I don't believe it—under or over, I am going to find one of 'em if it takes till doomsday.'

"We sailed west, around close to this great wall of ice for two weeks without seeing any evidence of a current of any kind, until there came on a storm from the northwest that drove a great deal of ice around the great ring, but it seemed to keep rather clear of the great wall of ice and to go off in a tangent toward the south.

"The lead showed no bottom at one hundred fathoms, even within a quarter of a mile of the ice.

"It was getting late in the season, the mercury often going down fifteen below zero, and every night the Aurora became brighter. We sailed slowly around the open water for more than a week, and finally found a place where the sheer precipice of ice disappeared, and the shore sloped down to something like a beach. Putting out a sea anchor, the *Duncan McDonald* kept within a half a mile of this icy shore. The captain had determined to land and survey the place, which far away back seemed to terminate in mountain peaks of ice

"That night the captain and I sat on the rail of our ship talking over the plans for to-morrow's expedition, when the ship slowly but steadily swung around her stem to the mountain of ice—the engines had been moving slowly to keep her head to the wind.

"Captain Burrows jumped to his feet in joy. 'A current!' he shouted; 'a current, and toward the north, too—old man Providence again, son, he allus takes keer of his own!'

"Some staves were thrown overboard, and, sure enough, they floated toward the ice; but there was no evidence of an opening in the mighty ring, and I remarked to Captain Burrows that the current evidently went under the ice.

"'It looks like it did, son; it looks like it did, but if it goes under we will go over.'

"After a few hours of sleep, the long boat landed our little party of five men and seven dogs. We had food and drink for a two weeks' trip, were well armed and carried some of our instruments.

"It appeared to be five or six miles to the top of the ice mountains, but it proved more than thirty. We were five days in getting there, and did so after a dozen adventures, that I will tell you at another time.

"We soon began to find stones and dirt in the ice, and before we had gone ten miles found the frozen carcass of an immense mastodon, its great tusks only showing above ground, but its huge, wooly body quite plainly visible in the ice.

"The ice was melting, and there were many streams running towards the open water. It was warmer as we proceeded. Dirt and rocks became the rule instead of the exception, and we were often obliged to go around a great boulder of granite. While we were resting on the third day for a bite to eat, one of the men took a dish, scooped up some sand from the bottom of the icy stream and 'panned' it out—there was gold in it, gold enough to pay to work the ground.

"About noon of the fifth day we reached the summit of the mountain, and from there looked down the other side upon a sight the like of which no white men had ever seen.

"From the very summits of this icy ring mountain the northern side was a sheer precipice of more than three thousand feet, and was composed of rocks, and rocks only—the foot of the mighty crags being washed by an open ocean, and this was lighted up by a peculiar crimson glow.

"Great white whales sported in the waters, huge sea birds swung in circles above the water, yet below us, and with our glasses we could see, on the rocks at the foot of the crags, seals and other animals that were strange to us.

"But follow the line of beetling crags and mountain peaks where you would, the northern side presented a solid blank wall of awful rocks, in many places the summit overhanging and the shore well under in the mighty shadow. Nothing that any of us had ever seen in nature was so impressive, so awful.

"We started on our return after a couple of hours of the awe-inspiring sight to the north, and for full two hours not a man spoke.

"'Father Burrows,' said I, 'what do you think that is back there?'

"'No man knows, my son, and it will devolve on you and I to name it; but we won't unless we get to it and can take back proofs.'

"'Do you think we could get down the other side?'

"'No, I don't think so, and we seem to have struck it in the lowest spot in sight. I'd give ten years of my life if the *Duncan McDonald* was over there in that duck poad.'

"'Captain,' said Eli Jefferies, the second mate, 'do you know what I've been thinkin'? I believe that air water we seen is an open passage from the Behring side of the frozen ocean over agin' some of them air Roosian straits. If we could git round to the end of it we'd soil right through the great northwest passage.'

"'You don't think there is land over there somewhere?'

"'Nope.'

"'Didn't take notice that the face of your "passage" was granite or quartz rocks, hey? Didn't notice all them animals and birds, hey?——'

"'Look out!' yelled the man ahead with the dog sledge.

"A strange whirring noise was heard in the foggy light that sounded over our heads. We all dropped to the ground, and the noise increased until a big flock of huge birds passed over us in rapid flight north. There must have been thousands of them.

"Captain Burrows brought his shot-gun to his shoulder and fired. There were some wild screams in the air, and a bird came down on the snow with a loud thud. It looked very large a hundred feet away, but sight is deceiving in this white country in the semi-darkness. We found it a species of duck, rather large and with gorgeous plumage.

"'Goin' north to Eli's "passage" to lay her eggs on the ice,' said the captain, half sarcastically.

"We reached the ship in safety, and the captain and I spent long hours in trying to form some plan for getting beyond the great ice ring.

"'If it's warm up there, and everything we have seen says it is, all this cold water that's going north gets warm and goes out some place; and rest you, son, wherever it goes out there is a hole in the ice. The rocks may head us off, but there is a notch in the ice.'

"Here we were interrupted by the mate, who said there were queer things going on overhead, and some of the sailors were ready to mutiny unless the return trip was commenced at once.

"Captain Burrows went on deck at once, and you may be sure I followed at his heels.

"'What's wrong here?' demanded the captain in his roaring tone, stepping into the midst of the crew.

"'A judgment against this pryin' into God's secrets, sir,' said an English sailor, in an awe-struck voice. 'Look at the signs, sir,' pointing overhead.

"Captain Burrows and I both looked over our heads, and there saw an impressive sight indeed. A vast colored map of an unknown world hung in the clouds over us—a mirage from the Aurora. It looked very near, and was so distinct that we could distinguish polar bears on the ice crags. One man insisted that the main mast almost touched a snowy peak, and most of them actually believed that it was an inverted part of some world slowly coming down to crush us.

"Captain Burrows looked for several minutes before he spoke. Then he said

"'My men, this is the grandest proof of all that Providence is helping us. This thing you see is only a picture, it's a mirage, the reflection of a portion of the earth on the sky. Just look and you will see that it's in the shape of a crescent and we are almost in the center of it, and, by the gods, it's a picture of the country just in front of us. See this peak? See that low place where we went up? There is the great wall we saw, the open sea beyond it, and, damme, if it don't look like something green over in the middle of that ocean! See, here is the *Duncan McDonald* as plain as A B C, right overhead. Now, there's nothin' to be afraid of in that; if it's a warning, it's a good one—and by the knock-kneed Israel, if anyone wants to go home to his mother and's old enough, *he can walk!*'

"The Captain looked around, but the sailors were as cool as he was—they were reassured by his honest explanation.

"Captain Burrows took me by the arm and, pointing to the painting in the sky, said:

"'Old Man Providence, again, son, sure as you are born; do you see that lane through the great ring? There's an open, fairly straight passage to the inner ocean, except that it's closed by about three miles of ice on our side; see it there, on the port side?'

"Yes, I could see it, but I asked Captain Burrows how he could account for the open passage beyond and the wall of ice in front; it was cold water going in

"'It's strange,' he answered, shading his eye with his hand and looking long at the clear passage, like a great canal between the beetling cliffs. All at once he grasped my arm and said in excitement, pointing towards the outer end of the passage

"'Look!'

"As I gazed the great mass of ice in front commenced to slowly turn over, outwardly.

"'It's an iceberg, sir, only a damned iceberg,' said the captain, excitedly, 'and she is just holding that passage because the current keeps her up against the hole; now, she will wear out some day and then—in goes the *Duncan McDonald!*'

"'But there are others to take its place,' and I pointed to three other bergs apparently some twenty miles away, plainly shown in the sky, 'they are the reinforcements to hold the passage.'

"'Looks that way, son, but, by the great American buzzard' we'll get in there somehow if we have to blow that berg up.'

"As we looked the picture commenced to disappear, not fade, but to go off to one side just as a picture leaves the screen of a magic lantern; over the inner ocean there appeared dark clouds, but this part was visible last, and the clouds seemed to break at the last moment, and a white city set in green fields and forests was visible for an instant, a great golden dome in the center remaining in view after the rest of the city was invisible.

"'A rainbow of promise, son,' said the captain.

"I looked around, but the others were gone, they were tired of the scene and Captain Burrows and myself were the only ones that saw the city.

"We got under way for an hour and then stood by near that berg until eight bells the next morning, but you must remember it was half dark all the time up there then.

"While Captain Burrows and myself were at breakfast he cudgeled his brains over ways and means for moving that ice or preventing other bergs from taking its place. When we went on deck our berg was some distance from the mouth of the passage and steadily floating away. Captain Burrows steamed the ship up cautiously toward the passage, there was a steady current coming out.

"'I reckon,' said Eli Jefferies, 'that they must have a six months' ebb and flow up in that ocean.'

"'If that's the case,' said Captain Burrows, 'the sooner we git in the better,' and he ordered the *Duncan McDonald* into the breach in the world of ice.

"Gentlemen, suffice it to say that we found that passage perfectly clear and wider as we proceeded, this we did slowly, keeping the lead going constantly.

"The first mate reported the needle of the compass working curiously, dipping down hard and sparking—something he had never seen.

"Captain Burrows only said 'Let her spark.'

"As we approached the inner ocean, as we called it, the passage was narrow, it became very dark, and the waters roared ahead. I feared a fall or rapid, but the *Duncan McDonald* could not turn back. The noise was only the surf on the great crags within.

"As the ship passed out into the open sea beyond, the needle of the compass turned clear around and pointed back.

"'Do you know, son,' said Captain Burrows, 'that I believe the so-called magnetic

MAKE YOURSELF A **MECHANICAL ENGINEER OR DRAUGHTSMAN;** or qualify to take charge of, or to superintend the manufacture of Machinery, by devoting your idle hours to **Home Study,** by the method of

*THE CORRESPONDENCE SCHOOL OF MECHANICS, SCRANTON, PA.*

The course embraces instruction in Arithmetic, Algebra, Geometry, Trigonometry, Elementary Mechanics, Hydromechanics, Pneumatics, Heat, Mechanical Drawing, Steam and Steam Engines, Strength of Materials, Applied Mechanics, Boilers, Machine Design, Electricity, Etc. To begin, Students need only know how to read and write. **Moderate Charges. Diplomas Awarded. Send for Free Circular Giving Full Particulars.**

**Punches, Roller Tube Expanders, and Direct Acting Steam Hammers.**

☞ Jacks for Pressing on Crank Pins or Car Wheels made to order. Communications by letter will receive prompt attention.

## THE CHAPMAN JACK.

**PATENTED.**

THE screw being lubricated and protected, the Jack is always ready for instant service. Railroad men appreciate the importance of having Jacks always in good working condition. Serious delays frequently occur in getting common Jacks so that they can be worked when suddenly required in train service.

Common Jacks are frequently destroyed in efforts to make them work quickly after the screws are set with rust and dirt. This consideration alone makes the **Chapman Jack** the most economical one to purchase.

pole is a great ring around the true pole, and that we just passed it there. The whole inside of this mountain looks to me like rusted iron instead of stone, anyhow.'"

Here our story-teller rested and dozed for a few minutes, then rousing up, he said:

"I'll tell you the rest to-morrow; yes, to-morrow, I'm tired now. To-morrow I'll tell you about a wonderful country, wonderful cities, wonderful people! I'll show you solar pictures such as you never saw, of scenes, places and people you never dreamed of. I'll show you implements that will prove that there is a country where gold is as common as tin at home—where they make knives and forks and stew pans of it. I'll show you writings more ancient and more interesting than the most treasured relics in our Sanscrit libraries. I'll tell you of the two years I spent in another world. I'll tell you of the precious cargo that went to the bottom of the frozen ocean with the stanch little ship *Duncan McDonald*, the bravest, noblest commander, and the sweetest angel of a woman that ever breathed and lived and loved. I'll tell you of my escape and the hell I've been through. To-morrow——"

He dozed off for a few moments again.

"But I've got enough in this pack to turn the world inside out with wonder - ah! what a sensation it will be, what an educational feature. But it will send out a hundred harum-scarum expeditions to find Polaria—but there are few commanders like Captain Burrows; he could do it, the rest of 'em will die in the ice——"

"But when I get to San Fran——. Say, captain, how long will it take to get there, and how long before you start?"

Enoch and I exchanged glances, and he answered

"We wan't goin' to Frisco."

"Around the Horn, then?" said the stranger, sitting up; "but you will land me in Frisco, won't you? I can't wait, I must——"

"We're goin' *in*," said Enoch; "goin' north, for a three years' cruise."

"North!" shouted the stranger, wildly. "Three years in that hell of ice. Three years! My God! North! North!"

He was dancing around the deck like a maniac, trying to put his pack loop over his head. Enoch went toward him to tell him how he could go on the *Enchantress*, but he looked wildly at him and sprang out on the bowsprit, and from there to the jib. Enoch saw he was out of his mind, and ordered two sailors to bring him in. As they sprang onto the bow, he stood up and screamed:

"No! No!! No!!! Three years! Three lives! Three hells! I never——"

One of the men reached for him here, but he kicked at the sailor viciously, and turning sidewise sprang into the water below.

A boat, already in the water, was manned instantly, but the worn-out body of another North Pole explorer had gone to the sands of the bottom where so many others have gone before; evidently his heavy pack had held him down, there to guard the story it could tell in death as he had in life.

### Work of the Traveling Engineer.

In the address of President Conger at the Traveling Engineers' Convention, the following passages are found

"Railroads are operated nowadays on so small a margin of profit that the distance between a dividend and going into the hands of a receiver is measured by the small economies and savings in all departments. In our line, we know that by close economy in coal and oil, by looking after the machinery when in service on the road, and seeing that it is taken care of, so running repairs can be kept down, by assisting in enforcing good discipline, to avoid many of the petty accidents which waste money, we can do our part in saving money which can be easily wasted and not so easily accounted for. There is necessarily so much wasted on a railroad in keeping trains moving safely that it begets a habit of asking more than is needed, so as to *be sure to have enough*. *Gallons* of oil are used where *pints* would do the work. Tons of coal are burned, where a close watch of grades and stopping places would result in saving lots of it. Wheels are changed before they are worn out because we dare not risk having a broken one, and in a dozen ways familiar to us all unnecessary expenses run up. To draw the line between necessity and extravagance in the use of material out on the road is a hard task, but that is just what is expected of us, and we should be thoroughly posted on what is actually needed to get the engines over the road with economy and certainty.

"The traveling engineer has a great many duties to look after, some of them are pleasant, others are very disagreeable—all are responsible. The good men in charge of engines must be encouraged, the inexperienced instructed, and the indolent, careless ones notified, as quietly and certainly as possible, that if they do not attend to their work somewhere near as well as the best that they can expect to be disciplined. Mercy is sometimes thrown away on a lazy man, just the same as running repairs are thrown away on an old back number engine ready to be cut up and sold for scrap.

"The traveling engineer, no matter by what title he is known, has come to stay. A few years ago they were looked upon as one of the luxuries of railroad management, and there were very few of them in service; now there are over 500 of them, all more or less appreciated according to their usefulness. If we desire permanent employment or promotion, we must show the managers we can more than pay our way in the increased efficiency of the engines, in economy of fuel, and in looking after the small every-day leaks that can be stopped."

### Ignominy and Glory of Texas.

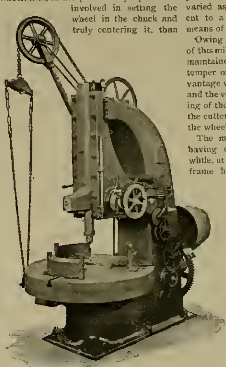
For several years past the principal labors performed by the individuals elected by the people of Texas to legislate for the interests of the State have been devoted to working out legal ways of robbing the owners of railroads. The railroads in Texas have been built almost exclusively with foreign capital. On this account it seems easy to incite legislators to act as if this species of property had no rights which people were required to respect. The policy adopted has been shortsighted, even when viewed from a Texas standpoint, for men with capital to invest in railroads are keeping severely away from the State, and railroad building will make no headway for years to come. This is to be regretted, for it leaves a splendid field of industry undeveloped, deprives thousands of people from obtaining lucrative employment and comfortable homes, and maintains fruitless vast regions capable of yielding rich harvests.

Few people realize the great extent and vast natural resources of Texas. Mr. Charles Hamilton, vice-president of the Texas Central, in a letter to the *Railroad Gazette* incidentally mentions that the State is "as large as New York, New Jersey, Delaware, Maryland, Pennsylvania, Ohio and part of Indiana, yet its size is only one of its characteristics. It has more coal area than Pennsylvania, more iron than Alabama, more granite than New Hampshire, more pine than Wisconsin, more oak than West Virginia, more prairie than Kansas, more corn land than Illinois, more wheat land than the two Dakotas, more cotton land than Mississippi, more sugar land than Louisiana and more rice land than South Carolina. It contains more mines than any other five States, has 500 miles of sea coast and 8,000 miles of railroads, with room for 8,000 more."

### A Novel Car-Wheel Boring-Mill.

William Sellers & Co., incorporated, Philadelphia, Pa., have recently put on the market a new wheel boring-mill, which we illustrate herewith. The following description from the makers will make its design capabilities perfectly plain:

Every master mechanic of a railway shop knows that more time is often consumed in "getting ready" to bore a car-wheel, *i. e.*, in the preliminary operations involved in setting the wheel in the chuck and truly centering it, than in the actual work performed by the machine.



SELLERS' NEW WHEEL BORING-MILL.

All the modern mills are so constructed that the time of rough boring, finishing, and facing the hub of the wheel is reduced to a minimum; but in this novel machine we have designed to save the time heretofore lost in setting, centering, and removing the wheel from the mill, by making these operations practically automatic, and we have thereby succeeded in not only increasing the capacity of the machine, but in reducing the labor and responsibility of the attendant, and removing altogether the liability to error on his part in truly centering the wheel. These results are secured by means of a self-closing universal chuck on the table, so arranged that the act of starting the machine causes the chuck to close upon the work and hold it securely in the true position for boring. *Per contra*, the stopping of the table automatically opens the jaws and releases the work.

The time heretofore lost in the gradual stopping of the rotation of the table is also saved, as in this apparatus the table may be stopped instantly, without shock, by the simple movement of a hand-lever.

An unusually stiff boring-bar, with double cutters having four cutting edges, insures quick and accurate boring of wheels which are hard in the hub, a common source of trouble in less powerful machines. The value of the double cutter, with its four cutting faces, has been demonstrated by years of use, and the simplicity of the locking device on this mill, permitting, as it does, change of cutters without loss of time, will commend itself to every practical mechanic.

The special crane designed for and attached to this mill is a convenient auxiliary, and contributes to the increased speed of the machine and decreased labor of the attendant.

The mechanism of the crane is such that when the wheel is raised to the proper height for swinging on the table, the hoist automatically stops, and when the attendant has swung the wheel into position it gently drops into its seat. The table is then started, the jaws of the chuck at the same moment close towards the center and hold the wheel in true position; the boring-bar with the double cutters descends through the hub, and the hole is rough bored; the boring-bar quickly rises clear of the wheel; the finishing cutters are immediately substituted for the roughing cutters, and the true hole is completed in a few seconds. The feed is varied as required, from a fine roughing cut to a five eighths finishing feed, by means of an adjustable friction device.

Owing to the great stiffness and power of this mill, quick speeds may be uniformly maintained, irrespective of the varying temper of the iron in the wheels, an advantage which lighter mills do not possess; and the very common annoyance of springing of the boring-bar and displacement of the cutter by "hard spots" in the hub of the wheel is obviated.

The mill presents the appearance of having enormous stiffness and power, while, at the same time, the contour of the frame harmonizes with the increased dimensions of the slide, table and gears; the machine is graceful to the eye, instead of appearing a clumsy affair.

This powerful mill, with its novel additions, is, of course, more expensive to build than those of the ordinary type; but it is believed that the additional first cost will be admitted to be but trifling when compared with the increased capacity, the superior accuracy of the work, the reduced manual labor and responsibility of the attendant, and other collateral advantages.

In a descriptive article published in the *Railroad and Engineering Journal*, June, 1892, the editor says: "The machine may be considered the latest development of its class, with all the improvements which experience has shown to be desirable."

### An Old-Timer.

Mr. E. N. Underwood, master mechanic of the Colusa & Lake Railway, at Colusa, Cal., has been making a visit East, after a California residence of twenty-four years.

Mr. Underwood was foreman of the Albany shops of the New York Central, or rather the Hudson River road, in the early fifties, and while in that position put the first cast-iron valve on a locomotive in this country. This was on the Breeze, Kneeland & Co. engine "Baltic," and done against the advice of the master mechanic and at the expense of the builders.

Mr. Underwood was a machinist runner, and as such attended the Engineers' Convention at Baltimore, November 6, 1855, where the Locomotive Engineers' Association of the United States was formed. This dragged along for a year or two; then the Brotherhood of the Footboard took its place, only to fail, and at last, in 1863, W. D. Robinson formed the present Brotherhood of Locomotive Engineers.

Mr. Underwood took out engines for the Breeze & Kneeland Co. for awhile, and while South in this capacity was offered and accepted the position of master mechanic of the East Tennessee & Virginia road, which he held until the war made it so hot he got out.

Mr. Underwood held several positions as master mechanic of Southern roads after the war, and finally went to California, where for seventeen years he was in the employ of the Southern Pacific.

Many of our well-known superintendents of motive power were shop-mates of Mr. Underwood, but most of them have gone over to the majority.

Mr. Underwood kindly loaned us a list of the engineers present at the Baltimore meeting, which is printed elsewhere in this issue. Many of these men are still alive, and some of them are running locomotives yet.

# Car Shops and Car Builders.

## Waitt's Brake-Gear for Six-Wheel Trucks.

The remarkably simple form of brake-rigging shown in the annexed engraving was designed by Mr. A. M. Waitt, general master car builder of the Lake Shore & Michigan Southern Railway. In connection with this gear Mr. Waitt writes us

"We have adopted during the past year a new arrangement of levers in connection with the application of the triple brake to six-wheel passenger trucks. This has been in use on some cars for nearly a year, long enough to fully prove its advantages and simplicity as compared with former arrangements.

"I send you a drawing showing the former generally adopted plan for applying triple brakes to six-wheel passenger trucks. You will notice in the old method that a peculiar-shaped forging, having a double reversed curve, has to be used in making the connection underneath the middle axle. You will also notice that in the old arrangement the top connection from the truck lever has to go over the top of the bolster and above the truck transom.

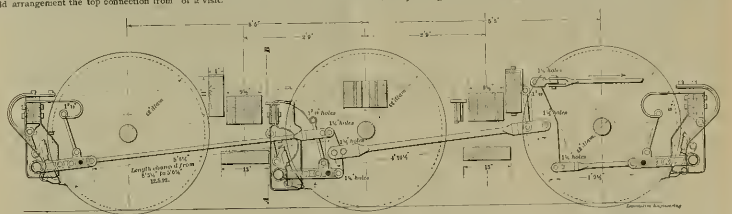
"Any one who has made an examination of cars equipped with modern six-wheel trucks with 38-inch or 42-inch wheels, well knows that there is very little room between the rigging attached to the body of the car and the top of the truck transom and bolster. In fact, on many cars the top connection chafes very hard on the transoms, or on some of the iron work or piping of the underside of the car body.

"With our improved arrangement, you will notice that we use for bottom connections nothing but straight forging, with the ordinary sizes of clevises, and the top connection is brought down low, it being on the outside of the truck, beyond both the bolster and transom, and, therefore, is in a position where there is plenty of room and no liability of the rods becoming cramped from coming in contact with any part of car body, or attachments to same.

"The arrangement in the drawing shows the device as applied to our standard six-wheel passenger truck, so made that it will take steel wheel 42 inches in diameter and will admit of the use of modern steel brake-beam and the M. C. B. standard type of brakehead, and the M. C. B. standard Christie shoe.

"As there has been quite a desire to do away with the crooked forged connection under the middle wheel, in the old style of application of triple brake, I present here an arrangement which is a simple device overcoming all of the difficulties of the old arrangement and providing several decided advantages, both as regards reduction in number of parts, simplicity of attachment, and ease of adjustment.

"You will also notice that we have provided for a release spring for the middle brake-beam; an arrangement which has not been much used, owing to the difficulty in application on most of the cars in the country equipped with the old style or triple brake."



## The Butler Draw-Bar Exhibit.

In the freight-car exhibit at the World's Fair the visitor is attracted to one car by the sheen of electric light inside. On climbing up the steps, which are hospitably easy, we find inside a fine display of Butler drawbars, Chapman jacks and a varied assortment of malleable iron castings made by the National Malleable Iron Co. All forms of the Butler draw-bar in use are shown as applied to the draft timbers. Having the method of fastening plainly exhibited on a bench where it can be carefully examined is found to be very convincing to visitors. This exhibit is said to have enjoyed the peculiar good fortune of making converts, who manifested their faith in the most welcome way by giving orders on the spot.

The Chapman jack exhibit comprises all the sizes made, from one monster jack three feet long to a tiny fellow that could be used for jacking up the equalizer of a locomotive. The car is very well worthy of a visit.

## Work For Master Car Builders.

The Executive Committee of the Master Car Builders' Association have laid out a generous programme of work for the next convention. Committees have been appointed to investigate the following subjects:

1. Tests of M. C. B. Couplers.—J. M. Wallis, J. S. Lentz, R. D. Wade, J. H. M. Connell, S. A. Crone and T. G. Duncan, committee.
2. Air-Brake Tests—G. W. Rhodes, S. P. Bush, George Gibbs, A. S. Vogt, E. A. Williams, committee.
3. Steel-Tired Wheels—R. E. Marshall, J. O. Pattee, C. H. Cory, A. E. Mitchell, H. Bartlett and T. A. Bissell, committee.
4. Road Tests of Brake Shoes—R. H. Soule, W. S. Morris, S. A. Crone, G. W. Rhodes, A. E. Mitchell, W. H. Lewis, J. W. Warden, A. M. Waitt, Jos. Townsend, Samuel Porcher, J. C. Barber and W. L. Hoffecker, committee.
5. Laboratory Tests of Metal for Brake Shoes—S. P. Bush, D. L. Barnes, J. W. Cloud.
6. Brake Beams—E. D. Nelson, J. H. Rankin, John Bean.
7. Safety Chains for Freight Cars—H. Coulter, W. H. Day, J. E. Simons, E. E. Carver, J. J. Casey.
8. Heating Passenger Equipment—W. L. Hoffecker, James Macbeth, George F. Wilson, A. J. Cromwell, John Hodge.
9. Ventilation of Passenger Equipment—R. P. C. Sanderson, William Forsyth, A. C. Robson, G. W. West, J. M. Holt.
10. Lighting Passenger Equipment—C. A. Schroyer, W. H. Fry, L. B. Paxson, William Apps, L. Packard.
11. Wheel and Flange Gauges—J. N. Barr, Thomas Anderson, T. Sutherland, Joseph Townsend, Thomas Fildes.
12. Lubrication of Cars—A. M. Waitt, W. H. Thomas, I. E. Wood, F. A. Stinard, W. K. Carr.
13. Air-Brake and Hand-Brake Apparatus on Cars—E. D. Bronner, Pulaski Leeds, James McGee, William McWood, W. P. Siddons.
14. Compressed-Air Appliances and Hydraulic Machinery—J. C. Barber, William Garstang, William McCormack, H. L. Preston, J. R. Skinner.
15. Freight Car Trucks—J. J. Hennessey, Samuel Irvin, William Voss, John H. Davis, F. H. Stark.

## Who Built the First Sleeping Car?

Since the sleeping car business was made a success many different claimants have arisen for the honor of having designed the first sleeping car that carried passengers. We were lately assured that the Bradley Car Works built the first sleeping car after plans furnished by Mr. John Kirby, long master car builder of the Lake Shore, and we wrote trying to obtain copies of the drawing. Osgood Bradley & Sons answered very courteously, expressing regret that they could not furnish the drawings because they had been destroyed years ago by a fire that took place in the works. They assured us, however, that the sleepers they built from Mr. Kirby's designs were not the first introduced, as they had previously built a sleeping car on designs prepared by Ira Hopgood, a conductor on the Boston & Albany. The inventor of this car died shortly after it was built, and the drawings were burned in the fire referred to, so no particulars about the cars could be given. If any of our New England readers can give us any information about these cars we feel certain that our readers would appreciate it.

## The Smilie Coupler Exhibit.

A great many people exhibiting car couplers have invented appliances for making the trucks carrying the couplers move so that the coupling and uncoupling could be clearly displayed. But all attempts in this line have been comparatively crude compared to the mechanism arranged by Mr. Taylor for exhibiting the Smilie coupler at the World's Fair. He arranged couplers on stationary draft timbers at the two limits of his space. Between these he wanted to run a car with couplers on each end which would move to and fro between the stationary couplers and couple and uncouple when contact took place.

It was desirable to provide means that would keep the car constantly moving when visitors were there. Many schemes were tried. Mechanical engineers and electrical engineers were consulted, but none of their plans promised success. Finally Mr. Taylor set to the task himself and arranged an electric motor, which makes the car perfectly automatic in its movement. As the coupler on the car strikes the stationary coupler a reversing stop is touched, which reverses the motor, and the car starts away back, unless the coupler is set to couple. It is generally set open, and all day long the car moves too and fro, coupling and uncoupling. The exhibit attracts crowds of railroad men all the time.

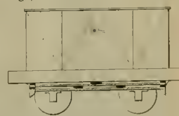
## Wooden Springs.

Mr. E. J. Rauch, of the Manhattan Elevated, formerly a Philadelphia & Reading machinist, foreman and master mechanic, writes us Your correspondent, De Sanno, asks for some information about the wooden car spring in use on the P. & R. R. R., and on some others also, until within the past few years.

About 1850, a workman in the wooden coal-car shops of the P. & R. R. R. Company conceived and patented the idea of using an ash or other kind of wooden spring on coal cars. Failing in introducing it into use, he sold his right to Jas. Millholland, then master mechanic of the P. & R., who put it on the four-wheel wooden coal cars and on the trucks of eight-wheelers, when they came into use, and realized a handsome sum from the royalty. A few years later, Mr. Millholland traded his interest in the spring to the firm of Heywood & Snyder, of Pottsville, Pa., in exchange for the engine and blowing cylinders for the furnace of the Leesport Iron Co., of which he was a member.

The spring was very cheap, and for cars hauling coal, ore or other coarse freight was about as good as steel.

I send you a sketch of the spring as it appears on a four-wheel coal car It consisted of two pieces of ash about 9 feet long, 7 in. wide and 2 in. thick, secured to



the sill of car by pockets. On the top piece in the center was a rubber block bearing against the sill of the car, and between the pieces were two rubber blocks as shown. The ends in pockets were kept apart and from sill by wooden blocks.

## Steel Growing Popular in New England.

The introduction of steel axles and forgings generally throughout New England is quite marked. This is more noticeable during the last year. While the Middle States and Western roads have adopted steel quite generally, the New England roads have adhered to iron, for two reasons, we think: First, on account of the better quality furnished by the New England forges, for which they were willing to pay; and second, because of a desire to encourage those domestic manufacturers who were conscientious in their efforts to supply a reliable article. Of course, there was more or less prejudice to steel based upon experiences dating back some six years, and which was put in competition in price with the first quality of iron axles.

It was found to wear rapidly and heat badly. These defects seem to have been entirely eliminated in the manufacture of the best qualities of steel of to-day. Among

the New England roads recently using steel heavily are the Boston & Albany, Fitchburg, New York & New England, etc. Steel scrap finding its way in wrought scrap and this inferior quality of wrought scrap thrown in the market during the past years of "dear cheapness" practiced heretofore so generally, has reversed the condition of things in New England, as it has elsewhere throughout the country, and wrought axles are found to wear unequally, and are becoming dangerously troublesome. The head of the car department of one road tells us of his experience, which certainly demands serious consideration.

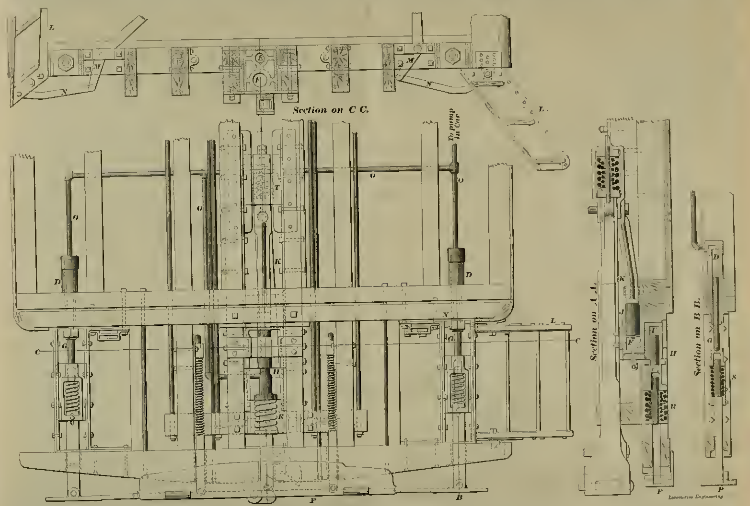
### Leonard's Hydrostatic Buffer.

The object of this buffer is to provide means of holding adjacent cars firmly together, thus increasing the friction between the buffers and lessening the length. The cylinders $F$, $E$, $D$, $D$ are all connected to the same system of piping, and the pressure per square inch will be the same in each. This pipe $O$ is connected to a pump and reservoir inside the car. The pipes, cylinder and reservoir are filled with water or other fluid.

In the ordinary systems of coupling cars used in this country with couplers of the Janney and Miller type, the couplers and buffers are usually so arranged that when the cars are coupled the springs that force the buffers out are compressed to a certain extent, thus forcing the buffer together and tending to hold the cars steady. The amount of this compression and the subsequent pressure upon the buffers is, however, limited, since in order to effect a coupling the cars must be driven together with sufficient force to compress the buffer springs and allow the couplers to engage. If the springs are too stiff this impact is too great, and will not only dam- pressure in the adjacent ends of two cars is pumped up to about the same amount (sufficient to put the springs under a heavy compression) as shown by the gauges.

If one buffer has more pressure in the cylinders than the other, the buffer will move toward the car on which there is the smaller pressure. The leakage is very small and may be supplied by a few strokes of the pump when required. The long buffer plates shown increase the area of friction surface between the buffers, and this combined with the greater pressure between them has a marked effect in reducing the oscillation of the cars. It also tends to hold the end of the car up on uneven track. In case of a low joint or depression in the track the truck will drop and with the ordinary buffer the body of the car will follow the truck, and as the truck rises again the body of the car meets it and produces a shock. With the hydrostatic buffer, however, the friction between car and the platform end timber. By increasing the width of the platform it becomes necessary to use hinged steps which can be turned up out of the way when the train is running. The step $L$ is pivoted as shown and is raised and lowered by the lever $M$ and link $N$. When in a station the step is lowered for passengers. When running it is raised in the position shown on the left hand side of the cross-section, and held in that position by a spring latch.

An improvement in refrigerator cars has been patented by Mr. John Player, superintendent of motive power of the Atchison, Topeka & Santa Fé, at Topeka, Kan. The principal claims made are a refrigerator car with the combination of an elevated ice-box communicating with the car, a duct beneath the floor communicating with the space beneath the ice-box and that inside the car. A series of troughs are placed beneath the bottom of the ice-



amount of oscillation due to curves and uneven tracks.

In the different views on the drawing the same letter refers to the same part. Two center cylinders, $E$ and $F$, cast in one piece, are firmly secured between the center sills of the car. The cylinder $E$ is fitted with a ram $H$, which forces outward against a cross-head pressing against the spring $R$, which transmits the pressure to the buffer $P$. The cylinder $F$ is fitted with a ram $J$, which is forced against the pressure-bar $K$. This pressure-bar is secured to the back end of the drawhead. When pressure is admitted to cylinder $F$ by the pipe $O$, the ram $J$ is driven back and the drawhead is drawn in. At the same time the pressure passes through the port to the cylinder $E$, and forces the buffer $P$ outward; thus the cars are drawn firmly together. Two side cylinders, $D$, $D$, are secured in the end sill of the car. Each of these is fitted with a ram, $G$, which bears against a crosshead and transmits the pressure through a spring, $S$, to the buffer $P$. The buffers $P$ are thus pressed together at three points on their age the cars, but will cause a disagreeable shock to the passengers. In some systems the coupler and buffer are so connected by levers or pressure-bars, that as the coupler is pulled forward the motion is transmitted to the buffer, and the opposing buffers are thus pressed together with greater force. In this case, however, the amount of pressure that can be put on the buffers is limited, since the springs must be compressed and the cars coupled by impact. In the English system of coupling, the cars are drawn together and pressure put on the buffers after the cars are coupled by a screw operated by hand. This method, however, is slow and crude, and involves the necessity of a man going between the cars. It is, moreover, inapplicable to automatic couplers.

In the hydrostatic system the pressure is let out from the cylinders when the cars are to be coupled and a coupling may be thus effected with a slight impact. After the coupling is effected the pressure is pumped into the cylinders by an attendant in the car, and any desired amount of pressure may be put on the buffers. The the plates is sufficient to hold the end of the car up for the moment as the trucks fall, and a much steadier motion is the result.

In rounding curves, as the cylinders on the end of one car are all connected, one end of the buffer is free to move in while the other moves out, the fluid passing from one side cylinder through the pipe into the other as the rams move, and thus serving the purpose of an equalizing bar to maintain a uniform pressure on each end of the buffer.

In case of a collision the hydrostatic buffer would afford much more protection to the cars and passengers than the ordinary system both on account of the greater area of buffer and also because the shock will be better absorbed by the hydrostatic buffer, since the force necessary to compress it is much greater.

In connection with this buffer the platform is extended out nearly to the width of the car body; this gives a wider space for the vestibule if one is used and increases the strength of the platform by affording an opportunity to put in additional timbers between the end sill of the box and the floor of the car to maintain a body of cold water at this point, whereby the air passing into the duct is brought into contact with the troughs and cooled.

The Boston & Albany Railroad management deserve sympathy rather than blame for the terrible accident which happened to a passenger train on that road on the last day of last month. A weak bridge was undergoing repairs for the purpose of strengthening it. The men had cut out the rivets from the old plates as a preliminary to putting strengthening plates on. They left the girder in this weakened condition and went to dinner. Before they returned the Chicago limited came thundering along and went through the bridge, killing thirteen persons and injuring many others. The man in charge of the repairs was clearly to blame for not requiring the speed of trains to be reduced while crossing the bridge in its weakened condition. There have been few fatal accidents on the Boston & Albany, and the immunity has been due to the use of first-class equipment of all sorts and careful operating

# ? A. What You Want to Know. ? A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(93) M. J. B., Poughkeepsie, N. Y., asks

Do you think power brakes on the drivers of an engine are bad for them? Do you think they do them harm? *A.*—No.

(94) C. A. J., Meridian, Miss., asks

I do not understand the storage battery process of electricity; can you give me any light in your next issue? *A.*—Storage batteries are so constructed that electricity can be, so to speak, pumped into them, much as you would pump air into a tank, this can be drawn off for use as wanted.

(95) L. A. P., Los Angeles, Cal., writes

What is the matter with the following method of finding the dead center on the road? Place end of chisel on frame of cross-head, so that in moving the engine pushes the chisel, which leaves a mark on the guide. The end of the mark indicates the extreme point of travel, and, therefore, the dead center, or at least close enough for setting an eccentric on the road. *A.*—That gets the dead center near enough to do the temporary work required on the road. Under some circumstances the crank-pin may, however, be a considerable distance away from the center when the cross-head reaches the extreme point of travel.

(96) W. N., McAdams Junction, N. B., writes.

Why does an engine slip more with small nozzles than with large ones? Am running a 10-wheel connected engine. Nozzles got gummed up, and the engine slipped so that I could not do anything with her. Got nozzles cleaned out and trouble from slipping ceased. *A.*—The only thing we can think of as a reasonable explanation of this phenomenon is, that the weight of the gum on the nozzles may have been sufficient to overbalance the weight on the driving wheels. If this is not satisfactory we give up the question, and leave it to those who imagine that a locomotive gets out of humor at times.

(97) H. R. R., New York, writes

"A" contends that an engine with 54-inch driving wheels will *start* a train quicker than an engine with 84-inch wheels, crank-pins same distance from hub, weight of engine and train the same in both instances. "B" contends that size of wheels have nothing to do with the case, but that the weight of engine accounts for quicker starting. Please say which is right and why. *A.*—"A" is right, the engine with small wheels has the advantage of leverage, the piston works on the short end of a lever, the long end is longer as the wheel is larger; to overcome the inertia of weight of train, the small wheel has an advantage on the start, were there no weight to move one wheel would start as soon as the other.

(98) Fireman, Buffalo, writes

We have some of Brooks' ten-wheelers with rocker set in front of forward drivers, short valve-stem and long eccentric rods, valve-stem has flexible joint about midway between rocker and packing-box, and is fitted with metallic packing with a soft metal-lined guard extending out from packing-box about 10 inches. In an argument with an old runner, he claimed the joint was put in valve-stem on account of the guard being there. I said the guard was used on account of joint, and joint was used on account of valve-stem being so short. Being only a fireman, I did not feel like opposing his ideas very strong, but determined to write to LOCOMOTIVE ENGINEERING and find out. *A.*—Your views are correct.

(99) J. Hartley, Philadelphia, Pa., writes

The *Engineering News* says that Fig. 144, in Grimshaw's "Locomotive Catechism," there given as an express passenger engine with two pony trucks, is not that but a double ended suburban engine. Which is right? *A.*—The engine alluded to is given on page 15 of Baldwin Locomotive Works' "Catalogue of Locomotive Details" as for "express passenger service," being styled by them "Class 8¼ C;" C indicating with those builders that four wheels are connected as drivers, the "8" that there are eight wheels altogether, and the "¼" that there is a truck at each end. The Baldwin Works, probably, know an express passenger engine when they see one. Mr. Grimshaw suggested this type of engine some years ago for his proposed run from New York to Chicago in eighteen hours; illustrating it in the *Journal of Railway Appliances*. From New York to Chicago is hardly suburban traffic.

(100) J. B. R., Indianapolis, Ind., writes

I am an apprentice in a railroad machine shop and I am trying to learn everything about the business which a foreman must know. Some of the men tell me that all I have to do is to learn now to do the work of the shop well. It seems to me that there are other things one ought to know which are not learned by a machinist in the shop. Some one advised me to write you about it. *A.*—A youth anxious to rise in a mechanical business ought to learn a great many things which he is not likely to find out in the shop. The best way is to attend a night engineering school. The ordinary machinist does not learn everything about the speed of tools and how to calculate the size of pulley to produce a certain speed. He finds out little about the strength of material. In these days a foreman must be familiar with hydraulics and electricity. He must be familiar with the principles of boiler design, the action of steam and a thousand other things. A studious youth may learn a great deal about these things from books, but the right place to get instruction is an engineering school.

(101) G. E. B., Bedford, Ia., asks

1. Suppose an engine should come in at an out-of-the-way roundhouse with all four eccentric blades bent, twisted and broken, so that it would be impossible to get the length accurately enough from them to send to headquarters, and you had no blue-print and no other engine of exactly same build was at hand, how would you get the length, close enough to allow for adjustment, to send to repair shop? (It is not probable that such an accident ever happened, unless in a bad wreck, but I use it simply as an illustration.) *A.*—Put engine on forward center, take up steam-chest cover, or use tram to set valve with proper lead opening, then measure from center of hole in top of link for eccentric-rod pin to shoulder on eccentric strop, drill holes after the blade arises, do same for back motion, and the two blades will be practically the same length. 2. How is the drop of the link-lifter arms of the lifting shaft determined? That is, when shaft is leveled on surface plate and center of reach-rod and pin-hole is perpendicular to surface, how is the distance (if any) calculated of the centers of pin-holes of lifting arms below centers of shaft bearings? *A.*—The throw of the tumbling shaft arm must be enough to move the link up and down the length between the eccentric blade connections; the bending down of arms is often done to avoid the boiler when the arms are at their highest point; the length of arm, of hanger and of the location of the tumbling shaft have a great deal to do with the distribution of steam. 3. What are the "Mansell" retaining rings and how are driving-wheel tires secured by them? *A.*—The Mansell retaining ring is two rings bolted to the outside of the wheel center, and having a lip on their insides that are let into grooves turned in the sides of the tire. 4. In laying off driving-spring hangers what is a good rule to observe in regard to the amount of draw to give a spring in relation to number of leaves and weight to be supported? *A.*—There is no set rule that can be followed in this case. 5. How is the tension of the driver-springs applied to the boxes of the "999"—by a downward pull connection at bottom of box, or pressure on top through system of levers? If at bottom how connected? *A.*—The springs are underhung, a heavy spring hanger being bolted across from one jaw of the driving-box to the other, the boxes are of Ajax metal and the connection made close to the bottom.

## A Great Thing, of Wind.

A man who signs himself Rev. W. R. Covert, has an article in the *American Journal of Politics* entitled "The Raub Gravity or Three-Cylinder Engine The Locomotive of the Future." We advise all railroad men to read the article—it's killingly comical. His reverend (?) giblets has evidently lent himself to the land-selling scheme at Elwood, Ind. The man of the cloth publishes a report on the test made by the Erie officials, and signed James H. Barrett, Gen'l Sup't, that goes a long way to prove that there are a whole lot of things about locomotives that Mr. Barrett don't know—just as a sample, he says "She carries no dead weight, since all the component parts of her are equally distributed around and about her center of gravity, and hence *saves all expenses of its carriage and maintenance*." He also suggests that the engine will make one hundred miles per hour with a train of seven Pullmans, *as a result of her doubled-tractive force and momentous centrifugal power*.

The reverend M. E. speaks of an engine whose "grates exceeded the limits of its *combustive center*," and also says that the new engine "enables the increase of the revolutions of the drivers without increasing the velocity of the *cylinder position*," also, in referring to an ordinary engine, says "When one piston of a *two-cylinder engine driver!*"—— If you have any money to invest and want to put it in a safe place—where you will never see it again—buy some shares in the Raub-Center-Power-Gravity-Locomotive and Farm-Land-Improvement-Co. (limited).

## National Railroad Master Blacksmiths' Association.

In response to the call of a committee of foreman blacksmiths, published in our last issue, about forty railroad foremen blacksmiths met in the Rookery, Chicago, on September 5th, and organized the National Railroad Blacksmiths' Association. The following officers were elected President, J. J. Thornton, Northern Pacific; First Vice-President, Stephen Uren, Southern Pacific; Second Vice-President, W. W. McLelland, Denver & Rio Grande; Secretary and Treasurer, Geo. F. Hinkins, St. Paul & Duluth. Mr. Hinkins is well known to our readers through his blacksmithing articles.

The president nominated the following members for the Executive Committee C. H. Williams, Cincinnati Southern, J. Buckley, Illinois Central; J. E. Mick, B. & O. S. W.; H. Jeffries, Baldwin Locomotive Works; William Young, Wabash Road.

Mr. W. W. McLelland of the Denver & Rio Grande then presented a very interesting paper on iron, treating the subject historically. It was admirably written, and displayed the results of a most careful study of the subject. The paper was warmly received and was followed by a paper from Mr. George F. Hinkins of the St. Paul & Duluth, in which the duties and aims of the blacksmith foremen were talked about in a most entertaining and suggestive manner.

Several topics were offered for consideration at the first regular meeting, which will be held in Pittsburg, in September, 1894. Among them were: "Work on axles and frames," "Best methods of handling scrap," "Furnace design," "Fuel gas and oil for furnaces," "Welding in locomotive and car work," "Electric welding," and "Piece work."

## Case-Hardening and Furnaces for the Work.

BY W. G. LOTTES.

My letter in September number on case-hardening seems to have drawn considerable attention, according to the personal letters I have received. The question asked in the letters is the time it takes to harden a certain size piece in a certain depth, which is a thing that depends a great deal on the furnace you have and the man that is tending the furnace. If you allow your heat to go up and down you will not get as good results as you would with a good even heat from the time you put it in until you take it out.

Next is the length of time you leave it in. If your case-hardening is packed right, the longer you leave it in, the deeper it will harden, providing you have your box packed so that your charcoal or charred bones or good ground bones will not burn to ashes, and have enough of them for the size piece you are going to case-harden. For instance, a crank-pin for a locomotive ought to have at least a layer of two inches all around it, and a good, tight box. If Jones & Loughlin machine steel, or a good close grain iron is used, you can harden it in as much as $1\frac{1}{16}$-inch by keeping it hot twenty-four hours.

I have been asked what kind of a furnace could be built for doing this work without much expense. This reminds me of the first case-hardening I had to do. We had an old firebox that had been taken out a sheet at a time and thrown in the scrap. It was taken and bolted together, and some big pieces of iron put in, to set the box on. After having the box in, the door sheet was hooked on, then we had a furnace that would burn both wood and soft coal, in fact all the old rubbish in the yard, and surely the old man could not kick on the expense of building.

Another cheap furnace is to lay a brick wall on the outside of your forge, 3 feet 6 inches to 4 feet high, and leave a hole on the top between stack and brick big enough to throw wood in. When you want to take your box out, pull right through the wall, or pull the wall down first, but you want to do it quick, so you will not lose any heat. This makes a cheap furnace, and the old man cannot kick on expense of building. He might kick if you break too many bricks, but you can work in a good many pieces. I have used them as many as twenty-five times.

---

A terrible rear end collision happened with a double section of Big Four's passenger trains near Kankakee, Ill., on the evening of September 18. The story is as old as railroad operating, and has been repeated hundreds of times. The first section was stopped unexpectedly and the flagman failed to go back. The engineer of the second section rushed along ignorant of danger and saw the rear end only in time to apply the brakes and jump. The engine plowed through a car loaded with passengers and killed eight, wounding many others. The use of time fusees would have prevented this disaster.

---

A patent has been granted to Mr. Harry C. Buhoup, the well-known railroad supply man, of Chicago, for his buffer and vestibule connection for passenger cars. There are eleven claims made for the invention. It is a combination of an independent lateral vertical buffer provided with rearwardly extending plates, which constitute vestibule face plates. There is a casing and door posts between which the plates slide. One set of buffers have a curved face and the others are flat-faced. The principal attachments necessary to form the vestibule are covered by the patent

## A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK.

VOL. VI, No. 11. NEW YORK, NOVEMBER, 1893. 20 Cts. Monthly \$2.00 Per Year.

### New Fast Express Locomotive, Central Railroad of New Jersey.

Our engraving shows one of the latest fast express engines built by the Baldwin Locomotive Works for the "Royal Blue" trains on the Central of New Jersey, designed by Superintendent of Motive Power and Equipment Chas. A. Thompson.

Owing to the limit for height Mr. Thompson was obliged to take the whistle and safety-valves off the top of the dome, but instead of putting the pops in a smaller dome, or on the boiler, as is done by the P. R. R. and several other roads, he places them on the back side of the dome proper.

Material of firebox, steel.

Thickness of plates of firebox, side, back and crown sheets, 5/16 and 5/16 and 3/8 in.

Material of firebox tube-sheets, steel, 1/2 in. thick.

Crown-sheet staying, 1 1/8 in. radial stay.

Diameter and height of dome, 31 1/2 x 20 1/2 in.

Working steam pressure per square inch, 170 lbs.

Kind of grates, water grate and pull-out bars.

Number of tubes, 260.

Diameter of tubes, 2 in.

Width of opening between tubes, 3/4 in.

Grate surface, 38.6 sq. ft.

Size of tender axle-journals, 5 x 8 in.

Wheel-base of tender, 16 ft. 2 in.

Spread of truck-wheel centers, 5 ft. 6 in.

Capacity of tank in gallons, United States, 3,500 gallons.

Fuel capacity of tender, 6.8 tons.

Total wheel-base of engine and tender, 49 ft. 3 in.

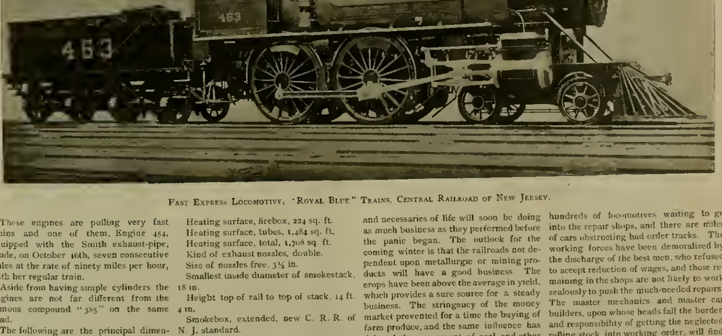
Total length of engine and tender over all, 59 ft 9 in.

### Entering the Winter with Rolling Stock Run Down.

The indications are that the railroads which derive their principal revenue from the transportation of farm produce, coal and necessaries of life will soon be doing as much business as they performed before the panic began. The outlook for the coming winter is that the railroads not dependent upon metallurgic or mining products will have a good business. The crops have been above the average in yield, which provides a sure source for a steady business. The stringency of the money market prevented for a time the buying of farm produce, and the same influence has delayed the movement of coal and other supplies that must be provided for the winter. There are now indications of unusual activity to make up for lost time, and the railroad companies will be the first to enjoy the benefits.

Very few railroads have their rolling stock in a condition to handle a rush of business during the winter months. A blind policy of cutting down shop forces has been pursued, and all work not absolutely essential for present needs has been shut down. Not a few of the managers acted as if there was no future. Most of them are now wakening up a little, and increase of force and lengthening of working hours is the rule of the day.

When the nights are long and dark, there will be full working hours in many shops and much overtime going on. This will compel the companies to pay a large premium for the small savings they effected by reduction of force and of working hours at the time when the work could be done to advantage. The volume of business has not increased very greatly yet, but some of the roads have every locomotive fit to haul cars in service. Should the winter prove severe, the roads that pursued the waiting policy are certain to be in a frightful condition. There are hundreds of locomotives waiting to go into the repair shops, and there are miles of cars obstructing bad order tracks. The working forces have been demoralized by the discharge of the best men, who refused to accept reduction of wages, and those remaining in the shops are not likely to work zealously to push the much-needed repairs. The master mechanics and master car builders, upon whose heads fall the burden and responsibility of getting the neglected rolling stock into working order, will find themselves in a most unenviable position. They were generally opposed to the policy of senseless reduction, their advice was generally in favor of putting the machinery in order at the season when men could work to the best advantage. After their advice went unheeded and chaos has come, they are called upon to put things to rights, and they will be blamed if they fail to do it at small expense. The coming winter is certain to witness roads blockaded with cars because there are not locomotives enough to move them, and freight delayed because there are not cars to haul it.



Fast Express Locomotive, "Royal Blue" Trains, Central Railroad of New Jersey.

These engines are pulling very fast trains and one of them, Engine 454, equipped with the Smith exhaust-pipe, made, on October 16th, seven consecutive miles at the rate of ninety miles per hour, with her regular train.

Aside from having simple cylinders the engines are not far different from the famous compound "385" on the same road.

The following are the principal dimensions:

Cylinder diameter and stroke, 20 x 24 in.

Size of steam ports, 1 1/2 x 20 in.

Size of exhaust port, 3 1/2 x 20 in.

Slide-valve traveling full stroke, 6 1/2 in.

Slide-valve lap, outside, 1 in.

Slide-valve lap, inside, 0.

Slide-valve lead, full stroke, 1/16 in.

Diameter of driving-wheels, with tires, 78 in.

Diameter of truck wheels, 36 in.

Size of driving axle journals, diameter and length, 8 x 12 in.

Material of outside shell of firebox, steel, 5/8 in. thick.

Heating surface, firebox, 224 sq. ft.

Heating surface, tubes, 1,484 sq. ft.

Heating surface, total, 1,708 sq. ft.

Kind of exhaust nozzles, double.

Size of nozzles free, 3 1/2 in.

Smallest inside diameter of smokestack, 18 in.

Height top of rail to top of stack, 14 ft. 4 in.

Smokebox, extended, new C. R. R. of N. J. standard.

Total weight of locomotive, working order, 123,800 lbs.

Total weight on driving-wheels, 88,400 lbs.

Total wheel-base of locomotive, 22 ft. 3 1/2 in.

Distance between driving-wheel centers, 7 ft 6 in.

Distance between front driving-wheel centers and cylinder centers, 11 ft. 4 1/2 in.

Length of main driving-rod, center to center, 7 ft. 2 1/2 in.

Weight of tender, empty, 32,500 lbs.

Weight of tender, with fuel and water, 82,000 lbs.

Number of wheels under tender, eight.

### Erie Train Service and Cars.

The advantage secured in the moving of trains safely by having a good signaling system has been very well illustrated this season on the Erie. This road has been carrying a very heavy excursion business of people going to the World's Fair, trains often running in five or six sections. This is the most difficult kind of business to handle safely, but, thanks to the excellent block system, the trains have been run without accident.

In connection with the large passenger business done by the Erie this season, their latest pattern of passenger cars is worthy of more than a passing notice. Within the last year the company have received nearly one hundred new passenger cars, that are unusually substantial and comfortable. They embody all the latest improvements and conveniences for the comfort of passengers. The interior finish is in mahogany of a rich, neat design, with quarter oak head-lines tastefully decorated. The trimmings are bronze, and Forney seats are used, upholstered in crimson and old-gold plush. The cars have Pintsch gas, Westinghouse quick-action brakes, air-signals and platforms of the improved Janney-Buhoup pattern. A very desirable feature about these cars is that the space between the bed timbers is filled with mineral wool, which is said to have a decided effect in deadening noise.

### Use Fusee Signals.

There is a growing sentiment in favor of railroad companies being compelled to employ block signals for the safe movement of trains. Every rear end collision resulting in loss of life makes new converts in favor of a system that will keep trains apart. If railroad companies wish to delay legislation in favor of block signals they had better use every means to make the flagging system more effective. As a radical improvement on or addition to the methods of the rear brakeman we commend the following plan recommended by Col. Haines.

"More extended recognition should be given to the use of the time fusee. Its use at night should be obligatory, not only by the flagman but also by the engineer. Whenever he is about to stop or slow down his train at an unusual place, he should drop a lighted ten minute fusee on the right hand side of the track on which the train is running, one mile before the stop is made, and an interval of ten minutes ahead of the following train is at once secured by a sentinel that will not desert its post, by a signal whose unmistakable light will illume its surroundings, let the wind blow and the rain fall as they may. Such a use of the fusee will not do away with the protection afforded by the flagman, but rather increase it, for as he crosses a bridge on his way to the rear he will feel personally safe so long as he sees that purple blazing between him and the approaching train. Even in the day time, the smoke from a lighted fusee would attract the attention of a following train."

The damage caused by one wreck would probably cause more loss than the expense of providing time fusees for a whole year. Why this excellent system of signaling has been so long neglected is something we cannot understand. No road that is without block signals can afford to neglect the fusee method of protection to trains.

### A Brazen Affair.

"Did you ever hear how the expression, 'The cheek of a government mule' originated?" asked the Old Member at the last meeting of the club.

No one was aware how that classic phrase arose, so the Old Member proceeded to enlighten them thusly.

"Away back in the year—well, no matter what year—the Coal Combine road was supplied with brass by the Brazen Body Company, whose headquarters are in Jersey. The manager of the company, Mr. Scheme, was noted for his aggressive business methods. He did not sell all the brass in his possession, but kept a good stock on his face to do business with.

"They had been furnishing brass to the Coal Combine Company for years, and were making a good thing out of it. It came to pass that a new master mechanic came to the road, and as the times were a little hard—just as they are now—Mr. Charles, as the master mechanic was called, got looking into how he could reduce expenses, and he discovered that the company were paying more than the market price for their brass. This was a good opportunity to retrench, so he sent out a request for bids for the supply of brass, and the circular went to the Brazen Body Company as well as to others.

"Next morning Mr. Scheme was bright and early waiting on Mr. Charles.

"'What does this paper mean?' he inquired with some heat. 'Is our brass not good enough for you?'

"'Yes,' replied Mr. Charles, 'it is good enough, but it is too dear. You charge more than the market price.'

"'Now, you may just as well stop right here,' retorted the man of brass. 'We are going to continue supplying your company with brass at the price we are getting, and don't you forget it. There is a power behind the throne that will quickly pull you down if you don't look out.'

"'That is all right,' returned Mr. Charles, who has a quiet, easy way of talking, 'just bring out your power as soon as you like, but bring down your price by the first of next month or I shall order a supply of brass from some one else.'

"Mr. Scheme walked out in a rage and proceeded to pull all the ropes within his reach, but none of them were strong enough to dislodge Mr. Charles from his position. He tried all sorts of actions to prevent the price from being reduced without success, and finally got a friend who was corporation counsel to give notice that a suit would be brought against the railroad company for causing a smoke nuisance with their locomotives. After this notice was given he went to condole with Mr. Charles.

"'Now, Mr. Charles,' he said, 'I am very sorry to hear about this suit, for it will be a serious reflection on you. But I may be able to help you out. The mayor is my friend, and I will try to get the suit withdrawn if you will continue the brass contract at the old figure.'

"'Mr. Scheme, you got this suit begun, and now you want to dicker with me to stop it. You have the cheek of a government mule, but your kick has missed. Our president has seen the mayor and the suit is already withdrawn.'

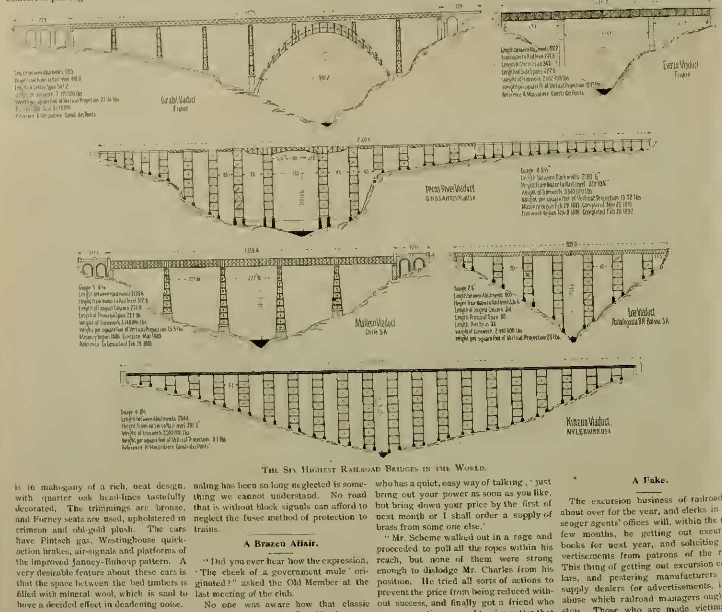
"The answer so much amused railroad men, that 'the cheek of a government mule' has become a proverb."

### The Highest Railway Bridge.

The expression, "highest in the world," has to be modified every now and then—some other "highest" has gone up a few feet.

Kinzua Viaduct, on the Erie, long had the reputation of being the highest railroad bridge in the world, but, as can be seen by the drawings of other bridges on this page, there are several bridges higher—just at present the Garabit Viaduct, in France, is holding the medal.

We are under obligations to General Manager J. Kruttschnitt, of the Southern Pacific, for the drawing here reproduced. All the details for each bridge is given on the engraving, so that a detailed description in type is unnecessary.



THE SIX HIGHEST RAILROAD BRIDGES IN THE WORLD.

### A Fake.

The excursion business of railroads is about over for the year, and clerks in passenger agents' offices will, within the next few months, be getting out excursion books for next year, and soliciting advertisements from patrons of the road. This thing of getting out excursion circulars, and pestering manufacturers and supply dealers for advertisements, is an abuse which railroad managers ought to stop. Those who are made victims of this business invariably say that they have been subjects of blackmail. We are certain that very few railroad managers would countenance the practice of soliciting advertisements for folders and other pamphlets, if they only were aware of the abuses connected with the practice.

The actual number of LOCOMOTIVE ENGINEERING printed during the year ending September 30th was 243,624—an average circulation of 20,302 for each month. We keep no back numbers. We will give a prize of a yellow poodle pup to any one who will name any other railroad paper that can prove they issued one quarter that number during the same time. Come early and avoid the rush.

### Rogers Compound for Jamaica.

The Rogers Locomotive Co. have recently sent to Jamaica a heavy ten-wheeled compound, a picture of which is shown herewith.

They have some heavy grades there, and coal is expensive.

This engine has cylinders 20 inches and 30 inches in diameter by 26-inch stroke, driving wheels, 50 inches in diameter, with 12 feet 3 inch rigid wheel base and 22 feet 9 inches total wheel base. She is standard gauge and weighs in working order 137,500 pounds, 97,000 of it being on the drivers.

Rogers Compound Freight Engine for Jamaica.

The starting gear of the Rogers compound is quite simple, the intercepting and reducing-valve being controlled by a connection to the reverse lever, as shown just ahead of the air-pump. When the reverse lever is in the extreme forward or backward notch of the quadrant the curved slot of the bell-crank is brought into a position to hold the reducing-valve open and work the engine simple; when the lever is taken out of the corner the engine commences to work compound.

### Compound for Cleaning Paint.

The tanks on the South Carolina road all look as if they had been recently polished, and we knew there must be a reason for it—there is.

First Elevated in New York, 1873.

The superintendent of motive power, E. M. Roberts, has a complexion preserver for tanks and other paint work that does the business. He makes up face wash for paint as follows: Four gallons of water, one pound of borax, one quart of lard oil; and the directions read as follows.

"First, wipe off all dust with dry waste, then use compound, rubbing over paint for a space of about three or four feet, and then wiping off clean. It is not advisable to let it dry, and if a greater space than this is covered at one time it is likely to be difficult to wipe off properly. This cleans paint work beautifully, and preserves the luster of the varnish for a very long time."

They only use the compound on tenders, but we can't see why it is not good for any painted and varnished surface.

### Boston & Albany Shops.

The general air of neatness and order which prevails in and around the shops of the Boston & Albany road makes and leaves a most pleasing impression upon the visitor, and is just as sure to result in economies to the railway company. The Springfield machine shops were not entitled to this word of praise up to a very recent date, but under the charge of the new master mechanic, Mr. C. H. Barnes, order and neatness already prevails, and many changes are taking place which bespeak efficient management. At East Albany, under Mr. Purvis, a visit alone can convey a correct idea of his able management—even the scrap heap is made a feature of order and attractiveness.

What is said in praise of the locomotive department holds with equal force in regard to the car shops. Mr. Adams' department has long been a model for order and efficiency throughout the country, his equipment both in freight and passenger departments standing at the head of the list. The attractive and modern features of his passenger cars has had much to do with the building up of the strictly first-class suburban traffic held by this road, and we believe has drawn this trade from other lines to no inconsiderable degree.

### An Old-Time Royal Carriage.

A period of fifty years represents in the history of railways a rate of progress and development almost incredible to those who only look at what lies in plain sight, and take for granted the things of to-day, without a thought of the experiments and failures which have led up to them.

The old-fashioned rolling stock and railway relics in general which are to be seen at the Chicago World's Fair must emphasize the above statement very strongly to the crowd of sight-seers, and ought, it would be supposed, make modern travelers appreciate somewhat more highly than they appear to do the advantages of sleeping and dining cars, such as are now available to almost any one.

As an additional pendant and contrast to the ordinary Wagner or Pullman cars that run on all the main lines to-day, we illustrate an old-time "Royal Saloon," which would now be deemed by a third-rate drummer as quite unfit even to carry his samples, let alone his own valuable person.

This "Saloon" was built fifty years ago, in 1842-3, for the old London & Birmingham line, which used it principally, if not entirely, for Queen Adelaide, the relict of King William IV. It was, therefore, known as the "Queen Dowager's Carriage," and has been preserved as a curiosity in the railway company's works at Wolverton ever since finally passing out of service. The London & Northwestern Railway, into which the London & Birmingham was merged, now own a very different "Royal" train of cars for Queen Victoria's use.

The under frame of this relic was constructed in the company's carriage works, then situated at Euston, and the body at a coachmaker's shop in Birmingham, under the superintendence of the late Mr. Joseph Wright. Originally this saloon had three compartments, with the rear one so arranged that when used for sleeping the feet of the occupants extended under the arrangement projecting outward like the "boot" of an old-fashioned coach.

The body of this carriage was only 5 ft. 1½ in. wide inside, 6 ft. high from sills to apex of roof outside, and 11 ft. from rail to top of lamp. The body was 16 ft. 6 in. long over all, and the total length over bumpers 21 ft. 9 in. The wheel base was 10 ft.

A Queen's Coach, 1842.

### An Old Experiment with Balanced Valves.

In the development of railway machinery a great many inventions which promised to effect radical improvements have been tried, and rejected as impracticable. After they were thrown aside for years others took them up and by a few minor changes succeeded in making them a success. The balanced valve for locomotives is one of the best instances of this kind. Balanced valves have been tried more or less ever since locomotives were brought into use, but it is only within the last ten or twelve years that they have been made a decided success. With the high-pressure and large slide valves now employed a locomotive works under severe disadvantages when the valve is not balanced. The well-known engineer and inventor, Mr. Jerome Wheelock, of Worcester, Mass., read a paper twenty years ago at the Master Mechanics' Convention on balanced valves, which makes interesting reading to-day. The following are extracts from the paper:

"Experiments with so-called 'balanced valves' have been legion, and the results, if we may believe the statement of those interested, have been truly wonderful. I have listened to statements where one of these inventions has effected a saving of 33 per cent., besides a great saving in wear and tear of the valve-gear; but up to this time I do not believe it possible to show by actual test any case where, after having given the ordinary slide its proper proportions and adjustment, a fair comparative trial has resulted in any saving of fuel or material in favor of the balanced valves. On the contrary I am fully persuaded that the opposite is the result. I know I am on ticklish ground, and some of my associates will question these views, but I have had the disease. I have been through with a series of experiments to demonstrate the value of balanced valves for locomotives, and I assure you the dose has entirely cured me.

"My early acquaintance with the locomotive led me into the common error that a very great amount of power of the engine was being absorbed to move the valves; in fact, it appeared to be self-evident. As figures would not lie, it was easy enough to make out a case. Taking the area of the surface of the valve, multiplied by the steam pressure per square inch, made the sum total of the load to be moved perfectly enormous. To stand by and see the valve-gear shake as an engine was leaving a station was, it appeared, sufficient to satisfy anyone.

"I was made aware that the subject was not new, as upon my becoming an inventor in this direction, my attention was called to between thirty and forty different devices gotten up to relieve the pressure on the valves. Many had been tried and some had not; and I will here say that some of these devices are marvels of genius; complicated though they may be, they yet have occupied some of the best brain power of this nation."

A description of the valve was then given. It consisted of a cylindrical casing with a conical plug, through which the steam was admitted. Several railroads in New England were willing to give the valve a trial, and it was applied to an engine. Experience with the engine and views of balanced valves generally are then given as follows:

"The engine came out, and as she moved up and down the yard everything seemed to work as it should, and she was attached to a freight train and the trial began. Using steam quite freely for the work performed, it was suggested that the engine was just out of the shop and was stiff. It was evident that the valves did not go hard, as the reverse lever could be handled with perfect ease. If the latch was raised out of the notches, the lever would stand at any point without holding —a result I considered very satisfactory. Arriving at the first descending grade steam was shut off as usual, when it was expected speed would increase by the inertia of the train. This, to my surprise, was not the case. The engine was indeed 'stiff.' Steam rapidly accumulating, the furnace door was opened, when a very strong exhaust was discovered, drawing hard on the fire, and the firebox was soon emptied of the fuel, the engine blowing off violently. I will here remark that my valves were allowed an end play, or movement of about one-half inch, working away from their seats when steam was shut off. This I had expected would be sufficient to relieve the engine when running down grade. I was greatly surprised at the result, as were my companions. Where all this exhaust came from was a mystery; but as it had made the engine steam well I tried to persuade myself and others that it would result to an advantage.

"This round trip having been made, and several promiscuous trials on different trains gone through with, the engine was at length put upon her accustomed passenger train. Here the comparative trial began, and after about a year's use the trial ended.

"The engine 'blowed,' and the valves must come out to be looked at. When taken out they had the polish of a mirror. Anti-compression and relief-valves were put in, and changed this way and that way. One day one thing and the next day something else would suggest itself as being necessary to make the engine better. I will here remark that I was in the hands of friends. Never were men more anxious for success than were the officers of that road that these valves should succeed. Every facility was furnished and every assistance rendered that could be. The engine was taken off her train while I applied a second pair of valves with some of the details changed. And thus I worked, and tugged, and studied, until I nearly wore myself out during that year all to no purpose, trying to make that engine do as well as she had done with her old valves.

"I am fully persuaded that the trial was as exhaustive as has ever been made in this direction, and I verily believe the results were as favorable to balanced valves as any that were ever tried; but still the verdict must be that the engine did not do as well as with her old style of valve.

"There are several reasons why balanced valves are not practical for the locomotive. High-pressure steam is a terrible searcher, and will find the minutest outlet. It affects metals variously at various pressures. Expansion and contraction of metals are among the evils to contend with. Thus, while a pair of valves might be practically tight at 60 pounds, they would be found to leak badly at 120 pounds pressure. The walls and cover of the steam-chest subjected to great strain are warped, more or less, and do not remain absolutely as when fitted. Then comes the wear. But, perhaps, it will be argued there is no wear with the valves balanced. Ah! gentlemen, this is preposterous, as you could not wipe a woolen cloth over the surfaces the number of times the valve is moved without perceptible wear. But enough of this."

## Two Swiss Locomotives.

The two fine engravings shown herewith were made from photographs secured by a lady on a recent trip through the Alps, as was also the mountain climber, shown on another page.

We have been unable to gather much data about them, in fact none so far as sizes go.

The six-wheeled engine is one of a class in use for the past five or six years for mixed traffic—a practice of running trains that exists to the great discomfort of the passengers.

V. S. B. means "Vereinigte Schweizerbahnen" (United Swiss Railroads). This road has many curves and heavy grades, especially on the line from Winterthur to St. Gallen, and from there down to the lake of Constance.

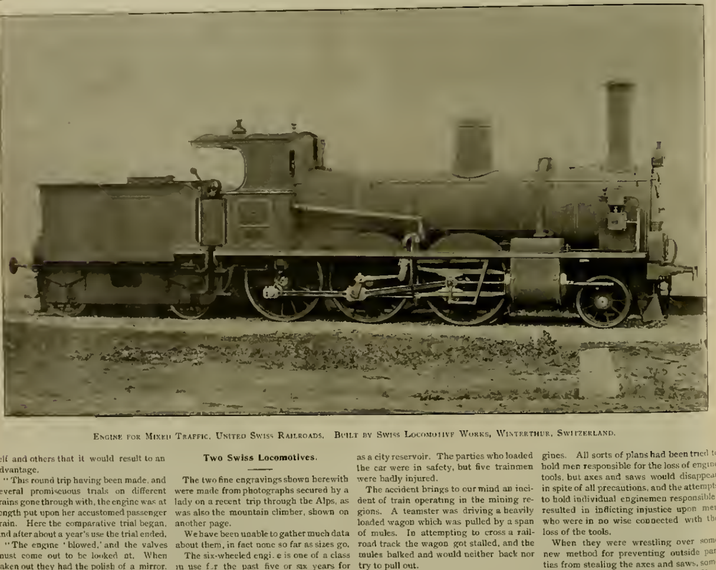
The drivers are about four feet six, but the size of the cylinders we do not know. Like most engines built in Switzerland, they have the Walschaert valve motion and outside steam pipes.

The curved lever on the tank is the tender brake-lever.

The four-wheeled coupled engine belongs to the "Schweizerische Nord-Ost-Bahn" (Swiss Northeastern R. R.), one of the most important lines in the little republic, and is used also for mixed traffic.

These lines have until recently used a continuous system of steam-brakes, but have discarded them for the Westinghouse air-brake.

Both engines were built by Swiss Locomotive Works, at Winterthur.



Engine for Mixed Traffic, United Swiss Railroads. Built by Swiss Locomotive Works, Winterthur, Switzerland.

## Carelessness with Dangerous Loads.

There was a bad wreck out in Ohio the other day that shows how reckless some men grow when they are accustomed to handling dangerous material. A car was loaded with 234 kegs of powder, and an old car was used with doors so loose that sparks could pass through them as readily as through a smoke-stack netting. To make the thing worse there was straw and shavings left littering the bottom of the cars. What might have been expected happened. A spark started a fire in the car. It soon reached the contents of one of the kegs and the whole load went off in a blast that made a hole in the track as big as a city reservoir. The parties who loaded the car were in safety, but five trainmen were badly injured.

The accident brings to our mind an incident of train operating in the mining regions. A teamster was driving a heavily loaded wagon which was pulled by a span of mules. In attempting to cross a railroad track the wagon got stalled, and the mules balked and would neither back nor try to pull out.

Presently a heavy train made its appearance rounding a curve near the crossing. The driver of the wagon jumped off, and began running through the meadow like a scared deer. The engineer of the train opened his whistle when he saw the wagon, and the mules made a plunge and pulled the load clear just as the pilot was about to throw it in the air. The train stopped, and the crew began guying the teamster for running away.

"What was the matter?" asked the engineer, "did you think we would chase you through the prairie?"

"No," drawled the teamster, "leastwise I did not think you would come after me in a body. I was afraid of your parts."

"What do you mean by being afraid of our parts?"

"Well, that a're wagon is loaded with dynamite, and I did not want any of you fellows' legs or heads to be fired my way."

## Removing Tools off Locomotives.

At the first impression, the proposal to take the axe, saw and screw-jacks away from the locomotives, seems to be absurd, yet the question was discussed at a recent meeting of the New York Railroad Club, when a large attendance of master mechanics was present and the prevailing opinion favored the proposal. Few of those present had previously given the subject a thought, but when they listened to the arguments in favor of the plan, most of them were convinced that the change was a good one. The question came up, owing to a change which has lately been carried out on the Pennsylvania and Erie railroads. The mechanical officers of these companies found that the maintaining of axes, saws and jacks on locomotives that were not assigned to regular crews, was a source of expense that was not in keeping with the benefits derived from having these tools on the engines. All sorts of plans had been tried to hold men responsible for the loss of engine tools, but axes and saws would disappear in spite of all precautions, and the attempts to hold individual enginemen responsible, resulted in inflicting injustice upon men who were in no wise connected with the loss of the tools.

When they were wrestling over some new method for preventing outside parties from stealing the axes and saws, some one raised the practical inquiry: How much use or service is an axe or saw on a locomotive? This led to investigation, and it was found that there is really no use for an axe except in case of a wreck, and that a saw is used only to saw blocking for the cross-head, in case of break downs. The man who waits until breakage occurs before he gets the cross-head blocking ready, is not taking time by the forelock. If he depends on any piece of wood that can be picked up after an accident happens, he is likely to use blocking that will not be strong enough to hold the piston. Hundreds of cylinder-heads have been knocked out and more serious damage done by employing inferior blocking for cross-head. It seems sound business policy to require an engineer to provide himself with good blocking before an accident happens. All careful engineers do this without compulsion, and careless ones ought to have the screws applied, for compulsion that promotes safety is a kindness.

When all these things were considered, there appeared to be a good case made out for taking the axe and saw off the engine. The engine crew is, however, not deprived of the use of the articles referred to, for they are carried in every way car and are at the service of the engineman when required.

Screw-jacks are not things that get stolen frequently, but it was found that the jacks on the engines were so hard to keep in working order that they were also removed to the way car, where they could be kept locked up in a clean, dry locker. There was some disposition to censure enginemen because the jacks to be found in tender boxes are generally rusted and out of order. We do not think the enginemen are to blame for this. Tool-boxes for locomotives are seldom made watertight. Iron or steel articles cannot be kept clean and in working order without constant attention when they are exposed to soaking every time it rains and every time water is spilt in filling the tank. When men are not regularly assigned to an engine it is not fair to expect that they will devote much attention to keeping up the condition of tools they may never be called upon to use.

The introduction of the standard signal code into New England has begun, and will, no doubt, now make rapid progress. Most of the New England roads, being members of the Railway Association, should have taken the lead in the adoption of the standard code, instead of being the last to adopt it. The Fitchburg and the New York, New Haven & Hartford are now using it, and others are likely to follow suit soon. The Old Colony system, being now under the New Haven management, will likely be the first to fall in line. Under the vigorous and enlightened management of the new president, Mr. Tuttle, the Boston & Maine is likely to abandon many of its ancient ways, and no doubt the adoption of the standard signal code will come soon.

Only one passenger for every 1,491,910 carried were killed on our roads last year.

ENGINE FOR MIXED TRAFFIC, SWISS NORTHEASTERN R. R. BUILT BY SWISS LOCOMOTIVE WORKS, WINTERTHUR

## Heating Surface of Firebox and of Tubes.

By Angus Sinclair.

EVAPORATIVE EFFICIENCY OF FIREBOX AND DIFFERENT PARTS OF BOILER.

It has been proved beyond doubt that the walls and crown sheet of a firebox and the sheets of a furnace form the most valuable portion of the heating surface. These parts are exposed to the direct radiation of the fire, and are impinged on by the hot flames, so that a great portion of the heat generated by combustion is absorbed before the gases pass into the tubes. The annexed illustration gives a graphic illustration of the comparative evaporation of the different parts of a locomotive boiler as found by experiments made in England. It will be seen that the evaporation in the firebox is about equal to that of all the tube surface, and is ten times as great as that of the last section of the tubes. The first section of the tubes evaporates about four times the water turned into steam by the last section.

VERY LARGE FIREBOXES MAY WASTE FUEL.

These are interesting facts, and they are well known to nearly all locomotive designers, but there is good reason to believe that the admiration for the evaporating qualities of the firebox has frequently led to the building of locomotives that had excessively large fireboxes, and were deficient in tube surface. This has always turned out badly. When extremely large fireboxes are used, a large proportion of the water is evaporated by them, but the tendency is to keep the firebox temperature so low that part of the gases fall below the igniting temperature and cause waste of fuel. The size of grate necessary to burn the fuel required to evaporate the quantity of water used, ought to regulate the size of the firebox. Years ago, D. K. Clark, the famous engineer, made the statement that the grate area of a locomotive cannot be made too small, provided the rate of combustion does not exceed the limits imposed by physical conditions. This means that if the grate area is large enough to admit the required air to burn the coal with fair economy, the smaller it is the better. Locomotive designers have frequently ignored Clark's dictum, but no experiments have been made which proved his views to be wrong. Many locomotives are worked so hard at times that more fuel is consumed than can be burned economically, but they are run at other times so light that the grates are too large for the fuel consumed and waste of coal results.

RATIO OF GRATE TO FUEL CONSUMPTION.

With the fixed draft appliances used by a locomotive there is some ratio of fuel consumption to grate area which is the most economical. It may be the burning of 50 pounds or of 100 pounds to the square foot of grate area, or it may be more or less. The closer the average working of the engine can be made to conform to the most economical ratio, the better will be the results obtained. We are constantly seeing efforts made to have the grates large enough to produce a high ratio of economy, when the engine is working at its maximum steam-using capacity. As the engine may work in this way only a small proportion of the time, the grate area is too liberal in its supply of air for lighter working, and lighter working may be the service done by the engine the greater part of the time.

It is difficult to determine with accuracy the most economical ratio of grate area to rate of fuel consumption for a locomotive, and stationary boiler practice, where tests can be conclusively made, has guided designers to a great extent in establishing locomotive proportions. In stationary-engine tests it has been found that the loss of fuel is very great when the rate of combustion is raised from 10 to 100 pounds per square foot per hour. An ordinary locomotive, on the contrary, will use fuel more economically when burning 100 pounds of coal per square foot of grate, than it will do when the consumption is reduced to 10 pounds of combustible per hour to the square foot of grate. It has also been proved that the waste of fuel will be ten times as great when 100 pounds per square foot of grate is burned in the furnace of a cylindrical tubular boiler, as it will be when the same quantity is burned on the grates of a good locomotive. The abstract reasoning, then, that the grate area of a locomotive must be sufficiently liberal to approach stationary boiler practice, is based on an erroneous foundation.

RATE OF FIREBOX COMBUSTION.

Coal can be burned in the firebox of a locomotive with economy at the rate of 100 pounds to the square foot. As much as 200 pounds per square foot is sometimes burned without excessive waste, and 150 pounds per square foot of grate per hour is a common rate of fuel consumption. If a locomotive is designed with grate surface suitable for burning 150 pounds of coal per hour when the engine is working at nearly the maximum rate of steam consumption, the engine is likely to be well adapted for pushing to a higher rate of work or for being dropped to light steaming. It may be forced to 200 pounds consumption or dropped below 100 with fair economy. The important point is to calculate on proportions to suit a high average working.

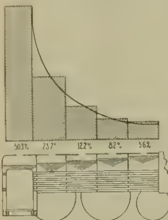
RATIO OF GRATE TO STEAM CONSUMPTION.

Let us take the case of some well-known locomotives pulling fast trains. The cylinders are $19 \times 24$ inches and the driving wheels are 78 inches diameter. One of these cylinders has a cubical content of 3.93 feet. The greatest drain of steam from the boiler per unit of time is when the engine is running at its highest velocity. Suppose the engine is running at 70 miles an hour and cutting-off at 6 inches or quarter stroke. As this portion of the stroke has to be filled with steam twice at each revolution there will be 3.93 cubic feet of steam taken at each turn of the driving wheels to supply the two cylinders. This does not take the clearance spaces into consideration, but they can safely be ignored since the compression brings the pressure up close to the admission line.

A wheel 78 inches diameter turns 258.73 times per mile. At 70 miles an hour we have $258.73 \times 70 = 18,111$ revolutions per hour. This number of revolutions multiplied by 3.95, the quantity of steam used per stroke, gives 71,177 cubic feet of steam to be supplied per hour. The steam is about 175 pounds boiler pressure or 190 absolute. At this pressure, the relative weight of steam to water is 149 to 1. We then have the problem $71,177 \div 149 = 447.65$ cubic feet of water to be evaporated per hour. A cubic foot of ordinary feed water weighs about 63 pounds, so we have $447.65 \times 63 = 28.202$ pounds of water to be evaporated per hour. It is found that a pound of good coal evaporates in these engines about 7 pounds of water even when the rate of combustion is about 150 pounds per square foot. Then $28202 \div 7 = 4029$ pounds the quantity of coal that must be burned per hour at the rate of steam consumption discussed. When this is divided by 150 it gives nearly 27, which is the square feet of grate required. As a matter of fact, the engines have 27.3 square feet of grate.

CIRCUMSTANCES INFLUENCE GRATE AREA.

When locomotives are intended for slower service the grates can safely be made smaller, but designers ought to cal-



culate the weight of coal that must be burned per square foot of grate when the engine is working under the condition when most of the work will be done. A large grate area is necessary for slow burning fuel, such as anthracite.

The grate area is not settled by any well established rule. The designer is to a great extent guided by circumstances. When the firebox is placed above the frames and there are no physical restrictions to ample grate surface it is generally made large, sometimes too large. By examination of a great many modern locomotives, we find that the total cylinder content in cubic feet multiplied by 3½ agrees fairly well for engines burning good soft coal In some cases, where the firebox is between the frames, the grate area does not exceed 2½ times the cylinder content in feet. With anthracite coal burning engines, on the other hand, the grate area is sometimes more than five times the total piston displacement in cubic feet. When the poorer grades of soft coal and lignite are burned in locomotive fireboxes, the grate area has to be increased to nearly the same proportions as those employed for anthracite.

TUBE SURFACE SUPERIOR TO COMBUSTION CHAMBER SURFACE.

The efficiency of the firebox surface for evaporating water has led many designers to increase the space open to direct radiation of the heat by adding combustion-chambers to fireboxes using bituminous coal. In a great many instances we have seen the combustion-chamber abandoned and the space filled with tubes, and in every case the steaming of the engine was improved. The combustion-chamber appears to act well with Wootten fireboxes, and it might be of some service with very shallow fireboxes of any kind, but with deep fireboxes the space is better utilized by tubes.

EFFICIENCY OF TUBE SURFACE.

The deliberate planning to make the tubes secondary to the firebox as a water evaporating medium is not good engineering. The multitude of tubes are what first made the locomotive boiler a success, and every attempt to make the tubes secondary to the firebox detracts from the efficiency of the boiler. If there is not sufficient tube opening for the gases of combustion to pass through freely, it exerts the same detriment to the efficiency of the furnace as a restricted smokestack does to a natural draft boiler. Although the last section of the tubes toward the smokebox may evaporate little more than 5 per cent. of the total water turned into steam, that 5 per cent. exerts its own influence on the consumption of fuel, and the heat is saved from passing into the atmosphere. A very long tube is not economical in a locomotive boiler because there is difficulty in keeping it from leaking, but within practical limits long tubes and economical combustion of fuel go together. The most successful locomotives in America have about 200 square feet of flue area to each foot of cubical content of both cylinders. If inferior or refractory coal is used a greater ratio of heating surface is necessary.

LONG AND SHORT TUBES.

There were some interesting tests made on a French railway that demonstrated the exact value of long and short boiler tubes. With an equal amount of total work performed, it was found that the quantity of water vaporized per pound of coal was always decreased when the length of the tubes decreased, but that the diminution inefficiency was small when the length was decreased from 23 ft. to 19½ ft., and even to 16½ ft. the decrease in economy was very slight. From 16½ ft. to 14¾ ft. the reduction in economy is much greater, and from 14¾ ft. to 13 ft. it is considerable. After this point is reached, a further reduction below 13 ft. in length reduces the economy regularly, that is, almost in proportion to the deduction of total heating surface.

It was further found that if it was desirable to consider, instead of the amount of water vaporized per pound of coal, the total amount vaporized in a boiler in a given time, the change in tube lengths produced a different result. When the length of tube was decreased below 23 ft., the total quantity vaporized in a given time was considerably increased, and kept increasing until it was at a maximum between 14¾ feet and 13 feet; but after that a further reduction decreased the amount evaporated. When the tubes experimented with were about 9.8 ft. in length, the total evaporation in a given time was reduced to be equal to that when they were 16½ ft. in length.

The result of these experiments was that tubes about 14 ft. long were adopted as standard. This is too long for American engines, because iron tubes of that length are too heavy, and vibrate themselves loose in the flue-sheets, but saving of heat calls for the tubes to be as long as they can be used without leakage.

## Lining Up and Marking Off Wedges.

BY W. L. BOYLE.

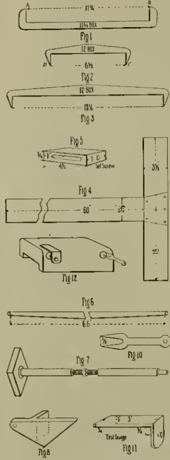
In keeping up rolling stock, one of the things to be avoided is the measuring by planer hands and other mechanics, and all the errors and "slight differences" due to this measuring.

I ignore the cylinders and the center casting in my measurements, and try to get my axles square in the frames.

To this end, I fit up several little inexpensive gauges, that save time on the planer, insure uniformity in all repair work on driving-boxes, wedges and shoes, and leave behind something to test the work by. These gauges, tools, templates, jigs, or whatever you choose to call them, cost little more than the lining up of one or two engines in the old way, and insure correct and uniform work with less labor and less skill.

In the first place, I make a set of gauges like Fig. 1 for each sized box in use, say, one for a 12-inch box, the next 11⅞ inches, another 11¾ inches, making one for each size less by an eighth of an inch for as long as the web of the box will stand planing off, using a smaller gauge as the box is cut away. Now, when you are re-brassing or refitting your driving-boxes, have the planer hand use one of these gauges, instead of "just skimming them up," regardless of the size they finish to. This will save you considerable trouble and delay.

Make some small trams, like Fig. 2, one for each size of box. Have the distance, $C D$, between the points just one-half the distance of $A B$, Fig. 1, plus ⅝ in. in each case. The reason for adding this ⅝ in. is explained further on.



Now, make another set of trams, Fig. 3, just like Fig. 2, except that they are just twice as long. I am putting the sizes I use on the sketches. These trams will be 1¼ in. (twice ⅝ in.) longer than the size of the box. All the above gauges and trams can be made of old spring leaves.

Make a long tram for spread of wheels, one for each class of engine, or difference in centers. This tram, Fig. 6, should have its points bent sideways, instead of down; this prevents sagging when handled.

Make four (for eight-wheeler) studs like Fig. 7 to screw between wedge and shoe, keeping them in position. Then make four angle brackets like Fig. 8. These are slipped on to the round part of stud, Fig. 7, and when the inside flange is against the side of the shoe the top is level and is used to support a long straight-edge.

A long straight-edge and a T-square, Fig. 4, is all you require now to line up wedges on any engine.

The T-square requires four sliding jaws such as shown in Fig. 5, with a set-screw to hold them in place.

Suppose you were going to line up the wedges on an eight-wheeled engine, with drivers spread 8 feet 6 inches, and having driving-boxes 12 inches wide between wedge surfaces, you would put up your pedestol braces, shoes and wedges, placing a ¼-inch block between the live wedge and pedestal brace. Put your studs, Fig. 7, between the shoe and wedge, with the brackets Fig. 8, on them; get the flange of this bracket flat up against the side of wedge and tighten up the right and left hand-screw. Lay your straight-edge on these brackets and see that it is up firmly against all shoes and wedges 1, 2, 3, 4, then lay your T-square or straight-edge with blade across frame, and between the shoe and wedge.

Take the short tram, marked "12-inch box" and with one point in $A$ mark point $B$, then with a 2-foot square draw line down dead wedge or shoe to $D$.

Point $A$ is almost invariably marked on the frame by the builders, and is, or should be, the center point between the face of the front and back jaws.

Now move your T-square up against shoes on both sides of engine, and adjust the four sliding jaws on the inside and outside of each shoe, and set-up screws now move square so that outside sliding-jaw comes to line on shoe, then scribe a line on the inside of the shoe, and also on the inside and outside of the shoe on opposite side.

Then with the 12-inch tram from a point at $C$, mark $D$ on the shoe and $E$ on the wedge, and with the same tram from $I$ mark $F$, and see that the tram fits from $D$ to $F$.

Now take your long tram, 8 ft. 6 in., and from the points $C$ $D$ $E$ and $F$ lay out the points $G$ $H$ $I$ and $J$ on the other box. Do the same on the other side of the engine Now your wedges are ready for the machine shop.

Furnish your planer hand with a small, solid gauge, Fig. 10, made of ¼-in. round steel, with the points ⅝-in. apart.

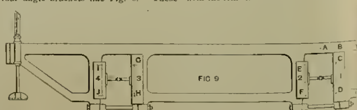
The planer hand uses this gauge to scribe a circle from each of the four points already marked on the shoes and wedges and the *edge* of this circle is the point to plane to.

Supply your gang foreman with a test gauge like Fig. 11, with a point just ⅝ in from inside of flat surface, and by laying this on the planed face of shoe or wedge it can be seen in an instant if the work has been done correctly.

Now the reason for lengthening all trams except wheel center tram, ⅝ of an inch is seen; it is to locate this measuring point far enough back on the flange of wedge that it will not be removed in rounding the corners and is where the work can always be tested.

When I find the boxes out of parallel with the frame I divide the difference.

By this plan of lining up wedges and boxes you keep your driving boxes the same size all the time; you line by the frame, and any unevenness of wear is taken off the face of shoes and wedges, keeping the box true in the jaws and the axle square with the frame.



The word "gas," which is now so familiar to people in every walk of life, was invented by Von Helmont, a Belgian chemist, about 1644, and applied to all volatile essences. It is supposed to have been taken from the German word "geist," ghost or spirit.

---

There were 2,554 railroad men killed in the United States, last year, and 28,267 crippled. Don't men taking these chances deserve better pay than men in less hazardous trades? And do they get it?

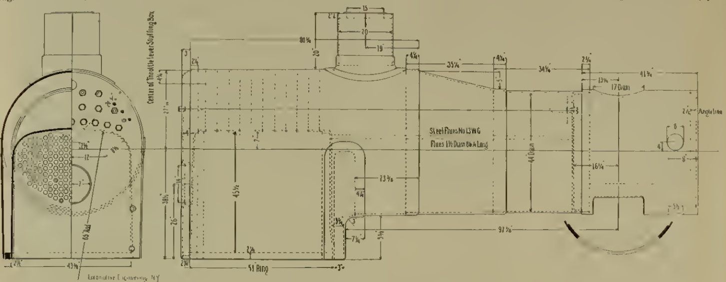
### Hedley's Locomotive Boiler.

The outline drawing reproduced on this page shows some innovations in locomotive boiler construction that seem to be in the line of improvement.

This boiler was designed by Mr. Edward Hedley, master mechanic of the Brooklyn Elevated road.

Mr. Hedley desired to use a wagon top boiler, radial stays, and to get the dome back close to the firebox.

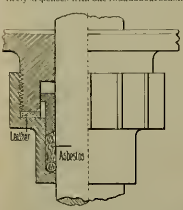
To accomplish this he had the back course of the shell sheets made 80¾ inches long, cut slots the length of the outside of



Hedley's Boiler, Brooklyn Elevated Railroad.

firebox, on each side, and then rolled up the sheet, the flat sides of the furnace were then straightened out, and the front end riveted up to form back part of boiler shell. This got rid of the riveted joint close up to firebox and gave room to put the dome on the back course and close to the firebox.

The throat-sheet was then formed and put up on the outside of the shell and water-leg. This makes a very neat job, is easier than the old form to repair, and entirely dispenses with one roundabout seam.



### A New Piston-Rod Packing for Driver-Brakes.

Men in charge of air-brake repairs have had more trouble than a little with piston-rod packing on pull-up driver-brakes. The leaking of packing at this point has caused accidents, prevented effective braking and introduced the push-down brake.

Packing becomes dry and hard under the pressure and heat, and the constant movement of the rod wears it out until it is useless for the purpose for which it is intended.

On the Vandalia road they have some seventy-five engines equipped with a packing designed by one of their foremen, Mr. Kelley, at the Terre Haute shop.

Mr. Kelley uses a loose gland inside the box, the top end of which is enlarged, and the outer gland, or box, screws up on to a shoulder, making an air-tight joint on a leather seat.

In this outer gland there are a couple of rings of fibrous packing, usually asbestos, but there is no pressure on this packing except when there is air in the cylinder; then the pressure on the enlarged end of the loose gland forces it down, setting out the loose packing and making a tight job; when the pressure is relieved the packing is loose, has no chance to harden or wear by movement of the rod.

The "Van" have had some of these packings in use now for over a year without being repacked and they are tight. They estimate the cost of the old style cup-leather packing for renewal was ten dollars per engine per year.

We would advise a test of this packing before the pull-up brake is condemned entirely, a little thing makes all the difference in the world sometimes.

### The Otis Elevating Railway, Catskill Mountains, N. Y.

The Otis elevating road is one of the latest things in use to take passengers to the hotel on top of a mountain.

It is a single track cable road, running cars up and down at the same time. This is accomplished by use of an automatic turnout half way up the mountain.

One of our pictures shows the entire road excepting a very short distance on the lower level. The road is 7,240 feet long, raising 1,800 feet in that distance. The Catskill Mountain House, shown to the left at top of this picture, is 2,250 feet above sea level.

Another view shows one of the passenger and freight and baggage cars approaching the summit. These cars are propelled by a double line of steel wire cable which passes around a drum in the power-house and reaches from one car to the other, one

car always being at the top when the other is at the foot of the mountain.

The power is supplied by two horizontal Corliss engines with reversible link motion. Each car is equipped with an arrangement attached to the bottom of the body, which, in case the cable breaks, is released and acts as a brake and stops the car by clutching the wooden guard rail shown in the roadway. In approaching the terminal points, should the engineer fail to stop the cars in the usual way, there is provided in the roadway between the rails a tongue or lever which is tripped by the car approaching the summit; this shuts the steam off from the engines and applies a Westinghouse automatic air-brake, located in the engine-room, and having the brake-shoes on the drum around which the cable turns, thus automatically stopping the cars at their proper places.

The track is composed of three rails except at the "turnout" or passing point, where there is a double track.

The "turnout" is formed by curving the right hand and middle rails to the right, and the left hand and an extra rail to the left. By this method the rails always remain in the same position and no switching apparatus is required. The total

length of the "turnout" is 400 feet, and it is, of course, situated at a point half way between the terminal points of the road.

Many accidents have been caused by the long push-bar used to span the pilot of a locomotive breaking when engines were pushing, and many leading railroads are projecting a bull-nose through the pilot far enough to couple with a car draw-bar. The Pennsylvania Railroad have followed this practice for a long time, and consider it much safer than the long push-bar. But it has one serious defect. If any animal is struck by the pilot with a bull-nose on it, the animal is likely to be pushed into the middle of the track, where it is in danger of throwing the train off the rails. This defect has been very neatly overcome by Mr. Pulaski Leeds, of the Louisville & Nashville, who hinges the bull-nose so that it can be turned up when the coupler is not in use. This invention is attracting much attention among railroad men at present, and is likely to be largely adopted. The Cincinnati Southern people are trying it, and intend putting a lip upon the under part of the bull-nose, which will act as a guard to catch a car or anything that is accidentally pushed up on the pilot.

At the Cincinnati, New Orleans & Texas shops, at Ludlow, Ky., they are changing a simple locomotive into a tandem compound. The engine will have many peculiar features, especially in the valve gear. A sort of double link is employed, with the curve reverse to the common type. In place of the slide-valve a gridiron-valve is used, giving very large port opening and having unusually short travel. We are afraid that the engine will suffer from the defect that interfered with a former well-known locomotive that had gridiron-valves. When the latter was under construction a locomotive engineer of large experience predicted to the designer that the valves would break every time the engine was reversed while in motion. "But they must not reverse the engine while in motion" exclaimed the patentee, and he gave orders that care should be taken to see that the engine was stopped before the reverse lever was pulled over. It is needless to say that the injunction was not very strictly obeyed, and that broken valves was a common breakdown.

The Lake Shore & Michigan Southern people have contracted for about one hundred furniture cars to be delivered next summer. It is the practice of this company to contract for the building of cars long enough in advance to have the lumber piled for six months before work on the cars begins. They consider from past

experience that the practice pays, for there is very little shrinkage to the wood after the cars go into service. We lately examined some cars belonging to this company that had been in use for nearly three years, and no appearance of shrinkage was to be found in the parts that generally give most annoyance from this cause

## Utility and Beauty of the American Locomotives at the Fair.

A conspicuous feature about the American locomotives exhibited at the World's Fair was the severe plainness of mechanism and the entire absence of attempts to form attractions by means of useless ornamentation. Plain iron and steel well-fitted and finished up in a workmanshiplike manner were the lines on which exhibitors endeavored to claim commendation. In this respect the American exhibits were in strong contrast to many of those that came from foreign countries. In these useless ornaments and elaborate finish of parts that were none the better of being polished indicated extra cost not justified by utility. In another respect the foreign locomotives did not compare favorably with those produced in our workshops. There was frequently displayed a tendency to use indirect methods of complex mechanism to perform a desired operation. American locomotive machinery, on the contrary, was noted for directness and simplicity. This was particularly noticeable in valve-motion mechanism. It is almost a principle with American locomotive designers to have as few joints or pins as possible between the actuating point of the motion and the valve, the foreign designers act as if increase of wearing parts were no detriment to a machine.

In another respect the foreign locomotives were far behind those of American manufacture. This was in the arranging of the appliances for operating the engine so that they are convenient to the engineman. This has originated to a great extent from the development of the American locomotive having been worked out or controlled by men who have themselves passed years on the footboard. This experience convinced them of the necessity for having everything handled by the engineer and fireman within easy reach and convenient to operate. It is only knowledge born of experience that gives a man a proper estimate of the importance there is in arranging the equipment of the cab so that the engineer can do his work without withdrawing his attention from the track in front. Experience on the locomotive is also necessary to convince designers that an engineer comfortably housed is likely to give his business closer and more individual attention than one exposed to discomforts of the weather or to the wearing action of a rough-riding engine. The men in foreign countries who exercised the greatest influence in establishing the existing form and attachments of locomotives were either civil engineers, shop mechanics or office draughtsmen. Many of them were accomplished steam engineers, and aimed to make a locomotive that would perform the greatest possible amount of work per unit of fuel consumed; others were well informed regarding strength and fatigue of material, and devoted their attention to the combining of strength and lightness in the machinery. But none of them had the training that gave a good estimate of the danger likely to result from having an injector difficult to start, an air-brake valve-handle in an awkward position, or a feed water-cock out of reach. Nor was it generally realized among these people that an engineman shivering with cold or exposed to saturating rain is likely to devote attention at times to escaping personal discomfort instead of watching for signals. The foreign locomotives exhibited all bore traces of the opinion that the convenience or comfort of enginemen was not worthy of consideration. The American engines manifested a spirit of rivalry to make everything as convenient as possible for the engineman, and to promote his comfort in every way consistent with the form of the locomotive.

Ten years ago, when the Exposition of Railway Appliances was held in Chicago, foreign critics had a good deal to say about the inartistic forms of domes, sand-boxes and other prominent parts of the American locomotives. This criticism was perfectly fair, for a fashion had become prevalent of using exceedingly unharmonious proportions of moldings and bases. In the ten years that have elapsed since that exhibition was held, great improvement has taken place in outward designs, and the American locomotives exhibited at the World's Fair had very little in outward forms that was unpleasing to the most fastidious taste. In this respect they were superior to all rivals except the Webb locomotive. It was curious to compare the outward appearance of the American and of the French locomotives. The French people are credited with being the most artistic of the nations that exhibited locomotives at the World's Fair, and it might be presumed that the national training would be manifested in machine designs. Americans, on the other hand, are supposed to be little influenced by anything that comes of art training. Yet the French locomotives are noted for their ugliness, in this respect excelling everything that runs on wheels. Ingenuity appears to be exhausted by French engineers to make the outward attachments of harsh looking forms and to convey extraneous pipes and rods in a shape to break up all the harmony of their surroundings.

From all points of view, American locomotive builders have good reason to be gratified with the display they made at the Fair. For simplicity of form, for adaptability to the work to be done, and for beauty of proportions, they were not surpassed by anything displayed against them.

## Angle-Cocks are Often Turned Without the Tramp.

Of late there has been considerable talk in this paper and among road and air-brake men about the turning of angle-cocks in the train-pipe by tramps or other irresponsible persons. That these cocks are turned once in a while, and disastrous wrecks caused thereby, we have no doubt, but that the turning is always done by the tramps, with malice aforethought, we don't believe. On the older passenger equipment the straight-way cock is employed, and this cock has a long handle. In much of the equipment this handle was pointed *down* and at right angles to the train-pipe when open—this is the most dangerous kind of train-pipe cock. A stone or piece of coal falling from a fast moving train, or a piece of ballast struck by any part of the running gear is liable to strike and close this cock—it has been done.

The angle-cock with the curved handle, lying on top of the cock is much better, but there is great danger of its being closed "automatically" when there is not a tramp within a thousand miles. They are closed by careless car building—almost criminal carelessness.

Unless the end of the train-pipe is securely fastened to the car, the jerking of hose pulling apart, and the regular jar and movement of the service will soon have the pipe carrying the hose in a condition to "rattle," and being springy, it moves all it can. Just as soon as it gets movement enough to strike the bottom of the car, it does so, and the top of the angle-cock, being the highest part, acts as the hammer head. This movement may be only a quarter of an inch or an eighth of an inch, but it is enough to do the business. When the top of the plug or the handle is struck, the taper plug is forced down a little, loosened in its seat, and the coil spring under it acts as a sort of a screw, to turn it ever so slightly at a time until the valve is at last closed.

Then it becomes necessary to stop; the engineer applies his brake, it don't work, a bad wreck takes place and the division superintendent sits on the case as judge, jury, executioner and coroner. If the engineer was killed, it was his fault—asleep at his post, perhaps. If he lives, and has witnesses that he was doing his duty, his whole duty and nothing but his duty, why, it was a case where the "air-brake failed to work." The real cause of the wreck was the saving of 15 cents per car by using a bad pipe fastener rather than a good one.

Some cases of cock closing were recently hunted up on the U. P., and the cause found as here stated.

We recently saw some new cars—part of an order for some hundreds—well designed, heavy cars with air-brakes and automatic couplers, but the train-pipe was held up under the end sills by a strip of $1\frac{1}{4} \times \frac{1}{8}$-inch iron with a hook on one end and a hole through the other, through this hole a $\frac{1}{2}$-inch lag screw went up into the wood—you could bend this clip and move the pipe with your hands, and the angle-cock was just in the right place to get tapped on the head when the pipe got a little "flop" to it. This is the usual fastening for train-pipe in the average contract shop, and it is entirely inadequate, and should be looked after by inspectors. The end fastenings of train-line pipe should be a clip that will prevent the pipe from moving, and grip it so tight that it cannot be pulled lengthwise of the car—this is what breaks off branch pipes.

On these little details depends the sure and safe action of the air-brake, a device that has doubled our train speeds, increased traffic, and saved more property and more lives than all the other railroad inventions besides. Look after these details.

Don't think because you have bought the best brake in the world that you have done all—the finest watch is useless if one turn of the hair-spring crosses another.

## The Appalling Death-Roll.

The Interstate Commerce Commission have just issued a volume of railroad statistics for the year ending June 30, 1892, from which we take the following statement about accidents to trainmen and passengers. The latter, it seems, are comparatively safe, but the list of dead and maimed in the ranks is something awful. If cholera had reached our shores this year with no more deaths than this, it would have paralyzed the nation and called for the expenditure by the Government of stupendous sums of money, and the employment of all the skill and force of the entire people to stop its course. What has been done, that could easily be done, to save the lives and limbs of these men who earn their bread in the train service of our roads? There are 821,415 employés of railroads in this country, one to every 79 inhabitants, and that 378 of these men should have been killed and 10,319 maimed, in coupling cars alone, in a single year, is nothing if not a national disgrace. Yet, when anyone wants the law requiring the adoption of automatic couplers rigidly enforced, the cry is set up that no road could stand the expense. Ten times the cost of this equipment would not pay for the lives and limbs of these yearly victims of the national plague.

"The number of railway employés killed during the year covered by the report was 2,554, being less than the number killed during the previous year. The number of employés injured, however, was in excess of the number injured during the previous year, being 28,267. The number of passengers killed was largely in excess of the number killed during the previous year, being 376 in 1892 as against 293 in 1891; while the number of passengers injured was 3,227 in 1892, as against 2,972 in 1891. An assignment of casualties to the opportunity offered for accidents shows 1 employé to have been killed for every 322 employés, and 1 employé to have been injured for each 29 men in the employ of the railways. A similar comparison shows 1 passenger killed for each 1,491,910 passengers carried or for each 35,542,282 passenger miles, and 1 passenger injured for each 173,833 passengers carried, or each 4,140,966 passenger miles. The largest number of casualties to employés resulted from coupling and uncoupling cars, 378 employés having been killed and 10,319 injured while rendering this service. Of the total number killed in coupling and uncoupling cars 253, and of the total number injured 7,766 were trainmen. The accidents classed as 'falling from cars' were, in this year as in previous years, responsible for the largest number of deaths among employés, the number killed in this manner being 611. Of this number 485 were trainmen. Collisions and derailments were responsible for the death of 431 employés. Of this number 336 were trainmen. This class of accidents is responsible also for the largest number of casualties to passengers. Thus 177 passengers were killed and 1,539 were injured by collisions and derailments during the year. Collisions alone were responsible for the death of 286 employés and 136 passengers."

## Screw-Jacks for Locomotives.

While traveling in one of the Middle States lately our train stopped between stations. Finding that no move was made after waiting twenty minutes, the writer went out to reconnoiter. He found four trains on the main line obstructed by something in front. On walking forward we found the cause of the obstruction to be a heavy mogul engine that had run over the end of a switch and sunk down in the mud at the end of the ties, in a position where she could not help herself without being jacked up. After waiting nearly three hours a wrecking train came along, and the derailed mogul was quickly put back on the steel with no apparent damage. They jacked up one side, put blocking beneath the wheels and the engine backed on herself. It was a simple operation, and the question naturally arose, why did the engineer in charge of the mogul not do that without waiting for the wrecking outfit? The answer is simple and conclusive, he did not have screw-jacks powerful enough to lift the engine. The jacks supplied to the engine were of the kind designed for lifting the class of locomotives in use twenty years ago—the kind that are still to be found on the most powerful engines of the present day. A screw-jack is a perfectly useless tool if it is not equal to the requirements, and there is good reason for believing that the greater part of this article to be found rusting in the boxes of locomotives are worthless for lifting the heavy weights they have now to deal with.

The efficiency of screw-jacks or of the other tool equipment of locomotives may seem a small matter, but the results that come from their inefficiency are sometimes very serious and expensive. In the case referred to, the whole train service of a railroad was obstructed for hours because a few dollars were saved on what would have been required for efficient jacks. The weight to be raised ought to be considered when screw-jacks are purchased for locomotives, just the same as other parts are proportioned to the work to be done. It would pay most railroad companies to equip their engines or trains with hydraulic jacks or the improved forms of screw-jacks now in use. A protracted delay due to the want of an efficient jack is likely to cost enough to equip a railroad with improved forms, and it is not good management to persist in clinging to obsolete articles of this important character.

### Automatic Signals Demanded for Train Protection.

There have been more serious accidents to railroad passenger trains during the last four months than there has ever been before in the same length of time. The accidents have been due largely to the congested condition of the passenger business carrying people to and from the World's Fair; but the number of trains on some of the roads where disastrous accidents happened has not been greater than it would have been in fairly prosperous times, when a full volume of freight was being moved. The prostration of the freight business for the last four months has put the railroads in unusually good condition to transport passengers safely, yet a heart-rending degree of death and suffering has overtaken travelers who trusted the railroads to convey them safely to Chicago and back. Most of the accidents have resulted from the want of proper and necessary appliances that have been invented to secure the safe movement of trains. The appliances most neglected on our lines are those that form a good system of signals.

The railroad system on this continent has developed slowly. The roads that are now most prosperous have grown up from the small beginnings which found trains running hours apart. While a road remained in this condition it was safe enough to depend on the care and vigilance of trainmen to prevent collisions, and the reliance upon these men was well founded, for no class of men have ever displayed equal success in avoiding accidents under difficult conditions. As traffic increased and rolling stock augmented in weight, the crude appliances for controlling trains had to be improved, and twenty-five years ago the air-brake forced its way with magic rapidity into use on passenger trains. This wonderful invention jumped into popularity because a point in train operating had been reached where the old appliances were unequal to the requirements. The necessity of the case brought the invention that met the needs. In the quarter of a century that has elapsed since the air-brake began to receive general application, conditions have been changing, and a point is again reached where another long-spanning step in the interest of safety must be taken. Fixed automatic signals that will keep trains a safe distance apart must be adopted by all railroads moving a certain volume of business.

Railroad companies in America have been extremely slow in recognizing the necessity for fixed signals to protect trains. The fact of their having exceptionally intelligent trainmen has delayed the conversion of railroad managers to the belief in signals. While they could reasonably hold men responsible for the safety of their trains without any mechanical aids, they have been ready to declare their reliance on good intelligent men in preference to mechanism that might break. This, in fact, has been a line of argument used as an excuse for failing to adopt all needed improvements.

Railroad history does not tell when the first fixed signal was first applied on this continent. It was doubtless used to warn trains not to attempt to pass over a draw-bridge when the bridge was swung. This was the first purpose for which fixed signals were considered a real necessity among American railroad managers, and we have no doubt that many of the same managers were convinced of this necessity very much against their will. At all events, the mechanical ability employed to design the signals introduced was of an extremely low order, for nothing could exceed the crudity of the devices brought into use. The frequent accidents that happened at grade crossings led to the protecting of these crossings by fixed signals in some districts, even before the State Legislatures began passing laws making it compulsory that trains stop before going over a grade crossing. The crude signals first brought into use as a protection at crossings led to numerous accidents, and they did much to break the confidence of railroad men and legislators in signals as a means of preventing accidents at such places. Had a good system of interlocking signals been first adopted for the protection of grade crossings and drawbridges, it is very unlikely that legislation calling for what are called know-nothing stops at crossings would have come into existence. Instead of this, legislation would have been directed to compelling the use of interlocking signals.

The next chapter in the introduction of signals was where trains began following each other so closely that there sometimes was not time for the flagman to go back and warn the other train in case of unexpected delay. The remedy adopted for this dangerous condition of affairs was to put up at each station a board intimating the time that each train passed. The engineer of the next train could by this means find out how many minutes ahead of him the other train was. This system was some help, but it gave no indication if something happened round the next curve which caused the train to stop. While he was pushing along under the assurance that the train was miles ahead of him, he was suddenly confronted with a red signal just as the back end of the train came in view and a smash-up was the consequence. This happened in hundreds of cases, and is going on daily where no provisions are made to keep trains a given distance instead of a given time apart.

The flagman who fails to go back in time has come in for his full measure of abuse, but the careless flagman is not so much to blame as the dangerous and unreliable system which makes him responsible for duties that are frequently hard to perform. We have known cases where it was certain death for any human being to stand out in the open track for hours without shelter, and yet there was a probability of a train coming along pulled by a locomotive that had strong snow brushes in front of the leading wheels. It was useless to put torpedoes on the rail. The brushes would sweep them off as they would sweep the snow they were used for, and a lamp set on a snowbank was likely to give no warning to an engineer looking through snow-covered glass.

The time signal has been tried under a great variety of forms, but it is thoroughly unreliable for a heavy traffic. Its utility is doubtful under any circumstances, for it tends to give confidence without indicating danger. There has been nothing said for time signals that was considered worthy of consideration except that they were cheap at first cost. Like nearly all other devices advocated on the score of cheapness they were in the end the dearest that could be used.

When time signals were demonstrated in many a bloody wreck to be unreliable, the absolute block system of signals came into use on the most progressive roads. An absolute block system of signals is operated by dividing a railroad into sections, protecting these by signals and arranging that the signals shall not be cleared to admit a train upon a section until the preceding train has passed off. There are several systems of block signaling, and some of them have been wonderfully developed. The Hall automatic block signal system, which so many railroad men have had the opportunity of watching in Chicago this season, performs the work automatically without attention from any person. All the trains on the lines of the Illinois Central Railroad in the neighborhood of Chicago, have been operated by this system, and the safe handling of the immense traffic gives the highest testimony as to its efficiency.

Space will not permit us to enter into the details of the system, but readers of Locomotive Engineering will be able to read a description of this and of the other leading signal systems in the near future written by an expert signal engineer. The New York Central, the Pennsylvania and other leading roads have their main lines operated under various forms of block signals, and their use reduces the possibilities of accident to the lowest limit. While human nature is fallible and while the strongest metals will break unexpectedly there will be railroad accidents; but the adoption of the most approved appliances is the duty of railroad managers, in order that the possibilities of securing safety may be exhausted. The air-brake is almost perfection, and little more can be expected from appliances to stop the train quickly. The next move waiting urgently for general adoption is the providing of signals that will intimate the necessity for stopping.

In replying to criticism of your communication, don't sneer, don't lament the intellectual density of the man who can't or don't grasp your idea—it only takes the editor's time and wastes ink scratching it out. Stick to the subject, talk mechanics, be fair, and don't be personal. Then the editor will put a postscript in your behalf to his daily petitions.

### BOOK REVIEW.

Compound Locomotives. By Arthur T. Woods, M. M. E. Revised and Enlarged by David L. Barnes. Published by *The Railway Age and Northwestern Railroader*, Chicago. Price, $3.00.

This is the latest and best book on compound locomotives, and we wish to say right here that no one can afford to buy copies of the first edition now, as they are already out of date and very incomplete.

When Professor Woods died, he had a revision of his book well under way and his widow undertook to finish it. The editing of the notes and memoranda was undertaken by Mr. Barnes, who was a close friend of the author. The work has been all rewritten, many new engravings introduced, and all the devices used on compound locomotives anywhere are illustrated and described. There is also a chapter on the selection of a type of engine for a given service, and one on reasons for economy that are entirely new. It is the only complete work on the compound locomotive up to date.

*Aeronautics* is the name of a new monthly journal published at 47 Cedar street, New York, by Mr. M. N. Forney. The paper has been started for the purpose of publishing the papers read at the International Conference on Aerial Navigation, held at Chicago last summer. The interest in aeronautics has grown so much lately that it was considered likely that a sufficient number of readers could be found to make a journal devoted to the subject a success, and Mr. Forney is trying the experiment. The papers on aerial navigation will run through twelve monthly numbers. If it is then found that the journal is receiving satisfactory support, it will be continued, if not, it will be stopped. The paper is got out in very good shape, and contains interesting matter of its kind. Every person interested in aeronautics should send for the paper. The price is $1.50 a year.

### PERSONAL.

Mr. H. A. Kennedy has been promoted from assistant superintendent to be General superintendent of the Cleveland, Canton & Southern.

Mr. W. H. Whalen has been made general foreman of the Wisconsin division of the C. & N. W., at Chicago, *vice* P. R. Jones, promoted.

Mr. H. Weston has been appointed general foreman of the car department of the Buffalo, Rochester & Pittsburg, with headquarters at Rochester, N. Y.

Mr. O. O. Winter has been appointed superintendent of the Breckenridge division of the Great Northern, with headquarters at Minneapolis, Minn.

Mr. F. L. Tompkins has been promoted from master of transportation to be superintendent of the Jacksonville Southeastern, with headquarters at Jacksonville, Ill.

Mr. Edward Eldon, master mechanic of the Toledo division of the Lake Shore, has been appointed master mechanic of the Buffalo division, with headquarters at Buffalo.

Mr. P. Ryan has been appointed superintendent of the Kalispell division of the Great Northern, with headquarters at Kalispell, Mont., in place of Mr. P. J. Welles, resigned.

Mr. T. B. Irwin, general foreman of the Central of Georgia, at Chattanooga, Tenn., has been appointed master mechanic of that road at Savannah, Ga., in place of Mr. J. J. Anderson.

Mr. John H. Bell has been appointed superintendent of the Reynoldsville & Falls Creek, with headquarters at Reynoldsville, Pa., in place of Mr. George Mellinger, resigned.

Mr. W. L. Blair has been promoted from chief clerk of the general superintendent's office to be superintendent of the Eastern division of the Nickel Plate, with headquarters at Cleveland, O.

Master Mechanic T. P. Jacob, of the Mexican National, at Acambaro, has been putting in a month at the Fair, leaving the grief and pass-book in the hands of Traveling Engineer I. M. Hutchinson.

Mr. E. W. Baker has been appointed purchasing agent of the Mexican Central, with headquarters in the Mason building, Boston, in place of Mr. Theodore Nickerson, general purchasing agent, resigned.

Mr. A. W. Johnston has been appointed general superintendent of the Nickel Plate, with headquarters at Cleveland, O. He has been for the last four years superintendent of the Eastern division of the same road.

Mr. Harry Flanders, late superintendent of the Central division of the St. Louis, Iron Mountain & Southern, has accepted the position of division superintendent of the Mexican Central, with headquarters in the City of Mexico.

In his speech on Railroad Day, at the World's Fair, Mr. M. E. Ingalls, president of the Big Four and the C. & O. roads, stated his belief that a system of profit-sharing was the true solution of the labor troubles on railroads.

Mr. C. M. Lawler has been appointed general superintendent of the Philadelphia, Reading & New England, with headquarters at Hartford, Conn. He was formerly superintendent of the Atlantic division of the Philadelphia & Reading.

Mr. Fred. Wells, foreman of the West Shore shops at Frankfort, N. Y., resigned last month to accept a more responsible position with the Fitchburg. Mr. Wells is one of the progressive shop men of the times and thoroughly understands repair shop management.

Mr. Gustav Jacobson has been appointed master mechanic of the Montpelier & Wells River road, with headquarters at Montpelier, Vt.

Spon & Chamberlain, of this city, have issued a little 50-cent book entitled "Cromwell's Easy Lettering," a very handy little guide for draughtsmen and others who wish to neatly letter drawings.

Geo. W. O'Brien, master mechanic of the C. R. R. of Georgia, at Augusta, Ga., died in that city on October 9th. He was formerly with the R. & D., and was well known among railroad men in the South.

Mr. P. R. Jones, general foreman of the Wisconsin division of the C. & N. W. Railway, at West Fortieth street, Chicago, has been promoted to the general foremanship of the Iowa division, with headquarters at Boone, Ia., in place of Mr. S. Mantashed, resigned.

Mr. Wm. Gibson, division superintendent of the Cincinnati division of the Big Four, has had his jurisdiction extended over the Sandusky division. Mr. Gibson has been exceedingly fortunate in his management of the Cincinnati division, and on this account had his territory extended.

Mr. C. E. Walker has been appointed master mechanic of the Toledo, St. Louis & Kansas City. Mr. Walker has been for several years division master mechanic of the Cincinnati, Hamilton & Dayton. Before that he was on the Cincinnati Southern, having risen through the grades of roundhouse foreman and general foreman.

Mr. R. W. Bryan, superintendent of the Breckenridge division of the Great Northern, has been appointed assistant superintendent of the entire Eastern division of the Great Northern system, with headquarters at Minneapolis, Minn. He will have charge of the maintenance of roadway and structures, stations and transportation.

Mr. James Bradeen has been appointed master mechanic of the Toledo division of the Lake Shore & Michigan Southern, with headquarters at Norwalk, O., in place of Mr. Edward Elden, transferred. He was formerly foreman at the Air Line junction and Toledo engine-house, in which position he is succeeded by Mr. James H. Calkins.

Mr. A. Bardsley has been appointed master mechanic of the Buffalo & Pittsburg divisions of the Buffalo, Rochester & Pittsburg, with headquarters at Bradford, Pa. He was for several years division master mechanic of the Northern Pacific, and was noted for the ingenious contrivances that he invented to facilitate shop work.

Mr. Alex. Gordon, president of the Niles Tool Works, at Hamilton, O., has returned home from a long sojourn in Europe. Mr. Gordon was for years a martyr to a peculiarly painful form of dyspepsia, and he went to Europe to try the effects of German mineral waters. His numerous railroad friends will be pleased to learn that Mr. Gordon is entirely cured, and that he looks stout and healthy.

Mr. F. P. Boatman has been appointed master mechanic of the Omaha & St. Louis, with headquarters at Stanberry, Mo. Mr. Boatman was long master mechanic of the Ohio & Mississippi, and left there to take charge of the machinery of the Cleveland, Cincinnati, Chicago & St. Louis. Dr. Barnard, who was formerly general manager of the Ohio & Mississippi, is now receiver of the Omaha & St. Louis; so Mr. Boatman goes among old friends.

Mr. John Robinson, master mechanic of the Lake Shore & Michigan Southern, at Buffalo, N. Y., is dead. Mr. Robinson was well known to railroad men of Western New York, having been a regular attendant at mechanical meetings. He was born in England, and was for some time in the employ of the London & Southwestern. He has been with the Michigan Southern since 1868, and was considered a very able mechanic. He was a member of the Master Mechanics' Association.

Mr. Willard Kells, son of the late Ross Kells, has been appointed general foreman of the Erie shops at Meadville, Pa. Mr. Kells has received an excellent mechanical training, which includes shop drawing, office, and technical school experience. From the active, energetic, and systematic way that he starts out, there is every prospect that he will make a decided success. He is one of the young men with influential friends who relies upon his own ability and industry to push him up the ladder of life.

Mr. W. D. Holland, master mechanic of the Guatemala Northern Railroad, has just recovered from an attack of yellow fever. Mr. Holland has charge of the locomotive and car departments. He likes looking after the repairing of locomotives and cars very well, but there is one line of work which the car department has to perform which he dislikes. Carpenters are not very numerous in the country, and when the necessity arises the car department is called upon to make coffins for the whole community. This line of work is distasteful to railroad men.

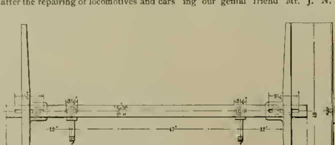

*Fig. 2*

Mr. J. B. Barnes, the well-known superintendent of motive power of the Wabash, has not been able to visit the World's Fair, because he was confined to his bed, nursing a broken leg at the time he had settled upon for his visit to the Jackson Park display. Mr. Barnes sometimes jeopardizes his life by riding behind live horses, and this led to the injury which prevented his seeing the Fair. We all sympathize with Mr. Barnes, but at the same time we cannot lose the opportunity this accident gives to impress upon our readers that it is the course of wisdom for railroad men to confine their admiration to the docile iron steed, which seldom runs away.

Mr. J. E. Phelan, well known to our readers as the author of "Air-Brake Practice," and who went, some three years ago, from the mechanical department of the Northern Pacific into the transportation, becoming superintendent of the Missouri division of that road, is going back to his first love, and on November 1 will become master mechanic of the Dakota division, with headquarters at Fargo, N. D., succeeding Mr. S. L. Bean, who has been promoted. We said at the time that we regretted to see "Jim" leave the mechanical department. He has spent his life as fireman, engineer, traveling engineer and master mechanic, and in this field he can be most useful to the railroads and to himself.

Mr. W. D. Ewing, who has been for the last two years assistant general superintendent of the Fitchburg Railroad, has been made general superintendent, in place of Mr. John Adams resigned. Mr. Ewing is a remarkably good executive railroad officer, and has made his mark on the Fitchburg during the short time he has been with the road. He rose from the lowest step of the railroad ladder, and has had experience in banking and newspaper work. While strict in seeing that duties are punctually and faithfully performed, he is kind to subordinates, and takes a keen interest in their welfare. He is a man capable of filling with credit a much higher position than he has yet reached, and we are mistaken if Mr. Ewing does not some day rank as one of the first railroad men in the country.

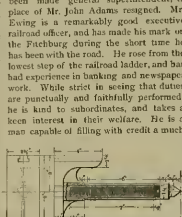

*Fig. 1*

We were recently alarmed on meeting our genial friend Mr. J. N. Barr, superintendent of motive power of the Chicago, Milwaukee & St. Paul, to find a striking change in his personal appearance. Those who witnessed Mr. Barr disporting in the sea at Cape May, will remember that he carried a heavy wad of adipose tissue on his front end. In fact, he was building up an extension front of the most pronounced type. What caused our alarm and astonishment on meeting Mr. Barr the other day was that the extension had disappeared. From neck to knee he was straight as a plumb line. The change has been induced by a peculiar form of exercise, which Mr. Barr is willing to recommend to all men who are suffering from the accumulation of superfluous fat. He is greatly improved in health since the change was effected.

Among the men whom one meets annually at the railroad mechanical conventions, none is more popular or better known than Mr. C. P. Krauth, treasurer of the Mc-Conway & Torley Co., of Pittsburg. Mr. Krauth is decidedly stout, and carries a coating of fat thick enough to keep his heart warm. Fat men are not generally noiseless sleepers, and the likelihood is that Mr. Krauth is no exception in this respect. At least he got an accusation of disturbing the silence of the night brought against him lately in a curious fashion. His home had been crowded with visitors, and his little daughter aged five years was sleeping with her papa. Towards morning Brother Krauth was awakened by two little hands persistently pulling at his ears. When he got fully awake he asked, "What is it, my little daughter?" The child answered, "Oh, papa, I want oo to stop making 'at noise wi oor nose."

## Double T-Square and Straight Edge for Squaring Locomotive Frames.

At the Waukesha shops of the Wisconsin Central road they use a special tool for squaring up shoes, wedges and frames, which we illustrate herewith.

The tool is a combined double T-square and straight edge but is designed and constructed especially for the purpose of squaring locomotive frames. Provided with means of adjustment to meet the requirements of all sizes of ordinary locomotives, with firm and reliable supports while applied to the work, T-heads perfectly parallel with each other and square with the straight edge body, its use insures an accuracy not solely dependent upon the judgment of the workman, and which cannot be obtained under the ordinary practice of using separate squares applied to a straight edge, generally supported upon wooden blocks wedged between the shoe and wedge faces of engine frames.

The general dimensions of the tool are given in the illustrations, and in detail its construction is as follows:

In Fig. 1, $A$ is a cast-iron bracket provided with a T-slot in its upper face to receive the head of a hand-bolt, by which the straight-edge is secured to the bracket. Into a boss projecting from the inner side of $A$ is pressed a tubular steel piece provided with an internal thread for about two inches at its outer end, and counterbored to full size of thread for the remainder of its length. Into this is screwed the center $B$, the thread of the latter being protected by a sleeve $C$, affixed to $B$ and passing over the nut-piece projecting from $A$. The sleeve is knurled its entire length and furnishes a hand grip by which $B$ can be unscrewed and extended sufficiently to secure $A$ between the shoe and wedge faces of the engine frame.

The straight-edge or body of square $B$, Fig. 2, and also the blades $cc$ of the T-heads are steel. $B$ is secured to brackets $AA$ by the hand-bolts $DD$, which pass through holes slotted lengthwise in $B$, to provide for a lateral adjustment of the same. The blades $cc$ are riveted to the center-pieces $GG$, which are secured at any location upon the outer ends of $B$ by means of the hand-screws $HH$, which pass through longitudinal slots in $B$, and engage in nuts affixed to $GG$. Both edges of $B$ are beveled for a distance of 16 inches from each end, the head-pieces $GG$ having corresponding recessed bevel, all constructed in such a manner that when heads $GG$ are secured by $HH$ they will draw up on the beveled edges of $B$, and preserve and maintain the accuracy of the T-head in any position of lateral adjustment.

The operation of applying the square to engine frames is as follows:

Having set and trued the cylinder lines, the brackets $AA$ are secured firmly against the shoe faces by screwing out centers $BB$ against the wedge faces. (The brackets and centers are so proportioned that they can be used either with or without the shoes or wedges in position.) The straight-edge is then placed upon the brackets and secured by the hand-bolts, after which the T-heads are placed on their respective ends of the straight-edge and set to the cylinder lines. The T-slots in tops of brackets admit of a side movement of straight-edge in order to bring either T-head parallel with one cylinder line, when, if the cylinder lines are parallel, the opposite head will coincide with the line on that side, or if any error exists it will be at once observed. Working lines on the frames are laid out from the straight-edge.

The tool is simple and inexpensive, and is an indispensable adjunct to any well-equipped locomotive shop. Its use detects and eliminates errors which cannot fail to exist when the common method is followed in the class of work to which the tool is applied.

"Sthand at head, Moike!" yelled the new fireman, from the top of the teoder, "She's aigen away from the watherin' spout."

## A Strange Boiler Explosion.

On the 27th of July last the boiler of Engine No. 4, on the C. C. division of the Seaboard Air Line, exploded, and the effects of that explosion seem to us to have been rather peculiar and very interesting.

This engine was a Baldwin eight-wheeler, but six years old, and the explosion was doubtless caused by seaming and pitting of one of the barrel sheets.

The engineer of the train, Mr. J. S. Bundy, the fireman, and a car-tracer, named Lewis, were on the engine at the time.

Speaking of the accident, the engineer said

"I had the '4' on Train 5 on the 27th of July, between Lawrenceburg and Charlotte, N. C. On nearing Nelson branch trestle, about four miles from Monroe, I shut off the throttle and we were rolling along about ten miles per hour, being dead on time, which was slow. When nearly across the trestle, I linked up the lever, and had or was just commencing to open the throttle when the boiler exploded.

"The barrel-sheet just ahead of the wagon-top blew entirely off, carrying away the sandbox and stripping a great deal of her machinery, derailing engine, tender and two box-cars, and also breaking two stringers in the bridge.

"The boiler was full of water, and the steam pressure was about 127 pounds when she let go. None of us were seriously hurt, although I was considerably shocked and bruised.

"None of us heard the report!

"The first hint I had that anything was wrong was the ringing of the bell, caused by engine riding the ties.

"I found myself turned around, with my head lying in the front window, and protected from the scolding water and flying pieces of wreck by the jacket, that had folded back over the cab.

"By the time I came to my senses I missed the fireman and Mr. Lewis, but they came to my rescue at once. I suppose the whole thing happened in less than a minute."

A Strange Boiler Explosion.—After Wreck Was Picked Up.

A Strange Boiler Explosion.—Ready to be Towed Home.

On looking at the engraving made from a photograph, taken at Monroe the next day, it will be seen that one entire sheet is gone from the boiler, and that there is evidence of a tremendous force exerted in all directions from the center of the cylindrical part of the boiler. The flues are bent out in every way from the center, the dry pipe is bent up and the heavy frames bent down, as were also the guides, pistons, etc.

It is believed that had this explosion taken place on *terra firma* instead of on an open trestle, that the engine would have turned over, and in all probability killed her crew; the theory being that the force of the escoping steam had a chance to get away and had no chance to lift the engine, as there was, so to speak, no place for it to lift from.

The force of the explosion must have been enormous to bend all the heavy parts it did.

As far as could be seen there was a deep seam along the horizontal seam in the sheet that gave out, and it is supposed that it was here the rupture started. The metal was not torn at the roundabout seams, either on the ruptured sheet or those to which it was attached, but the rivets tore out or the heads pulled off.

The strangest thing about the wreck is the statement of all three men that they heard no explosion, and none of them could have any incentive to tell anything else than the truth. We would like to have some scientific man come to the front and explain this phenomenon. Certainly the explosion made a report—why did not these men hear it?

## A Burning Question.

BY L. R. ANDREWS.

Less attention has probably been paid to the improvement of grates than to any other department of locomotive practice.

The result is that the various patterns and styles of grate-bars in use are almost without exception faulty in principle, construction and operation, and that they are in many cases extremely wasteful of fuel is evident to every observant superintendent of motive power, master mechanic and engineman.

The usual method of cleaning a fire with slice-bars, pokers, and clinker-hooks, necessitates keeping the furnace doors open a long time at each cleaning, reducing the steam pressure during this interval, with a corresponding lowering of boiler temperature, and consequent strain on plates, in addition to which is the injury to tube-sheets and grate-bars by the severe pounding of the tools necessary to dislodge the dirt.

In addition to the bad effects of the cold air rushing between the bare grates, and through the open furnace door during this process, on the tubes and tube-sheets, they are subjected to further severe strain by the harsh use of the blower necessary to restore the pressure quickly, which in turn clogs the tubes, spoils the fire, and causes the direct loss of a large amount of water and steam, besides being wasteful of fuel.

Where rocking-grates are used, of either the finger or perforated plate pattern, much good fire is lost when grates are shaken, as the tendency is naturally for the fire to drop through with the ashes and dirt, and as there is nothing to prevent this taking place, the result is a large loss of fuel only partially burned; especially is this so, if, as is often the case, a clinker or other substance lodges between the grates when same are tilted at an angle, thus preventing their returning to their normal position and causing them to be burnt out.

Water bar-grates fitted with drop-bars, or bars which are drawn out when fire is to be cleaned, are open to the same objection, a large and entirely unnecessary loss of good fire.

The levers attached to the arms of the various rocking grates extend through into the ashpan, interfering with proper cleaning of same, and in case of leaky tubes, the ashes which accumulate behind the levers, freeze in cold weather, thereby rendering the shaking apparatus useless.

When removing or replacing such bars it is usually necessary to take down the ashpan, which is a considerable item of expense.

The prime object to be attained in cleaning a fire is to remove the ashes, dirt and other products of combustion which accumulate at the bottom thereof, without disturbing the body of the fire more than is necessary to loosen it up and admit the proper amount of air to and through it, as nearly the entire amount of air needed for perfect combustion should be passed through the fire from beneath in order to get the best results from the fuel.

A fire should be disturbed or broken up on top as little as possible, and will seldom need to be touched by the tools if a grate is used that will do all the cleaning from the bottom.

I propose a geared rotary grate-bar, designed for use in locomotive, marine or stationary boilers, or in furnaces generally, where the fuel admits of cast-iron grates being used, and I claim for them cheapness in construction, simplicity of operation, economy in fuel and better combustion.

The principle on which they are designed, constructed and operated will keep the entire bed of fire constantly clean and bright with the minimum waste of fuel, time and labor.

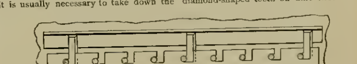
Combustion is improved by reason of the fact that the round shape of bars with their blunt, diamond-pointed teeth or projections, arranged spirally in rows from end to end, offer the least possible resistance to the passage of air around and between them, thus preventing the fire from coking, as is apt to be the case on bars having a large flat or "dead" surface, on which the fuel does not readily ignite.

I believe a lighter fire may be carried on the rotary grates, as it can be kept constantly clean and bright by frequently revolving the grates a trifle, thereby causing the boiler to steam freer, and, as is well known, a dirty fire requires much more coal than a clean one.

There are no levers, arms, bolts, nuts or other weak and complicated parts to the rotary grates to break or get out of order at a critical moment, and they may be fitted to any firebox or furnace at a merely nominal cost, and bars can be removed or replaced in a few moments' time without taking down the ash-pan, or in some cases without knocking the fire out. How this is done is shown in upper sketch. They drop into an L-shaped slot, and are prevented from coming out by the shield.

The bars are cast hollow to avoid unnecessary weight, and have apertures in each end allowing the air to circulate through them, thereby cooling them and rendering them less liable to be burnt or warped, and this contingency is further reduced by the fact that the bars are being frequently revolved.

The spiral arrangement of the blunt diamond-shaped teeth on bars offers the least resistance in revolving same, and affords the greatest leverage in crushing clinkers, etc., present at all times a uniform surface to the body of the fire; they have no edge, point or surface to be broken or burnt off, and permit at all times the freest circulation of air around and between them.



Andrews' Proposed Grates.

Motion is imparted to bars by means of gears cast on one end of each bar, which is in mesh with adjacent bars.

A journal, terminating in a slight

shoulder, is on each end of every bar, fitting into holes and L-shaped apertures in the side strips which support the bars, and in which they revolve.

A shaft extends the length of the fire-box, supported at each end by lugs fastened to the under side of the mud-ring, on which are mounted gears, beveled to engage with corresponding gears mounted on studs attached to the lower side or side strips supporting bars.

These latter gears have also a flat face, which, in turn, engage with gears on the bars at back end of shaft, outside of furnace is mounted a ratchet-wheel (worked by pawl) to arm of which a rod is attached which leads to deck of locomotive, by which operator imparts motion to the bars.

A perforated hood, which may be made out of old boiler-plate in any desired length, extends over the gears of bars, preventing the lodgment thereon of fire or other substance, and is perforated to allow air to pass to fire resting on top of it. The hood has lugs fitting into suitable apertures in the side strips, which lock it and also the bars in position, avoiding the use of bolts or nuts for this purpose.

The best results will be obtained by operating the bars frequently a trifle, and an arrangement for this purpose can be readily and cheaply effected by a small cylinder, using steam or air.

### An Index of Some Account.

Fred. De Land, publisher of *Electrical Engineering*, Chicago, issues an index of current technical literature, which he calls a "synoptical index." It tells what the article is, whether editorial or correspondence, how many words it contains, how many illustrations and how many tables, with the briefest kind of a synopsis of the article itself. Here is a specimen from October:

"Railroad Coppersmithing" By John Fuller (Suggestions on planning and equipping a coppersmith's shop, based on the railway shops in London. 1½ p., 5 i.) *Locomotive Engineering*, September.

This shows that the matter occupied 1½ pages, had 5 illustrations and can be found in the paper named for the month of September. It's the only index of mechanical literature that is worth anything. Most of them give titles only, and in many cases a title does not tell what the article is about.

There was a splendid exhibit of wood-working machinery at the World's Fair, several foreign countries having made a most creditable display in this department. The exhibits by American manufacturers was exceptionally fine. The J. A. Fay & Egan Co., Cincinnati, carried off the highest honors, and everybody familiar with machinery of this class who examined the various exhibits will agree that the honors were fairly awarded. The exhibit obtained the "Premier Medal." The machines that took prizes were Medal and diploma, for car mortising and boring machine, automatic double cutting-off saw, fret scroll saw, triple cylinder, lightning flooring machine, sill and timber dressing machine, automatic dovetailing cutting machine, triple drum sand-papering machine, Universal wood-worker; double planing and smoothing machine; band re-saws, car graining and tenoning machine, spoke lathe. Special mention was made of the triple drum sander as being the latest and showing the most advancement in this class of machinery.

The exhibits of rolling stock and machinery at the World's Fair have constituted good sources of information to the numerous railroad men who visited the place. This was particularly noticeable in the case of machine tools and wood-working machinery. The writer visited the Manning, Maxwell & Moore exhibit and that of Pratt & Whitney with several railroad master mechanics and they all found tools and appliances that they had never seen before, and which are made specially for railroad work. The railroad companies are likely to have requisitions made for tools that would not have been thought of but for the new light thrown upon them by the exhibition. We noticed that the J. A. Fay & Egan exhibit of wood-working machinery attracted the superintendents of machinery and the master car builders. One of the former, who is in charge of the machinery of a large railroad, remarked that the machinery in this single exhibit was capable of turning out more finished work than all the machinery now owned by his company.

The passenger cars exhibited at the World's Fair attracted extraordinary attention from visitors, there having been a constant stream of people passing through the different cars every day. The day coaches were noted for the simplicity and elegance of their interior finish, and for this were highly commended by those who had good judgment as to the furnishings best adapted to passenger cars. The seats and the upholstery were particularly worthy of admiration. For this the Hale & Kilburn Company deserve much credit, for all the day coaches we examined were equipped with their seats.

There has been a great deal of talk for several weeks about having a race between the New York Central's locomotive "999" and the London & Northwestern Webb compound, exhibited at the World's Fair. A race of this kind would have no engineering value. It would make some excitement, but it would prove nothing and mean nothing, except giving some advertising to the projectors of the scheme.

The Pullman Car people built a large number of cheap sleeping cars to accommodate the World's Fair travel, and we feel assured that those cars have done more to bring the owners into disrepute with the traveling public than anything ever done by a corporation that has incurred the enmity of many people. The cars are poorly built, and have inferior seats upholstered in third-class style. The greater part of them have neither dressing-rooms nor smoking-rooms, and they are indifferently lighted with oil lamps. We happened to travel several times in these cars, and each time we heard bitter complaints about the accommodation, and violent abuse of the company that charged first-class rates for third-class cars.

The H. W. Johns Manufacturing Company, of New York, are making asbestos gaskets for air-pumps which are highly spoken of by the engineers using them. A case lately came to our attention where these gaskets had been applied to the air-pump of a switching engine. The engine was in use night and day, and there was a good deal of trouble in keeping the steam piston-gland of the air-pump tight. With common packing, it had to be repacked every two weeks. When we saw the engine, one set of asbestos packing had been in use fourteen weeks, and was still in good order. All the attention that it had required during that time was to screw up the gland a little once or twice.

The Baldwin Locomotive Works have received an order for ten Vauclain compound locomotives for the Philadelphia, Reading & New England Railroad. Of these, seven are consolidation freight locomotives, with high-pressure cylinders 13½ x 24 in., low-pressure cylinders 23 x 24 in., and driving-wheels 50 in. diameter. They will weigh, in working order, about 125,000 pounds. The other three are passenger locomotives, with high-pressure cylinders 12 x 24 in., low-pressure cylinders 20 x 24 in., and driving-wheels 68 in. diameter, estimated weight, in working order, about 96,000 pounds.

General Manager Payson Tucker, of the Maine Central, has issued a timely official order to all employés concerning the care of steam-heating apparatus. Mr. Tucker proposes that every trainman shall know his duty about the heaters, and will hold the proper parties responsible for all cases of freeze up or other alleged failure. The road uses the Consolidated Company's system and believe that, properly handled, nothing seriously can happen to or from it.

The Wells & French Co., of Chicago, have contracted to build one hundred refrigerator cars for the Armour Packing Co., of Chicago. The cars will be first-class in every particular, with M. C. B. couplers, Westinghouse air-brakes and Cambria steel axles treated by the Coffin process.

The Hicks Cattle Car Co. are figuring on the ordering of some new cars, and the order may probably reach 1,000. In spite of the depression of business, this company has been doing a heavy business, which would have been greater if they had had sufficient cars to meet the demands.

At the last meeting of the New York Railroad Club, Mr. D. L. Barnes' paper on Building and Inspecting Locomotive Boilers to Prevent Explosions was read and illustrated by lantern slides. The paper will be discussed at the next meeting of the club.

The Mt. Vernon Car Mfg. Co., of Mt. Vernon, Ill., have secured the contract for 250 coal cars for the Louisville, Evansville & St. Louis road. They have orders enough on hand to keep the plant running full time until February.

The Falls Hollow Stay-Bolt Co. started up their mill on October 1st, after a shut-down of less than three weeks for repairs. They have nearly doubled the capacity of the plant.

An improved form of metallic end panel for car seats has been patented by Henry Cochran, of Chester, Pa. It is a very simple and strong form.

## New Ten-Wheeler for Chesapeake and Ohio.

We show three sections of a new ten-wheel engine, recently designed by Mr. W. S. Morris, superintendent of motive power of the Chesapeake & Ohio, for handling the heavy passenger trains which are common on the road. Some portions of the system are noted for having steep grades, and the engines are well adapted for working trains in such districts. For the engines to be used on the mountain divisions, the driving-wheels are six inches smaller than those employed on the other portions of the line.

The leading characteristics of the engine are ample heating surface and great tractive power. No essential has been sacrificed to combine these in an unusually large ten-wheel engine. The cylinders are 20 x 24 inches, and the diameter of the driving-wheels is 68 inches for ordinary service, and 62 inches for those employed on the parts where grades are steep. With the latter size of wheel, the engine develops 155 pounds of tractive power per pound of cylinder pressure. As the boiler pressure is 180 pounds to the square inch, the engine will be capable of exerting about 24,000 pounds on the drawbar in starting a train.

The boiler, as will be seen in the engravings, is of the extended wagon-top type, with radial stays to support the firebox crown. The dome is set in front of the firebox on a section that is kept of the same diameter as the firebox. The latter has the mud ring set above the frames, but it is dipped down toward the back flue-sheet to give as much depth as possible at that point. The boiler is 60 inches diameter at the front sheet, and has 247 2-inch tubes, 13 feet 10 inches long. The firebox is 8 feet 9½ inches long, and is 41¼ inches wide, and has 30.2 square feet of grate area. In the tubes there are 1,790 square feet of heating surface and 170 square feet in the firebox, making a total of 1,960 square feet. The fire area through the tubes is 593.6 square inches and the ratio of grate area to heating surface is 1 64.9. The cylinders being 20 x 24 inches and there being 1,960 square feet of heating surface, it will be found that there is about 224 square feet of heating surface per cubic foot of cylinder capacity. This is precisely the ratio of cylinder to heating surface that the Lake Shore engines have that were built by the Brooks people for the fast trains that run from New York to Chicago in twenty hours.

The weight is transferred to the driving-wheel boxes by means of underhung springs arranged in a very skillful manner. The expansion-link is located behind the front axle, and transmits the motion through a radius-bar which spans the axle. This plan dispenses with the long, heavy eccentric rods found on so many ten-wheel engines. The cross-heads are of alligator pattern, supported by a guide above and below. Richardson balanced valves are used covering ports of generous size. All the most approved fittings are used on the engines, which include Westinghouse air-brake, with American brake applied to drivers and tender wheels, Nathan triple sight-feed lubricators for valves, Jerome packing for glands. Monitor injectors are used in both sides. The boiler is covered with asbestos, the mud-ring is double riveted, and the firebox contains a brick arch supported on tubes.

The following are a few of the leading dimensions

Cylinders, 20 in. diameter and 24 in. stroke.

Steam ports, 1¼ in. wide, 17 in. long.

Exhaust ports, 2½ in. wide, 17 in. long.

Lap of valve, ⅞ in.

Travel of valve, 5½ in.

Diameter of driving-wheels, 62 or 68 in.

Driving-wheel base, 13 ft. 6 in.

Total wheel base of engine, 24 ft. 4 in.

Total wheel base of engine and tender, 49 ft. 3 in.

Diameter of truck wheels, 30 in.

Diameter of boiler at smokebox end, 60 in.

Thickness of boiler sheets, ⅝ in.

Number of tubes, 247.

Length of tubes, 13 ft. 10½ in.

Thickness of tube sheets, ½ in.

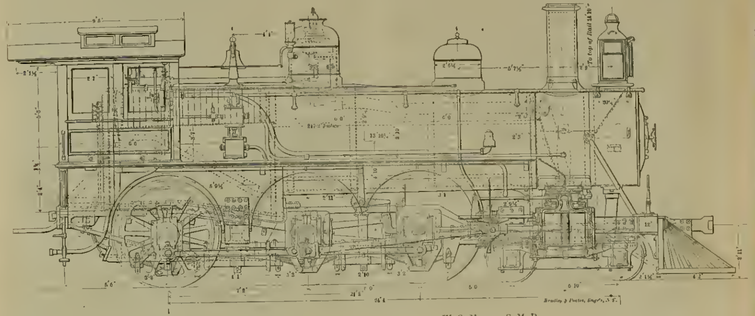
Steam pressure, 180 pounds per square inch.

Weight on drivers, about 108,000 pounds.

Total weight of engine, about 139,000 pounds.

Total weight of tender, about 68,300 pounds.

Tank capacity for water, 4,000 gallons; coal, 7 tons.



New Ten-Wheeler for C. & O. Ry. Designed by W. S. Morris, S. M. P.

## The Jackson Accident.

The month of October of this year has been memorable for the number of fatal accidents to passenger trains. An accident which happened at Jackson, Mich., on the Michigan Central, was not the most sanguinary in the list of disasters, but it was deplorably bad, for it cost thirteen lives besides much suffering to a long array of people who were severely injured. As the peculiar character of this collision has led to considerable discussion concerning the cause of the collision we have carefully collected the essential facts and submit them to our readers.

The first section of an excursion train to Chicago stopped at Jackson station to allow the passengers to eat breakfast. While standing there, protected by a semaphore signal, it was run into by the second section of the train. The rear car was crushed by the heavy locomotive, and it smashed the next car ahead killing and wounding the greater part of the unfortunate passengers who failed to get outside before the collision happened. The engineer of the train alleges that on approaching the station he applied his brakes, and finding that they failed to check the train he whistled for hand brakes. The conductor of the train, on hearing the whistle, pulled the air-valve in one of the cars, and his evidence is that no air escaped, so his prompt action was useless. After the accident occurred, it was found that the angle-cock at the back of the tender was shut, and attempts have been made to lead to the belief that a tramp, or some evil-disposed person, who was riding on the platform of the baggage-car, closed the angle-cock as the train was approaching Jackson station. When the railroad men went to pull back the train which had done the damage, they had to bleed the auxiliary reservoirs under the cars before the train could be moved.

The distance from Detroit to Jackson is seventy-six miles. In the course of that run the train was stopped four times and the brakes are reported to have worked perfectly. The last stop before reaching Jackson was at Grass Lake, which is ten miles distant. When stopping at this

### TANGYE'S HYDRAULIC LIFTING JACK.

A good, reliable jack for lifting or pushing in any direction. The lever is for pumping it up, the key lowers and stops it at any point, when it is again ready for lifting, saving time and trouble.

Various sizes made, from 4 tons to 200 tons.

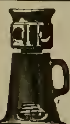
Joseph F. McCoy Co. 26 Warren St., NEW YORK.

### CUYAHOGA FALLS, O.

ROLLED HOLLOW STAY BOLTS ARE STRONGER AND SAFER THAN DRILLED ONES.

Mandrel rolled from the finest charcoal iron. All sizes, from ⅝ to 1¼ inch, with any sized hole required from ⅜ to $\frac{5}{8}$ inch. Let us send you a sample and quote prices. A set for one fire-box will convince you of their merits, safety and economy.

## THE CHAPMAN JACK.



PATENTED.

THE screw being lubricated and protected, the Jack is always ready for instant service. Railroad men appreciate the importance of having Jacks always in good working condition. Serious delays frequently occur in getting common Jacks so that they can be worked when suddenly required in train service.

Common Jacks are frequently destroyed in efforts to make them work quickly after the screws are set with rust and dirt. This consideration alone makes the Chapman Jack the most economical one to purchase.

THE CHAPMAN JACK CO., CLEVELAND, OHIO.

To begin, Students need only know how to read and write. **Moderate Charges. Diplomas Awarded. Send for Free Circular Giving Full Particulars.**

place to take water, the brakes stopped the train short of the water tank and the engineer had to use steam to reach the desired point, which indicated that the brakes were powerful enough to hold the train easily. The distance from Grass Lake to Jackson was passed at a very high rate of speed, evidence being given that the ten miles were run over in thirteen minutes. There is a descending grade all the distance of 14 feet to the mile. Jackson yard, which embraces the tracks connected with the locomotive repair shops, begins about a mile and a half east of the point where the accident occurred

It is in evidence that the engineer reduced the speed of his train as he entered the valve in the car. The natural inference is, then, that the engineer applied the brakes, but that the air supply left was not sufficient to control the train. Railroad men who were on the train say that there were several applications of the brakes made as the train was approaching Jackson. The supply of air was in this way exhausted

This reputed failure of brakes was like many others. There was excessively fast running, there were repeated applications of the brakes on approaching the stopping place, and when the final application was made there was not enough pressure of air remaining in the reservoirs to stop the train promptly.

---

It is surprising the number of freight cars that have been built within the last two years without having air brakes or couplers of the standard form. This seems to indicate very short sighted policy on the part of the owners. The extra cost of

It would have surprised some of the members of the Master Mechanics' Association to have noted the interest of the Traveling Engineers at their recent convention. Out of a total membership of 107 there was 78 answered roll call, and although the convention was held at the main gate of the great fair, 78 men answered every morning, and 90 per cent. got up on their pins and said something in debate. More interest was manifest than at any meeting of men we have ever attended.

During a speech to railroad men at Louisville, Ky., recently, Eugene V. Debs made the following statement "The

Group of Traveling Engineers, Taken on World's Fair Grounds, at the First Annual Meeting of the Association.

the yard, and that the brakes at that time showed no signs of failing in their functions. Engineer Whalen also asserts that he applied them again at a point which is about half way through the yard, and he had no reason then to suppose that anything was wrong; but that when he attempted to apply them as he came near the station they failed to check the train, and he called for hand brakes. These are the facts as they are carefully sifted by evidence submitted. It may be added that Whalen, the man in charge of the engine which did the damage, was a freight engineer.

The numerous air-brake experts among our readers will be certain to form conclusions for themselves as to the cause of the collision. For ourselves, we attach no importance to the theory that the accident was caused by the angle-cock being closed behind the tender, even though the cock was found closed half an hour after the collision. If the angle-cock had been closed when the train was running with the brakes released, there would have been a good pressure in the air-pipes, and that being the case the conductor would have heard the air escape when he pulled open the valve in the train; but if the angle-cock was open and the engineer applied the brakes with full force the train-pipe would be empty and the conductor would hear no air escape when he pulled open

### The Traveling Engineers Group.

This picture was taken on the World's Fair grounds with the thermometer at about 98 deg., so that about half the party refused to be parboiled for the sake of a picture. Commencing at the first row and reading from left to right the victims are

these improvements would not be very great when the cars are contracted for. As air-brakes and vertical plane couplers will be compulsory attachments soon for cars engaged on interstate commerce, it is strange to witness the apathy in some quarters about having the cars so equipped There is a belief that the day of reckoning can be put off, but we do not think there is much likelihood of the law being suspended to accommodate those who have displayed no disposition to comply with it.

In the course of a private letter, one of our most intelligent railroad master mechanics, who has visited the World's Fair many times says "One of the exhibits generally neglected by mechanics is the Ferris wheel. This is worth notice and study mechanically. It is a bold design, most skilfully and thoroughly executed in all details, and, to my mind, is the distinctive feature of the Exhibition. A creation, in fact, as creditable to the designer and executor as the Fair itself Most singularly, I do not find that railroad mechanics I meet are interested in the wheel generally. This is a mistake, I think, as it not only deserves its full share of attention, but cannot help leaving its influence on the average mind if made enough of a study to make its mechanical features understood."

home is the foundation of American government. Destroy that home and you destroy the government. I know railroad men pretty thoroughly, and I know they do not spend enough time in their homes. You spend too much time about the roundhouse, telling old chestnuts and descanting upon impossible runs you say you have made that were never made or never will be made. Spend your time at home, showing the pictures to the babies, or, if you are not married, spend your spare time with your sweetheart. Remember this No man ever landed in the penitentiary who spent all his leisure time at home."

Hereafter the Lukens Iron and Steel Company will conduct its railroad department direct from the works at Coatsville, Pa. Messrs Coolbaugh & Pomeroy, of 29 Broadway, this city, have been the railroad agents of this mill. The Lukens mill was established, in 1810 and made the first steel boiler plates in America. Their plates are being used very extensively by railroads now.

Don't fail to secure our three Educational Charts—if you don't want or don't need the yourself you know some bright apprentice boy who would think them priceless The paper is worth more than the $2 to you.

## Over the Chesapeake & Ohio.

"What brings so many Americans abroad to do European scenery when you have such magnificent scenery at home?" This question was asked by a Scotch gentleman, as a passenger train was speeding over the fine track of the Chesapeake & Ohio Railway through the Kanawha Valley, in West Virginia. The party had gone through from Washington, and were filled with admiration of the rich country through the battle-fields of the war that are so numerous between the Potomac and Staunton, Va. Between Alexandria and Staunton we hear such names as Manassas,

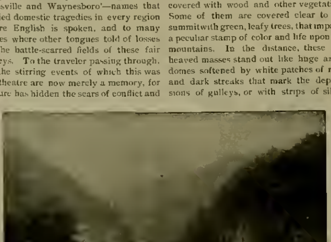
HAWK'S NEST CAÑON.

Rappahannock, Rapidan, Orange, Charlottesville and Waynesboro'—names that carried domestic tragedies in every region where English is spoken, and to many places where other tongues told of losses on the battle-scarred fields of these fair valleys. To the traveler passing through, all the stirring events of which this was the theatre are now merely a memory, for Nature has hidden the scars of conflict and it looks as if the red rain of that fierce strife still makes the harvest grow.

As time heals the sores of the great conflict the trip through the battle-fields of Virginia will grow in popularity, for no scenes on earth attract the attention of mankind so eagerly as the fields where brave men fought and fell. These scenes will be classic ground that future generations will ponder over as seriously as they now do over the battle-fields of Marathon, of Bannockburn and of Waterloo.

As the train speeds westward the traveler's eyes are feasted with fine views of the Piedmont Valley, with its smiling farms and picturesque woods—a valley so striking to view that Governor Spotswood on first seeing it gazed in admiration and exclaimed, "Behold! the Valley of the Euphrates!" He had seen the most imposing scenes in many lands, and compared this with the most striking within his memory; and yet the Virginia Valley was the fairest of them all. Crossing many a clear running stream, darting through stretches that look English manor parks, but richer in foliage and more luxuriant in vegetation, we draw toward the Alleghany Mountains. The railroad in its way from the Chesapeake to the Ohio follow a series of natural passes, and traverses the route that the earliest inhabitants of this continent used in their journeys for trading or war purposes. After a long climb, twisting round bold hillsides and toiling over many a rock cutting and steep embankment, we rush into the darkness of a long tunnel which cuts through the summit of the highest mountain pass. From here we descend into West Virginia through the most picturesque scenes of the Alleghanies.

The mountains present many majestic views from the east side, but the wildest, most rugged and most impressive scenes are witnessed as we descend the western slope. While the scenery possesses peculiar grandeur, its magnitude is on a smaller scale than the best known Rocky Mountain scenery; but nevertheless, it is more attractive to those having an eye for variety of tints and harmony of coloring. The Rocky Mountain scenes are striking for their savage desolation where the projected rocks tower up in lifeless bareness. The Alleghany scenes are all clothed. Everywhere we see gray rocks and rugged crags standing out in all their native bareness, but the mountains as a whole are covered with wood and other vegetation. Some of them are covered clear to the summit with green, leafy trees, that impress a peculiar stamp of color and life upon the mountains. In the distance, these upheaved masses stand out like huge azure domes softened by white patches of rock and dark streaks that mark the depressions of gulleys, or with strips of silver where water brooks and cascades gleam in the sunshine.

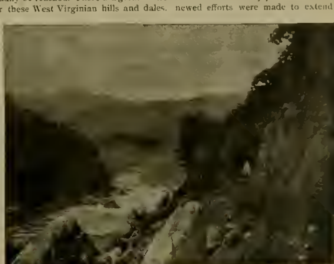


NEW RIVER.

From the summit of the mountains to Charleston, a run of about 150 miles, the scenery is the finest I have ever seen, but the earth, torn into fantastic forms, is not the only attraction. There are mixed with the scenery the source of natural riches which await only the hand of labor and the breath of capital to fill the wilderness with comfortable homes. Running into the wilds there are numerous small valleys with excellent farm lands. These will some day be cultivated, for they lie in

NEW RIVER VALLEY.

a genial climate, where all varieties of crops can be grown. Some of them are now under cultivation, but these are merely enough to show the natural riches of the land. The woods afford fine protection for stock, and thousands of cattle could be wintered in the lower regions with next to no attention. The mountains are full of iron and coal, and their sides are covered with valuable timber that can readily be reached. There is a great future for these West Virginian hills and dales.



CAÑON OF NEW RIVER.

The railroad that has opened up this wilderness to easy reach is worthy of more than a passing notice. It is many years since efforts were made to join the Chesapeake and Ohio rivers by a railroad traversing the shortest passes through the intervening mountains. Railways were no sooner demonstrated to be a more successful means of intercommunication than canals before the progressive statesmen of Virginia began to agitate the connecting of the Old Dominion with the rising sun of prosperity beyond the mountains by means of a railroad. A dearly cherished, far-seeing scheme was to bring the agricultural products of the Mississippi Valley to the Chesapeake for shipment. There appeared to be a possibility of making Norfolk or some other port on the Chesapeake Bay an active rival of New York.

In 1835 the Louisa Railroad Company was incorporated, with authority to build from a point on the Richmond, Fredericksburg & Potomac to Gordonsville, or beyond to the mountains if found desirable. This was the first link in the chain that subsequently formed the Chesapeake & Ohio system, but it was a weak one for many years. Others were slowly forged. The Virginia Central Railroad Company was formed out of several valuable railroad fragments, and it did the first important work of connecting the broken links. It swallowed the Louisa Railroad among others. When the war broke out in 1861, there were detached railroads with small intervening blanks that dotted the route from Richmond to Charleston, W. Va. The war put an end to this kind of improvement for a time.

Peace was scarcely proclaimed when renewed efforts were made to extend the railroad westward. The States of Virginia and West Virginia offered valuable inducements for the Virginia Central to push the line through to the Ohio River. In 1867 the offers were accepted, and the following year active operations were commenced, the name of the reorganized company being changed to the Chesapeake & Ohio. The work of building the blanks connecting the finished portions of the system proved much more expensive than was anticipated, but the work was accomplished within five years, and a splendid new route between the East and West established. Prosperity did not smile for many years on those who had risked their money in building this boon to the Virginians. The road had been costly and trade developed slowly. The towns and farms and mines and timber lands along the route increased rapidly in value, but

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

the road struggled on in poverty till within a few years. It may now be regarded as one of the best railroad properties in the country.

Of late years the management have devoted close attention to developing the natural resources of the country traversed, and the road is reaping the benefit. Road-bed and rolling stock and methods of operating display the effects of good management. There are about 1,300 miles of track operated. The company have 350 locomotives and 13,000 cars. No railroad in America has a better quality of cars and locomotives. President Ingalls has reason to be proud of the material progress of the road since he took charge. His policy of management is fairly carried out by an excellent staff of executive officers, with General Manager Stevens at their head.

### Engineer to Be Responsible for Protecting Train.

In the course of an admirable article on railway accidents, read at World's Railway Congress by Colonel Haines, president of the Plant Railway System, the following paragraph occurs

"It is safe to say that a majority of the rear collisions between stations are due to a failure of the flagman to comply with the rules prescribed by the standard code for his guidance. Here is the principal cause of rear collisions, and here a remedy should be applied by relying less upon the intelligent and willing discharge of the duties thus placed upon the flagman. The most intelligent and most experienced man in the train crew should be the engineer; the best acquainted with the curves, grades, bridges, cuts, embankments and other physical characteristics of the road; the best informed as to the trains passed and to be passed, and when a stop is made or the train slows down at an unusual place he knows the cause and the probable detention, not only after it occurs, but also before, and can often select the safest place for a stop. It is he, then, and not the flagman or conductor, who should determine when the rear of his train is to be protected, and the flagman should act promptly when the signal is given to him, but not before, except in emergencies that can readily be suggested. If the burden be plainly put upon the engineer to determine and upon the flagman to act, the action of the latter would be controlled by the most intelligent and best informed man of the train crew."

Throughout the paper Colonel Haines argues with much force in favor of the block system, but admitting that many railroads cannot afford to introduce this system, owing to the great expense, urges the adoption of improved methods of flagging. The plan of protecting a train by sending back a flagman is such a crude one that most people consider it unworthy of being reduced to a system, and so the protection of trains stopped between stations is put on a brakeman, who may or may not think it necessary to go back. The proposal to put the protection of the train in control of the engineer is good, but it has its drawbacks. Colonel Haines is an old locomotive engineer himself, and has probably considered all the disadvantages, as well as the advantages, of the plan he proposes, but concludes that the gains in the interest of safety are sufficient to offset the losses. One objection which occurs to us is that the engineer being at the head of the train might have difficulty in finding out if the flagman has obeyed the order to go back. Another objection is that the train may be stopped owing to some disorder of the engine, which monopolizes the attention of the engineer to such an extent that he forgets all about protecting the rear end. We understand, however, that the plan is in operation on the roads of which Colonel Haines is president, and presumably it works well or it would not be recommended for general adoption.

---

We have received a very fine specimen of work done on a new forming lathe built by the Meriden Machine Tool Co., Meriden, Conn. For small brass parts they fit up special tools for their lathe, that finish an ordinary piece, such as a torch-top, at one movement of a lever.

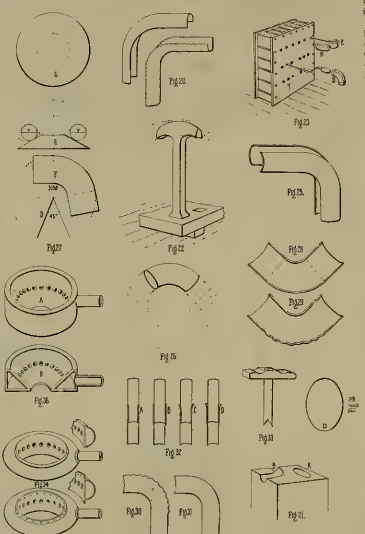
### *Railroad Coppersmithing—III.

By John Fuller, Sr.

MADE BENDS.

When bends are made directly from the sheet, and not formed by filling the ready-made pipe and then bending, we have two ways of doing it. One way the seams are at the sides, the other the seams are in the throat and at the back. When the seams are at the side, the inner piece is called the saddle, the outer piece the back. To make a bend saddle and back, take two strips of copper, each one-half the circumference of the pipe desired in width; let the saddle piece be nearly the diameter of the pipe shorter than the back piece; file brought round to the template by hollowing the center of the back in a hollowing-block, Fig. 21, allowing the wrinkles to come up regularly until the back has curled about a third less circle than the template. Now gradually work out the wrinkles, first a little on one side right around it, and then on the other, then over a T stake, as shown in Fig. 22, until they are all worked down and the sides are smooth and the edges fit the edges of the saddle half. Then thin each side with a double piened hammer, Fig 5, on the inside of the two half saddles and back and file the edges true along them.

They will now be ready for softening and cleaning, which is done at one and the same time by covering the parts with a



edges of each piece up carefully, half-round, with a fine-cut file, so that there are no rough burrs nor small cracks made by the shears in cutting the strips left in them. Bend each piece to the working template. It will be found that the saddle, as the edges are being worked over on a mandrel, has a tendency to straighten out too far away from the template; this may be obviated by bending the saddle piece before commencing a third smaller than the bend is required when finished, as shown in Fig. 20; that is, if a mallet is used in making the saddle. If the saddle is made with a hammer and drawn over on the anvil, shown in Fig. 4, the hammer will curl it round enough to bring it to the template as the work proceeds, because the edges will be drawn longer. When the work is performed with a mallet, the center is upset nearly as much as the edges of the strips are drawn, and therefore the thickness is more equalized and a much better bead obtained. The back is turned in a similar way, under the same conditions as the saddle, and the edges are puckered or wrinkled at regular intervals and then

strong brine of salt and water and heating them to a cherry red (out of the sunshine), and quenching them in a vessel or trough of clear water, and scouring them with a clean wisp of tow and clean sand and water. The saddle is now ready for cramping, as shown in Fig. 20. When cramped, open the outside cramps with the tweezer (Fig. 9), and bring the back to the saddle; let one cramp go inside and one outside; pull them up together in a vise, and see that the joint is evenly lapped along it, and wire them fast together as shown in Fig. 23. Dress down the cramps and hammer them close and even on a bent mandrel *H*, and a cod to fit. A cod is an egg-shaped casting, Fig. 24, having a square hole through its transverse axis, so that it can be keyed on a square iron mandrel, bent as shown at *D* and *E*, one end of which is fastened in the mandrel block *T*, Fig. 23. After the joint is laid and the cramps are hammered down smooth, chatter the joint, when it may be charged with spelter and made ready for the fire.

SEAM IN THROAT AND BACK.

We will now work on the other two halves, top and bottom, Fig. 25. In working these two halves into shape, the method usually adopted by workmen is to draw down the throat on an anvil, Fig. 4, and then hollow up the back in a block, but this is not at all satisfactory, nor can a real good job be done in this way, because the throat is drawn much too thin by the hammering, and there is considerable difficulty in keeping the work to the template; then, again, there is an excess of stuff in the back which must be cut off; yet this method is still in use. While engaged at this kind of work, the writer discovered a very much easier and better way of doing this work, by which the throat is scarcely touched and no excess, if proper care is exercised in working, and when the bend is finally shaped, the throat is practically the same thickness as the sheet from which it was cut.

This method I have never taught to any but one apprentice boy, and it is given to the trade direct for the first time now—that is, the formula for cutting the pattern and the manner of working it up. It is known that bends are in the abstract but sections of a hollow cylindric ring, and a square bend is one-fourth of a hollow ring, having the straight part, if any, joined to it or left unbent. A little mathematical knowledge is now necessary for one to be able to fully understand the groundwork or the theoretical part. Referring to Fig. 26, let the inner dotted diameter of the diagram be equal to 9, and the diameter of the pipe *X* equal 6; then the outside diameter of the diagram will be 21. Now we want to unroll the outside edge of one-half of this hollow ring (see Fig. 27) when cut horizontally, }`}'¹, and form it into a frustum of a cone, *E*. To do this we proceed thus First find the convex surface of the whole ring. Here the inner diameter of the ring is 9, and the thickness or size of the pipe is 6; then

$$(9+6)\times 6=15\times 6=90, \text{ and } 90\times(3.1416)^2= 90\times 9.8698=888.2820,$$

the convex surface of the whole ring, then $\frac{888.2820}{2}=444.1410$, one-half the surface, and $\frac{444.1410}{.7854}=565.4964+$. Now add the square of 9, the inner diameter of the bend or ring, to this last result, and $565.4964+81=646.4964$. Extracting the square root of this last sum gives us 25.4262, the outside diameter of the circular disk *G*, Fig. 27. Now we want to transform the flat disk-ring, *G*, into a frustum of a cone, *E*, whose convex surface is equal to the flat disk-ring, *G*. Practice has shown that a frustum of a cone formed of 315° of a circular ring is the best pitch it can have to obtain the result required with the least work. To raise this disk-ring *G* to a frustum of a cone, proceed thus

$\frac{25.4262\times 3}{5.25}=14.5292$, the radius or slant height of the complete cone, of which the frustum *E* is a part. Now take for a square bend one-fourth of 315° of the circle *D*, or 78.75°, one-half the circumference of the pipe in width *F*, and add to it whatever is required for the straight part at either end, if any; then round up the edges (as before directed) smooth with a fine-cut file, and the pattern is then ready for forming up into a half bend, proceeding as follows Take two pieces of copper, *F*, and curl them round a third smaller in diameter in the throat, Fig. 28, than they are required to be, the circular part forming one-fourth of the cone *E*, and turn them right and left in opposite directions, forming one-fourth of a cone with the part intended to form the bend. Now turn the throat in a course, Fig. 28, on a suitable mandrel with a round-faced mallet to begin the forming; then turn the outer edge up a course, and pucker or wrinkle the edge at regular intervals, as shown in Fig. 29; then take it to a hollowing-block, Fig. 21, and sink it in the hollow in the corner, letting the wrinkles come in regularly all alike, until it is curled up enough, Fig. 30; now work out the wrinkles partly in the block on the inside, and part on a cod outside, until the

Midland, together with a justification of their authenticity, he will add a valuable page to his history of the locomotive engine, but until then we must accept Mr. Hedley's version as the probable one.

*London, Eng.* MERNOK

### That Foreigner.

*Editors*:

The engine illustrated on page 397 of your issue for the month of September is not a German, but a French one, belonging to the Paris, Lyons & Mediterranean Railroad. It was built in 1854 by André Koechlin, of Mulhausen (now the Societé Alsacienne de Constructions Mécaniques, in Belfort, France).

The engine has since been reboilered, the new boiler being of the type adopted since 1869 by the P. L. M. R. R.

The dimensions are as follows

Diameter of driving-wheels, 5 ft. 5 in.
Heating surface, firebox, 72.44 sq. ft.
" " flue tubes, 927.31 "

Total, 999.75 "

Grate area, 12.27 sq. ft.
Working pressure, 106 lbs.
Diameter of pistons, 15¾ ins.
Stroke of pistons, 22 ins.
Wheel base, 10 ft. 10 in.
Weight, empty, 60,390 lbs.
Weight, in working order, 67,364 lbs.
Weight on each coupled wheel in working order, 24,860 lbs.

The tender accompanying the engine is a four-wheeled one; it was built in 1856 by Parent et Shaken (now the Fives-Lille Co.).

Weight, empty, 25,102 lbs.
Capacity of water-tank, 1,498 gallons.
Weight of coal carried, 8,800 lbs.
Weight in working order, 48,400 lbs.
Diameter of wheels, 3 ft. 7.3 ins.

Amongst features of interest note forked connecting-rod, overhanging firebox, and the position of cylinders ahead of the smokebox. There are many engines of this type still running on the French railways.

E. GOBERT.

*London, W. C., Eng.*

### Jigs for Drilling.

*Editors*:

About the first thing that caught my eye in the September issue of your paper was the clipping from an English paper and your comments thereon, under the above heading.

"A jig is merely a device for holding work so that machine work may be done on a number of the same kind of pieces precisely the same way"

Probably it is in your office, but it is not so always in modern shop practice. I have made a great many jigs in my time and the work held the jig, especially in use on a drill-press.

When a device is secured to the machine it becomes a chuck, nothing more nor less. A chuck is a device for holding the work to be operated upon. It may be either movable or fixed. If attached to the rotating spindle, it is movable; if rigidly secured to the platen or table, it is fixed. Its shape or form alters not its real name, although when in the latter condition it sometimes is termed a vise.

Suppose, for instance, we have several flanges 8 inches square to have holes drilled in them equi-distant; our jig would be a cast-iron, spider-shaped affair having ears projecting at right angles to its face from the edges, and a clamp-screw to prevent its lifting from the work, and where the holes were to be drilled in the flanges we would put hardened steel thimbles in it, with holes in them just the size of the holes to be drilled. This is the simplest form of jig, and the piece to be operated upon actually holds the jig, and is perfectly free at all times to be moved about upon the table Often the nature of the work requires a special form of drill, which is used for no other purpose whatever

There are some people who call this type of a jig a "template," but a template is used for *laying out* the work to be done, and is not used for doing it; skilled labor being required to secure "accuracy and perfection" afterwards, which does not exist in any form whatever. The "jig" does the multiple parts perfectly, and requires generally nothing more than a good stocky boy.

"A device that insures accuracy and interchangeability without 'setting' or measuring each piece," as you state it, is not a "jig" always by any means, as an angle plate could be used to do all that you state, and nobody in the shop would think of calling it a jig.

W. S. ROGERS.

*Troy, N. Y.*

[Mr. Rogers may have only stated the facts in his letter, yet this does not prove that our description of a jig was not correct. Other things may be used for the same purpose, yet a jig is just what we said it was.]

### Fast Running Half a Century Back.

*Editors*:

Below I give an old English "working time-table" for Great Western express trains. It is dated 1845. The engines employed on the service had 16 x 24 in. cylinders, a single pair of 7 ft. driving-wheels, and were practically smaller editions of the "Lord of the Isles" (1847 type now at the World's Fair. The original gauge of the Great Western was 7 ft — the widest ever employed, I believe. Eventually the company used the broad and standard gauges in conjunction, but up to the last the 7-foot gauge maintained its popularity with travelers, and the fastest passenger trains were always run on it.

### A New Safety Angle-Cock.

*Editors*:

The angle-cock seems to be the center of attraction with railroad men just at the present time, for it seems to be the missing link to air-brake perfection or absolute safety. The demand is for an angle-cock that cannot be either maliciously or accidentally moved from its proper running position without the knowledge of the engineer or train crew.

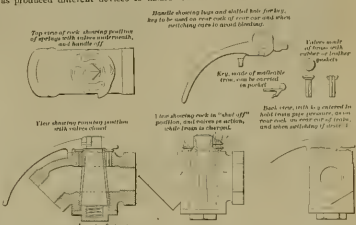
There has been many disastrous wrecks and great loss of life which can be attributed to the closing of an angle-cock between the time of leaving a station and stopping at the next. Imagine, if you can, the suspense an engineer is in running along sixty miles per hour and knowing there are four or five tramps on the head end of mail or express car, some of them sitting on car platform with their legs hanging down and feet resting on angle-cock on rear of tender. Now, then, the safety of this train, the lives of the passengers, the crew and the tramps all depend on whether this particular tramp carelessly closes the angle-cock or not. I well remember an accident that occurred on one of our trunk lines by "an air-brake failure."

On investigation, it was found that the end of a broken brake-rod had thrashed around on the ground until finally it turned up in such a position as to close the angle-cock, and the inevitable accident happened, and as is always the ease, was head-lined in the papers as an accident caused by "failure of air-brakes." In reality it was a failure of air-brakes, but one that could have been avoided.

Why is it that in this age of progress this condition of affairs is allowed to exist? Air-brake companies and some "first-cost" railroad officials may say that there is a great deal of imagination or apparent fear that is causing the demand for a safety or automatic angle-cock. Now, imagination is one thing and a twenty or thirty thousand dollar accident accompanied by the loss of several lives is another, and very substantial evidence that something is wrong.

After several years of careful study, I must say that I think the angle-cock the one weak part in what is otherwise an absolutely safe device for stopping trains.

There have been of late a great many articles written and suggestions made to overcome this dangerous point in air-brake practice. I notice that inventive genius has produced different devices to insure safety, which are worthy of only a passing notice, from the fact that their operation causes a delay in pumping off brakes at division terminals or points on the road where it is necessary, from any cause, whatever, to cut the train. Delay is one thing, disaster another. But the former frequently contributes to to the latter. Why not do away with both as near as lies in our power.



Mr C. Skinner, general foreman of the O. & M. shops, at Washington, Ind., comes to the front with an angle-cock which, in the opinion of all the practical men who have seen it, fills the bill, and makes the angle-cock a safety instead of a danger device. I trust you will give the blue print sent herewith space in your paper, so that it will pass under the eyes of the critics. It is simple in its construction, and the accompanying cut is self explanatory. The small key is to be inserted in the handle in case the train is to be cut, and on rear of train, this prevents valves from raising, otherwise air will escape and apply the brakes as in emergency. When handle is in running position, it is so arranged that both small valves are closed, but when moved to cut-out position the train-pipe is bled and the train stops suddenly.

This valve cannot be "monkeyed" with or closed accidently or through malice without stopping the train then and there.

S. D. HUTCHINS.

### Some Odd Troubles on the Road.

*Editors*

On page 441, December, 1892, number of LOCOMOTIVE ENGINEERING, F. S. Thorne, of Brandon, Manitoba, asks how to prevent the water freezing up in the delivery-pipe from air-pump to main reservoir. If the main reservoir is on the engine, have the pipe tapped into *top* of reservoir, and not into the end, so the pipe will be perpendicular at that point, and it will not give the water any chance to lay there. If there is any brass about this coupling, either the piece screwed into the drum, or the nut and collar, take them out and substitute iron. Brass is a better conductor of heat than iron, and the water, or even vapor, that comes through the pipe will freeze fast in a brass coupling where it would pass an iron one. Our whistle signal reducing-valve is connected to the train line pipe in the cab, where we can get at it handily, and as far from the boiler as the width of cab will permit. It does not freeze up there, but we have trouble from their gumming up in a short time, which they will not do when outside. If the reservoir is placed on top of back end of tender, don't try to keep it from freezing up; that is what they are put on the back end of tender for, *to freeze up*.

Some time ago I found an engine blowing through, we placed her in proper position and tested her, when all the signs showed the blow was in piston packing on left side. A few days previous it was decided she was blowing through in that manner; the old packing rings were taken out and new ones that fitted the cylinder very close and nice were put in, but she blowed just as bad—if any change was noticed she got gradually worse. Of course, after that, it was a sure thing that the blow was in the valve, which must be faced. To settle the matter we placed the engine, where she blowed through worst, just back of top quarter left side, took off the forward cylinder-head, hooked her clear in ahead, gave her steam, and it was easily seen by the way the steam came past the piston where the trouble was. The rings were just a little too wide, and were "follower bound," so the first time the engine was shut off the play up and down of spider crowded the rings in and they did not spring back. Those rings were dressed down to the right thickness and stopped that blow

Here is another case The engine blowed bad in 10 inches, but not any when valve covered all ports, of course, it was settled that the packing was at fault Cylinder-head was taken off engine brakes set and throttle opened a little. No steam came past the piston when in any part of its stroke, but when the valve was moved to forward end of its travel, steam came out of the port in great volume The valve-seat was hollowed out, and, as usual in such cases, the valve did not fit tight at all parts of its stroke Both of these engines, when tested out on the road, gave the same symptoms, yet had different diseases.

One of our engines had a boiler check that was a chronic for sticking up, in which case the check-valve in end of injector generally failed to work, so water from boiler went back into tender unless the overflow and lazy cock shut tight. It was taken down and ground in, the wings of the valve cased off, lift regulated and everything done that could be thought of It was finally fixed by taking the delivery-pipe from injector to boiler check off the boiler, and standing it up on end, when a piece of the brass check-valve that belongs in the end of a Sellers injector slid out. When the injector was working, this

Midland, together with a justification of their authenticity, he will add a valuable page to his history of the locomotive engine, but until then we must accept Mr. Hedley's version as the probable one.

*London, Eng.* MERNOK.

### That Foreigner.

*Editors*:

The engine illustrated on page 397 of your issue for the month of September is not a German, but a French one, belonging to the Paris, Lyons & Mediterranean Railroad. It was built in 1854 by André Koechlin, of Mulhausen (now the Societé Alsacienne de Constructions Mécaniques, in Belfort, France).

The engine has since been reboilered, the new boiler being of the type adopted since 1869 by the P. L. M. R. R.

The dimensions are as follows

Diameter of driving-wheels, 5 ft. 5 in.
Heating surface, firebox, 72.44 sq. ft.
" " flue tubes, 927.31 "

Total, 999.75 "

Grate area, 12.27 sq. ft.
Working pressure, 106 lbs.
Diameter of pistons, 15¾ ins.
Stroke of pistons, 22 ins.
Wheel base, 10 ft. 10 in.
Weight, empty, 60,390 lbs.
Weight, in working order, 67,364 lbs.
Weight on each coupled wheel in working order, 24,860 lbs.

The tender accompanying the engine is a four-wheeled one; it was built in 1856 by Parent et Shaken (now the Fives-Lille Co.).

Weight, empty, 25,102 lbs.
Capacity of water-tank, 1,498 gallons.
Weight of coal carried, 8,800 lbs.
Weight in working order, 48,400 lbs.
Diameter of wheels, 3 ft. 7.3 ins.

Amongst features of interest note forked connecting-rod, overhanging firebox, and the position of cylinders ahead of the smokebox. There are many engines of this type still running on the French railways.

E. GOBERT.

### Jigs for Drilling.

*Editors*:

About the first thing that caught my eye in the September issue of your paper was the clipping from an English paper and your comments thereon, under the above heading.

"A jig is merely a device for holding work so that machine work may be done on a number of the same kind of pieces precisely the same way."

Probably it is in your office, but it is not so always in modern shop practice. I have made a great many jigs in my time and the work held the jig, especially in use on a drill-press.

When a device is secured to the machine it becomes a chuck, nothing more nor less. A chuck is a device for holding the work to be operated upon. It may be either movable or fixed. If attached to the rotating spindle, it is movable; if rigidly secured to the platen or table, it is fixed. Its shape or form alters not its real name, although when in the latter condition it sometimes is termed a vise.

Suppose, for instance, we have several flanges 8 inches square to have holes drilled in them equi-distant; our jig would be a cast-iron, spider-shaped affair having ears projecting at right angles to its face from the edges, and a clamp-screw to prevent its lifting from the work, and where the holes were to be drilled in the flanges we would put hardened steel thimbles in it, with holes in them just the size of the holes to be drilled. This is the simplest form of jig, and the piece to be operated upon actually holds the jig, and is perfectly free at all times to be moved about upon the table. Often the nature of the work requires a special form of drill, which is used for no other purpose whatever.

There are some people who call this type of a jig a "template," but a template is used for *laying out* the work to be done, and is not used for doing it; skilled labor being required to secure "accuracy and perfection" afterwards, which does not exist in any form whatever. The "jig" does the multiple parts perfectly, and requires generally nothing more than a good stocky boy.

"A device that insures accuracy and interchangeability without 'setting' or measuring each piece," as you state it, is not a "jig" always by any means, as an angle plate could be used to do all that you state, and nobody in the shop would think of calling it a jig.

W. S. ROGERS.

*Troy, N. Y.*

[Mr. Rogers may have only stated the facts in his letter, yet this does not prove that our description of a jig was not correct. Other things may be used for the same purpose, yet a jig is just what we said it was.]

### Fast Running Half a Century Back.

*Editors*:

Below I give an old English "working time-table" for Great Western express trains. It is dated 1845. The engines employed on the service had 16 x 24 in. cylinders, a single pair of 7 ft. driving-wheels, and were practically smaller editions of the "Lord of the Isles" (1847 type now at the World's Fair. The original gauge of the Great Western was 7 ft.—the widest ever employed, I believe. Eventually the company used the broad and standard gauges in conjunction, but up to the last the 7-foot gauge maintained its popularity with travelers, and the fastest passenger trains were always run on it.

### A New Safety Angle-Cock.

*Editors*:

The angle-cock seems to be the center of attraction with railroad men just at the present time, for it seems to be the missing link to air-brake perfection or absolute safety. The demand is for an angle-cock that cannot be either maliciously or accidentally moved from its proper running position without the knowledge of the engineer or train crew.

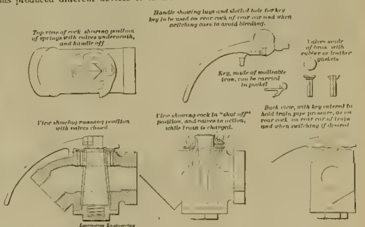
There has been many disastrous wrecks and great loss of life which can be attributed to the closing of an angle-cock between the time of leaving a station and stopping at the next. Imagine, if you can, the suspense an engineer is in running along sixty miles per hour and knowing there are four or five tramps on the head end of mail or express car, some of them sitting on car platform with their legs hanging down and feet resting on angle-cock on rear of tender. Now, then, the safety of this train, the lives of the passengers, the crew and the tramps all depend on whether this particular tramp carelessly closes the angle-cock or not. I well remember an accident that occurred on one of our trunk lines by "an air-brake failure."

On investigation, it was found that the end of a broken brake-rod had thrashed around on the ground until finally it turned up in such a position as to close the angle-cock, and the inevitable accident happened, and as is always the case, was head-lined in the papers as an accident caused by "failure of air-brakes." In reality it was a failure of air-brakes, but one that could have been avoided.

Why is it that in this age of progress this condition of affairs is allowed to exist? Air-brake companies and some "first-cost" railroad officials may say that there is a great deal of imagination or apparent fear that is causing the demand for a safety or automatic angle-cock. Now, imagination is one thing and a twenty or thirty thousand dollar accident accompanied by the loss of several lives is another, and very substantial evidence that something is wrong.

After several years of careful study, I must say that I think the angle-cock the one weak part in what is otherwise an absolutely safe device for stopping trains.

There have been of late a great many articles written and suggestions made to overcome this dangerous point in air-brake practice. I notice that inventive genius has produced different devices to insure



safety, which are worthy of only a passing notice, from the fact that their operation causes a delay in pumping off brakes at division terminals or points on the road where it is necessary, from any cause, whatever, to cut the train. Delay is one thing, disaster another. But the former frequently contributes to the latter. Why not do away with both as near as lies in our power.

Mr. C. Skinner, general foreman of the O. & M. shops, at Washington, Ind., comes to the front with an angle-cock which, in the opinion of all the practical men who have seen it, fills the bill, and makes the angle-cock a safety instead of a danger device. I trust you will give the blue print sent herewith space in your paper, so that it will pass under the eyes of the critics. It is simple in its construction, and the accompanying cut is self explanatory. The small key is to be inserted in the handle in case the train is to be cut, and on rear of train; this prevents valves from raising, otherwise air will escape and apply the brakes as in emergency. When handle is in running position, it is so arranged that both small valves are closed, but when moved to cut-out position the train-pipe is bled and the train stops suddenly.

This valve cannot be "monkeyed" with or closed accidently or through malice without stopping the train then and there.

### Some Odd Troubles on the Road.

*Editors*:

On page 441, December, 1892, number of LOCOMOTIVE ENGINEERING, F. S. Thorne, of Brandon, Manitoba, asks how to prevent the water freezing up in the delivery-pipe from air-pump to main reservoir. If the main reservoir is on the engine, have the pipe tapped into *top* of reservoir, and not into the end, so the pipe will be perpendicular at that point, and it will not give the water any chance to lay there. If there is any brass about this coupling, either the piece screwed into the drum, or the nut and collar, take them out and substitute iron. Brass is a better conductor of heat than iron, and the water, or even vapor, that comes through the pipe will freeze fast in a brass coupling where it would pass an iron one. Our whistle signal reducing-valve is connected to the train line pipe in the cab, where we can get at it handily, and as far from the boiler as the width of cab will permit. It does not freeze up there, but we have trouble from their gumming up in a short time, which they will not do when outside. If the reservoir is placed on top of back end of tender, don't try to keep it from freezing up, that is what they are put on the back end of tender for, *to freeze up*.

Some time ago I found an engine blowing through; we placed her in proper position and tested her, when all the signs showed the blow was in piston packing on left side. A few days previous it was decided she was blowing through in that manner, the old packing rings were taken out and new ones that fitted the cylinder very close and nice were put in, but she blowed just as bad—if any change was noticed she got gradually worse. Of course, after that, it was a sure thing that the blow was in the valve, which must be faced. To settle the matter we placed the engine, where she blowed through worst, just back of top quarter left side; took off the forward cylinder-head, hooked her clear in ahead, gave her steam, and it was easily seen by the way the steam came past the piston where the trouble was. The rings were just a little too wide, and were "follower bound," so the first time the engine was shut off the play up and down of spider crowded the rings in and they did not spring back. Those rings were dressed down to the right thickness and stopped that blow.

Here is another case. The engine blowed bad in 10 inches, but not any when valve covered all ports, of course, it was settled that the packing was at fault. Cylinder-head was taken off, engine brakes set and throttle opened a little. No steam came past the piston when in any part of its stroke; but when the valve was moved to forward end of its travel, steam came out of the port in great volume. The valve-seat was hollowed out, and, as usual in such cases, the valve did not fit tight at all parts of its stroke. Both of these engines, when tested out on the road, gave the same symptoms, yet had different diseases.

One of our engines had a boiler check that was a chronic for sticking up, in which case the check-valve in end of injector generally failed to work, so water from boiler went back into tender unless the overflow and lazy cock shut tight. It was taken down and ground in, the wings of the valve eased off, lift regulated and everything done that could be thought of. It was finally fixed by taking the delivery-pipe from injector to boiler check off the boiler, and standing it up on end, when a piece of the brass check-valve that belongs in the end of a Sellers injector slid out. When the injector was working, this

broken valve would get up under the check and hold it open. Each time the check was inspected, when the valve was lifted out, the piece would drop back down into the delivery-pipe and stay there, ready for the next chance to hold the check up. Moral—When you have a check that stays up too often, examine the delivery-pipe for stray chunks of scrap.

Some of the old-style Sellers injectors refuse to prime. An engine came in the other day, neither injector would prime. After a long trial, a bucket of cold water was secured to cool them off. Just as we were going to pour it on one of them, the bottom of the iron bucket hit the body of the injector a smart blow, and presto! she primed at once before the cold water touched it. The combining tube was stuck, probably the jar loosened it. The regular engineer for this engine was "onto this case," as the head of the bolt holding the injector to the boiler bracket was pounded flat where he had jarred it to loosen combining tube.

One of our engines kept shearing the bolts in front end of main rod off; did it right along for steady business, one or two each trip; so the engineer carried three or four extra bolts always on going out. The holes in strap and rod were reamed out to a perfect fit, pin in crosshead trued up, brasses made O. K., but it did not help her any. Finally, it was seen that the key did not touch the end of rod, but that all the bearing was on the back part of slots in strap. A thin liner was put in between the key and rod, so key did not touch the bottom of key-way in strap, and no more bolts were broken. After the trouble was located the key-way in strap was filed out so all the bearing was on the rod, and trouble was over.

A fast express engine with a good record of nearly a year's service without a hot box, suddenly began to have a hot driving-box every trip. She was put on a local freight to cool her down so she could be used on her own run again, and still got very hot. Engine was jacked up, so box was lifted off axles, when it was seen that oil recess in top of brass was worn out, leaving a spot half an inch in diameter for oil to get at the journal. It was not enough for that purpose. A good deep crease was made with a cape chisel. The box has not been warm since in the fastest kind of service.

One of the air-pump governors refused to attend to its work as it should. When engine had 125 pounds of steam, pump would pick up to 40 pounds of air. When she had 160 pounds of steam she would get about 55 pounds of air, and not stop altogether, but pump very slow. Took down the governor, and took out a small scale of iron that had got under valve 14, Plate B 2, N. Y. A. B. Co. Steam at 125 pounds just about balanced air at 40 in the governor. Of course, at 160 it would hold the valve open against a greater pressure of air. The small hole drilled through the seat in the New York governor gave the pump a chance to work slow.

The above are not hard puzzles when you know how, but they "tied up" some good men when they first happened.

C. B. Conger.

*Grand Rapids, Mich.*

### What is a Patent Good For?

*Editors:*

Will you kindly advise through your next issue the reason for the following

Presuming that A wishes to obtain a patent, and he has taken the proper course through a regular patent attorney at Washington, paid all necessary fees and obtained his letters patent, which he considered gave him the legal right to manufacture or dispose of same as he thought proper. He manufactures and places the article on the market for sale, when he is prosecuted for an infringement on a patent issued some eight years prior, judgment is obtained, and he is compelled to pay heavy damages, besides losing his patent and the government and attorney's fees originally paid by him. What kind of a law is this or what protection has a patentee? Was not the patent that A was prosecuted for infringing upon on record in the Patent Office at Washington? Was there any good reason why A's attorney could not have ascertained through the Commissioner of Patents from the records if A could have possibly infringed, before granting him his patent, as this fact was developed later in the suit against him by other attorneys. Is there not something radically wrong in such a system? A patentee depends entirely on the judgment and experience of his attorneys when he wishes to obtain a patent, and they should be able to say conclusively, before issuing a letters patent, if the patentee was fully protected.

J. B. Michael.

*Knoxville, Tenn.*

[Inventors are having lots of trouble of this kind. Some of it is due to the ignorance, but more to the cupidity, of patent attorneys (?)—many of them will get *some kind* of a patent (a combination on a combination or something of that order) for the purpose of pocketing his fees. There are many who believe that, for a very small fee the government should grant a patent to any applicant, and that the validity of same should be decided in a court—if the patent is worth anything it gets there anyway. The present system is doubtless a very faulty one, but an entirely satisfactory substitute has not yet been suggested.]

### Early Engines With Cast-Iron Valves—Some Old Timers—Chances of Education Forty-five years Ago.

*Editors:*

I saw an article in your October number about Mr. E. N. Underwood, stating that he put the first cast-iron valve on a locomotive in this country, and that was in the fifties. You are very much mistaken as to time, if not altogether. I went to work for the Central Co. in 1849, in the Rochester shop on the Rochester & Auburn division, just after a collision between a Baldwin and an inside Hinkley & Drury engine. I helped rebuild the Hinkley; both engines had cast-iron valves. The road was stocked with Hinkley & Drury, Baldwin, Rogers, Chetchem and Grosvenor engines, and each and every one had cast valves.

In the spring of '50 I went to Cleveland, Ohio, and the first job I had there was on an old engine called the "Pioneer," brought by Stone, Harback & Witt from Springfield, Mass. She had cast-iron valves. She had one pair of drivers; her crank fastened to hub of driver by bolts and keys.

It was here I served my apprenticeship. In '51 or '52 they commenced building locomotives at the Cuyahoga shop, in Cleveland, under the superintendency of Thomas D. Simpson. The first three six-feet drivers that were built there were erected by Robert McMillen and myself. I have never seen anything just like them. My son takes Locomotive Engineering, and it certainly is (as I told him) the most interesting jurnal I ever read. I could not help contrasting our facilities for learning forty-five years ago and now. I see you recommend the Correspondence School of Mechanics. If I were ten years younger, I should be strongly tempted to take a course myself, and avail myself of the advantages of this school.

Andrew J. Cole.

*Los Angeles, Cal.*

### Was the Engineer to Blame?

*Editors:*

I should like to hear a discussion in your columns by practical men as to what an engineer shall do in an emergency with driver and tank-brakes. Shall he reverse his engine or not? If so, shall he "give her steam" or not when she is in back motion? Then, too, if he has independent brakes on engine (air or steam), shall he use them or not, and is it well to reverse engine under those conditions?

We had a case a short time ago where an engineer reversed his engine with air set on it and ten cars, slid bad spots in drivers, and then hit the rear end of train ahead. Had he stopped twenty feet sooner, would not have collided. Was this engineer blameworthy, and would disciplining him be unreasonable in such a case.

Edward W. Pratt,
Air-Brake Inspector C. & N W.

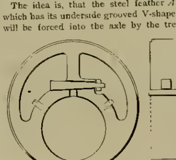
*Chicago, Ill.*

### An Eccentric Fastening.

*Editors:*

For the benefit of master mechanics who are wedded to the ancient form of eccentric with set screws as the only fastening, because of the ease of adjustment, I would submit the enclosed sketch.

The idea is, that the steel feather *A*, which has its underside grooved V-shape, will be forced into the axle by the tre-



mendous leverage obtained by the nut and wedge *B*, sufficient to hold it against any force less than that which would break the eccentric.

Fred. E. Rogers.

*Corning, N. Y.*

[If this form of fastening would not spring the eccentric out of true we don't know what would.]

### He Fired the Old "11."

*Editors:*

That engine No. 11, of the New York Central, shown in the September number, I was firing in '57; but not with that stack. She was a daisy in those days, and was named "Noah Vibbard." She was pulling a passenger train between Utica and Schenectady. It was lots of fun to go out and oil her valves—toe it along on the frame to get over to the steam-chest—she had no running boards; but I was young and supple then. She could pull three cars, I thought, then, to beat the world.

*Omaha, Neb.* J. C. Perkins.

### Would Links Move if Reach-Rod Broke?

*Editors:*

In your reply to J. A., No. 83, page 377, August number, with reference to reach-rod breaking when engine was running in back motion, I think you are mistaken. Links would not drop in forward motion; lower end of links might not stay up against link block, but would raise high enough to relieve engine through exhaust. To demonstrate it, let an engine be running in back motion, unlatch lever, and hold the latch with your hand to prevent dog dropping in quadrant, and give the links a chance to assume the position they would take if reach-rod broke, and I think you will find engine will drift right along, and if throttle was opened on an engine in condition described by J. A., the engine would be given an impetus in the direction it was running, same as if reach-rod had not broken.

*Newton, Kan.* W. R. Scott.

[When engine is running in back motion, it is the friction of the eccentrics that causes the pull-back of the lever—the tendency is for this friction to lift the eccentric-rods and link up. In running ahead, the friction acts in the same manner to pull them ahead. This pull, then, depends upon the fit of the straps on the eccentrics and the speed at which they are moving. If running fast, they might stay up, but when a slow-down was made, they would be very liable to drop ahead, unless held by a strong counter-balance spring or excessive friction somewhere. —Eds.]

### A Relic of Old Times.

*Editors:*

I have a plumb bob that was turned out of a pump plunger of the first English engine owned by the Philadelphia & Reading Railroad.

It was turned by Tom Barnett, formerly one of the first engineers in the company's employ. He quit the road and ran a brass lathe in the shop at Reading. He turned it and gave it to me in 1846. I was working there at the time as a machinist.

*Newton, Kan.* John Bourne.

### How Jackson Clark Knew He Had Lost a Main Tire.

*Editors:*

While looking at the article in the *Master Mechanic* about the wide firebox engines on the D. L. & W. R. R., it reminded me of times "en durin' de wah," and the names of the six "Smith & Jackson" engines was wonderfully refreshing to the memory of one who was there, and it called to my mind a circumstance that was somewhat amusing at that time.

Old Man "Jackson" was running the "Pennsylvania" on a coal train from Scranton to New Hampton Junction, and Gordon was firing for him. After they left Moscow, going towards Lehigh Summit, at the "Big Fill" one of the tires (it was cast-iron with chilled surface) broke, and left the wheel without doing any further damage, and it was not noticed until they got to Lehigh Summit, and then only when the old man went to oil around. These engines had six wheels connected, no truck, and it was the tire on main wheel, left side.

This occurrence caused much "roundhouse talk" among the engineers, all wondering how anyone could be so dumb as not to know when he had lost a tire, and a main one at that; and there was a plug-puller named Colvin who ran opposite to "Old Man Jackson" (kinder mean cuss), who did not have that brotherly feeling, such as is attributed to the man of Nazareth and other men we read of. He told Johnny Roach, a roundhouse man, that Jackson would not have missed the tire when he did if it had not been for a wood-chopper that come along with an axe on his back where Jackson was oiling, and asked him "Why he did not have one of *them things* on that wheel same as the others?"—and would you believe it, that made the "Old Man" real angry.

*Scranton, Pa.* James Hicks.

### Who is Neglecting His Work?

*Editors:*

I am employed by a certain railroad company, and my run calls for some careful air-brake work over a portion of the road, which is quite hilly.

We haul thirty loads for a train with heavy consolidation engine, and frequently we haul from eight to fourteen cars equipped with air on the head end of our trains. The engines are kept in good condition, as far as the brakes go, and they are expected to hold the train everywhere necessary. Brakes generally seem to be working all right before leaving, but when a stop is attempted, they are found to be almost useless. Brake-shoes badly worn, and so much slack in brake rigging that, were it not for the engine brakes, the train could wait for the friction of the journals and gravity alone to stop it.

When you have a set of brakemen not over anxious to get out on top in a stormy night, and must stop at a grade crossing

at the bottom of a steep hill, the "throttle-jerker" does a mighty lot of guessing as to whether he will make the stop or go in the ditch at the interlocking switch. Who is to blame for the brakes on these cars not being in proper order? E. F. H.

*Scranton, Pa.*

### Engineer's Brake-Valves that Work Hard—A Cure.

*Editors:*

The trouble with engineer's brake-valves working hard, as complained of by Fred. B. Armstrong, in your paper of October, 1893, is not on account of the lubrication or the kind of oil used. By referring to plate D 8, Fig. 1 (which is the valve he speaks of), you will see the joint for stem 11 is made by the leather gasket No. 12. This gasket gets worn so it allows the flat surface on the stem 11 to touch the under side of the nut 2; it is made so that the outside edge touches first, and they soon make a joint by working together. This gives an air pressure on such a large surface that it makes the lever work very hard. In every case I have relieved the trouble by putting in a new gasket or putting a piece of pasteboard under the old one. C. F. MILLS.

### "Where Did This Air Come From?"

*Editors:*

I was called to go out, and when I got to the engine I found the pump working and air blowing through train-pipe exhaust port. I could stop it only by putting valve on lap, and when restored to running or release position, it would blow as before. I thought something was wrong with piston 17 to prevent it from seating. I took the valve apart and found piston 17 O. K. I put it up, and it worked same as before; could get no pressure, of course. When coupled on to train, and ready to pull out, I discovered the cause of the trouble and fixed it, and went on my way rejoicing. What was it? W. C. WESCOTT.

*Albert Lea, Minn.*

### Those Air-Pump Disorders.

*Editors:*

In answering Geo. Bailie, of Topeka, Kan., I think that the trouble with air-pump No. 1 was a worn reversing-valve plate—that is, the plate was worn on the bottom very badly where the button or knob of the reversing-valve stem strikes on the down stroke. Such being the case, the reversing-valve would not be drawn down far enough to make the pump work properly. In answer to problem No 2, I think the steam port between reversing-valve bush No. 19, Plate D 6, and reversing cylinder No. 22 was stopped up with a piece of gum washer or something, preventing steam from getting on top of reversing piston No. 23. If such was the case, main valve would be lifted up, allowing steam to enter through steam ports in upper main valve bush No. 25, to the top of main steam piston 10, and the piston would be forced down and reversing-valve would uncover the end of the port leading to top of reversing piston, but if the port was stopped up, the reversing piston and main valve would remain up, preventing steam from getting under main piston to lift it; consequently, there would only be one stroke, and that would be downward.

While I am talking about pumps, I would like to say a few words against the oiling of pumps through the receiving-valves, which I think should never be done unless the oil passage is closed up from air-cylinder oil-cup. I caution engineers and firemen about it, but I often see them with the tallow-pot lid partly full of stuff called oil or lubricant, dosing the pump through the bottom valve chamber. All the oil should go through lubricator and air-cylinder oil-cup. It will go then direct to the pistons, where it should go without passing through the receiving-valve. Putting oil through the valve will cause it to become gummed up, so that it in many cases will stick to its seat, preventing air from being drawn in, thereby causing the pump to pound on the stroke towards the gummed-up valve, supplying only about half the amount of air that it should, and jarring the piston loose.

The air-valves, in my estimation, need no oil, and the pistons very little at a time—just enough to keep them from making a noise—and the oil should be the right kind, too. In choosing oil for the lubricator, for steam end, it is not nearly so particular, as the steam will cut it up and carry it through, leaving no gum. Any one who will give the subject a little study will readily see that as the receiving-valve has only the atmospheric pressure to lift it, and being only an inch in diameter, it has an area of only .7854 of a square inch exposed to the atmospheric pressure. This, along with loose packing rings, which do not produce a very effective vacuum, is almost sure to make the valves stick. The discharge-valves will not stick because they are forced open by the action of the steam on the steam piston.

FRED. B. ARMSTRONG.

*Camden, N. J.*

### Angle-Cocks—How to Tell How Much Air is Coupled Up—Oiling Air Cylinder—The Air-Brake Puzzles.

*Editors:*

LOCOMOTIVE ENGINEERING right on time, and contents perused, as usual, with care and pleasure. I have made the Westinghouse air-brake a study for the past four years, and with our Texas friend find my only "kick" is in the stop or angle-cocks at ends of train-pipe. With the army of unemployed men now roaming the country, there are, doubtless, many who, in "beating their way," have been put off by trainmen. There are doubtless many with such evil dispositions that will be fiendish enough to wait until air has been tried at terminals, and under cover of darkness when train starts, slip in between cars and shut off cock. There is many a wretch, in the disguise of a man, who knows enough to do such a dastardly deed. If trainmen and air inspectors were equipped with a handle each (and handles on cocks were taken off), they would soon become so proficient in their use that there would be really no more delay than at present in turningthe handles.

Another thing about these same stop-cocks I do not like is, that cars equipped with plain triples have handles on stop-cocks working just the reverse, to open or close cocks, to cars having quick-acting triples. The former, when cock is open, handle stands at right angles to train pipe; the latter, when open, is in direct line with train pipe. No matter how careful a brakeman is, once in a while he will (unless he looks at slot in plug) turn one of these handles wrong; of course, if an engineer is watching, and understands by the pressure he has lost in coupling up, and by the working of his pump, just about how many cars are coupled, he can instruct brakemen to look for cock turned the wrong way; or if he "tries the air" every time cars are picked up, he can tell by exhaust from brake-valve just about how many cars of air are coupled up. But as it is not always practicable to do this; it would be far safer if all stop or angle-cocks turned the same way. I have, several times, sent brakemen back to open cocks that they were positive they had opened, and were surprised to find I was right. I can always tell, within two or three cars, just how many cars of air I have coupled, and the brakeman knows this, and does not attempt to dispute me, but goes right back. A good many runners, who are not very observing, and consequently not so sure how many cars of air they have coupled, sometimes have to nearly quarrel with trainmen to get them to look over train twice; and if these handles were all put on plugs the same, time and accidents would be saved and harmony would prevail. This is a good subject for our "air-brake men" to discuss.

I would like to ask any engineer to whom the question may apply, why they run their air-pumps so fast, when as a rule there is no necessity for it? It only serves to burn the pump up and therefore to wear it out. It is all right to run the pump at a fair speed, but if oil is kept out of air-cylinder and piston is kept packed, and connections kept free of leaks, it is surprising how moderately a pump can be run, and still supply air to forty or fifty cars. I have been running an engine on these long trains for three years, and she was run a year before I got her, and the same pump is on her yet, and all the work that ever has been reported is "lift of air-valves reduced" once. Engine is now in shop for overhauling, but pump is as good as ever. Air-cylinder has not had oil more than a dozen times in four years. I use a little of the oily water out of lubricator every two days. Our trains are all heavy ore trains, the grades very steep, and we never have less than thirty-five cars of air. It would be only fair to state, however, that air is well kept up on cars, that piston travel of brakes rarely exceeds seven inches, and that we only carry sixty pounds of air, train-pipe pressure.

In answer to W. N. Horton's "Curious Brake Action," would say that graduating spring in one of the quick-acting triples was either weak or broken, allowing triple-valve to move far enough to open port on top of emergency piston; air pushing it down, of course, carried emergency-valve away from its seat, and this brake went on quick action, and of course the rest had to. Still, with ninety pounds reservoir pressure and only eleven cars of air, train should have charged up to at least sixty-five pounds unless main reservoir was very small. In answer to Paul Synnesvedt's question of safety, would say that I would not care for a quick-acting triple-valve on tender except in passenger service. As in switching, hostling, etc., on a freight or switch engine, quick action would be used so often that wheels would be injured. Think in passenger service a quick-action brake on tender would be proper. As to the large feed-groove on tender triples, it should only be used on passenger trains where train has to be charged quickly; as if it is used on long freight trains, tender auxiliary will charge first, and when air equalizes tank-brake will set.

We have at different times on this road had same trouble with engineer's valve, as W. F. Relyea mentions, and found packing ring on graduating piston a little too strong or stiff. This ring must be adjusted with care, as if joint opens too much air can get out of train-pipe through joint as fast as through preliminary exhaust port, consequently piston won't raise, and if ring is too stiff and joint butts together, it won't raise either.

The air-brake men have a grand field before them. They have my best wishes for success, and are welcome to any assistance I can give.

L. D. SHAFFNER.

*Anaconda, Mont.*

### The New Equalizing Discharge Valve.

*Editors:*

In the August number Geo. Holmes gives a good illustration of the difference between old equalizing discharge valve and the new pattern with reducing valve attachment. For my part, I cannot see any benefits that can be derived from the use of the reducing-valve attachment. In fact, many things can be done with valve equipped with feed-valve, Fig. 5, Plate D 5, that cannot be done with valve equipped with reducing device. On a freight train, for instance, composed of from twenty-five to fifty cars, train breaks in two, engineer blanks valve, to accumulate sufficient pressure to release brakes; but owing to governor being attached to main reservoir, can only get about 90 pounds. This is not enough to release the brakes, and he has to stand till brakes are pumped off or have trainmen bleed cylinders. If some switching is being done, and a few switches have been made while holding on to a number of cars, pressure has been reduced in train line below the maximum; owing to the equalizing device you have no excess pressure to insure a prompt release of the brakes. You may also want to pick up eight or ten cars whose auxiliaries are not charged with air. They are coupled on to those already charged, with the same result as breaking in two; wait till the pump can help you out.

The advocates of the valve will say you should make several applications in backing down to couple on to those cars, and in place of equalizing your reservoir and train-line pressure each time, just let enough back to throw the triple, and then move brake-valve to lap. In this way you reduce train-line pressure and will be able to release the brakes. What a waste of air to help out the reducing-valve! and then too this device was got up to prevent brakes creeping on, caused by leaks in train. If you lap brake-valve when you are going to couple on to those cars, you will have to arrange with the brakes not to creep, otherwise you will have no excess pressure. With brake-valve containing feed-valve and excess pressure regulated by feed-valve spring, and governor on train-line, these precautions would not be necessary. In case of break in two, sufficient pressure can be acquired in main reservoir to release all brakes and enable engineer to get train moving as soon as train is coupled up. On roads where trains are numerous this might prevent a rear-end collision. With brake-valve containing feed-valve attachment, engineer can make any number of switches and still retain the excess pressure regardless of how much train-line pressure has been reduced, and can pick up quite a number of cars not charged and not have brakes stick, and not have brake-valve on lap either, although the latter is a precaution that should be taken.

There is another bad feature about the reducing-valve, the feed-valve may be held off its seat by dirt and allow main reservoir pressure in train line. This pressure in the hands of a careless individual would probably result in some slid wheels. The same thing would obtain when warning port in brake-valve gets stopped up so handle can be carried in release position without engineer's attention being attracted by escaping air. Constructively, without the reducing-valve attachment, the new valve is a marked improvement over all the preceding ones. The reducing-valve, I believe, is retrogressive and will not prove to be a successful feature of the brake-valve. Its object, as stated, to allow engineer to carry brake-valve handle in running position no matter how bad the leaks in train line, is nothing more than feed-valve will do. With the new device no excess pressure can be obtained with brake-valve in running position until maximum pressure in train-line has been obtained. With a leaky train of twenty-five or thirty cars, the average pump will hardly compress sufficient air to enable you to get the excess pressure, and if you don't you might just as well have your brake-valve in release position; not so with the feed-valve. If your train leaks so you can only get 40 or 50 pounds in train-line, you can carry brake-valve in running position and have 20 pounds excess pressure in main reservoir. "Oh, yes," the Westinghouse people will tell you, "we know it can be done, but how many of your engineers will carry brake-valve handle in running position with the old equalizing valve?" If they don't carry it in running position with the old one, they won't do much better with the new one. Better inaugurate a campaign of education than try to overcome ignorance with mechanical devices.

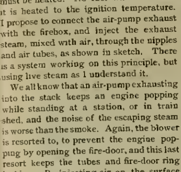
*Newton, Kan.* W. R. SCOTT.

### Something About Smoke.

*Editors:*

We are taught that smoke is the unconsumed parts of fuel, principally carbon. Wye Williams's theory is to prevent smoke by a perfect combustion of the fuel or its combustible gases. What finer illustration have we of perfect combustion than in the ordinary kerosene lamp? Well, smoke is a nuisance, and might be abated when we find out just the right way to do it. If it is burnable, let us try to burn it. If we can get *enough* heated air in contact with the gases, smoke is prevented; but the air must be heated. No fuel will burn until it is heated to the ignition temperature. I propose to connect the air-pump exhaust with the firebox, and inject the exhaust steam, mixed with air, through the nipples and air tubes, as shown in sketch. There is a system working on this principle, but using live steam as I understand it.

We all know that an air-pump exhausting into the stack keeps an engine popping while standing at a station, or in train shed, and the noise of the escaping steam is worse than the smoke. Again, the blower is resorted to, to prevent the engine popping by opening the fire-door, and this last resort keeps the tubes and fire-door ring leaking. By injecting air on the surface



of the fire we dispense with the evils of the blower and noise of air-pump, and possibly get rid of some, if not all, the smoke. Fig. 1 shows a 2-inch pipe with elbow at end of pipe and tees to suit the air-tubes through water space. *A* is a piece of 2¼-inch pipe about 8 inches long, and screwed on the injector-pipe *B* near the first nipple. (The number of nipples being optional.) The air-pump exhaust-pipe *D* enters the piece *A*, leaving an air inlet *C C*, in the form of an injector. By taking in a portion of the air at this point, it gives us a chance to raise the temperature before forcing it into the firebox. Fig. 2 shows another design or scheme to get hot air into the firebox. *A* shows the arch-brick, *B* is a piece of 1-inch pipe put in the brick at the time it is moulded. When the arch is put in, these pipes are to correspond with the air openings in leg of boiler. Knowing that the arch is about as hot as anything about the engine, we know that air forced through the pipe *B*, would be of a very high temperature, giving us a chance to get our work in on the smoke. I have no patented interest in this system. Use it if you want to.

*Indianapolis, Ind.* W. de Sanno.

### A Valve Out of Order, with Nothing the Matter with It.

*Editors:*

There recently came under my notice a very interesting experience with air-brakes, which is so instructive I cannot let it go unpublished. It was told me by Mr. Hedendahl, air-brake man on the U. P. R. R.

An equalizing discharge-valve of the 1890 pattern was found to act very queerly every time it was coupled to a certain train of passenger cars, while with the lone engine or any other train it seemed to work all right. In reducing pressure in the service application the blow-out of the train-pipe exhaust would first open for a time, then close for a couple of seconds, and then open again and continue to blow as long as air was allowed to escape from the equalizing reservoir. The action was not intermittent, but, on the contrary, only occurred once during each application of the brakes.

The valve was very carefully examined and found to be in first-class condition, there being no gum or dirt anywhere. The conclusion was very manifest, therefore, that the trouble was in the apparatus on the train, and so it was found to be after a little experimenting.

The engineer was instructed to set the brakes several times, while the doctor went back and watched the action of the valves under the cars. One of the triple valves was tardy in setting, and then, when it did set, applied with quick action. Here, then, was the cause of the trouble. This action made a sudden reduction in the train-pipe of about 20 to 30 pounds, which, of course, caused a seating of the equalizing discharge valve until the pressure in the upper cavity was again reduced below that left in the train, when the valve opened again, and thenceforth continued to blow until the handle was moved to the lap.

This case is one of the most striking on record to emphasize the fact that each and every part of the brake is dependent on each and every other part. That a defect in one part may show itself in another with which it seemingly has no connection. The engineer's valve was out of order, not from any fault of its own, but because the triple valve was not working properly.

*Chicago, Ill.* Paul Synnestvedt.

### Testing Air-Brakes.

*Editors:*

A bad wreck occurred to a passenger train a few days ago, and the account given in the daily papers attributed the cause of the accident to a failure of the air-brakes. The superintendent of the road was interviewed by a reporter, and his statement was that the train stopped at a junction about a mile from the place where the wreck occurred, and there the brakes were tested and found to be all right; that it was down grade from there to the scene of the accident. The engineer had the speed of his train pretty well controlled, but on nearing the station he saw the train he was following standing there, and attempting to apply his brakes, found they would not work. He whistled for brakes, and the conductor opened his valve in the passenger coach; but "the brakes would not work," and a serious collision occurred. The officials were mystified, and the engineer stated that he had never before known of such peculiar action of the brakes.

Car inspectors usually test brakes by seeing that they all apply, and then signal the engineer to release them; then, if they don't all release automatically, the inspectors bleed them off and it's no test at all, for the engineer should be able to apply and release all brakes in his train if they are in good condition. Now, suppose that the engineer had tested his brakes at the junction by an emergency application and exhausted all, or nearly all, of his train-pipe pressure; the inspector gave him the signal to release the brakes, and he pushed his valve-handle around to the left; but being hurried, suppose that he only moved it as far as the "lap" notch. When the spring brought up against the shoulder he may have thought he had struck the release position. The inspectors were in a hurry to get the brakes off and the train out; thought the engine didn't have air enough to knock the brakes off, and they may have bled every auxiliary reservoir in the train. If the engineer's valve was of the 1890 pattern, the black hand could have registered a good pressure in the train-pipe if there wasn't an ounce of air in it. It isn't very far from lap to running position, and the engineer may never have noticed it, and when he tried to apply his brake he didn't have the stuff to do it with.

This theory may explain why the Westinghouse Company have made their brake-valve of 1892 to empty the small reservoir when handle is at emergency—in order that the gauge may not register a train-pipe pressure when there is none.

But I wonder why the duplex gauge is connected as it is with the new valve. There is no more use of gauging the main reservoir pressure than there is of gauging the signal line—not as much. The governor regulates the main reservoir pressure, and when you want to know if it cuts off steam from the pump at the right pressure, just place the brake-valve handle in full release position, and the black pointer will tell you by registering main reservoir pressure. I believe a better way would be to have the red hand indicate direct train-pipe pressure, and not gauge the main reservoir. Then it would be unnecessary to waste the air from the valve reservoir in an emergency application, and the engineer would always know just exactly how much pressure there is in the train pipe.

Speaking about testing brakes, I was passing through a coach yard the other day, and stopped to look at a new coach just out of the shop. While I was there, two car inspectors came along to test the brake, triple-valve, signal-line, etc. They had a hand force-pump with hose attached. Connecting it with car hose they pumped up a pressure, and then tested the triple-valve—plain triple—*by turning the four-way-cock handle to straight air*, of course the brake applied. Then they turned it back to automatic, and what knocked me out—the brake released. They had stopped pumping when they began testing and the train-pipe pressure under the one car after being reduced by filling the brake cylinder was sufficient to force up the triple and release the brake. When the four-way-cock handle is turned to straight air, the pressure below triple piston escapes through the exhaust ports and the piston falls, until the slide-valve pulls down far enough to close the exhaust port; and the fact that the brake released immediately on turning the handle back to automatic, would lead one to think that the auxiliary reservoir had not been fully charged. This is one way that air-brakes are tested, but the two men appeared satisfied and disconnected the hose and went away.

*Terre Haute, Ind.* Will W. Wood.

[Our correspondent is misinformed about the train being inspected so near the wreck.]

### That Sticky Engineer's Valve.

*Editors:*

Mr. Fred. B. Armstrong, of Camden, N. J., inquires through the columns of your valuable journal what causes the Westinghouse equalizing and discharge valve of the old pattern at certain times to stick and handle hard. I can say that I have had the same trouble with the valves, which is nothing more than friction, caused by wear. The trouble can be overcome by rounding the corners of the ports of rotary valve and seat and grinding them with powdered glass and put tallow on. That friction is overcome on the '92 valve by the seat being of iron.

S. G. Ogden,

*McComb City, Miss.* Ill. Cent. R. R.

### Answers to Air-Brake Questions.

*Editors:*

Pump No. 1.—Reversing piston stem was broken off close to head. It had been running in that condition for some time, but on this particular occasion, and at end of upward stroke, the piston cocked itself and refused to descend when pressure was applied above, through action of reversing valve; hence it is plain to see why main piston stopped.

Pump No. 2.—By close scrutiny, Mr. Wright noticed that the reversing valve bushing had the appearance of having been recently renewed. He thought possibly it might have been improperly fitted, so removed it. Upon examination, file marks were plainly discernible, showing that the bushing had been found to be a little too large for its fit, and was reduced by hand filing. As a result, an untrue surface was produced, causing the bushing to bear in spots on the wall of its cylinder.

The course of the steam could be easily traced from the live steam port, between the bushing and its fit, to the small exhaust port provided for the escape of the exhausted energy above the reversing piston. The action of the steam had made slight depressions in the surface of the bushing fit.

When the live steam reached this bushing, enough passed directly to the exhaust passage to make deficient the energy required to reverse the main steam valve.

The top head was swung in the lathe, the bushing fit trued up, new bushing put in, after which pump worked properly.

*Topeka, Kan.* Geo. Bailie.

### Those Rules that Can't Be Lived Up to.

*Editors:*

I have noticed in your columns a statement, sometimes direct, at others implied, by your correspondents. It is one very many accept of and advocate. It is that the laws governing the practical operation of railroads embraced in their book of instruction cannot be followed in all cases successfully by employer or employé.

For the general enlightenment of your readers, will you invite a short statement, comprising a synopsis of case and number of rule that could not have been obeyed, that has come under the observation of your subscribers. As the rules on the majority of roads are about the same, a glance at instruction book would enable those interested to follow.

*Jersey City, N. J.* L. W. Evans.

[Cast-iron rules about not exceeding certain speeds, and then train orders that invite higher speed in order to get over the road, without authority to run it, will be considered as very common practice. We hope our correspondents will mention any others that may come under their notice.]

### Good Advice to a Young Man.

*Editors:*

I would like to advise the young man who, in asking for advice on page 761 of the October issue of your paper, signs himself "J. B. R., of Indianapolis, Ind.," or any other young man who is anxious to learn and willing to devote some of his spare time to study, to take a course of study in the "Correspondence School of Mechanics," of Scranton, Pa. I believe it to be just what he needs, and in my dealings with them have found them to be reliable parties. M. E. Watts.

*West Nanticoke, Pa.*

### That Cylinder-Head That Was Knocked Out by Compression, Again.

*Editors:*

Mr. Charles A. Greene asks in the October number how I managed to keep steam in the cylinder until compression ran up to 1,920 pounds.

Perhaps Mr. Greene don't remember that it often happens that a piston travels as much as 16 inches without any port opening whatever "on the other side;" and sometimes engines run ahead while in back gear; and that there are in use such things as balanced-valves, where the pressure "on top" is very little instead of "150 square inches," being exposed to a pressure of 80 pounds or more per inch.

*Waycross, Ga.* A. A. Brown.

### Those Pump Disorders.

*Editors:*

Under above heading, I see Mr. Bailie, of Topeka, puts two problems:

Pump No. 1. The probable cause in this case was the reversing plate was very badly worn, or more probably was loose on the piston, consequently on the bottom of stroke the valve stem wouldn't get movement enough to move reversing valve

Pump No. 2. If the main steam-valve stop was broken it would, I believe, cause the pump to work in the manner described.

*Raton, New Mexico.* W. Upward.

# Car Shops and Car Builders.

### A Sleeping Car Used in 1840.

One of the best-informed men in the country concerning details, past and present, of railroad rolling stock is Dr. Williams, of the Baldwin Locomotive Works. Dr. Williams has an exceptionally retentive memory, and can relate with accuracy particulars of things he has seen away back in his boyhood. A peculiarity about him is that he remembers things *accurately*, a very rare characteristic with reminiscent people. Those who are interested in the development of the American railroad car will read with pleasure the following extracts from a letter written to us by Dr. Williams

"In the October number of your paper, page 457, you make an inquiry as to the construction of the first sleeping car. Now I cannot answer that question, but I can give some information which may be interesting Some time when you are here I will show you in our model-room a little model of a car constructed on a scale of three-quarters of an inch or thereabout to the foot, which has on it the following legend 'Made by Richard Imbrey and Jacob Dash, car builders, Bush Hill, Philadelphia, built in 1840.' This model has been in our possession ever since I first knew the Baldwin Locomotive Works, years before I became connected with it, and very soon after I first heard the subject of a sleeping car mentioned.

"Our late Mr. Parry told me that this car was modeled from one constructed for the Cumberland Valley Railroad, at the time that it connected with the canal at Harrisburg and the National road—a highway of which you undoubtedly have knowledge—extending from Washington to Wheeling, in Virginia. He said the car was run regularly on trains, and that a charge of fifty cents, in addition to the regular fare, was paid for its use There were two tiers of berths, the lower extending like sofas along the sides of the car, and the upper folding against the side. They were covered with leather, and the person in charge informed passengers that they were not permitted to get into the berths with their boots on, because the car was a very expensive affair, costing not far from $800.

"With regard to the fact of the car running I have no knowledge, but this one thing I do know, that the model evidently dates back beyond any car built in New England. In this connection, there is another interesting feature. Alba F. Smith, at that time general superintendent of the Hudson River Railroad, patented, in 1860, the raised roof for passenger cars. This model has a raised roof, and on the car is the legend, in addition to the one I quoted above, as follows: 'They made car "Victory" with a raised roof in 1834.'

"I frequently talked with Mr. Parry about this matter, and his mind was always perfectly clear in connection with it. I think the model came to us, together with a lot of patterns and other things which Mr. Baldwin at one time purchased from Richard Imbrey."

### Hot Car Boxes.

"Those who are anxious to avoid trouble from hot boxes ought to keep a sharp lookout on the gang that works on trucks," said Mr. Bronner, of the Michigan Central, at a recent meeting of the Central Railroad Club After it was certain that the trucks are put together square and the weight evenly distributed on the wheels, the boxes are in a fair way to run cool, and the wheels to wear out without cutting the flanges. To keep the boxes running cool they ought to have good brass bearings well fitted, and they should be started with a thin lining of soft metal. The box should be filled with wool waste saturated with good oil. These were Mr. Bronner's remedies for hot boxes. Our private opinion is that they cover the whole field. If all trucks were well made, the bearings properly fitted, and good lubricants employed, hot boxes would be unknown, unless attempts were made to have the bearings carry a load away beyond the cool limit. What we see on a good many roads, however, is trucks thrown together by hazard, the poorest kind of brass for bearings, with no attempt at fitting, and the axle-boxes anointed with the worst oil to be found in the market because it is the cheapest, and then all concerned are mystified because hot boxes are common and cannot be cured.

### Disputes in Car Interchange.

The St. Louis & San Francisco had to change worn-out wheels under a car belonging to the American Live Stock Co., and put in axles with journals 3½ x 7 inches, although there was stenciled on the truck axles 4 x 7 inches. It was held that the journals of the axle removed were worn down to 3½ inches diameter, and that therefore, those put in were as good as those taken out. But the stock company refused to pay for the new wheels on the ground that the axle put in was too small. The contention was advanced that as the axles were originally 4 x 7 inches, and as that size was stenciled on the truck, no smaller size ought to have been used. On the case going to arbitration, it was decided that the San Francisco company were not required to put in a larger axle than the one removed. Also, that stenciling a size on the truck had no bearing on the case.

A rather interesting dispute lately arose between the Richmond & Danville and the Alabama Great Southern concerning a broken drawbar. The former road had carded a Lake Shore car delivered to the Alabama Great Southern for a cracked Hinson coupler. The latter road renewed the coupler, and charged the Richmond & Danville the cost of a complete coupler. This charge was objected to on the ground that the full charge included the knuckle which was not broken. The repairing road replied that the repairs had to be made with a form of coupler which took a steel knuckle, and that the malleable iron knuckle would not fit, consequently it was good only for scrap On the dispute being referred to the Arbitration Committee it was decided that the carding company were not responsible for the knuckle when it was not broken.

Another curious dispute about a drawbar was settled. The Choctaw Coal Railway carded for a wrong draw-bar a car delivered to the San Antonio & Aransas Pass The latter company applied a new draw-bar and charged the carding company 40 cents for labor. Payment of this was refused on the ground that the wrong draw-bar was of malleable iron, and it had been replaced by one of cast iron. Instead of paying the 40 cents the claim was made for $1.30, because the malleable iron draw-bar removed was worth more than the cast iron one put in. The Arbitration Committee decided that the claim for $1.30 on account of the removed draw-bar being malleable iron was not fair, and that the charge of 40 cents for labor was all right.

A dispute arose between two roads about the value of a car that had been entirely destroyed in a wreck. The settlement is well worthy of attention. A car belonging to the Louisville, Evansville & St. Louis was destroyed on the Cleveland, Cincinnati, Chicago & St. Louis. A bill was sent in for the value of the car, less 6 per cent. yearly depreciation for three years and ten months. A question arose about the age of the car, and confession was made that the body of the car was built in 1889 to replace one totally destroyed, but that the trucks were old ones rebuilt equal to new. The C. C. C. & St. Louis refused to consider the rebuilt trucks as new, and the case went to arbitration. The decision was that the body of the car should be paid for with the depreciation for three years and ten months deducted, but that the deduction for depreciation of the trucks should be made from the time the trucks were originally built.

The New York Central carded a car belonging to the Cudahy Packing Co. for a wrong draw-bar, and when the repairs were made a charge was sent in for bolts and nuts used in applying the proper draw-bar. This part of the bill was disputed, and the case went to arbitration. The decision was that a charge for bolts and nuts is not admissible. The Cudahy Packing Co are becoming noted for raising disputes that have to be appealed to the Arbitration Committee.

**CHART for Ascertaining the Amount of Power Required or in Use on a Passenger Car with 10-inch Brake Cylinder, Hodge System of Levers, 4½ and 4 to 1 Truck Levers, 4-Wheel Trucks, and One Brake Beam to Each Pair of Wheels.**

| Westinghouse figures, representing total braking power, per hole | Multiply original power by distance to fulcrum, divide for power received by distance from fulcrum to Hodge lever hole used. | Power obtained or strain on Hodge lever rod | Proportion of Hodge lever | Pull on top end truck lever. | Proportion of truck lever | Power on each pair wheels | Number pair wheels | 90 per cent braking power | Total weight of coach on rail |
|---|---|---|---|---|---|---|---|---|---|
| 28,600 | 4.700 x 12 / 17.75 | 3.177.46 | ÷ 2 = | 1.588.73 × | 4<br>4½ to 1 | 6 354 92<br>7.149.28 | × 4 = | 25.419.68<br>28 597.14 | or 28.244.08<br>or 31.774.6 |

| 33 300 | 4.700 x 12 / 15.25 | = 3.698.36 | ÷ 2 = | 1 849.18 × | 4<br>4½ to 1 = | 7 396.72<br>8.321.31 | × 4 = | 29.586.88<br>33 285 24 | or 32 874 3<br>or 36.983 6 |
| 36.200 | 4.700 x 12 / 14 | = 4 028.57 | ÷ 2 = | 2.014.28 × | 4<br>4½ to 1 = | 8 057.14<br>9 064.28 | × 4 = | 32 228.56<br>36.257 13 | or 35.809.5<br>or 40 285.7 |
| 39 800 | 4.700 x 12 / 12.75 | = 4.423.52 | ÷ 2 = | 2 211 76 × | 4<br>4½ to 1 = | 8.847.04<br>9 952 92 | × 4 = | 35.388.16<br>39 811.68 | or 39.320.1<br>or 44.335.2 |
| 44.000 | 4.700 x 12 / 11.50 | = 4 904.34 | ÷ 2 = | 2 452 17 × | 4<br>4½ to 1 = | 9.808.68<br>11 034.76 | × 4 = | 39.234 72<br>44.139 06 | or 43.594.1<br>or 49 043 4 |

Strain on fulcrum is original power at one end, added to power obtained at the other end.

Brake cylinder pressure or original power.

INSTRUCTIONS.

The pressure is 4.700 pounds at brake-cylinder, and the leverage from there to fulcrum remains constant, power being increased or diminished by shifting position of Hodge lever-rod. The strain on this rod should be 10 per cent of the total weight of coach with 4½ to 1 truck levers, this multiplied by 9 should be 90 per cent. of the total weight of coach.

Half the pull on Hodge lever-rod is strain on top end of truck lever in any case, 4½ times this strain is the pull on one brake beam; 2 25 times strain on Hodge lever-rod should be the same, and 4 times this should again be 90 per cent. total weight.

Where truck levers are 4 to 1, twice the strain on Hodge lever-rod will give power on each pair of wheels; 4 times strain on top end truck lever the same, 4 times this is 90 per cent total weight. 8 times strain on Hodge lever rod also 90 per cent. This sum divided by 9 and multiplied by 10 should be total weight of coach.

Standard 4 to 1 truck levers measure 28 in., 21 on long end and 7 at short end. Short end divided into total length gives proportion of truck lever, 28 ÷ 7 = 4.

Standard 4½ to 1 truck levers measure 36 in., 28 on long end and 8 at short end. Short end divided into total length gives proportion of truck levers, 36 ÷ 8 = 4½.

AIR BRAKE LEVERAGE CHART, USED BY GEO. HOLMES, AIR BRAKE INSPECTOR OF THE NORFOLK & WESTERN R. R.

The Peoria, Decatur & Evansville applied some brasses to a car belonging to the Terre Haute & Indianapolis, and, according to Rule No. 8, made a charge for the amount of brass used, giving credit for scrap. Heavier brasses than those used by the T. H. & I. were applied, and the latter company objected to the charge on the ground that too much brass had been charged. The company applying the brasses replied that the actual quantity used was charged for, but the other company insisted that they had no right to pay for more weight than their own standard brass. On the case going to arbitration, it was decided that the charge was correct and ought to be paid.

---

A dispute arose between the Philadelphia & Reading and Lake Shore companies concerning the proper charge for a broken Janney coupler on a car that was carded by the latter road. Against this card the Reading people made a bill for $12.50, and the Lake Shore people held that the manufacturers' price was $10. The case had to go to the Arbitration Committee for settlement, and they decided that $10 was the correct charge.

---

An extraordinary dispute arose between the International & Great Northern and the Houston & Texas Central people concerning a question as to whether brake-beams and rigging belonged to the body of the car or to the truck. The latter road repaired trucks of one of their own cars, carded by the I. & G. N., and sent in a bill for the work done, which included a charge for four brake-beams complete. The carding road refused to pay for the brake-beams, on the ground that they had settled for the car body, which was destroyed, and that the brake-beams belonged to the body of the car. The H. & T. C. insisted that the brake-beams belonged to the truck, and the matter went to arbitration. The Arbitration Committee decided on the common sense ground that a truck is not complete without the brake-beams, and, therefore, held that the charge was correct.

---

A dispute arose between the Choctaw Coal & Railway Company and the St. Louis & San Francisco concerning a charge for axles. The first named company had repaired some of the latter company's cars, and put in new axles for which they charged $10 each. The San Francisco people objected to the charge, and said that according to the Master Car Builders' rules it ought not to be $10 unless the car were 60,000 pounds capacity, while the car in question was only 50,000 pounds. On the case going to arbitration it was pointed out that the latest edition of the Master Car Builders' Rules of Interchange provide two charges for axles. Cars of 60,000 pounds capacity have the axles charged at $10, those of 40,000 pounds capacity are charged $9. As the car that the dispute was about was of 50,000 pounds capacity, the committee decided that the charge of $10 was correct, although the rules did not specify the exact charge.

---

That fertile subject of dispute, the amount to be deducted for depreciation for a destroyed car, led to a quarrel between the Chicago, Milwaukee & St. Paul and the J. I. Case Threshing Company. A car belonging to the latter company had been destroyed on the C. M. & St. P., and the railroad company decided to settle for the car. The car had originally been built in 1885, but it had been repaired and air-brakes applied in 1892. The railroad company were willing to pay the cost of the air-brake equipment, and then figure the depreciation from the time the car was originally built. The owners of the car wanted to charge the expense of the repairs effected a year ago, and the railroad company would not agree to this. On the case going to arbitration, it was held that the railroad's position was correct. A great many disputes have arisen on this question, and always have been settled in the same way. It is about time that the owners of cars were beginning to understand that depreciation stands against the car from the time it was originally built, and not from the time it received repairs, no matter how thorough the repairs may have been.

---

A car belonging to the Northern Central was destroyed by the Pittsburg, Shenango & Lake Erie, and the latter company elected to return the trucks. They sent them to Baltimore, but they did not deliver them to the Northern Central depot, and a charge for $10 was incurred for cartage. It was held that the owners of the trucks had a right to pay this charge of $10 because the trucks were delivered in a town where they had a depot. This was disputed, and the case went to arbitration. The decision, of course, was that the road returning the trucks was bound to deliver them free of charge.

---

A dispute which arose between the St. Louis Southwestern and the Houston, East & West Texas, illustrates the fact that specific complaints must be made to receive the attention of the Arbitration Committee. The former company had rendered various bills against the latter for renewal of car brasses, and complaint was made that brasses were changed when efforts ought to have been made to make the brasses run cool by proper oiling. It was also mentioned that the road had no trouble with hot boxes with the cars on its own line, and that they did not expect bills for changing brasses anyway, or they would have sent off-setting bills against the other road. A number of other vague complaints were made. On the case going to arbitration, the H. E. & W. T. were ordered to pay the bills.

---

### Iron Axles Running Hot.

During a discussion at the Central Railroad Club on the lubrication of cars, Mr. A. M. Waitt, of the Lake Shore, expressed the opinion that the principal cause of hot boxes is the use of iron axles that have seamy journals. Mr George W. West, of the Ontario & Western, agreed with Mr. Waitt, and insisted that good steel axles wore with a smooth journal that ran cool with little lubrication. Others expressed similar views, and strong preferences were manifested for axles made by the Coffin toughening process. This axle was held to be superior to all others, not only in strength and durability, but also in the smooth skin that the journal quickly acquired in use. For these reasons the speakers considered that the Coffin-treated axle was, in the end, the cheapest that could be used.

### Holmes's Chart of Air-Brake Leverages.

The chart on page 503 is reproduced from a large one furnished to air-brake inspectors and repairers on the Norfolk & Western by George Holmes, the general inspector.

Mr. Holmes early found out that there were very few men, even those holding responsible positions, who could figure out the leverage on a car, and that the number who could take the Westinghouse Instruction Book, and, beginning at page 44, figure out the leverage by their formula, was about as scarce. To put this problem into such shape that they could *see into* the whyfor, he got out this chart. It puts the matter into such unmistakable shape that any man can follow it out. In very many cases the sizes of levers and weights of cars he gives will tally with the work on hand, but where they don't, the way to figure is so plainly put that no one could go far wrong. We will send this chart, printed on tough paper to carry in the pocket, to any one interested whose name is on our subscription list to the end of 1894.

## ?A. What You Want to Know. ?A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(102) J. Lundburg, Gothenburg, Neb., asks

Does the crank-pin, in passing back dead center, cause the crosshead to rest a longer time at that point than at forward dead center? *A.*—No. Crosshead stops and starts the same at each center; but it takes longer for it to go from the center of guides to *back* end and return to the center of guides than to go from the center of guides to the *front* end and return—this is because of the angularity of the main rod.

(103) John Torber, Cleveland, O., asks

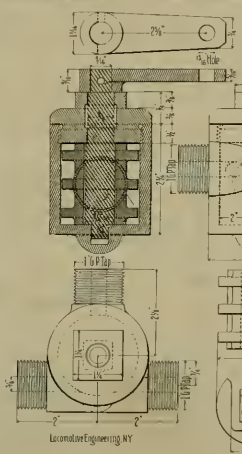
1. After having found the dead center of an engine, how do you proceed further in setting a slide-valve when an engine is being put up in a shop? *A.*—See article on setting valves in our January issue of this year. 2. What is meant by the rigid and total wheel-base of an engine? *A.*—The rigid wheel-base is the distance between the centers of the coupled wheels, the total wheel-base is the distance between centers of the front and rear wheel on the engine, regardless of what wheels they are.

(104) Thos. F Hall, New York, asks

Will you please answer following question in your November paper. In the Vauclain 4-cylinder compound engine is it possible to admit live steam to all the cylinders at the same time—if so, where does the high-pressure cylinder exhaust when using steam in that way? *A.*—Yes. When high-pressure steam is used the low-pressure cylinders do all the work, steam is admitted to *both sides* of the high-pressure pistons and they are thus balanced, or are in equilibrium.

(105) J. H. H., Danville, Ill., says:

Please mention in the columns of your paper the weight per yard of steel used on the mountain roads of the West; also, where the heaviest steel is used in the United States. *A.*—The Rocky Mountain roads use on their mountain grades steel of from 65 to 72 pounds per yard; narrow-gauge rails, 50 to 55 pounds. The heaviest rails we know of in this country are in the Fourth avenue tunnel on the New York Central & Hudson River road, in this city, and those in the St Clair tunnel, under the Detroit River, they weigh 100 pounds per yard.



### A New Cylinder-Cock.

The device shown herewith is a very efficient form of cylinder-cock designed by Mr. Frank Hedley, master mechanic of the Lake Street Elevated Railroad in Chicago.

Only one cock is used on a cylinder, this is located midway between the cylinder-cock holes and is connected to them by pipes and elbows.

As can be seen by the engravings, the valve consists of a series of disks cast solid on a plug; for about one-third of the circumference the plug is solid and *bottoms* in the case.

By turning this plug to a certain position, both cylinder-cock pipes can be opened to the drain-pipe or opening, but it cannot be turned to connect the two ends of the cylinder.

This valve cannot stick, requires no packing whatever and is as cheap as one ordinary cylinder-cock. Only two are used to an engine. They are smaller than one ordinary cylinder-cock, and call for just half the rigging to operate them.

By putting packing rings on the disks, an absolutely tight three-way valve would be had for many other purposes than that for which they are now used. Mr. Hedley has recently received a patent for this valve. They are in extended use on the elevated roads of Brooklyn.

Designed by THEO. N. ELY, Chief of Motive Power.] PENNSYLVANIA RAILROAD'S NEW CLASS "P," WITH 78-INCH WHEELS. [Built at Juniata Shops, Altoona, Pa

### Some New Express Locomotives for the Pennsylvania Railroad.

On our front page will be found engravings of two new locomotives recently built at Altoona for the New York division of the P R. R. In the upper picture railroad men will find something new in design—the P R R 's new compound "1515." called class "T" This engine is fairly well described by a P. R R. engineer, who said, "She is a cross between a 'K' and 'Jack the Ripper'"—the Webb compound.

In many respects the "1515" is one of the finest looking locomotives we have ever seen She stands up boldly and looks clean and business-like. Her running boards are low, like the English practice, and she has wheel houses; this may not be as handy as our own engines, but it looks well.

A six-wheel tender, very Englishy, is used, and the men say that it is a very easy riding tender, too.

The hurricane deck is curved down in front to the standard height for P R R. pilots, and has trap doors through it to work on valve chest heads, etc

The engine is a two-cylinder compound, having one 19½-inch and one 31-inch cylinder with 28-inch stroke.

She has a direct motion valve-gear, no rockers, the link blocks are on the back of the valve-stems She has piston-valves 12½ in in diameter located in the saddle between the cylinders, this leaves the cylinders without chests on top, and they look very neat

The engine has steel drivers 84 in. in diameter and truck wheels 42 in. in diameter, the wheels of the tender are also 42 in.

The boiler is of the Belpaire type, built entirely of steel, 65 in. in diameter at the smallest ring. The firebox, 9 ft long inside and 40 in. wide; there are 289 flues, 1⅞ in. in diameter and 11 ft. 9½ in. long The working pressure is 200 pounds.

The drivers are 8 ft. between centers, and from center of front driver to center of cylinder is 12 ft. 1¼ in.

It is 15 ft from the rail to the top of the stack, and 9 ft. to the center of the boiler, while the center of the cylinders is 42½ in. above the rail.

The total wheel base of the engine and tender is 48 ft 1 in, while the total length over all is 58 ft. 6½ in.

The engine weighs 145,500 pounds, 48,500 being on the main drivers, 46,700 on the rear drivers, and 50,300 on the forward truck.

The tender weighs, ready for service, 77,000 pounds, it carries 3,000 gallons of water and 15,000 pounds of coal

This engine is now running on heavy, fast express trains between New York and Philadelphia, and has made up time with twelve Pullmans.

Taken altogether, the "1515" is the greatest departure from what may be called regular practice, or standard engines, that has appeared in this country since the Strong and Raub engines were turned out to astonish the world, but she seems to be quite a practical engine, and, barring her piston-valves, there is not so much to be criticised in her design, for all the details have been admirably worked out. She was built at the old shops in Altoona, the new "P" having been built at the Juniata shops, Altoona, these shops build new engines only.

THE NEW CLASS "P" ON THE PENNSYLVANIA.

Some of the handsomest locomotives running in this country come into Jersey City, opposite New York, and among those in the front rank are Mr Ely's new "P.'s" They have the well known Pennsylvania ear-marks, but there has been considerable change over the old "P."

They have a box for dry sand, the old wheel cover boxes of wet sand having been abandoned for this class of engine, at least. The Belpaire boiler is 57 in. in diameter at the smallest course, 175 pounds of steam is carried, and 78-in. wheels used.

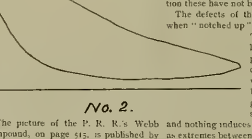
The air-pump is located on the left side, out of the engineer's sight, the engineer's valve is on the left side of the boiler, the handle being on the right side and connected to the valve by bell cranks and a reach-rod.

The cut shows the door in the front of the water-tank leg. This space is a box, the water only coming to the row of rivets just ahead of the striped panel. In the left side box is located the pump used to return the water of condensation from the train heating system to the tender, this is not unlike the air-pump in appearance.

The following are the general dimensions of the engine

Cylinders, 19 x 24 in.
Diameter of drivers, 78 in.
Diameter of truck wheels, 36 in.
Spread of drivers, 7 ft. 9 in.
Spread of trucks, 6 ft 7 in.
Size of boiler (Belpaire), 57 in.
Length of firebox (inside), 9 ft 11⅛ in.
Width of firebox, 3 ft, 4 in.
Number of tubes, 258.
Length of tubes, 11 ft, 4⅞ in.
Diameter of tubes (outside), 1⅞ in.
Working pressure, per square in., 175 lbs
Height from rail to top of stack, 15 ft
Height from rail to top of cab, 13 ft 4 in.
Weight of engine (empty) on drivers, 80,600 lbs.
Weight of engine on trucks, 41,700 lbs
Weight of tender, 23,800 lbs
Weight of tender (loaded), 63,800 lbs.
Capacity of tender (coal), 15,000 lbs
Capacity of tender (water), 30,000 gals

These engines are handling the heaviest and fastest express trains between New York and Philadelphia.



*No. 2.*

The picture of the P. R. R.'s Webb compound, on page 515, is published by request of many readers. "Wes" Hartman looms up well, and it will be seen that he has a box to sit on, the roof of the cab extended back twice its original size, a bell, a headlight and a pilot—American improvements that have been grafted on to "Jack the Ripper" here.

### A Tender Subject.

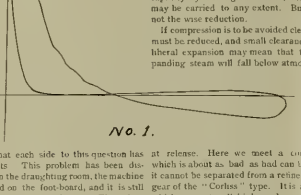
A speaker at a meeting of the Western Railroad Club made the following remarks about locomotive tenders "The American roads have followed the stereotyped design for tenders. There is no originality about them at all. Every tender on any New England road is just like the tender on the Union Pacific or Georgia Central. There has been no attempt made to improve. It is inconvenient in many respects and unworthy, I think, of our American genius in designing locomotives."

We do not take such a despondent view of the American invention of tenders as the speaker quoted appears to entertain. We do not believe that the uniformity in tenders arises so much from poverty of inventive fertility as from the form being susceptible of little improvement. The American tender did not at once assume the form that is now so familiar. It grew up gradually into that form, and the arrangement is the survival of the fittest. We have never seen tenders that were much different from the American form that were not inconvenient to the fireman. He is the principal man to be accommodated in the design of a tender. If it suits him the tender may be considered about right.

### Cylinder Compression.

BY HARRIS TABOR.

An editorial in your September issue on schemes for reducing compression in locomotive cylinders and a reply to the same by Mr Paul Sords, in November number of *Journal of the Brotherhood of Locomotive Engineers*, furnish very conclusive



*No. 1.*

proof that each side to this question has adherents This problem has been discussed in the draughting room, the machine shop and on the foot-board, and it is still an unsettled one in theory. The advocates of compression (which really means the present link motion) point to its long and successful use on railways, and its opponents keep in mind the more economical results obtained from stationary engines with elaborate valve-gear and small clearance. Whenever this question comes up there are certain railway conditions to be met with which the disputants are inclined to ignore, and in the controversy in question these have not been considered.

The defects of the link are felt most when "notched up" to the earliest cut-off. This position of the link gives greater expansion in a single cylinder than economy warrants. We must bear in mind that the greatest foe to expansion is condensation, and nothing induces condensation so much as extremes between high initial pressure and low terminal The builders of single valve automatic engines, which have practically the same distribution as the locomotive, do not advise cutting off earlier than quarter stroke, and many recommend even later cut-off. Excessive expansion in locomotive practice is more likely to be reached than in stationary engines, for the reason that they are running in an atmosphere of much lower temperature, which gives an increased condensation.

If the link was never abused by being "notched up" beyond its economical limit, its defects as a valve motion would not be so apparent. It is only when cutting off so absurdly early, that locomotive diagrams look so infernally "ornary" And it is only when working under such conditions that excessive compression and early release occur.

If a canvass of the runners who have a reputation for economy were made, it would show that very little running is done with the link in position cutting off earlier than one-third of stroke; such a canvass might also show that when the load to be hauled would not warrant a full throttle, the position of the link would not be changed, but the throttle would be partially closed to suit the work. The fact is the link is more likely to be condemned by cards it ought not to make than by cards taken under average running conditions.

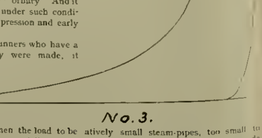
Within certain limits, variable compression, as produced by the link, is a source of economy. While it may not be necessary, as Mr. Sords suggests, to have large cylinders to start all trains, it is necessary, on nearly all American roads, to have a larger cylinder than is necessary for average hauls to help over grades; and where such necessity exists, it is important to have some means of making cylinders larger or smaller at the will of the engineer. The Lake Shore is an exception. On that road the famous Exposition Flyer is drawn by locomotives with 17 x 24-inch cylinders. On the N. Y. C the same trains, at slightly increased speed, call for cylinders 2 inches larger.

It is true that a valve-gear which gives a small amount of fixed compression and a variable cut-off may reduce cylinder capacity by cutting-off earlier, and this may be carried to any extent. But it is not the wise reduction.

If compression is to be avoided clearance must be reduced, and small clearance with liberal expansion may mean that the expanding steam will fall below atmosphere at release. Here we meet a condition which is about as bad as bad can be, and it cannot be separated from a refined valve gear of the "Corliss" type. It is an evil which comes to all high-grade expansion engines with small clearance when running under too light a load. If the steam in cylinder expands below atmosphere and makes a partial vacuum, this space will be filled with cold air as soon as exhaust is opened. (See diagram No 1.) The cylinder is at once cooled by the air and the incoming steam for next stroke is condensed It is much better to reduce the cylinder by paring off the card at both ends by variable expansion and compression than by depending solely on cut-off.

It is questionable if compression, treated independently of all other conditions, produces economy. It may be considered as a spring which consumes force in compression and gives back that force when extended. Of course this generates heat, which helps to warm the cylinder, but at the same time it lessens the cylinder's capacity, and this must be made up by carrying steam farther in the stroke, which means a higher terminal pressure The effect of this will be understood when we consider that the *power* given off by an engine is determined by the area of the card and the *cost* of the power by the pressure at terminal or release.

In locomotive practice compression undoubtedly increases expansion. This may seem paradoxical. One of the bad conditions in locomotive cylinders is excessive clearance. It is a necessary evil As a rule, this amounts to from 10 per cent to 12 per cent. of piston displacement These cylinders are supplied from compar-



*No. 3.*

atively small steam-pipes, too small to give a fair initial pressure at piston speeds above 500 ft. per minute, but quite as large as the limited steam room in boiler will permit. The clearance makes the cylinder so much larger that its effect would be to further wire-draw the steam in the insufficient pipe and thus reduce expansion Compression relieves the steam-pipe by filling the clearance, thus giving a higher initial. That quality in the link which reduces port openings as expansion is increased makes a variable compression necessary. But care should always be taken to see that neither expansion nor compression is carried too far

The influence of compression on the running repairs cannot be gauged by comparison. It may be safely assumed, judging from high rotative speed practice in stationary engines, that it is beneficial. Whether it is or not, it would be difficult to find engines of any type doing as hard service with so little cost for repairs.

Reduced clearance in locomotive cylinders would give better coal results. The question is whether this service will safely stand such reduction. The limited steam room, bad water, and constant agitation from running induce priming in locomotive boilers. When this occurs there must be a storage reservoir somewhere for this non-compressible fluid to avert broken cylinders. Large clearance furnishes this reservoir, and since this waste room is necessary why not relieve the steam-pipe by filling it with compression The fact that no engine builder in the country would attempt the rotative speeds at which locomotive engines run without liberal compression is in itself a strong argument that its effect on running qualities is beneficial.

It is hard to imagine a combination of lines more pleasing to the eye than a diagram from the cylinder of an engine of the "Corliss" or "Buckeye" type, cutting off at about quarter stroke. When the great master, Hogarth, described the curve as a "line of beauty," he could not have had in mind a finer example than the expansion line of such a diagram. It is the hyperbola, the most beautiful of all curves. But this line is pleasing only when it harmonizes with other lines on the diagram. It is the one line on the indicator card which determines economy in steam consumption. When this line sweeps gracefully from the point of cut-off to a terminal of such pressure that fair expansion is assured, without undue loss from condensation, we call it right.

What is needed to insure economical lines on an indicator card? The load of the engine must be equal to a given mean effective pressure to warrant the results often obtained from mill and factory engines. When the successful engineer makes a contract to furnish an engine which shall deliver a horse power for a given amount of coal per hour he does not accept conditions which may be fatal to his contract, but he builds to suit a fixed load, which is practically an unvarying one. If an old engine is to be replaced, the contractor sends an expert, with an indicator, to determine the exact amount of power required before his guarantee is submitted. He guesses at nothing, and as a result the factory will get an engine which will furnish 500 or 600 horse power at an expense in coal of less than half of what would be burned in the firebox of a locomotive to produce the same energy

The question of load is not the only one to be considered. High grade expansion calls for an initial pressure closely approaching boiler pressure, which may be obtained only through large ports and pipes. An 18-inch cylinder with a piston travel of 500 feet per minute, will require a steam pipe of at least 6-inch diameter (and this must not be too long) to insure fairly high initial. These conditions are easily obtained in stationary practice, and they are absolutely necessary to the steam economy, which has made the "Corliss" type of engines famous.

The locomotive designer is met at the start with restrictions which do not hamper the stationary engine builder. He must confine his work to a 10 ft roadway; within this narrow space and with length limitation he must construct a machine, self-contained, capable of delivering power on call in quantities varying from 50 horse power to 1,300 horse power, he must conform to rotative speeds, ranging anywhere between 50 and 350 per minute, and with mean effective pressures quite as variable; the piston velocity may have a maximum of 1,400 ft, and run through the whole scale down to 150 ft. The more favored designer of stationary engines may have any where from 10 square ft. to 14 square ft. of heating surface per horse power in boiler, but the locomotive must be content with less than one-third of this amount. His grate area is reduced to such small dimensions that at least four times the coal burned under the stationary boiler, per square foot of grate, must be consumed. With all these limitations against him, his boiler must be supplied with water varying in temperature from 35 deg. to 60 deg, and his cylinders are exposed to blasts from 25 deg. below zero to 100 deg. above. Given such a problem, the builder of stationary engines would, if wise, furnish his customer with a single-valve automatic, which would make indicator cards wonderfully like those from a locomotive doing the same duty.

Diagram No. 2 was taken from a passenger engine with 19x26-in cylinders, 78-in. drivers, running sixty miles per hour, revolutions per minute 280, and piston travel 1,313 ft. per minute, with a total horse power for both cylinders of 960, the actual cut-off was at one-third stroke.

Diagram No. 3 was taken from a "Buckeye," 14x28 in., running 120 revolutions per minute, with a piston speed of 559 ft. It is a beautiful card, and one that will bear a close analysis.

These cards are so unlike that it seems unfair to compare them, yet each is a fair representative of its type It is such comparison that make the average believer in the indicator feel like reforming the valve gear of locomotives

Card No. 2 is possible within certain speed limits. Now let us see what is necessary to approach perfect cards from locomotives With a rotative speed of 280 a positive valve motion would be imperative, with a piston velocity of 1,200 ft. the ports must be at least 20 per cent of the cylinder area, which would make them 3x19 inches to be uncovered; this would call for a valve travel of at least 15 inches, and probably it would equal the stroke of piston. A high initial, such as prevails in "Corliss" engines, would call for main steam-pipe not less than 11 inches diameter, with branch-pipes leading to cylinder at least 8 inches diameter With such steam passages, fed through a wide open throttle, there would be mighty little water left in the present form of locomotive boiler after the first few turns, so we must have a boiler with more steam room. Such changes would not produce the fine card of the higher grade of stationary engines, they would only approach them. Economy from such changes as have been outlined might result occasionally, but for all-round work, such as the average locomotive performs, the coal consumption would not be diminished, and the cost of running repairs would be multiplied.

The majority of men who have taken up the study of steam enthusiastically, have, at some time, had an itching for revolutionizing the locomotive. Many have attempted it, as abandoned monuments of "revolutionizing" scrap iron throughout the country will show. This disposition on the part of steam engineers to carry reform to the rails, attacks men just as the red necktie and hair oil period of Dickens does the boy, luckily it comes but once and is soon outgrown.

*Elizabeth, N. J.*

## Cost of Maintaining Locomotives.

The committee appointed by the Master Mechanics' Association to investigate the "Cost of Maintaining Locomotives," has sent out a very copious circular of inquiry with a view of securing information on which to base a good report. The chairman, Mr. G. W. Rhodes, may be depended upon to submit a valuable report if he succeeds in obtaining the required data The committee is expected to report on the comparative cost for repairs of locomotives built in contract shops and those built in railroad shops, a subject which has excited no end of private discussion, and one which deserves to be thoroughly investigated Nearly all master mechanics who build locomotives in the shops under their charge will argue that they can do the work as cheaply as contract builders, and that the engines turned out are greatly superior to those purchased, but we have never seen figures to sustain these claims There is good reason to believe that the latter part of the claim is well-founded, but we do not think there is a railroad shop in the country that can fairly compete with the first-class contract shops. Locomotives are now selling on very small margin of profit, and the margin has never been high of late years The method of doing work in railroad shops and the tools provided put the men in charge at a great disadvantage with those engaged in regular manufacture, where every possible means is taken to keep down the cost of production.

Manufacturers are constantly devising improved methods which cheapen production, and any new tool put upon the market which saves labor is promptly purchased. The railroad shop is different from this, for it is almost impossible to convince the purchasing authorities that a tool ever gets too old for economical service, and it is nearly as hard to obtain permission to order new tools on the plea that production would be cheapened. The prevailing policy is to make the tools in use last till they can no longer be used, and only to purchase new ones when it is represented that the shop can no longer do the work without them This is the general practice. While it is followed, there is little use in a railroad shop trying to compete in price with a contract shop. It is well, however, to find out the relative cost of work done in the different kinds of shops, and the report of the Master Mechanics' Association on the subject will be highly interesting.

We believe there is good ground for the complaints so often heard about defective work on the locomotives turned out of contract shops, which materially reduces the service of the engine and sends it prematurely into the back shop. The committee call for information on the failure of firebox sheets, frames and cylinders, the request no doubt being inspired by the frequent failure of those parts before new engines have performed a decent mileage Loose cylinders is a defect which is extremely common with new engines, and is doubtless due to the contract system, which induces workmen to pay more attention to quantity than to quality. Badly fitted cylinder fastenings are hard to detect by inspectors, and therefore many engines leave the builders with the cylinder bolts poorly fitted.

The failure of firebox sheets in new locomotives is nearly always due to the purchase of inferior material. The remedy for this is with the company submitting the specifications for the engines First-class material in locomotive fireboxes very rarely fails prematurely, third-class material as seldom gives satisfactory service. The purchasing agent who saves a few dollars per engine by ordering cheap steel imposes upon his motive power department a very expensive article. There is no single article purchased for railroad companies where cheapness in first cost proves so dear in the end as in the ordering of cheap firebox steel. The cost of applying a new firebox, or the expense entailed by leaky sheets is out of all proportion to the first outlay. There are three or four concerns in the country that make first-class steel, and the character of their material is well known. There are other

THE WEBB COMPOUND ON THE PENNSYLVANIA. PUBLISHED BY REQUEST concerns that make notoriously inferior steel, and the quality of their product is equally well known. We seldom hear of the inferior steel being specified for fire-boxes, and yet it is used as much or more than good steel. When no maker is specified, railroad companies may depend on getting the cheapest, and therefore the most inferior, material. To specify that the steel must pass certain physical or chemical tests is merely to invite deception, unless the mechanical department has the reputation of seeing that the tests are rigidly carried out, and those that do this are the exception. As the quality supplied by the different makers is well known, it is a wise course to mention the make of the steel in addition to the physical and chemical properties required.

An investigation into the cost of maintaining locomotives will not be complete unless the influence of good or bad material in all important parts be considered. In addition to this, the proportions of the engines ought to receive careful attention. Badly designed engines, with tractive power and adhesion out of proportion are expensive machines to maintain and directing attention to the fact always exerts a beneficial influence. There have been great improvements effected in the proportions of locomotives in the last ten years, and much of it has been due to the educational work performed by the Master Mechanics' Association. Another costly form of engine to keep in running order is that with deficient heating surface. In engines of this character, an intensely hot fire must be maintained to keep up steam, and the firebox sheets get burned out through incessant forcing of the fire. Then there are engines with poorly designed valve motion that cause destructive strains to mechanism, and others so badly counter-balanced that they hammer themselves apart.

The committee call for a great many particulars about the cost of repairing locomotives. If efforts are made by most of the members to answer all the questions, there will have to be various home investigations engaged in. Incidentally this investigation may lead to more uniformity in the keeping of motive power accounts, a consummation devoutly to be wished. At present there is great diversity in practice. The majority of roads cannot show what any separate operation costs, and many of them act as if they did not want to know. Any influence that will help to change this condition of affairs is certain to prove beneficial to railroad companies.

## Forty Years of Throttle Pulling.

Such is the record of Charles H. Burr, the oldest engineer in point of continuous service now in the employ of the N. Y. C. & H. R. R. Co.

"Charlie" Burr entered the company's employ, as engineer, in 1853, he is one of the best-known railroaders along the whole system; capable, energetic and fair, and always manages to retain the respect and regard of men who have been under him, as well as the officers above him.

Though several years past the three-score turnstile of Time, he is rated as one of the best railroad story-tellers in the Brotherhood, of which he has always been a prominent and active member, refusing office from his fellow members on several occasions.

Charles H. Burr was born in Boston, 1830, after leaving school going to Taunton, Mass., where he was apprenticed for five years to learn the trade of locomotive machinist, serving under that well-known locomotive builder, William Fairbanks.

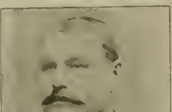
Finishing his apprenticeship, he accepted an engagement with the N. Y. C. & H. R. R. Co. to take the position of engineer at the Greenbush roundhouse, then in course of construction, the machinery and whole plant being put in under his supervision.

At that time railroading in America was in its infancy, and no trains on the H. R. R. ran through to Albany, a stop being made at Poughkeepsie, half way.

Mr. Burr afterwards was sent on the road, his first train being the Emigrant, which he ran from Poughkeepsie to Albany, relieving the well-known "Harry" Dawson, there, who was in charge from New York to Poughkeepsie, also having the honor of running the first "newspaper" train.

In 1854 he removed to Poughkeepsie, N. Y., and has held the throttle continuously since. Among the famous engines, which in those days were wood-burners, he pulled the throttle on, were the "Matteawan" and "Putnam," the latter being entirely rebuilt by him.

Men have come and men have gone, and changes unlimited have occurred on



the "greatest railroad in America," but this old "Knight of the Throttle" is still in the harness, beloved by all for his genial, sunny ways and even disposition.

He is stationed permanently at Poughkeepsie, and with his family occupy a pretty home on Harris street in that city.

During his forty years of railroading he has not forgotten an incident of his experiences, never was injured or in a wreck, and regales acquaintances for hours at a time with stories of the infancy of American railroading.

He has been importuned on different occasions to accept political honors at the hands of Poughkeepsie's citizens, but persistently refused, preferring the congeniality of the cab to aldermanic and other civil honors.

His habitual care and attentiveness to duty manifests itself in his every-day life by the exactness, taste and carefulness in dress, it is safe to say the Central has not a better dressed man in its employ than the Brummellesque old throttle-jerker at Poughkeepsie, N. Y.

## Dangers Encountered by Surveying Engineers.

The reading world has received many romantic stories about the hardships endured and the hair-breadth escapes made by engineers surveying railroads in the Western States, when wild Indians and all sorts of other wild animals prowled over the wastes that the railroad engineers were laboring to bring within the supremacy of civilization.

But the perilous experience of engineers has not been confined to the West. The men who located railroads had occasionally exciting experiences in some of the mountainous regions of the South. Moonshiners have always been afraid of strangers, and they never displayed much discrimination between an engineer looking for a practicable route and a gauger searching for illicit distilleries.

A well-known railroad engineer talking of exciting experiences said:

"I was building a railroad down in Georgia in my younger days. I am a Georgian, you know. Once following our surveys I saw a chance to ride across the mountains, and thence to my home to visit my father. It was early in the afternoon when I started on my long ride. The moon was shining high in the heavens when I began to climb. I was jogging peacefully up the incline, when from a shadow a horse and rider came out from the side of the road and fell in at my side.

"'Good evening, stranger,' said the man politely.

"'Good evening, sir,' I said, glad of even unknown company.

"'Which way you going?' asked my new companion.

"'Over the mountains,' I answered.

"'Reckon I'm going that way, too,' he said, and then I had an opportunity to look at my friend's face. It was a strange face. Smooth-shaven, young and yet old. It was calm and placid, as expressionless as stone, and yet there was a certain set about the jaws that kept me uneasy. And no matter how often I looked at him, how quickly I turned my glance on his face, his deep-set eyes were always watching me. I felt, even when I did not look at him, that he was watching me like a cat. We rode for hours, talking as one does with that class of people, until at nearly daylight we had crossed the mountains and were making our way along a comparatively level road. When we came to a river which we had to ford, my friend reined up.

"'This is as far as I go,' he said.

"'I am sorry to lose you,' I replied civilly.

"'Stranger,' he said, when my horse's forelegs were in the river, 'where are you from?'

"'Georgia,' I answered, 'this is my State.'

"'Who's boy are you?'

"'Judge S——s.'

"'Is that so?' he said, in a calm voice. 'Why, do you know what I took you for? Revenue! Yes, sir, and I came near shooting you, sir. Half a dozen times on that ride I made up my mind that you were revenue, sir, and each time I was just ready to do it. But I hated to do it, sir, you looked so square. I'm glad I didn't.'

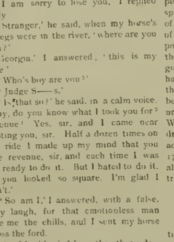
"'So am I,' I answered, with a false, jerky laugh, for that emotionless man gave me the chills, and I sent my horse across the ford.

"'Good-by,' I cried from the other side.

"'Good-by, sir,' he answered. Then his horse carried him off in the gray light, and I felt a sudden sense of great relief."

## The Mason Safety Stop.

A number of railroads have recently asked if pump governors could not be furnished with some means whereby the pressure, both from the air reservoir and



the train-service-pipe, would control the regulator. The essential point is, that as the train-pipe pressure at 70 pounds, when the brakes are set, does not control the regulator, then the reservoir pressure should be brought to bear upon the regulator and control it, in order that the reservoir pressure may not be forced up too high by the pump governor, when the train-service pressure ceases to act.

The Mason Regulator Co., of Boston, have recently put on the market such a device, and it is being used on the Pennsylvania Railroad.

The device is in the form of an auxiliary regulator, the sectional view of which is seen in the cut. The train-service connection is through the pipe 14, and the connection is made with the air reservoir at 18. The service pressure at about 70 pounds, coming through the pipe 14, goes through the passage way 13, and at the end of this passage, after curving around through the slide-valve 17, goes into the pump governor. So, it will be seen that when the brakes are not set, the service pressure controls the pump governor, as it does ordinarily. When, however, the brakes are set, and the service pressure at 70 ceases to work, and the steam-pump still going, as it is allowed to do, by the governor, the pressure in the air-reservoir soon rises above 90 pounds. This pressure is connected through the pipe 18 and through the passage way 12 and the chamber 9, under the diaphragm 7, and when it exceeds this pressure of 90 pounds, it lifts this diaphragm against the spring 6, thus opening the check-valve 8, letting the excess pressure down on the top of the piston 15, forcing that down against the spring 19, and carrying with it, by means of the pin 16, the slide-valve 17. The top of this slide-valve is carried from the upper port 13, closing the lower port, but opening the upper part of the port 13 into the governor to the reservoir pressure, which has come up through the pipe 18. It will thus be seen that the pump governor will be under the control of the reservoir pressure instead of the train-service pressure. When the reservoir pressure at 90 again drops below that amount, the reverse action will take place, and the slide valve 17 will again return to its normal position, allowing the pump governor to be controlled by the train-service pipe.

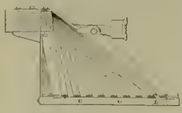
## Answer Circulars Promptly.

At every one of the mechanical conventions there are complaints heard repeated year after year that few members display sufficient personal interest in the association to answer questions raised by circulars. It frequently happens that those who take an active part in the proceeding at the annual meetings, display no disposition to help during the remainder of the year, even to the small extent of answering circulars. A suggestion has recently been made by the chairman of a committee that notices of those who answered and those who failed to answer the circulars be incorporated in the reports of committees. We think, should this suggestion be carried out, that it would shame not a few members of the associations into a realizing sense of the duty they owe to the organizations they belong to. The season is now at hand when investigation committees' circulars of inquiry will be reaching members of the different associations. We wish to mildly proclaim that a pigeon-hole is not the place for these circulars. Keep them at hand and proceed at once to answer them. If the necessary data is not at hand call for it, but do not push the circulars aside to be taken up when a slack time comes. The slack time will not arrive before the convention, and if you wait for it the circular will not be answered at all.

The Committee of the Master Mechanics' Association appointed to investigate the subject "Cracking of Tube Sheets," have sent out a circular calling for facts bearing on this troublesome and expensive defect. We understand that the members of the committee are making vigorous personal efforts to collect information on the subject. If the members answer the questions asked in the circular there will be valuable data collected, which will point the way to an effectual remedy.

### A Folding Pilot Coupling.

The annexed engravings illustrate an improvement invented by Mr. Pulaski Leeds, of the Louisville & Nashville, on the coupling used for locomotive pilots. It is well known that with the ordinary bull-nose used on the pilots for coupling, there is great liability of stock being thrown on the track when struck, in which position they



are very likely to derail the train. Owing to this, the safety of the pilot is very greatly decreased. To obviate this danger, Mr. Leeds designed a bar that could be turned upward, as seen in the engraving, at the same time providing the means of holding it very secure when set for coupling. The improvement is already very favorably received by roads using this kind of push-bar, and the indications are that they, the folding-head, will soon be generally adopted. The engravings are so plain that a detailed description is not necessary, the "backbone" of the device is a steel casting and the draw-head can be made of the same material or a forging, we believe both kinds are in use.

### Good Work in the Motive Power Department of the Union Pacific.

When Joseph McConnell became superintendent of motive power of the Union Pacific road some three years ago, he found a great many varieties of locomotives, all kinds of draft appliances and all kinds of road delays. He set to work to get heavier power in place of the worst engines by building new ones and charging them to repairs, and to standardize as much as possible. He took off the extension fronts of every kind and put on short fronts and diamond stacks. The men say this did the business, but of course, everything done to bring the power up contributed its share to the general improvement, which is shown in the statement, just made, that in 1892 the road handled 189,000,000 tons of freight one mile in excess of what it handled in 1890, and this was done with 2,335,000 less engine miles and 87,000 less tons of coal.

During the first six months of 1893 they made 140,000,000 car miles as against 130,000,000 car miles made the first six months of 1892, but the engine miles was 117,000 less than in '92, and they hauled 60,000,000 tons of freight one mile more than they hauled in the same period of the year before.

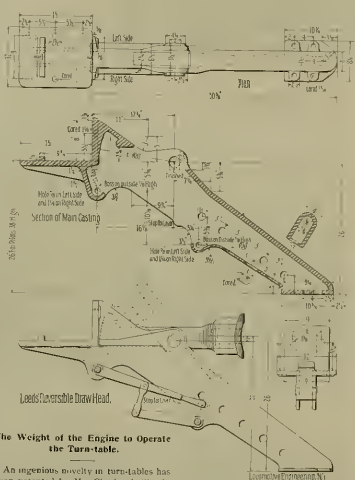
The Union Pacific has more than a thousand locomotives in service.

This record of improved engine service shows up wonderfully for the motive power department, and the head thereof ought, it seems to us, to have had his salary increased in some ratio to the saving he has made—but they cut him 10 per cent. this summer, just the same as the rest.

### Whitewashing by Air Pressure.

We have several times lately received inquiries from railroad men about the apparatus used by the Southern Pacific mechanical department on whitewashing shops, and which was referred to in Locomotive Engineering. In answer to a letter of inquiry, Mr. H. J. Small sends us the following particulars of the apparatus and method followed

"The portable outfit used for whitewashing shops, last year, consisted of an 8-inch air-pump, two locomotive main-air reservoirs for holding the whitening mixture under pressure, the lime to be slacked and thoroughly mixed and strained before putting into reservoir. Add 35 pounds common salt to each barrel of lime used. Air-pump can be located at any point convenient for the work and steam connections. The pump discharge to be connected to the air-reservoirs with 1-inch hose, in lengths as circumstances may require, the air to be discharged into the drums through 1-inch perforated pipe running parallel with and near the bottom, thus keeping the whitening agitated under pressure of about 70 pounds. The discharge from drum to be connected on top, having the discharge-pipe run down into drum within one inch from the bottom, using ½-inch hose with piece of ¼-inch pipe of suitable length, with stop-cock, for the discharge, and to the end of the ¼-inch pipe attach the spray-nozzle with 1/16-inch hole for the discharge. Make the end of nozzle cupped, or spoon shaped, so that the mixture, striking against face of spoon when discharged through the 1/16-inch hole, will form a spray of fan shape, at an angle of about 45 degrees to the surface to be whitened."



### The Weight of the Engine to Operate the Turn-table.

An ingenious novelty in turn-tables has been patented by Mr. Charles A. Shank, Albany, N. Y. His idea is to arrange the track that carries the turn-table in the form of an inclined plane and make the locomotive turn itself by gravity. The theory of operation is that the locomotive being so placed upon the table that the greater part of its weight is upon the end of the table toward the higher part of the track, the wheels under the weighted end will tend to run down the incline until the lowest point is reached, the other end of the table being entirely clear of the track. If it is necessary to turn the engine beyond the lowest point in the track, its weight is shifted toward the opposite end of the table, bringing its wheels down upon the higher part of the track when the table will turn by gravity as before

This thing looks practical enough, and we do not see why it should not work all right. It it works as well as it looks on paper, it will be a great benefit to men in charge of engine-houses. The labor of turning heavy turn-tables is very tiresome at places where many engines are handled during the day and night

### Material for Boiler Tubes.

At the last Saratoga Convention of the Master Mechanics' Association there were some remarks made about the most suitable material for locomotive tubes which indicated that the subject is well worthy of investigation. In the report on tests of iron and steel, the committee said "We are advised that in the case of a large number of steel tubes, the results, so far as wear is concerned, have been unfavorable. . . . An engine was equipped with 114 iron tubes and 113 steel tubes in December, 1890. The iron tubes were placed on one side of the center and the steel tubes on the other side. All the tubes were removed in March, 1892. Seventeen of the iron tubes were condemned on account of pitting and corrosion, while 64 of the steel tubes were condemned for the same defect."

In the discussion that followed the reading of this report, Mr William Forsyth said "I agree with the conclusions of the committee in the fact that steel tubes do not seem to be as durable as iron tubes, and that has been our experience with steel tubes. The fact of the matter is that steel blooms can be made a great deal cheaper than iron blooms, and the tendency of the manufacturer is to supply steel tubes at the same price as iron tubes, and thus force them upon the market A steel tube at the same price as an iron tube, I cannot believe to be as good. There may be steel tubes drawn solid and seamless which are as good as iron, but they cost a great deal more.

"In addition to the trouble from corrosion, we have had trouble with the weld of steel tubes. It is difficult to weld a steel tube and make it stand in locomotive service. So I will caution our members to look out for this matter when manufacturers try to give them steel tubes of an ordinary quality at the same price as iron tubes"

We have brought up what was said on this subject because we have heard a great deal lately about the failure of steel tubes in service. Steel is becoming popular for boilers, and this increasing favor of the material seems to induce motive-power men to accept steel tubes without looking into the suitability of steel for this purpose. There is good reason to believe that steel is more susceptible to corrosion than iron under the action of bad feed-water; but its liability to corrode is not the worst feature about a steel flue. It is well known that tubes are made by bending a long strip of iron or steel and welding the edges. Every mechanic who has experience in the working of metals knows that steel does not weld readily When steel is used for tube making it is found that bad welds are extremely common, and that it is impossible to detect them till the tubes go into service. The welds will be tight enough to withstand a high pressure in the testing-house; but when it becomes subjected to the expansion and contraction of locomotive-boiler service the weld draws apart, and a failure of the engine on the road is the result. The failure of a boiler-tube is such a serious matter, that a material likely to make this source of delay and annoyance common should be sternly refused Those who have had the most experience with both kinds of material in tubes also say that the steel tube is much more given to getting loose in the sheet than the iron one

First-class makers of tubes use nothing but the best of iron. The best tubes in the market are made of the best charcoal iron, which consists of iron melted and refined with charcoal in a Lancashire hearth. The raw material from which the iron is made is kept as uniform as possible, and the mixture used is one that careful chemical analysis and long experience have shown to be the most fit for boiler tubes. Before the finished iron is worked into tubes it is subjected to careful physical tests which it must withstand, otherwise it is rejected. When care of this character is exercised in the manufacture of tubes, there is no fear of failure happening after the article is inside of a boiler.

Railroad men need to have this subject of boiler tubes thoroughly ventilated. Those who purchase steel tubes do so without realizing the weak point about them. Those who pause to reflect that the seam of a tube must be welded will at once be suspicious about that operation being well done when steel is used We think that this would be a good subject to discuss at the railroad clubs. It is not hackneyed, it is a subject that every mechanical man would have some ideas about, and it is one which needs the healthy breath of public opinion.

---

Engine failures on the U P. are less than on any other road in this country that we know of.

---

Passengers and freight are carried for less money per mile in the United States than in any country in the world.

---

The picture of the "1515" on the first page was made from a photo taken by Mr. F. W Blauvelt, of the Du Bois Mfg. Co., this city

---

The C M & St. P. made the best investment last month ever indulged in in the history of the company. They restored the 10 per cent cut off the men's pay in July. They won't lose a dollar by the move.

---

Do you know where the injectors, the brake-valve and the gauge light should be to be handiest and safest for yourself? If you think you do, you should try for one of those $100 prizes for the best design of cab and boiler fittings.

---

In Europe they have little jacks for putting in car brasses that are a little better than some of ours. They are made with claws on the base, that fit on to the rim of the wheel and reach up, on an angle, to the box. When this is lifted the wheel stays down, and there is no prying to get the journal low enough to get the brass in.

### The Illinois Central's World's Fair Train Service.

Hearing that Mr. A. W. Sullivan, general superintendent of the Illinois Central

No. 1. Loading. Dead Stop. (Looking South.)

Illinois Central had a series of interesting photographs illustrating the operating of the enormous passenger traffic which his company handled so successfully during the World's Fair, we applied for a set for the purpose of having cuts made. Mr. Sullivan had given away all that he had, but he sent us the annexed cuts, which had been made and used by the *Railway Age*. From that paper we take the following particulars about the illustrations.

"During the six months ending October 31 the Illinois Central Railroad carried on its special World's Fair trains, in cars built for the purpose and having the exclusive use of two tracks, almost 8,800,000 passengers, besides nearly 10,200,000 carried in its regular suburban trains running on other tracks. While the regular suburban service covers an extended mileage over several lines and carried the local travel to and from a large number of stations, which passengers were constantly entering and leaving, the World's Fair trains ran only between Van Buren street and Jackson Park, without an intermediate stop, so that in respect to capacity for prompt handling of multitudes the work of these latter trains was far greater than that of the suburban trains, or of any other trains that have ever been run. Ocular evidence of the rapidity with which the loading and discharging of passengers was accomplished is given in a series of photographs received from Vice-President Harahan, which we have here reproduced on a reduced scale. A study of these views tells the story of this remarkably efficient service better than any words. It may be added that only on one occasion, 'Chicago Day,' was the entire special equipment called into service, and the real capacity of the service was never fully tested. On that day the World's Fair and suburban trains combined carried 509,786 persons. The views are as follows.

"No. 1. Loading process, showing the platform and train at the instant the latter had come to a dead stop and before any of the passengers had entered the cars.

"No. 2. The same 10 seconds later—the train filled with passengers, the people shown in the foreground in view No. 2 not being the same individuals who are shown in view No. 1, this illustrating the constant flow of passengers to the platform and the facility with which they were seated in the train. Views 1 and 2 looking south.

"No. 3. Loading process, looking north at the moment train had come to a dead stop and before passengers had entered cars.

"No. 4. The same 15 seconds later. Remarks as to passengers in foreground of No. 2 apply to the background of this picture.

"No. 5. Unloading process. View looking south. As this platform has been used only for discharging passengers, there were no other people on it when the train stopped. This view shows the situation 11 seconds after the train stopped. The relative apparent sizes of the train and the crowd give a very good impression of the carrying capacity of these cars.

"No. 6. Same 80 seconds after the train had stopped. The track was cleared in 55 seconds, and the platform, as shown in the view, was cleared in 80 seconds.

"These views were not taken on days when extra large crowds were being handled, but fairly represent the normal condition of the business in connection with the World's Fair special trains. Of course, on special days the tracks on each side of the loading platforms were used simultaneously—*i. e.*, trains were loaded from both sides of the platform."

No. 2. Loading. Train Filled in 10 Seconds After Dead Stop.

The Baltimore & Ohio Railway Company have decided to form a museum at Mt. Clare, Baltimore, of all the old engines and models which they exhibited at the World's Fair. They are fitting up an old roundhouse for the purpose, and everything will be done to make the display as perfect as possible. Anything that has been missed will be added to the collection after it has been put in place. A great number of photographs, drawings and engravings which they have illustrating the development of the transportation system are to be put in a hall where there is good light to show off to visitors. There has been, in connection with this exhibit, a great many pictures and drawings, for which there was not room in the World's Fair. These will be shown with the rest, and will make a most attractive collection.

### Development of the Train Brake.

One part of the Baltimore & Ohio exhibition at the Fair attracted particular attention. This was a line of photographs and engravings showing the development of the train brake. The series begins with the crude forms of levers used on common road wagons and the more elementary form of coal car, for arresting the motion of the car. The first appliances were hand-levers pressed upon the wheels, or pushed in between the spokes of the wheel, and were very inefficient for reducing speed.

The first important development is where a lever, having blocks placed above and below the fulcrum, gives the means of braking by fairly good hand arrangement. A modification of this is still the most common brake in use in Europe for freight cars. There are some curious pieces of mechanism to be seen in connection with the first attempts made in England to attain power in applying brakes. The staff and chain that were the first steps in America from the hand-lever to a second power never came into use in England. The screw received a good deal of application, and the mechanism transmitting the power to the brake-shoe was, in many instances, very complex and ingenious. We see in the Baltimore & Ohio illustrations, methods of applying brake-blocks that jam up between the wheels like a wedge, and there are others that are pushed down from the top. One of the earlier form is a "toggle" arrangement that applied the brakes by the main connecting pin being pushed downward. When we come to the first attempt at applying steam to operate a brake the "toggle" is again used between the brake-blocks, and steam power is applied by blowing the rod upward. This is first seen in the steam brake that was tried by George Stephenson, as early as 1833. The brake appears to have all the elements of what made the American steam brake a success, and it is rather surprising that it did not get into general use. The brake was applied between the driving-wheel and the trailing-wheel of the loco-

No. 3. Loading. Dead Stop. (Looking North.)

motive. As brake-beams were not employed in connection with brakes in England, it opened the way for a great deal of curious mechanism which was attached to the frame and transmitted the power to the brake-blocks.

All the early cars, both in Europe and America, had wooden blocks for brake-shoes. The objections to them were that they generally took fire when the brake was applied for any length of time, and they were merely a good makeshift in the line of development. After Stephenson attempted to use a steam-brake on an engine, there appears to have been little done to develop power-brakes for twenty years.

In 1853 the "Creamer" brake was invented. It was an emergency brake, and consisted of a coiled spring, which was kept wound up on each car. When anything happened to require a sudden application of brakes, a latch was released which let the spring apply the brake. It did good service in many instances and was a valuable step in the line of brake development Two (2) years afterwards Loughridge applied his first continuous chain brake upon a train of cars belonging to the Baltimore & Ohio. The chains passed from the engine to all the brakes in the train, and were operated by a drum placed below the running board of the locomotive. A great many improvements and modifications of the chain-brake were carried out with a view of making it more efficient, but it was always a very unreliable appliances and no amount of improvement could make it reliable. Chain-brakes were employed on a few trains, but the great mass of cars run in every country was dependent upon hand-brakes, until 1869, when George Westinghouse brought out his atmospheric brake, commonly known as "straight air." The Westinghouses effected a revolution in methods of applying power to brakes, and after this great invention was tried improvements followed the lines, either of air, steam or vacuum.

The Smith vacuum-brake was invented in 1872 and a great many of them came rapidly into use. As a non-automatic brake it appeared to be as efficient as the Westinghouse, and but for the necessity of the automatic feature it is very likely that the vacuum would have been more popular than the air-brake. The mechanism of all the later forms of automatic air-brakes are shown and present a very interesting, graphic record. It is to be hoped that the pictures shown will find their way into some museum, where future trainmen may have the opportunity of following this line of development in a way that "He who runs may read." The exhibit in this department is very interesting, but by no means so complete as it might be A very large number of inventions were brought out to try and apply brakes by means of the compression of the draw-bar; these have been known as bumper-brakes. Only one specimen is shown. There were also a variety of steam-brakes introduced, and the Loughridge air-brake was for a time a rival of the Westinghouse, but it does not appear, although the Baltimore & Ohio was the scene of its hopes and of its failures.

### Curious Railroad Accidents.

In an article on "Train Running for the Confederacy," by Mr Anderson, published in this issue, a curious accident is mentioned where, in a collision, the body of a box car was thrown forward upon a flat car, and was drawn through in the position it took on the jump.

There are various authentic records of cars jumping out of trains and going down the bank without being missed. Among the records of curious train accidents there are two mentioned by the *Railroad Gazette* as having happened last month, which are well worthy of mention

A west-bound freight of the Pittsburg, Fort Wayne & Chicago, on arriving at Alliance, O., was found to have one empty car under which there was only one truck. Investigation brought to light the fact that the truck jumped out on a descending grade, near Garfield, and had sufficient momentum to carry it completely across the adjoining main track and into the ditch. No other damage was done

This is a stunning argument in favor of the link and pin-coupler, as a vertical plane-coupler must inevitably have let the car body down upon the rails.

Another curious accident occurred near Massillon. While descending a grade the men on the rear cars discovered that the train had parted and went out to set the brakes. The first brakeman had gone only one or two car lengths, when there was a shock which knocked him down and extinguished his lantern. He recovered, however, and was setting another brake, when there was a second shock, the forward portion of the train having been stopped by a train ahead of it, and the two parts running together. Two cars were damaged, and the conductor, in examining his list preparatory to setting them off, found that he was short two cars. They were found about two and a half miles back, standing clear of the main track. These cars also were empty, and it is supposed that they were derailed by a draw-bar falling on the track. The momentum of the cars behind them pushed them clear of the track and the connection was broken without any injury to the draft rigging. The night was quite dark, so that the two men on top of the train passed by the unruly cars without noticing them.

---

We have received from Mr Rotheram, locomotive superintendent of the New Zealand railways, a table showing the consumption of oil for cars on the different sections of the railway system, which is narrow gauge, for a number of years. The average is what we would consider remarkably low, being only .67 quart per box per annum. The mileage of the cars or the weight per box is not, however, given, which are very important factors missing.

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK

Address all communications and make all orders payable to

LOCOMOTIVE ENGINEERING,
5 Beekman Street, New York.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } Editors and Props.
JOHN A. HILL, }
GEO. W. WOLLASTON, Mgr. Adv'g Dept.
FRED S. HILL, Mgr. Subscription Dept.

### Subscription Price.

$2.00 per year, $1.00 for six months, postage paid to any part of the world. Single copies, 20 cts.

### Special Notice.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary—always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as Second-class mail matter.

W. Williams, 21 Pink's Bdg., Melbourne, Australia.

18,500 of this Issue Printed.

### Notice to Our Readers—No Back Numbers.

Recognizing the fact that LOCOMOTIVE ENGINEERING is of no use to dead men, and that those yet unborn will probably want something fresher, we have decided that every copy printed shall get out and do some good while it is young, vigorous and alive.

On the first day of February, 1894, we shall scrap every back number in this office, except copies of January. Hereafter, there will be *no back numbers*, beyond the current year. We will have, by December 15th, about fifty bound volumes of 1893, for sale at $3 each, and a few copies of each issue as far back as June. For 1894, we will bind 100 volumes, and they will constitute the back numbers. We would like your subscription to commence with January of each year and will try to supply copies that far back—but please remember that this is no morgue.

### Notice to Subscribers—Those Charts.

We have many enquiries about those charts, and to make it perfectly plain to all, we say:

Charts will be sent *only* to those whose names are on our list to December, 1894. If your subscription runs out a month before that you can get the charts by sending 20 cents to extend your subscription, 40 cents for two months, 50 cents for three months, etc., or you can renew for another year—any way that carries your subscription to or beyond December, 1894.

Charts will be sent as they are finished, and only to those paid on our list for the whole of 1894.

We will mail the charts, without the paper, to anyone for $1.00: one Jan. 1st., one in March, and one in May.

*Don't write asking if you are not entitled to the charts, unless the date on your wrapper is Dec. '94 or a later date.*

### Notice to Club Raisers and News Agents.

We have to announce that we do not furnish specimen copies of the current number of the paper. All specimens used will be back numbers only. Please don't ask for *last month's*, we can not supply them.

### To Club Raisers.

Please don't order "a set" of those charts—The Three Little Schoolmasters—we will mail you one as soon as ready in December. The others will not be issued until March and May. If your subscribers want them, be sure they pay to the end of 1894—no others can get them free.

Remember there are but a few bound volumes for 1893 (50)—there are no back numbers for '93 beyond June, and only a few of them—first come first served.

### Present Standing of Compound Locomotives.

Many railroad companies are obtaining valuable experience concerning the real value of compound locomotives in comparison with simple ones, but there still appears to be a decided conflict of opinion about the merits of the two types of engines. During a recent visit to Cincinnati, the writer talked with different officials of the Cincinnati, New Orleans & Texas Pacific about compounds, and they were all enthusiastic about the performance of the engines they have in service. The engines have certainly been running long enough to demonstrate their strong and weak points. The Erie people have had several compounds running over a year, and they have ordered nine new ones of a lot that the Baldwin Works are building. In the West there is a tendency among railroad men to depreciate the compound, and many of them say plainly that the craze in the direction of compounds is over. The Chicago, Milwaukee & St. Paul has given apparent encouragement to this idea by changing a compound locomotive into a simple engine, and this is quoted as a positive proof that compounds are worthless. We have not been able to learn why the change referred to was made, but we think that those who regard it as decisive proof that the compound cannot compare successfully with simple engines are permitting their prejudices to run away with their judgment.

There is no railroad in the West where a closer record of locomotive performance is kept than on the Chicago, Burlington & Quincy, and that company have had exceptional opportunities of judging what a compound locomotive is worth. They have had a compound of their own at work for about three years. She is pulling freight trains where the engines are run on the chain-gang plan and it takes its turn with the others and is handled by any crew whose turn falls to take her out. The coal tickets show that the engine effects a saving of 15 per cent. over the simple engine with the best fuel record, and about 25 per cent. over the average engine. She is handled as easily as a simple engine and is below the average for cost of repairs. What is of even greater importance, the engine pulls the same train as a simple engine, and can take a car more over the heaviest grade, is always ready to go out when wanted, and has given no annoyance from breakage. The owners are so well satisfied with the engine that they have built two more like her and expect to have them soon in service. Moreover, some officers of the company, who appreciate the importance of saving 20 per cent. of fuel, confidently predict that the compound is the freight locomotive of the future. The Vandalia people, who are using a Pittsburgh compound, speak enthusiastically about the performance of the engine, and they also regard this as the type of engine that will soon monopolize the work of pulling freight trains.

On some roads, where compounds are used on passenger service, there is a strong feeling against them. There is good reason for thinking that the compound does not give satisfaction when it is run with very high piston speed, but there is certainly no difficulty in maintaining a speed which few simple engines are capable of reaching. A curious thing about some of the compounds pulling fast passenger trains is, that they are reported to be very economical in the use of water, and that they burn as much or more fuel than simple engines doing the same work. A paradox of this kind is well worthy of investigation. If an engine is doing certain work with less consumption of water than another engine, it means that she is using less steam. If a smaller volume of steam is required there ought to be less fuel employed in evaporating the water. If the quantity of fuel is not reduced, it follows that the boiler or the draft arrangements are at fault, and that fuel is being wasted from some cause or other. Where a case of this kind exists, it is the duty of the men in charge of the locomotives to ascertain why it takes more coal per unit of water evaporated in the compound than in the simple engine.

### Our Prize Designs for Locomotive Cab and Boiler Fittings.

On another page will be found the announcement of our prize contest for the best design for cab and boiler fittings for a locomotive. This subject deserves attention, and the contest cannot fail to do good and excite interest.

It has become so common to read in the papers, day after day, of the scalding to death of engineers and firemen, that little attention is paid to it. The accidents, which are intensified by escaping steam or hot water, from broken boiler fittings, form a large percentage of the total engine accidents and they furnish most of the "horrors."

Much has been said and written about this subject, but very, very little has been done.

Excepting, perhaps, the use of a few inside checks *there has never been any improvement in the safety of boiler fittings;* but on the other hand the danger has been increased, because on modern locomotives there are so many more fittings than there formerly were. Inventors of various devices seem to think nothing of putting a valve of any size into the boiler until they bristle like an armory rack.

We open this competition of design for the benefit of the 75,000 men who earn their daily bread running and firing American locomotives—to save their lives, to aid their families, and to make their daily work more comfortable and secure.

A decrease of the risks they run must benefit them in securing cheaper insurance, and benefit their brotherhoods in the reduction of the death rate.

The enginemen of our roads do not run all this risk. We have only to think of the Quincy disaster on the Old Colony, or the frightful accident last year on the Colorado Midland, where a boiler check broke off in the side of a passenger car, to remember instances, enough to make this a question of the safety of the traveling public.

The first condition is for the safety of the enginemen. The second, for more convenience in handling, meaning comfort to the crew and better service for the company. The third condition is for the benefit of the railroads, as a more convenient arrangement of parts for the economical maintenance of running repairs must be a distinct saving of money for the company.

LOCOMOTIVE ENGINEERING has no selfish motive behind this offer, it expects an interest in the subject and in the paper on account of it that is natural, but there is no "if" to the awards. There has been "oceans of talk" about doing something in this line. Let's stop talking and *do that something*.

Here is pay for designing and a chance for the poorest and most obscure man in the field to bring his idea (if it has merit) before the railroad world. Can there be an improvement made? Cannot its adoption be made quite general if the designs selected possess merit? Will railroad men take an interest in this contest? To all of those questions LOCOMOTIVE ENGINEERING would answer, "Yes."

The editors of LOCOMOTIVE ENGINEERING have each put in more than ten years on the footboard of a locomotive, and know to what extent this danger exists. They expect support and help from the men from whose ranks the victims of these frightful executions and tortures by scalding are selected.

Something can and must be done—let's do it, and do it now.

### Our Sixth Birthday.

With this issue LOCOMOTIVE ENGINEERING completes its sixth year, and is now "goin' on seven."

During the past year we have printed *and distributed* 243,601 papers, an average of 20,302 per month, and we cannot help feeling that all this has done some good in our particular part of this little world.

Although we printed 25,000 copies of the first months of the year, *not a single copy* of any of the first six months' issues are left unsold—we were entirely out of January issues in April.

That the paper has been appreciated we have had the best kind of assurances—financial ones. To be sure the hard times has affected LOCOMOTIVE ENGINEERING, as it has everything else; some advertisers have quit, some have died, failed or gone out of business—but the best business houses still have their signs on our pages, and pay for them.

We do not believe in curtailing expenses in ink during hard times, being thoroughly convinced that then is the time to advertise, and give more for the money than at any other time; we have just invested some thousands of dollars in new and original things for our readers.

LOCOMOTIVE ENGINEERING for 1894 is going to be as much better than it was in 1893 as we know how to make it. Right on the start, it will have a cover, this has long been needed to keep the paper clean, to allow of side stitching to keep it in better shape, and to admit of printing 16 pages of solid reading matter in front and 16 pages of solid advertisements behind, in order to enable our pressmen to do better work on both forms.

We are going to give away $2,000 worth of educational charts with subscriptions to the paper for '94. There are three of these going to each subscriber, and they are going to do $20,000 worth of good.

The paper will contain several series of articles from the pens of the best posted railroad men in this country on especially timely subjects.

But there will be one feature that we believe will be especially interesting and do a lot of good at the same time, and that is the prize competition for safe, handy and economical designs of boiler fittings for locomotives. We are offering $350 in cash for the best designs for two classes of engines. This contest must excite interest, because it appeals to the life saving instinct of human nature—the victims of scalding accidents reach into the hundreds every year. It appeals to the men on locomotives who seek more comfort and convenience as well as safety, and it appeals to railroad officers, as a design that means cheaper repairs means a great deal in money saved as well as more miles per month for the power.

Word comes from our 400 club raisers, almost to a man, that all the old subscribers will renew, "because they are so pleased with the paper," and that they will get new ones besides. The American News Co. have just increased their monthly order to 4,000 copies, and—well, there is an incentive for us to do something handsome by our friends for 1894.

There will be 30,000 copies of the January issue printed, and no attempt will be made to keep back numbers beyond the current year. When that 30,000 are gone, that ends it, and that issue will be "out of print" forever.

To the thousands of friends at home and abroad who have an interest in LOCOMOTIVE ENGINEERING we send greetings, and wish them a Merry Christmas. Every last one of them will have a Happy New Year if they get a copy of their favorite paper in its new overcoat.

### A New Appeal for Block Signals.

A railroad disaster which happened on the Chicago, Rock Island & Pacific, near Chicago, last month, again emphasizes the urgent necessity for block signals where trains are numerous. The men who stand out in favor of the time interval being sufficient to prevent accidents will see how it worked under circumstances which appeared favorable. The Chicago, Rock Island and Pacific is one of the best managed railroads in the West. The rules for the safe movement of trains under the interval of time system were as well framed as possible, and the personnel of the train service are fairly well drilled to follow the rules. Yet a destructive tail-end collision happened between two passenger trains and twelve people were instantly killed and many others severely injured.

A suburban train went out at 5 30 P.M. in a dense fog and lost time on the way. There was a rear brakeman at the hind end of the train whose duty it was to put down torpedoes and throw off a lighted fusee at frequent intervals. The required signals of danger were not put out, and an express train that started half an hour after the local, dashed into the rear car of the latter with the dreadful result detailed. The engineer of the express had no intimation that the local train was in the way till the rear-end lights loomed up in his face through a thick bank of fog. The brakeman and the conductor of that local train murdered the passengers who lost their lives. Yet with the loose morality about holding men responsible for performing their duties, it is doubtful if anything more serious than the loss of their positions overtakes these men.

The company are, however, by no means blameless, for it has long been apparent that the time interval is a delusion and a snare in places where trains are numerous. The heavy passenger business of last summer made railroads in the neighborhood of Chicago peculiarly dangerous when not protected by block signals. In being without the protection of a block signal system, the C. R. I. & P. were not, however, different from many other roads that needed this medium of safety as badly or worse, but they have been the great sufferers, although their loss is small compared with those who met death and suffering in the wreck. It seems that fatal accidents are necessary to force into use every improvement in railway appliances calculated to secure safety.

Tertullian's saying that, "The blood of the martyrs is the seed of the Church," has applied well to railroad management ever since people began to travel behind a locomotive. The martyrs of accident cried out against the inefficiency of hand-brakes and the air-brake was forced into use. The martyrs of another species of accident cried out loudly against the dangerous car stove and improved means of car heating were adopted. The blood of other martyrs is now lamenting over managers and directors who are satisfied with time intervals between trains, and the people are asking why are block-signals not brought into general use? This question will not long be repeated patiently.

### Spark Prevention.

The article which we published in June last which took the ground that spark arresters and other obstructions to draft often caused spark throwing instead of abating the evil, has been taken up by Mr. Fenwick, locomotive superintendent of the Formosa railway in China and discussed in our correspondence columns. Mr. Fenwick has evidently had much experience of locomotive operating in England and in other parts of the globe. His views are the same as ours in regard to spark arresters. A case is mentioned in the letter where the fuel consumption was reduced nearly one half by dispensing with spark arresters and putting in what appears to have been a well-designed exhaust-pipe. After this important change was made the engines threw less fire than they did when the spark arresters were employed.

American railroad companies have not yet got to the habit of dispensing with spark arresters altogether, but the tendency is to reduce the obstructions to draft which were long considered necessary to prevent spark throwing. Invention labored diligently for years to multiply appliances that intervened between the points where the fire gases were evolved, and where they passed into the atmosphere. The engineer and the fireman struggled to prevent the use of draft-stifling appliances, but the inventor and the fire-claim agent used their influence to magnify the necessity for obstacles to a natural flow of the fire gases, and the master mechanic was pulled to and fro by the contending interests, his own preference generally being in favor of simplicity. Sound engineering principles are slowly but surely making progress on this question. Taking the spark-arresting devices out of the smokestack was an important move in the right direction. Since then the tendency has been decidedly in favor of throwing out all the appliances that compel the gases to follow a tortuous course. The time will come when all the obstructions will be abandoned, and men will generally agree that no spark-arrester is the best provision for preventing fire throwing.

### "Poor's Directory of Railway Officials."

The eighth annual of the above mentioned book has been received. The value of a work of this character lies in its scope and in its accuracy. From a careful examination of the book, we are forced to the conclusion that it is neither so accurate nor so comprehensive as other works of the same character already familiar to railroad men. Another fault which we find with the book is that its record is too old. Changes that have been made among officials for about six months are not incorporated in this list. For instance, Mr. H. H. Vreeland has not been general manager of the New York & Northern for six months, but his name is still in this directory as general manager of the road named. Mr. J. S. Graham has been away from the Lake Shore for six months, but this directory says he is master mechanic of that road. We might fill a page with the record of similar inaccuracies. Our impression is that this list is not prepared so much as a work of reference as a medium for the securing of advertisements that few railroad officials will see. This is said to be the eighth annual number of *Poor's Directory of Railway Officials*, yet we have never seen it used in a single railroad office as a reference, although we are constantly visiting such offices, and frequently see directories of railway officials referred to. This will indicate the value of the book to those who advertise in it. It is sold for $3 by the publishers, whose address is New York.

### NEW BOOKS.

ELEMENTARY LESSONS IN PRACTICAL MECHANICS AND MACHINE DESIGN. By Robert Gordon Blaine. Cassell & Co., New York.

This book is formed principally from examples worked out by students who were learning practical mechanics at Finsbury Technical College, London. Prof. Perry in an introductory note says of the examples found in the book: "It will be observed that they are all of a much more practical character, that is they are more calculated to educate the practical mechanical engineer than the examples usually to be meet with in books on mechanics." From a careful examination of the book we are led to conclude that it is the best work of the kind we have ever seen, but the problems by no means easy for those who have not got a good grounding in mathematics. We cordially recommend it for the use of draughtsmen and mechanical engineers. The price is $1.

PROCEEDINGS OF THE MASTER CAR BUILDERS' ASSOCIATION.

The report of the proceedings of the Twenty-seventh Annual Convention of the Master Car Builders' Association has been received. The volume bears evidence of the usual careful work put upon it by Secretary Cloud, and is a highly creditable production in every respect. It covers 404 pages, besides having a number of inserts containing engravings of the principal standards. Intimation is given that lithograph copies of the drawing standards and recommended practice may be had from the secretary. They are adapted for taking blue prints from. It is to be hoped that railroad companies generally will obtain these lithographs, for their use will be certain to keep standards up to the proper dimensions.

The report contains besides the proceedings of the Annual Convention, all the decisions of the Arbitration Committee for the year and the decisions concerning the letter ballots.

PRACTICAL INSTRUCTIONS RELATING TO THE CONSTRUCTION AND USE OF THE STEAM ENGINE INDICATOR. Published by Crosby Steam Gage and Valve Co., Boston, Mass.

This valuable little book is divided into two parts. The first part treats of the general design and construction of steam engine indicators, special design, construction and use of the Crosby indicator, with directions for its attachment and the construction of suitable mechanism for operating the drum, together with full instructions for taking diagrams, computing horse power, etc., to which is added complete directions for using Amsler's polar planimeter and Peabody's calorimeter.

The second part is by Albert F. Hull, and consists of articles treating on the generation of steam, boiler tests, and other subjects which are interesting and valuable for those who are acquiring a knowledge of steam engineering. The author of this part is a little ostentatious in trying to parade his knowledge of mathematics, but that does not detract much from the value of the book to plain, practical men.

---

Our correspondent, Mr. Holmes, whose letter will be found on another page, mentions a discovery that he has made with angle-cocks. He found that by striking short sharp blows with a hammer on top of the handle of the angle-cock that every angle-cock on a train could be closed. An exception was found in a cock having the spring wound left handed. When it was shut it could be tapped open. Those with the spring wound right handed could all be tapped to close. There is likely to be this tapping action experienced in service when train-pipe is insecurely fastened. A rough riding car would produce vibration enough to close a cock. As it is not wise to permit any possibility for self-closing of angle-cocks to exist, we think that springs wound to the left should be applied to all these cocks.

---

Since the close of the World's Fair there has been a great deal of talk about races and competitions between the various locomotives exhibited, but there is not likely to be anything come out of it. The talk of a speed race was absurd, but we think it would have been interesting to obtain particulars of a test between two engines of about the same capacity pulling a train of the same weight at a required speed. We understand that Mr. Wimby, proprietor of the "James Toleman," was anxious to run his engine in competition with the favorite engines at the Exposition, every engine to pull a train of 200 tons a distance of 200 miles. The proposition was very fair, and we do not understand why something of the kind was not done. Before the Fair began there was a great deal of talk about having tests of the locomotives, but it all frittered to nothing.

### PERSONAL.

Mr. George P. Gardner has been appointed superintendent of the Pittsburgh, Akron & Western, with offices at Akron, Ohio.

Mr. James H. Hustis has been appointed assistant superintendent of the Harlem Division of the New York Central & Hudson River road.

Mr. Ira L. Beebe, for some time past foreman of the Dayton roundhouse of the C. H. & D., has been transferred to the Lima roundhouse in place of R. E. States, resigned.

Mr. W. W. Peabody, Jr., has been appointed assistant to the first vice-president and general manager of the Baltimore & Ohio Southwestern, with head-quarters at Cincinnati, O.

Mr. A. J. McCabe, superintendent of the Montana division of the Great Northern, has been appointed superintendent of the Cascade division, with headquarters at Leavenworth, Wash.

Mr. Henry James, the well-known railroad supply man, has accepted the position of sales agent for the railway department of Minnett & Co., varnish makers, Philadelphia, Pa.

Mr. W. D. Crosman has resigned from the editorial staff of the *Railway Age*. Mr. Crosman is one of the best known railroad journalists, having been with the *Railway Review* for many years.

Mr. Sumner J. Collins has been appointed general superintendent of the Wisconsin Central. Mr Collins has been for three years general superintendent of the Louisville, New Albany & Chicago.

Mr. W. E. Bailey has been appointed superintendent of the Lehigh & Hudson River, with headquarters at Warwick, N. Y. He was formerly superintendent of the Philadelphia, Reading & New England.

Major G. W. Vaughn, who has been chief engineer in charge of the construction of the Santa Fé, Prescott & Phœnix, has been elected general manager of the road. He still retains the position of chief engineer.

Mr. E. W. Batchelder has been appointed superintendent of the Montana division of the Great Northern, with headquarters at Havre, Mont. He was formerly assistant superintendent of one of the Eastern divisions.

Two new improvements on car couplers have been patented by Geo. W. Smillie, Newark, N. J., inventor of the well-known Smillie coupler. Both the new patents relate to improvements in the locking arrangements of the coupler.

Mr. J. E. Holtz has been appointed master mechanic of the Chicago, Rock Island & Texas road, with headquarters at Fort Worth, Tex., taking effect November 1. He will have charge of motive power, rolling stock and shops.

W. C. Walsh, formerly air-brake inspector of the St. Louis & Henderson Divisions, Louisville & Nashville R. R., has been appointed roundhouse foreman at Howell shops, Evansville, Ind., vice Irvin T. Carr, transferred to other duties.

In the death of Mr. W. H. Griggs one of the veteran master mechanics of New England has passed away. Mr. Griggs was a brother of Mr. George Griggs, of the Providence & Worcester road, who was celebrated as one of our pioneer locomotive designers.

The citizens of Dickinson, N. D., gave Mr. and Mrs. J. E. Phelan a reception before they left the place. There was a ball, a banquet and a presentation, in the latter connection a solid silver tea set and a solid silver set of knives and forks performed an important part.

J. C. Currie, the genial engineer of the new compound on the P. R. R. has just been appointed advertising agent of the *Brotherhood of Locomotive Engineer's Monthly Journal.* "Jimmie" is a genial, whole-souled fellow and deserves success and has ability to win it.

We understand that Mr. J. B. Hawks has been appointed general manager of the Detroit, Bay City & Alpena road, with headquarters at Detroit, Mich. Mr. Hawks is one of our best known railroad men, having been for years chief engineer of the Michigan Central. He left railroad work for a time, but has now returned to the fold.

Mr. George P. Hamlin, who was superintendent of construction on the railroad between St. Petersburg and Moscow, in Russia, died at his home in Baltimore, Md., November 12. Mr. Hamlin served as machinist's apprentice to Ross Winans, and he went to Russia in Mr. Winans' service, to act as superintendent of construction.

In a letter on safety and economy in car heating, Mr. William C. Baker, of car-heating fame, mentioned that in a trip from Boston to Springfield in a drawing room car heated by steam, he noted that the attendent opened and closed the regulating valve twelve times at the complaint of the passengers. It goes without saying that Mr. Baker has no use for steam.

Early in October, Thomas Baer, a crossing watchman at Catasauqua, Pa., gave the wrong signals and caused a collision, killing two engineers. Baer acknowledged that he was alone to blame, said he got excited when the two trains got close to the signal. Then he went home, got a gun and went out to a tree in his yard and blew his brains out.

Mr. A. D. McCullum, a machinist in the C., H. & D. shops, at Lima, O., has been promoted to the position of roundhouse foreman at Dayton, O., having charge of the engines and men on the D. & M., as well as the C. H. & D. division. Mr. Cullum served his apprenticeship under the late John Black, and came up through the shop, being noted as a painstaking and reliable mechanic.

Mr. W. C. Squire, who has been for several years on the editorial staff of the *Railway Age*, has been appointed western agent of the Boston Railway Equipment Company. This company handles the Marden brake-beam, and a variety of other railroad supplies. Mr. Squire was formerly in the test department of the C. B. & Q. He is an excellent writer on railroad subjects, and we regret to see that he has left the editorial sanctum.

Mr. James Meehan, superintendent of motive power of the Queen & Crescent, has resigned, the position being abolished. Mr. Meehan is one of the best known railroad master mechanics in the country, having been with the Queen & Crescent road for upward of ten years. Mr. Meehan is largely interested in manufacturing concerns in Chattanooga, and is perfectly independent of the railway business, but we understand that he wishes to obtain another position as superintendent of machinery.

There appears to be great uncertainty now about when and where the first sleeping car was run. We believe that the case mentioned by Dr. Williams in our November issue, where a sleeping car was run in 1840, tells of the very first car used for this purpose. According to the *Railroad Car Journal*, Mr. Poole, purchasing agent of the Western New York & Pennsylvania, ran the first sleeping car into New York. It was a Woodruff car, used by ladies only. There is no reason for believing that the first sleeping car used in the country was run into New York City.

Mr. W. D. Ennis, son of Mr. Ennis, master mechanic of the New York, Susquehanna & Western, has entered the Stevens Institute of Technology as one of the scholars of the Master Mechanics' Association. Mr. Ennis has been several years away from school and has been learning the machinist's trade. He had to study very hard to prepare himself for passing the entrance examination to the Stevens Institute, which is very stiff. The Master Mechanics' Association have now the full complement of scholars at the Stevens Institute. There will be an opening for one more scholar next September. Ambitious young men eligible for these scholarships ought to be preparing themselves for the examination.

Several changes were made among the mechanical officers of the New York Central Railroad on the first of this month. Mr. Geo. H. Hazelton, who has been for years master mechanic of the Rome, Watertown & Ogdensburg, has been appointed assistant superintendent of motive power of the divisions west of Syracuse, in place of Mr. J. D. Campbell, resigned. Mr. James Buchanan, who has been master mechanic in charge of the West Albany shops, has been appointed assistant superintendent of motive power of the divisions east of Syracuse. Mr. P. T. Lonergan is appointed master mechanic of the Rome, Watertown & Ogdensburg. He has been for ten years chief draughtsman of the New York Central mechanical department, and was formerly on the Delaware, Lackawanna & Western.

M. N. Forney is publishing each month in his paper, the *American Engineer and Railroad Journal*, a list of the accidents that have befallen engineers and firemen for the month. Mr. Forney is horrified at the frightful casualties to enginemen and he may well be for it makes every honest man sick at heart to read the details of the awful deaths and tortures suffered by these men. Some relief must be had, and it must be had soon, for this matter has grown to be a national disgrace. Mr. Forney collects his data from the daily press, and, of course, his report is very incomplete, yet for September he reports 40 engine accidents, in which 13 engineers and 14 firemen were killed, and 21 engineers and 19 firemen injured. Friend Forney, more power to your pen. If we can do anything on earth to help, even a little, we are with you, heart and soul.

Mr. Robert B. Campbell has been appointed general manager of the Baltimore & Ohio Railroad, succeeding Mr. J. T. Odell. Mr. Campbell rose from the position of telegraph operator on the Central Pacific road to be assistant superintendent, from there he went to the Chicago, Milwaukee & St. Paul, where he made an excellent record as a superintendent. Those who were familiar with his work on that road anticipated that he was likely to climb high on the railroad ladder. He left the West to become general manager of a railroad in Jamaica, but did not remain there more than a year, when he came back to the States and became general superintendent of the Baltimore & Ohio Western lines. His success in the latter position commended him for that of general manager. We feel certain that he will prove a great success in the position he now assumes.

The Pennsylvania Railroad people appear to have a great deal of confidence in mechanical engineers as judges of the material likely to give the best service in railroad appliances. It is said that Mr. Lewis, the chief purchasing agent will be succeeded by Mr. A. W. Sumner, who has long been his assistant, and that R. E. Marshall, superintendent of motive power of the Philadelphia, Wilmington & Baltimore, will be made assistant, the intention being to utilize Mr. Marshall's engineering knowledge in the selection of purchases. The rumor is also current that Mr. Mullin, purchasing agent for the lines west of Pittsburgh, is about to retire, and that his place will be taken by Mr. E. B. Wall, lately superintendent of motive power of these lines at Columbus, the understanding being that Mr. Wall's experience as a mechanical officer can be utilized to good advantage in the purchasing department.

One of the most unassuming of our railroad magnates is Mr. George Gould, who controls more men and interests than kings do in some of the older monarchies. His kingdom is of a particularly real character, and be it told to his credit there is no disposition on the part of this ruler to curtail the income or comfort of his subjects. He is generally to be found in the fifth story of the Western Union Building, New York, sitting in his shirt sleeves in a very plain room. All the cranks in the country appear to want to see Mr. Gould on some pretext or other, but they are warded off in an extremely amusing manner. An intensely polite young man takes the messages of visitors and goes back into another room. In about five minutes he returns, looking grief stricken, and says, with many expressions of regret, that Mr. Gould has stepped out somewhere, and he does not believe he will be back again to-day. The thing is so well acted that the visitor generally goes away under the impression that Mr. Gould will be heart-broken at not having seen him. The young man is an excellent actor.

The annual meeting of the New York Railroad Club, which was held in the rooms of the Society of Mechanical Engineers, New York, on November 23d, was very largely attended; there having been more than 100 members present. The following officers were elected: President—R. C. Blackall, superintendent of motive power and machinery, Delaware & Hudson. First Vice-President—George W. West, superintendent of motive power, New York, Ontario & Western. Second Vice-President—A. E. Mitchell, superintendent of motive power and machinery, New York, Lake Erie & Western. Third Vice-President—W. H. Lewis, master mechanic, Delaware, Lackawanna and Western. Secretary—John A. Hill, editor LOCOMOTIVE ENGINEERING. Treasurer—C. A. Smith, superintendent Union Tank Line. Executive Committee — Thomas Millen, superintendent and master mechanic of the New York & Northern; W. C. Ennis, master mechanic, New York, Susquehanna & Western; H. H. Vreeland, president Metropolitan Railway Company; W. W. Snow, president, Ramapo Iron Works; W. G. Wattson, superintendent, West Shore. Finance Committee—F. M. Patrick, H. W. Johns Manufacturing Company; F. W. Coolbaugh, Messrs. Coolbaugh & Pomeroy; R. A. Parke, Westinghouse Air-Brake Company.

The railroad men who are not acquainted with Engineer Nat Sawyer are not familiar with the leading throttle-pullers on this terrestrial sphere. Nat is the New York Central engineer. There may be others who know something about running locomotives, but Nat is the veteran. He represents them at the engineers' conventions, and takes care that loyalty and good feeling prevail among them. He was in his glory last summer, in charge of the "999" at the World's Fair, and his admiration of the fast engine never flagged, and he never tired of expatiating on her beauties and merits. It was expected that he would stay with the engine and see her home safe, taking a share of the glory that awaits the return trip, but Nat did not remain in Chicago after the close of the Fair. When Mr. Buchanan began getting letters from Nat, saying that it was absolutely imperative that he should return home, Mr. B. concluded that the veteran was tired out with his long talk to railroad men and needed rest. He was relieved, and immediately on reaching the Grand Cental Station, at New York, he made urgent application for passes to Boston. There was a doctor there whom he must see immediately. His friends were rather alarmed, and the passes were furnished without delay. Their anxiety was entirely dissipated a few days afterwards, when Nat returned with a brand new wife.

Mr. Enoch Lewis, the well-known purchasing agent of the Pennsylvania Railroad, has resigned, after a service of forty-three years with the company. Mr. Lewis, like so many other successful officers of the Pennsylvania Railroad, rose through the mechanical department, in which he had a record well worth being related. He learned the machinist trade in the shops of Eastwick & Harrison, the well-known locomotive builders, and remained with them for six years. In 1844 he went to Russia in the interest of the firm, took charge of a shop near St. Petersburg, and superintended the building of cars and locomotives for the St. Petersburg & Moscow Railroad. Returning to the United States two years afterward, he held positions with several builders of locomotives and of machine tools. In 1850, he entered the service of the Pennsylvania Railroad as a round-house foreman. From that he rose by degrees to be general superintendent of the road. This arduous position he held during the trying times of the war. When peace came he retired from active service to secure needed rest, and shortly afterward the position of purchasing agent was created for his benefit and given to Mr. Lewis. Mr. Lewis was a good draughtsman and he left his mark on some of the pioneer locomotives which brought celebrity to American builders. In March last we published an engraving of the "Gowan & Marx," from a drawing made by Mr. Lewis when he was a young man. That engine was famous in its time. She was the first locomotive ever built that pulled forty times her own weight.

In the office of Mr. C. A. Thompson, superintendent of motive power of the Jersey Central, there is to be seen part of a patched firebox, which is well worthy of examination. The material of the original firebox was Lowmoor iron, and it had been in use in a district where the feed water had a strongly corroding tendency. The firebox had been in use seventeen years, but one part was patched with a piece of steel plate five years ago. The steel shows as bad a case of pitting and general eating out as anything we have ever seen, but the iron that surrounds it shows very little traces of corrosion.

In speaking on the care of boilers at a meeting of the New York Railroad Club, Mr. G. R. Joughins, master mechanic of the Norfolk Southern, mentioned several cases where he had extraordinary trouble with boiler tubes pitting and corroding where slightly saline water was used. In some cases the tubes corroded through in a few months. He found that metallic zinc placed in a boiler proved an effective remedy. The tubes that proved most susceptible to corrosion were made of steel.

A curious invention, intended to prevent the derailment of railroad cars, has been patented by Henry W. Kirchner, Denver. He proposes to employ a middle rail. Attached to the under part of the truck is a frame that carries two wheels set in bevel shape one clasping each side of the rail. The plan would no doubt be effective, but it would greatly increase the expense of operating a railroad.

## EQUIPMENT NOTES.

The Mahoning Valley road are about to order five passenger cars.

The Illinois Central people have ordered 150 new freight cars from Pullman.

The Sinnemahoning Valley road are in the market for fifteen passenger cars.

The Philadelphia & Reading have ordered the building of 100 new coal cars.

The Columbus, Hocking Valley & Toledo are said to be in the market for 1,000 cars, mostly for coal business.

The seventy-five passenger cars required by the Long Island road will not be let until the middle of December.

The Minneapolis, St. Paul & Sault Ste. Marie are getting four new coaches for through business built by Barney & Smith.

The Laconia Car Works were awarded the contract for 300 box cars for the Fitchburg R. R. They are to be equipped with Gould couplers.

The Lake Shore & Michigan Southern have contracted with the Peninsular Car Co for 300 cars, some of them for carrying furniture, others common box

The Lake Street Elevated, of Chicago, have just ordered twenty-five coaches from Pullman, in addition to the order of 100 being built by Gilbert's, at Troy

The Illinois Central people have contracted with the Harvey Car Works, of Chicago, to convert the cars they used for the World's Fair suburban business into freight cars.

The Armour Packing Company, of Chicago, have awarded a contract to the Indiana Car Company for 100 cars and to the Missouri Car and Foundry Company for the same number.

The first deliveries on the seven engines for the Jacksonville, St. Augustine & Indian River road are being made by the Schenectady Locomotive Works. Six more of these engines have been ordered.

It is reported that before leaving for Europe, President Reinhard, of the Atchison, Topeka & Santa Fé, made arrangements for purchasing a large number of new locomotives. Baldwin's people have got the order and it is said to be for seventy-five engines.

The Long Island Railroad have issued specifications for the building of new passenger cars, most of them being intended for suburban business. The talk is that an order will be given for seventy-five cars. The intention is to have them built in first-class shape.

The Morton Safety Heating Company, of Baltimore, is now busy equipping 100 cars of the Lake Street Elevated road of Chicago for its system of car heating It also has orders to put this system on a number of cars of the Grand Trunk, which had cars equipped with this system in service last winter

The vacuum brake is slowly disappearing from the passenger equipment of the Long Island Railroad. The Westinghouse air-brake is being put on the engines on the Manhattan Beach and Rockaway Beach divisions, and also on the ten compound locomotives built in 1892. All these engines have heretofore been equipped with the vacuum brake

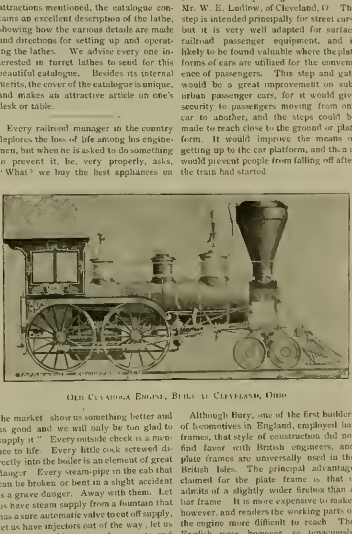
The fine train of Wagner cars exhibited at the World's Fair was brought to New York by engine "999," along the lines of the Lake Shore and the Central. The train excited as much interest on the way as a circus, thousands of people thronging the stations to witness the train and engine that have attracted so much attention. Both train and engine will be put into regular service soon.

One of the handsomest illustrated catalogues we have ever examined has lately been issued by the Jones & Lamson Machine Co., of Springfield, Vt , illustrating some of the turret lathes built by the company and the work which the lathes are capable of finishing. In connection with the tools shown, there are illustrations of the development of the turret lathe, which will be found highly interesting There are cuts of how this type of lathe looked in 1857, 1858, 1870, 1882, 1886 and 1891. It is a graphic history of the tool, and it is supplemented by an exhaustive article on the evolution of the turret lathe Besides the attractions mentioned, the catalogue contains an excellent description of the lathe, showing how the various details are made and directions for setting up and operating the lathes. We advise every one interested in turret lathes to send for this beautiful catalogue. Besides its internal merits, the cover of the catalogue is unique, and makes an attractive article on one's desk or table.

Every railroad manager in the country deplores the loss of life among his enginemen, but when he is asked to do something to prevent it, he, very properly, asks, "What? we buy the best appliances on

announcement that the Carnegie companies had determined to reduce the price of steel rails $5 a ton. There has been for several years a combination among the steel-rail makers which maintained prices of steel rails at about $30 a ton. The action of the Carnegie people brings the price down to $25 a ton. A prominent steel maker in Pittsburg, talking to the writer a few days before the announcement of the cut was made, said that steel rails could be sold for $20 a ton and leave a good profit. If the tariff on steel rails be reduced to 25 per cent , as reports say it will be, American makers of steel rails will have to sell their product at $22 a ton to compete with English rails.

We have lately examined an extremely ingenious invention, which consists of a combined car step and gate, invented by Mr. W. E. Ludlow, of Cleveland, O The step is intended principally for street cars, but it is very well adapted for surface railroad passenger equipment, and is likely to be found valuable where the platforms of cars are utilized for the convenience of passengers. This step and gate would be a great improvement on suburban passenger cars, for it would give security to passengers moving from one car to another, and the steps could be made to reach close to the ground or platform. It would improve the means of getting up to the car platform, and then it would prevent people from falling off after the train had started



OLD CUYAHOGA ENGINE, BUILT AT CLEVELAND, OHIO

the market show us something better and as good and we will only be too glad to supply it " Every outside check is a menace to life. Every little cock screwed directly into the boiler is an element of great danger Every steam-pipe in the cab that can be broken or bent in a slight accident is a grave danger. Away with them. Let us have steam supply from a fountain that has a sure automatic valve to cut off supply, let us have injectors out of the way , let us have comfortable seats and arm rests, and above all, safe and handy cabs There are brains enough in this country to devise a safer arrangement than is now in use—let us use those brains

From what has been learned about the invention of the link motion, by examining the older locomotives at the World's Fair, an impression has gone forth that to America belongs the credit of the invention of the link motion. The manly letter from Mr. Clement E. Stretton, C.E , of Leicester, England, on the subject, published in another column, shows that English engineers are disposed to give honor where honor is due on this important question. From what Mr Stretton says, it is likely that the invention of James exerted important influence on the development of valve motion in England, since the drawings sent from America by the inventor of the link induced Forrester & Co., locomotive builders, of Liverpool, to adopt the four eccentrics, which prepared the way for the reinvention of the link motion

There was considerable excitement among steel men early in the month by the

Although Bury, one of the first builders of locomotives in England, employed bar frames, that style of construction did not find favor with British engineers, and plate frames are universally used in the British Isles. The principal advantage claimed for the plate frame is that it admits of a slightly wider firebox than a bar frame It is more expensive to make, however, and renders the working parts of the engine more difficult to reach The English were, however, so tenaciously wedded to the slab frame that we supposed the idea of bars was an abomination, yet we notice in the *Engineer* that a firm of English builders have begun to construct small locomotives with bar frames

A decision has been rendered by Judge Townsend, of the United States Circuit Court, in the suits of the Westinghouse Air-Brake Company against the New York Air-Brake Company for infringement of the patents relating to the mechanism employed in their quick-action brake The decision decrees that the New York Company's engineer's valve, and all forms of their triple-valve are infringements of the Westinghouse patents. The company using the devices named are enjoined from the sale of them and an accounting in each case is ordered. The decision allows George Westinghouse, Jr., very broad claims as inventor of the quick-action brake

During the World's Fair 1,453,611 people paid 50 cents each to ride around in the Ferris wheel, $726,805 50 was "blown in" this way. After paying off $300,000, their indebtedness on bonds, they divided $426,805.50 with the Exposition management, and after paying all expenses of operation divided $150,000 among the stockholders. Now, William Somers, of Atlantic City, N J., sues the Ferris Wheel Co. for infringement of his patent, proves that Mr. Ferris rode on his little wheel at Atlantic City, and gets judgment in the Circuit Court—damages not yet decided on.

We are in receipt of several letters asking if we expect the surrender of patentable devices shown in our prize designs No , it makes no difference to us or the railroad public if a device is patented or not, if it is only good and does the business Anything new is not injured by such publication, but is protected by it It is patentable any time within two years after the description, and the publication is proof of priority of invention

The parties who have control of the Harvey process of treating iron and steel are making experiments to find out its effect on the wear of rails, tires and other parts subject to rapid wear. The process is reputed to be highly suitable for strengthening car coupler knuckles, and the Smillie Car Coupler Company are making experiments to ascertain how far the claims are well founded

The Wells & Coutan Co , of New York, have issued a notice intimating that they are manufacturing high-grade steam gauges, various forms of relief valves, and that they handle the thistle gauge class so much used for locomotive work They intimate that they depart from stereotype methods, which enables them to offer superior inducements to those who buy the class of goods mentioned.

What is said to be a certain remedy for chilblains has been sent us by Dr Helen Mack, of Boston, daughter of the well-known injector inventor, for the benefit of engineers and firemen who suffer from that trouble during the winter. It is a homeopathic remedy, and is to swallow one tablet three times a day, of xxx croton tiglium. It is said to be a certain cure

There are quite frequent requests from different parts of the country asking us to publish picture and description of the "999", these requests mostly come from new subscribers to this paper, and to all of them we must say, that it is against the law to repeat We published such a description in June, and copies of that issue can be had at 20 cents each

The officers of the two Brotherhoods owe it to their members that they aid in the crusade against dangerous boiler fittings. It is their brothers who are crushed and cooked and done to death against these boiler-heads. To lessen these accidents should be a work of love and duty—and they can be lessened.

B. M Jones & Co., Boston, are not saying a word about hard times They say that orders fell off for two or three months, but the whole year's business will compare favorably with that of other years. The sales of Taylor stay-bolt iron has been as good for November as they were for the same month last year

The men using the Hancock inspirator on locomotives say that if there is water in the tank it has to come This apparatus for feeding boilers is making a remarkably good record in districts where the feed water is heavily charged with solid matter. Incrustation does not seem to affect the inspirator

When an English engineer (driver) reverses his engine to avoid an accident, he says he "fixed" her In an accident not long since, we note the driver reported "On seeing shunting engine outside the home signal, I applied the vacuum, fixed engine and jumped off "

### The New York Railroad Club Surprises its Treasurer.

An exceedingly pleasant episode happened at the last meeting of the New York Railroad Club. A few of the officers, advised of the secret, had the venerable treasurer, Mr C. A. Smith, employed looking over the books of the club, when Mr A E. Mitchell superintendent of motive power of the Erie, rose and said

"We have sitting here at the desk, Mr. Smith, who has been treasurer of the club since 1871. He was the moving spirit among those who met to organize the club, and ever since that time he has been the most active member in keeping it alive When others were discouraged about keeping up such an organization and wished to let it drop, Mr. Smith's friendship for the club never faltered, and he succeeded time and again in reviving the flagging interest that was in danger of ending the existence of the institution. We all thoroughly appreciate the great services which Mr Smith has rendered to this club, and through it to all similar clubs in the country. It has been the success of the New York Railway Club that brought all the others into existence, and therefore we may call Mr Smith the father of all our railroad clubs. In tendering the public thanks of this club to Mr. Smith for the able work he has done for it, I wish to present this token of regard as a slight indication of our gratitude and good will"

Mr. Mitchell then presented Mr. Smith with a very handsome gold-headed umbrella, having a suitable inscription thereon.

### Weight on Wheels.

The New England Railroad Club follows a practice that is well worthy of imitation by other organizations of this kind. They bring together men belonging to the various departments of railroads, and have subjects discussed from the standpoint of the managers and superintendents, of the chief engineers and road masters, of the master mechanics and car builders, and of the inspectors and traveling engineers In following this practice they lately had "Permanent Way and Rolling Stock" discussed Were this practice followed more generally there would be less conflict between different departments, and the higher interests of railroads would be better served.

The following points were made concerning weight on wheels What is the proper weight to be employed? For many years it was considered that nine tons per wheel, or 18,000 pounds was the extreme limit. My own preference would be never to go over eight tons, provided that would furnish sufficient adhesion for the work * * * There are locomotives to-day made to run trains at high speeds, which I assume to be more destructive to the track than those at slow speeds, that have a weight of 44 tons upon the four drivers or 11 tons to each wheel—an enormous weight resting upon one point of the rail, and that point a knife edge almost, bounding along at 70, 80, 90, 112½ miles an hour. Now, I think if it is necessary, in order to get steam to do the work required by modern railroading, to have such enormous weights—and I believe it is—that we must resort to different types of engines, we must have more driving-wheels, so that this great weight may be distributed over more bearing points. I now speak of engines for passenger service This means going into the complications of 10-wheel engines or moguls. * * *

I believe the true solution is this When the character of our grades is such, and when the weight of the trains is such, that an engine running, not to exceed 55 tons, cannot do the work, it is vastly more economical and safer to divide the trains and make two where before one was run. Between Boston and New York the Boston & Albany road did this very thing a year or two ago Their train leaving Boston at 11 o'clock at night got so heavy that it was difficult to make time with it, and they wisely divided it into two. The Shore line has done the same thing within a year. I believe that is true economy, although you can figure out that it costs more to operate the trains, because it adds so much to your train mileage, but the question of whether it costs more on that account does not cover the whole argument. The question of safety is a most important factor, and I believe that if you have got to use more than an ordinary 18 x 24 cylinder engine on our New England roads, it is better to divide the train, that it is vastly safer than to attempt to run such enormous trains as some of us are doing to-day Perhaps as heavy a train as is run in New England is our Fall River steamboat train. On my last trip to New York I went by

INTERIOR VIEW MODERN PULLMAN COACH

that train We had 10 vestibule cars, weighing 32 tons each, and 3 parlor cars, weighing 45 tons each. Fourteen cars is the regular train. That train is handled by an 18 x 24 cylinder engine.

Instead of increasing the weight of passenger engines, I believe we can get better results with a lighter engine carrying a higher pressure of steam. I am free to say we have got all over being afraid of 200 pounds of steam. I do not believe there is any more difficulty in constructing a boiler that is safe with 200 pounds than with 100 pounds. It is simply a question of design, material and workmanship, and a 50-ton engine with 18 x 24 cylinder, carrying 200 pounds of steam, will handle a train that a 60 or 70-ton engine with a lower pressure would have difficulty in taking care of. It is a mistaken idea that it takes an immensely heavy engine to furnish the proper amount of adhesion to handle a passenger train. Anyone who has made experiments with the dynamometer will understand this.

With reference to freight engines the problem is different, we must have adhesion there to get the trains over the hills, and this means that we have got to have heavy engines. This problem was years ago, and on heavy freight trains you see the mogul and the consolidation. * * * On freight engines there is not so much objection to multiplying parts as there is on passenger trains, but we must not jump at the conclusion that we will order a lot of freight engines to weigh 75 or 80 tons each without consulting the chief engineer, as is sometime done by managers and directors.

The January issue of LOCOMOTIVE ENGINEERING will be printed and distributed before the holidays. Copy for changes in advertisements must be in this office by December 12th, and hereafter we cannot insure changes in adv. unless copy for same is in our hands by the 15th of each month, the new form of the paper requiring that we go to press on that day with sixteen pages of advertising.

We are informed that the Norton ball-bearing jack has received the highest award at the Chicago World's Fair. The company report that their business is very good considering the dull times in other lines.

The committee of the Master Car Builders' Association investigating the subject of steel tired wheels have sent out a very comprehensive circular which ought to bring in a great deal of information about the service of all sorts of wheels The chairman of the committee is Mr. R E. Marshall. He appears determined to find out all there is to be learned about the subject he has on hand

### Heating of Driving-Boxes and Eccentric Straps.

A few years ago there were numerous complaints heard of delays caused on railroads from the heating of driving-boxes and of eccentric straps, with frequent breakage of the latter. Numerous explanations were heard as to the cause of the trouble, and various remedies, more or less fallacious, were suggested. After a time the real cause was found out, and the trouble is disappearing as the remedy goes into operation. Too much weight for the size of the bearings was what ailed the driving-boxes and too little bearing surface for the power transmitted was the weak point of the eccentric strap. There were other minor causes of disorder, but those mentioned were the most important.

A report presented to the Central Railroad Club by Mr W. Lavery, of the Erie, covers the subject very well. He said

"Driving-boxes and eccentrics heating can be traced to many direct and indirect causes that would require pages of reports to cover, were it necessary. We are of the opinion, if these parts are properly designed, carefully constructed, of good material, and proper lubricants used, the causes for heating have been covered. And if proper care is taken by those having our locomotives in charge, the prevention also is given. Driving-boxes and eccentrics well designed should have strength without unnecessary weight, filled with oil cellars or recesses for the lubrication of the wearing parts. Constructed true and square in order that the surface may have easy contact with one another without pinching or binding. The material should be well considered, being strong and tough to carry the weights, as well as to resist the strains to which they are submitted.

"The lubricant should be of the best grade of oils, sufficiently light in body to penetrate to the surfaces, and yet not run off quickly after being applied. Presuming our locomotives are equipped as herein noted, we may reasonably expect good service if attended with care by those having them in charge, and in our judgment the heating of driving-boxes and eccentrics will, to a large extent at least, be prevented."

The Railroad Commissioners of Illinois have been investigating the condition of the track of the railroads within the State and have recommended improvements in some places and the reduction of the speed of trains on a few roads. If the Commissioners would start out on foot and inspect some of the lines under their charge, we feel certain that there would be very decided recommendations both for betterment and for reduction of speed. Inspecting a railroad while riding in a palace car is not the way to learn the condition of the structure. Some time ago the writer walked a considerable distance over a railroad in Illinois, and a good, sound tie was the exception very rarely met with. The iron was in wretched condition, and on nearly every embankment the ties stood out from six inches to a foot without support There did not appear to be a single bridge on the division that was safe. It was the worst track we had ever seen, yet the Railroad Commissioners make no recommendations about it.

A very sensible order has been issued by the President of the New York. New Haven & Hartford, to the effect that the heads of departments must not retain their relatives in the employment of the company. If a rule similar to this existed on all railroads, there would be fewer incompetent men holding important positions For years there was very little of the evil known as nepotism in the railroad world, but it has been growing very rapidly of late. On some roads there is scarcely an officer to be found who is not a nephew or cousin or brother-in-law, or some relative of a man in high authority. The thing is not fair to the company where it exists, and it is a real grievance to good men who have earned promotion.

### It Cured the Old Man.

The railroad superintendent who thinks that every detail of work, from the driving of a spike to the entering of a voucher, the repairing of a passenger car and the building of a bridge are all dependent upon his personal supervision, is fast disappearing, but he still is represented. There was once a superintendent named Pettibone, on a New England road, who was the worst representative of this class I have ever met, remarked the promoted conductor.

Pettibone was one of the small bore men who not only persistently bossed everything, but made himself intensely hateful to the men he was directing in the wrong way.

It came to pass that Pettibone fell sick, and there was rejoicing all over the road, for he was confined to bed. He fretted and fumed and acted like a mad man in bed, exciting himself in a fashion that threw him into a very serious condition. He felt that everything was going to rack and ruin, that office clerks were reading stories in business hours, that the shopmen were talking politics instead of working, and that the trackmen were devoting more time to their garden patches than to raising low joints. These thoughts were gall and bitterness. He felt that if he lay there another week all the locomotives and cars belonging to the company would be battered up in wrecks. There was not a train dispatcher on the system who could keep trains apart without his advice—so he thought, and the engineers would be running like rockets when they knew that he was on his beam ends.

Between a real fever and fretting his condition became so serious that his physician told him that he might die at any moment. On hearing this he sent for Conductor Burns, the only man on the road that he had confidence in. Burns and the super had been brakemen together.

"How are things on the road, Jim?" he asked, when Burns was shown into the sick room.

"First rate," said Burns, "they were never better."

"How many accidents have there been since I was confined in this cursed room?"

"Accident? Not any accident that I have heard about."

"No accidents! Have there been no collisions or trains getting ditched?"

"Nary a collision, and no ditching, except what the trackmen are doing."

"Do people talk much about my sickness?"

"Never heard a man say a word about it except Phil Green, the office cleaner, and he remarked that there had been peace in the place since the old man was laid up."

"But, Jim, you must have noticed that my illness must have depressed the stock of the road?"

"Depressed? It's up to 71, and it never got above 66 before."

"Well, well," groaned Pettibone. "No man is ever missed in this world. The road just going on as well as if I were around! The stock rising while I am lying here! A man might as well die and be done with it." And he lay down and resigned himself to his fate. Resignation was what his system needed, and he was out in two weeks. The first thing he did was to discharge Phil Green, but he reinstated him next day.

The old man was never quite so domineering after his term of sickness.

Scene in a street car.—Conductor comes along asking for fares. A stylish young lady takes a purse out of her bag, deliberately takes out a dime and hands it to the conductor, then closes her purse and puts it back in her bag. Next passenger is a Chinaman, who takes a nickel out of his *ear* and hands it to the conductor. Conductor hands the young lady the nickel as her change. Her purse is already in the bag and she puts the nickel in her mouth while she unfastens the bag. From Chinaman's ear to young lady's mouth! Ugh. Moral: Never put money in your mouth.

### My Experience as a Hay-Maker.

BY SAM SHORT.

Finding customers for railroad supplies these days is like searching a general superintendent's office for news about a wreck. Hard work and persistence are needed for those who are determined to succeed. It was in the spirit of the hard work part that I found myself at the headquarters of the Texas Nothern last month. Hope with no solid foundation took me there. But I did not start to tell you about my round of disappointments in the Lone Star State. A yarn which Superintendent Brown spun seems worth repeating to the readers of LOCOMOTIVE ENGINEERING.

The hard times was naturally the theme of conversation, and reminiscences of other days when work was scarce and money hard to find were in order.

"Times are not so hard as they were in '74," remarks Mr. Brown, "but when a man is out of work it pinches now just as hard as it did then, and I feel sore at having to lay off men, be they laborers or business solicitors. The panic of '73 hit me personally, and I know how to sympathize with those who are in similar luck to-day.

"When business collapsed in the Fall of '73 I was one of the unfortunate engineers laid off by the Michigan Central. I lay around Jackson all winter thinking that things would mend and that I would get back to work. They grew worse instead of better. In the spring I started out to look for something to do. Going round looking for work in hard times is about as distressing an experience as a man can go through. When I started out I was looking for a job as engineer, but it was not long before I was willing to take anything I could get.

"It is amusing to think about the different kinds of receptions a man gets from the people he asks work from. The majority of men refuse civilly but there are natural brutes who appear to enjoy insulting the unfortunates who have to 'beg a brother of the earth to give them leave to toil.' There is a wicked sentiment all over the country towards men who are looking for work. Many thoughtless people treat all men seeking work as tramps and vagrants. It was a common thing to be told that my class ought all to be sent to jail, although I was merely asking for work.

"I had gone from place to place until I found myself dead broke in Southern Iowa. There I struck a big German farmer named Hahn for a job of hay-making and was taken on with the promise of 50 cents a day and board. After I had been at work there for a day or two I found in the barn a threshing machine engine that had been through a fire. I asked Mr. Hahn what he would give me to fix up the engine. He offered me $10 but I stood out for $20 and he agreed.

"Hahn had a large family of ruddy, healthy looking children, and the eldest daughter was, I thought, the finest looking girl I had ever seen. She was the life of the household, overflowing with animal spirits and besides a standing reference for all the rest of the household. If the father lost his pipe, Bessie knew just where it was laid; if Robbie cut his finger, Bessie was the person appealed to to salve the wound. When Tillie cried because she could not do her sums, Bessie was the one to explain away the difficulty. When the older boys became unruly, it was Bessie who toned them down, and she was ever ready to take the lead in the parlor music which was the chief amusement of the household. The girl had the mental vigor that made her a leader in work, in study or in play.

"Bessie was pleased to take a compassionate interest in my case. She was full of regret that an engineer should need to turn to farm work, and doctored the blisters on my hands, that were too soft to operate a pitchfork all day without showing signs of distress. When a man is down a small word of kindness is magnified, and I looked upon Bessie Hahn as a sort of ministering angel. Her region of travel had been quite limited and she nightly questioned me about places I had seen, and seemed fascinated with my tales of railroad life. The person who has traveled is always heroic in the eyes of those who have never gone beyond their native county. A railroad engineer receives, on account of his calling, the interest that used to be taken in an old soldier. Passing through dangers and hardships brings the reward that always has been given to endurance and ungauged courage.

"I worked at hay-making for a week, and put in time evenings working on the engine. When the hay was all in I spent three days more working at the engine and finished the job by getting up steam and running her to show that she was all right. The job had turned out to be more difficult than I expected. The flues were all loose in the boiler, and the working parts were badly twisted, but patience and hard work put everything in good working order.

"I had a vague idea about how to set valves, but had never done the work myself, and I was at first considerably puzzled with the threshing engine. After a good deal of labor I managed to make the valve uncover the ports as the cross-heads moved away from the centers. That finished the job before firing up, and I was proud to have Bessie Hahn and her brothers watch what to them were mysterious operations.

"A small embarrassment was in store for me, however. When the engine was started she ran the wrong way. The thick-skinned old Dutchman roared when he saw the engine start, and I was amazed at his amusement till he told me that she was running backward. My experience with locomotives made me think that the right motion for an engine's fly-wheel was the same turn as a right-hand screw. When my rustic employer put me right in the most offensive way in his power, I soon put the machine right by moving the eccentric.

"My work was now finished and I saw it was time to go, although I felt very much inclined to linger about the place. I figured that I would leave the farm with $23.50, a sum that would help me into Kansas where I expected to find railroad work. On telling Hahn that I was ready to go and ready to take my pay he handed me $5 and said that was all my work was worth. I differed from him naturally, and we had a very sultry visit for a short time. But he would not give me any more money and ended by calling me a damned tramp and telling me that I deserved a good kicking.

"Well, I did not wait to provoke the kicking, for Hahn stood about six feet four and weighed 250 pounds. I felt very much like trying to take some of my money's worth in kicking the farmer, but finally concluded that discretion was the better part of valor and went my way. Anyway I did not want to have blows with Bessie Hahn's father. I started to walk to Oseoloosa. I had not gone far when a farmer driving a buggy overtook me. He stopped and asked if I wanted to ride, so I jumped into the buggy. He had seen me working in Hahn's field and asked how I got on with his neighbor, so I told him the story. He laughed and said that was just like Hahn. That Hahn would cheat his father if he got the chance and enjoy doing it.

"This farmer told me that they were building a railroad near Oscaloosa, and that I would be likely to get a job there if I tried. He took me as far as he was going in my direction, and I found my way to the headquarters of the railroad building. Nothing but grading was going on, and I went to work shoveling dirt. When Mr. McDonald, the contractor, came around, I offered myself as a candidate for running the first engine when track laying should begin, and got the promise of the job. Mr. McDonald appeared to take an interest in me, and always spoke when he came to the place where I was at work. I had not been wielding the shovel but two or three weeks when Mr. McDonald asked me if I knew anything about book-keeping. I answered that I had been a telegraph operator before I went into a railroad shop, and knew something about how railroad accounts were kept.

"'Come to the office in the morning,' he said, and I gladly realized that my experience doing the heavy toil of railroad building was ended.

"Next day I reported at the office, and was installed as time-keeper and book-keeper. The office was on the main street, and was a good place for seeing all that was going on in the town. About three months after I was appointed book-keeper there was a circus show in the town, and I was sitting looking at the loads of rustics driving in to see the show. In the procession I recognized Farmer Hahn and all his family, except Bessie, who was, no doubt, left to look after the farm. I thought now is the time to do some dunning; so I followed his team to the stable where he stopped. There I demanded the balance of my money, but Hahn only laughed, and said he had paid me all my work was worth.

"As I was engaged giving the farmer a bit of my mind, which was far from complimentary, Mr. Sharp, the contractor's lawyer, came up and asked what was the matter, for a crowd had collected. I explained the case, and he was highly amused. 'Come on,' he said, 'and leave the thing in my hands. We must put the mean cuss in for all the expenses we can.'

"It is for lawyers to tell how Mr. Sharp managed it, but he soon built up a long bill against Hahn. If business took him in the old man's neighborhood he would make a visit there and ask him for the money. He permitted the thing to drag on for about six months, and then entered suit against Hahn for my $18.50 and $97 expenses. Before the case came up for trial Hahn settled by paying an even $100."

"Did you get the first engine to run, as you were promised?"

"No, Mr. McDonald said he could do better by me and I remained in his office. When the operating of the road was begun I was made superintendent. It was afterwards absorbed by one of the trunk lines and I came on here."

"Did you ever see the Hahn girl again?"

"Yes, she's my wife."

The many railroad friends of Pedrick & Ayer will be glad to learn that their shop is again in operation. They are working 10¼ hours per day with about half the force, and orders are coming in fast enough to warrant continuous running. The shops are yet under the charge of Mr. James M. Hibbs, the assignee, but a new company is being formed, in which Mr. D. W. Pedrick will be the principal stockholder, Mr. Ayer retiring. These shops got their reputation on the mechanical ability of Dan. W. Pedrick, and users of the tools will be sure of the quality of the future product when they learn that Mr. P. will give the works his personal supervision as heretofore. The special tools devised or built by Mr. Pedrick have so cheapened the cost of locomotive repairs as to make his name known from one end of this country to the other.

In July, 1892, Division Master Mechanic M. L. Flynn, of the Michigan Central, at St. Thomas, Ont., built and turned out a new passenger locomotive, a 19x24 in. ten-wheeler, number 344. Since that time she has made 99,778 miles, and has just gone into the shop for her first repairs, her tire being worn down 3/4 of an inch. Pretty good service and pretty good mileage.

Please don't ask for our calendar unless you are a subscriber. It's a daisy.

### Carborundum.

Makers of machinery in the neighborhood of Pittsburg, Pa., have lately commenced using an abrading wheel made from a material called "carborundum," as a substitute for an emery wheel, and extraordinary accounts are given of the cutting qualities of the wheel. It is said to abrade metals with much greater rapidity than the emery wheel, and to do the work with less heating We understand that several railroad companies have bought carborundum wheels for trial, and that its performance is away beyond all expectation.

The material is a carbride of silicon, and the method of its manufacture was worked out by Mr E G Acheson, an electrical engineer. The hardest cutting material known to man is the diamond, which is crystallized carbon Mr Acheson believed that it might be possible to crystallize carbon after fusing it by means of the intense heat of an electric current, and he proceeded to make the experiment. His idea was to dissolve the carbon in melted silicate of aluminum and obtain crystallization as the mass cooled He succeeded in obtaining intensely hard crystals, but they turned out not to be pure carbon but a combination of carbon and silicon They were, however, so hard, that they cut diamonds, and are consequently harder than any of the oxides of aluminum, such as emery and corundum, which have generally been used for abrading wheels.

The manufacture of the compound was undertaken for commercial purposes, and it promises to take the place so long held by emery and corundum. Several diamond polishers in New York City are using the carborundum for the work that was formerly done by diamond dust, and for which no other material was previously found hard enough. Persons who are interested in learning more about this wonderful material should apply to the Carborundum Company, Monongahela City, Pa. The story of how the making of the compound was worked out reads like a romance when told by the principal actor, Mr Acheson.

---

One of the railroad papers, for advertisers only, feels bad about our friendship for the Traveling Engineers, the B. L. E., John Alexander, and the Ananias Corner. It cannot see why we publish a good many things that we do, and thinks it strange that the rank and file should take Locomotive Engineering, and that railroad officials should say it was interesting instead of falling in love with the mixture of ink and wisdom turned out in their advertisement foundry It is curious that, despite the scriptural injunction to "love thine enemies," the B. of L. E., the Traveling Engineers' Association, etc., should prefer their friends. There is no accounting for taste—we do not try. "The boys" like this paper, this paper likes "the boys" and if "the boys" and the paper can stand it, why, we guess the other fellow will have to.

---

The fast runs which Engineer Hogan made with the "999" on the New York Central appear to have stimulated the local muse to an alarming extent. They were evidently more gush-inspiring than the first buds of spring or the beautiful snow. Most of the effusions found early oblivion, but General Passenger Agent Daniels has snatched a few of the "poems" from the brink of the Lethean stream and given them the brief fame that folder affords. Four effusions are thus preserved Anyone who wishes to see how a fast locomotive can be done up in verse should send to Mr. Daniels, at the Grand Central Station, New York, for the folder that is "all about '999.'"

---

In the course of a personal letter the assistant locomotive superintendent of one of the British railways says "I have seen it hinted in some of our papers here that the Webb compound is going to be run against Buchanan's '999.' If this is so it is the worst mistake ever made by the designer of the compound engine. If all the talk we hear about these dromedaries, as they are called, is true, they are the laughing stock of railroad men on this side of the Atlantic. It is said that before getting their train started they often have to uncouple and run forward and then back up and be attached again, only to stand slipping until some passing engine gives them a start from behind."

---

We learn from an officer of the Caledonian Railway that they have adopted the six-coupled 18 x 26 class of engines for their heavy gradient passenger coast traffic, and that they rattle away at a rising grade of 1 to 75 with eighteen coaches. They have just completed at St. Rollox at Glasgow, twelve condensing tank engines for the underground Glasgow Central Railway. The engines look very much like American 8-wheel engines with a water tank added. The cylinders are 17 x 24, and the engines have 1,100 square feet of heating surface At the same shops they are building six 18 x 26 8-wheel engines, with driving-wheels 72 inches diameter, for express business, and six others of similar dimensions, but with 4-wheels coupled, for heavy passenger and fast freight traffic. These are equipped with the Westinghouse air-brakes.

---

There is intense indignation among many of the parties who exhibited car couplers at the World's Fair with the manner in which they were treated by the judges. The complaint is made that the judges examined only a few of the couplers exhibited, the impression being that the awards were all arranged in advance. It is certain that several of the couplers which are in great favor with practical railroad men received no mention whatever. Novel features of a highly valuable and practical character received no attention. A similar feeling exists about the treatment of other railroad appliances.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates They are made by Bradley & Poates, 251 William Street, New York City.

### OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in Locomotive Engineering. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the Star Engraving & Printing Co., 607 & 609 Sansom St., Philadelphia, Pa.

Sinclair & Hill.

### Group of the Foreman Blacksmiths' Association.

At the recent meeting of the above association, in Chicago, the above picture was taken. It is pretty foggy, but the men will feel just as if they were in a blacksmith's shop without ventilation, if the faces are indistinct. Commencing on the left and the first row, the personnel of the group is as follows

A. D. Wilkins, Pittsburg, Pa., Pgh. Loco. Wks., Jno. E. Mick, Chillicothe, O., B. & O. So. West; Jno. Buckley, Chicago, I. C. R R., C. H. Williams, Ludlow, Ky., C S. R'y; S. Uren, Sacramento, Cal., So. P. R R, J J. Thornton, Brainerd, Minn., N. P. R. R, Harry Jeffery, Pittsburg, Pa., Pgh Loco. Wks.; Geo. F. Hiokens, St. Paul, Minn., St. P. & D R R., A. Younger, Sacramento, Cal., So. P.R.R, Jos. Hughes, Bloomington, Ill., C & A R. R; Jas. Walker, Aurora, Ill., C. B. & Q. R. R.

### The Wabash Report.

The fourth annual report of the Wabash Railroad shows that the condition of this fine property has greatly improved under the able management of Mr. Chas. M Hays. The following extract from the report voices a sentiment well worthy of universal acceptance "In order to show the disposition of surplus earnings, a profit and loss account has been opened, to which the surplus of each year has been credited, and to which extraordinary expenditures for betterments have been debited. This account indicates clearly the disbursements which are not legitimately a part of the operating expenses, and obviates the necessity of adopting the questionable method of debiting and crediting "cost of road" under cover of a construction account, which is too often used as a cloak to conceal charges which should be included in operating expenses. Open construction accounts, although indispensable during the progress of construction of new lines, are always objectionable after a certain period when a road is supposed to be completed, or at least when it has arrived at that stage of completion when its earning capacity is to be tested and the net profits of the traffic are to be given as the basis of its value. Conservative railway management in the United States is understood to imply the maintenance and repair of lines from the yearly earnings, and, although it often becomes necessary to provide for deficient or incomplete construction from other sources than earnings, it is generally considered more in accordance with sound principles of finance to make definite appropriations to meet the required expenditures, either by the issue of bonds or capital stock, when the new construction is authorized."

### Cutting of Wheel Flanges.

An extremely expensive defect to railroad companies is the cutting of wheel flanges, which requires the renewing of the wheel long before it has made the mileage to be expected had the wheel worn evenly. A great many remedies have been tried, but we still see repair yards crowded with cars that are sent in to get wheels changed because some of them have been running to one side. The diamond truck comes in for a good share of the blame for flange cutting. To prevent flange cutting and unnecessary resistance from friction, the wheels ought to be held so that the axles are parallel and the wheels on each side made to revolve in parallel planes at right angles to the axles. The diamond truck fails wofully in holding the wheels in this desirable manner, and so long as it is generally used the railroad companies will have to put up with the expense of removing wheels prematurely because the flanges are cut. A crying need of the day is a freight car truck that will keep the wheels running straight on the track.

At the last meeting of the New England Railroad Club Mr N. Lauder gave a very lucid explanation of how many flanges get cut. It is rather novel to be told that cut flanges are more common on straight than on curved roads, but we believe the statement to be true. Mr. Lauder said

"The Western roads have long tangents and few curves compared to the Eastern roads, and, although the statement may seem strange, I think there is a much greater tendency to sharp flanges on those straight Western roads than on our crooked New England ones. The ordinary freight car is called center-bearing, but it soon gets down on side bearings. Most cars are built of green wood, by contract, with the wheels perhaps ¼ to ½ in out of gauge, and it cannot be expected they will remain center-bearing very long; they become side-bearing. The side bearings are put in there to keep the cars from tipping over. When the car gets down on side bearings it takes an enormous force to swivel the truck under that car When that car rounds a curve it takes a jump and swings to one side, and when it leaves the curve it comes back only far enough to allow it to run on the rail, it runs on that tangent for miles and miles, and there not being swing enough to bring it back, it grinds on the flange all the way until it comes to another curve and takes a swing the other way. I think a center-bearing car is a humbug, and that the car should have side bearings, and such bearings that the tendency of the load will be to bring the truck back straight with the sills of the car, straight with the track it is to run on."

### Balanced Slide-Valves.

At a meeting of the Southwestern Railway Club, Mr. Sanderson, of the Norfolk & Western, read a paper on Balancing Slide-Valves, which represented the results of very careful investigation and calculation. The author of the paper gave figures showing the pressure on the valves during the whole stroke, the relative positions of valve and piston being shown graphically An engine carrying 140 pounds boiler pressure had a maximum valve pressure of 26,300 pounds.

The conclusions arrived at by Mr. Sanderson were that balanced valves, as a rule, do not have sufficient of the area exposed for downward pressure balanced. In view of the large valves and intense pressures coming into use, these conclusions are deserving of serious attention. We would suggest to the roads that are using valves with circular balancing devices to calculate how much of the surface there is left without anything to relieve the downward pressure of the steam.

### The Locomotive Yields to the Trolley.

The success of trolley electric railroads in many cities is forcing the managers of different elevated and suburban railroads to investigate the relative expense of steam locomotives and of electricity in the operating of cars. It is difficult obtaining the data necessary for accurate comparison, but those who are most familiar with the subject say that the car ton can be moved by steam locomotives at about half the cost for fuel entailed by the use of electric motors. The mere cost of fuel is, however, a small part of the considerations involved. If a more convenient service can be provided by running electric cars than what is practicable with trains pulled by locomotives it may be found the best paying plan to run electric cars, even when the expenses for fuel are largely increased The case of the Brooklyn, Bath & West End Railroad, N. Y, is representative of many others. This road has been operated by steam for years, but lately part of the line came in competition with trolley electric cars, and the latter cars were securing a great part of the business because they ran oftener than the steam trains. It did not pay to run a steam train as frequently as electric cars were run on account of the high wages account, and so the railroad company abandoned locomotives and put electric cars upon their line The Kings County Elevated Railroad Company is considering the propriety of making a similar change.

The business men of Memphis, Tenn., are striving to bring manufacturing concerns to their city In pursuing this policy they made an offer some time ago to the Letchworth Car Co., now located at Letchworth, Ill., to remove their plant to Memphis. The offer has been accepted, and the car plant will soon be removed.

## *Railroad Coppersmithing—IV.

By John Fuller, Sr

BRAZING AND SOLDERING THE JOINT

We shall now proceed to make use of the firepot, and describe the process of hard soldering by its aid. The pipe having been placed in position, care should be taken that the socket is level across the brim, perhaps it is better secured in the pit, or fastened to the forge or some other suitable and convenient place, so that the roller and chain overhead is handy, if necessary to the job. By referring to the engraving, Fig. 37, the clamp to hold up the pot is seen, which is made of $2\frac{1}{2}$x$\frac{3}{8}$-inch iron, the arms being formed so that they will clasp the pipe, and are held there by two bolts, as shown. There should be enough space between them so that they could be used for different sized pipes. These clamps are fastened close up under the bottom of the socket, then the iron plates which form the bottom of the firepot are laid on, as shown in Fig 38. Now spread a thin coat of moist clay over the plates and around the pipe, and hollow it up the socket from 1 inch to $1\frac{1}{2}$ inches. This is to keep the joint cool at the bottom, so that as the spelter melts it will not run through—that is, not lower than the clay. Now place the pot in position with the pipe in the center, as shown in Fig. 39. This is the most critical and important feature of the work. Care must be taken to have the flange of the socket, which is to hold the solder level, and the brim of the pot level with the socket flange. The pot would be better rather below than above, for if the spelter be too far out of the pot the blast is too low down, and if it is too low down in the pot there is danger of running out the seam in the upper pipe. Then, again, the joint cannot be skimmed off handily or so well attended. When the pot has been placed in proper position, draw the clay around the bottom of it outside so that the flame will not escape between the pot and bottom plates, then apply the blast-pipes. If the joint be less than 5 or 6 inches in diameter one blast-pipe will be enough, if the blast be of sufficient strength, but if the pipe to be joined is larger than 6 or 7 inches, then there should be two entries of the blast, as shown in Fig. 39. The socket-flange about the joint is now filled with clean mixed spelter and borax. If the joint to be made is on brazed pipe, then spread a little moist fire-clay over the seam up to the rim of the socket. Fasten the two screw-clamps, Fig. 40, opposite each other at the top of the pipe, and pass the traveler-chain through them and hook in a link or hook around the chain. On the other end of the chain a counter-balance weight is attached, nearly equal in weight to the male part of the job, or upper piece, or the chain may be fastened to the cleat or hitching-hook on the wall in such a way that it will take the weight of the top piece of pipe while the joint is hot.

We are now ready for the fire. First, place a little dead charcoal on the wet clay, then put a layer of live hot pieces, and cover them with a few more dead ones, and fill up the pot with nice clean coke of about the size of a walnut, covering the solder some two inches, that is, pile the coke up around the pipe in a conical form from the edge of the pot. Then let the blast in slowly, and be patient until the joint is red hot right through. While this is going on slowly, touch down the coke into a compact mass. When the joint is thoroughly red hot take the coke back a little from the pipe and dust some freshly powdered borax on the spelter, by this time the fire should be in good condition. Draw the coke up around the pipe again and replenish the fire, and let in the blast at a brisk rate, keeping a watchful eye on the solder and the blast slide. When the solder has run and the joint is full and well fluxed, skim it off with a red-hot poker or rod, Fig. 41, flattened at the end, and stop the blast, take off the blast-pipes and lift the pot, then throw a little common salt on the joint to kill the borax, which is hard on a good file. In all cases the draft through the pipe should be stopped, because the cold air going through tends to keep the joint cold, and, in case of larger pipes greatly retards the progress of the work. The directions above given are intended especially for learners, although old hands would save themselves some time and often much trouble, were they in a majority of cases to follow them out. The practice in many, perhaps most shops, is to make a large fire on the brick forge, and then take a shovelful of live hot coke and fill the pot with it, and a failure is sometimes the result. But practice will partly balance the chances, because a man *must* make himself acquainted with the "ropes" (customs) of the shop in which he gets employment, no matter how absurd they are they must be continued. Advance or innovation is seldom countenanced by workingmen without trouble. I never had any trouble, or a single failure, when the fire was started with charcoal as above directed.

SOFT SOLDERING THE JOINTS

To make a soft solder joint the firepot is placed in position in the same manner as for brazing, and charcoal is used in preference to coke entirely in this operation. The solder may be run from a suitable stick or from a ladle. Joints in small pipes can be made with the aid of a pair of round tongs made hot. Joints in large pipes are sometimes more conveniently made and a better job done, by using a pot of burning charcoal, Fig. 42, applied on the inside, held and lowered into the pipe with the chain, care being taken to keep the lower end of the joint cool, and sizing the male end with size made of ivory-black or lamp-black and gold size, or any other pigment that will answer the purpose of preventing the solder from running through the joint. The firepot for large soft solder joints is made to fit the pipe easily, and to hold a sufficient quantity of charcoal to do the work required. The bottom end of the pipe in this case is left open, if possible, so as to permit the draft, which in the other case is necessary to stop. It will be seen that the bottom of the socket must be kept cool enough to stop the solder from running through, or the possibility of a leak may be prevented by rubbing some moist clay into the end of the joint on the inside, if one can get to do it conveniently.

PATCHING PIPES

Patching copper pipes, like most of the other branches of coppersmith's work, requires perception first, and then skill, with patient persevering ingenuity. Pipes are liable to so many different kinds of fractures and breakages that one can hardly prescribe beforehand a remedy for all the many contingencies that may arise. We will, therefore, mention a few occurrences that are happening frequently, and let them serve as stepping-stones to the performance of others that may call for the attention and skill of the operator. It often happens that pipes burst at the seam, this may arise from one of several causes, namely From imperfect brazing, such as overheating while at the fire, or not enough heat to properly fuse the spelter so that it adhere firmly, or from freezing, continual jar, over-pressure from force pumps or flaws in the metal

If a fracture should occur from overheating, that is the part is burnt, it is best to cut it out, it can never be successfully repaired. If ever so good a job be done, it is all to no purpose, seeing the foundation of the work has been made rotten. Again, there is no satisfaction for the labor spent, and it is therefore useless, except in cases of extreme emergency, to waste time and material on it. If the fracture arises from the want of heat, or the spelter has not been run enough to adhere to or fill the joint, then open the joint and properly clean it, then close it down and give it a coat of warm borax and water, the borax having been previously dissolved in hot water, jar this through the seam, and charge it again with spelter either inside or outside, as seems best. If outside, the addition of a little fresh spelter will do no harm, if care is taken to see that it is all completely run. If from freezing, the fracture may be anywhere as well as at the seam, then the metal will be parted as if cut through with a knife. If this should be the case, file it down at the fracture, as shown at *C*, Fig 43, so that where the split is the edge is thin, making the scarf similar to those at the seam, and clean the split carefully on the edges. Now make the patch *A*, thinning the edges down to a suitable thickness, *B*, so that the edge of the patch will just cover the outside edge of the scarf on the pipe at *C*, and let the patch be thick enough to make the part of the pipe repaired the same thickness as any other part of the pipe

When the patch is properly fitted, anneal it with some wet salt previously smeared over it, then scour it clean and cover it with a thin coat of fine spelter and borax, and run it smooth over the patch at the fire, throwing off all that will leave it with one jerk while it is hot (this is to answer the same purpose as tinning). Now wire the patch fast to the pipe as shown in Fig. 44, and place the wires sufficiently close to keep it from bagging when hot, charge it with fine spelter, one half on the pipe the other on the patch, and put a little inside along the crack, when the solder has dried enough, make the pipe red hot slowly all around the back of the patch and along the whole length of it, preventing oxidation of the spelter by a supply of borax kept always at hand. When sufficiently hot, gradually turn it over, and offer the spelter to a moderately brisk fire. It should run and flow easily, and if carefully performed, a good, sound and durable job will be insured. The cleaning off or finishing the patch is next in order, which may be done as tastily as the job will admit, to make it look as if the work had been performed by a competent mechanic. If a fracture is caused by a continual jar or over-pressure by a force pump, it will in all probability be like that caused by freezing, and may be treated in the same way. Flaws in the metal arise from many causes, and their particular condition when discovered must govern what are the best measures to be taken to remedy the defects. If the flaws occur in large work they may be cut out and the patch cramped in or riveted in and then brazed.

It often happens that continual jar produces a lateral fracture at right angles with the length of the pipe or around the flange immediately above the solder. To repair this kind of fracture, a copper collar, *E*, Fig. 45, from $\frac{1}{2}$ to $\frac{3}{4}$ inch wide, is prepared, of about the same thickness as the pipe. The pipe is now taken to the fire, and the old solder run with a little fresh borax, and, when in a thoroughly liquid state, the solder is thrown off the flange with a sharp jerk, when cool, the pipe is cleaned as far up as necessary, then the collar is prepared to suit, and covered with fine solder as before directed, then coiled around the pipe and wired close, as at *D*, Fig. 46, the wire being placed close to the upper edge of the collar, to form additional room on which to lay the

solder. Care must be taken that the collar fits tight up to the pipe. If the work is done on a small pipe, it is left open, so that the heat may readily run up through the pipe to assist in running the solder laid about the upper edge of the collar *D*. If it is a large pipe on which the work is being performed, then the end is stopped with a piece of sheet-iron, clipped around the edges and bent up to fit, which is placed up the pipe at the lower end about a foot, instead of 3 or 4 inches, as is done when brazing on flanges.

TEMPLATE BOARDS.

The template boards are a very useful and convenient contrivance, made for the purpose of substituting the position in which pipes are to be coupled or occupy on an engine or tender or in a ship's hold. The single board is shown in Fig. 47.

This board, or rather two boards, are hinged together at *A*, and provided with two wings, *B*, about an inch wide, similar to that of a pair of compasses. These wings are fastened to the bottom leaf of the board, and slide through a loop which is fastened to the side of the other leaf.

The loop is provided with a thumb-screw, which being tightened on the wing holds the upright leaf of the board in any position the flanges may require. The double board, Fig. 48, is similar to the single board, but has two leaves. This board is to take the set of S-bends from templates when they are required to be set at right angles to each other, as shown by the pipe standing on the board, Fig. 48.

Here is an example, given to show its practical use

It often happens from continual jar or improper adjustment to allow for expansion and contraction, as in the case of steam pipes, feed pipes and suction pipes, that the pipe breaks off close up at the back of the flange, *A*, Fig. 49, and the flange is not damaged, or the pipe either, further than the flange being broken off, and it is necessary to put the flange back on the pipe again without piecing, and to have the bolt holes in the exact position after the pipe has been repaired as they were before the pipe was broken.

Suppose the pipe to be broken off at the bottom flange *C*, Fig. 47 First match the fracture, and take a template of it on the board by making the board fit the position of the flanges, as shown. When they are in their true position, as they were before the pipe was broken, mark the flanges around with a pencil on the board and all the bolt holes; then make a chisel mark on the edge of the flange, and at this point mark it on the board. Now all is prepared ready, and we can proceed with the repairing. Anneal and clean the end of the pipe inside and outside, and make a short thimble 2 inches long, *D*, Fig. 50, of light copper, and fit it tight into the end of the pipe, and place it so that when the flange is put on over it the thimble will come through the flange, *E*, Fig. 49, ¼ inch. Braze the ferrule in the pipe on two sides inside, and then run off all the old solder from the flange *A*, and when cool fit it to its place again, being careful to match the fracture and the holes and chisel mark on the board, then turn the end of the ferrule over the flange, forming a rivet to hold it on and to draw the flange close up to its place. Now make a collar of a strip of copper, *B*, Fig. 51, and scarf the ends, and after bending, as in *C*, Fig. 52, put it around the fracture, *F*, Fig. 53, making it wide enough to cover the break ¼ inch. Then wire it on tight, and after carefully charging it with fine solder around the top edge of the collar and coarse around the bottom, sling it over the fire, with the upper end of the pipe open, and run the solder. When the solder is set the wire may be taken off while it is hot quite easily. If the instruction here given be carefully followed, a strong, substantial job will always be the result.

## Wm. Baxter's Compound Locomotive, Built in 1870.

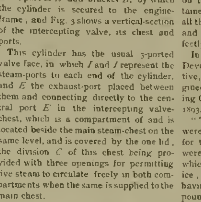
BY JOHN H. COOPER

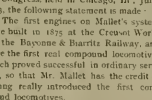
The writer is indebted to Mr. H F Colvin, of this city, who has discovered, identified and sketched Mr. Baxter's high-pressure cylinder (5 in. diameter x 12 in. stroke), as used by him on the Worcester & Shrewsbury R. R. early in the seventies. From these sketches I have made drawings, which are reproduced in the cuts accompanying this article.

Fig. 1 shows a plan of the cylinder, with valve faces and ports; Fig 2 shows a cross-section of Fig. 1, through the exhaust port *E E* and bracket *B*, by which the cylinder is secured to the engine-frame; and Fig. 3 shows a vertical-section of the intercepting valve, its chest and ports.

This cylinder has the usual 3-ported valve face, in which *I* and *I* represent the steam-ports to each end of the cylinder, and *E* the exhaust-port placed between them and connecting directly to the central port *E* in the intercepting valve-chest, which is a compartment of and is located beside the main steam-chest on the same level, and is covered by the one lid, the division *C* of this chest being provided with three openings for permitting live steam to circulate freely in both compartments when the same is supplied to the main chest.

When the intercepting valve *D* is placed





in the full line position shown, the exhaust steam from the high-pressure cylinder would flow freely through the *D* opening under the valve from the port *E* through *E*, and by the way of the port *F* to the low-pressure steam-chest, in which case the engine would work compound. When this valve was moved to the position shown by dotted lines, the exhaust from the high-pressure cylinder would flow from the port *E* through the connected port *H* to the atmosphere, at the same time live steam would flow from the steam-chest through the uncovered port *F* to the low-pressure steam-chest, in which case the engine would work as a simple one.

The pistons of both the steam cylinders were connected to crank-pins at right angles in the usual way, and the main slide-valves were worked by Stephenson's link motion, such as are in common use on the locomotives of to-day. The four driving-wheels were each 2 feet in diameter, and were coupled by solid end side-rods.

The low-pressure cylinder was 8 inches in diameter by 12-inch stroke, and was in every particular like the cylinder of the ordinary locomotive designed for simple running, its steam-chest being supplied with either the exhaust steam from the smaller cylinder, or with live steam directly from the boiler, according to the position of the intercepting valve *D* as already described.

The railway gauge was 3 feet. These locomotives were in regular daily service for ten years and over.

Mr. Wm Baxter, Jr, writes under date of March 25, 1891, in reference to his father's compound locomotive

"This locomotive was made about the year 1870, and the compound type of machine was used not only to insure greater economy, but also to meet the requirements of street railway service. The cylinders were so arranged that when the car was running on a level, it would work compound, but when it was desired to obtain more power to ascend the grade, both cylinders worked with live steam. In this way the power of the machine could be varied all the way from five to twenty H P. The first machine made, in addition to having a compound engine, had a compound boiler. The high-pressure boiler was surrounded by an annular low-pressure boiler, or regenerator, and into this latter the high-pressure cylinder exhausted. In this way, the back-pressure on the high-pressure cylinder was maintained uniform, and at the same time, all the condensed steam was regenerated and entered the second cylinder perfectly dry."

In Mr. A. von Borries' paper on "The Development of the Compound Locomotive," presented at the mechanical engineering section of the World's Engineering Congress, held in Chicago, Ill, July, 1893, the following statement is made

"The first engines on Mallet's system were built in 1875 at the Creusot Works for the Bayonne & Biarritz Railway, and were the first real compound locomotives which proved successful in ordinary service, so that Mr. Mallet has the credit of having really introduced the first compound locomotives.

"In these locomotives, the low-pressure piston received the full steam pressure when working non-compound, thus giving very unequal tractive force, and causing the train to shake at slow speeds

"Mr. Mallet has been engaged since 1874 in adapting the compound system to locomotives.

"The original Mallet system, as described, is to be classed as a two-cylinder locomotive, which may be worked either as a compound or as an ordinary engine."

Without disparaging the labors and inventions of other engineers, who are making noteworthy efforts in the right direction with much good result, this early contribution to the development of the compound locomotive by Mr Baxter must be regarded as not only an invention of supreme simplicity, but as one which solves most directly the problem of the two-cylinder compound locomotive.

With these dates and data before us, the case is clear that to Mr Baxter belongs the credit of making and using continuously on the road the first two-cylinder compound locomotive that may be run for any length of time, either simple or compound, at the will of the engineer.

## If He Had Kept His Hands Off, the Boiler Might Not Have Blown Up.

"Died with his hand on the safety-valve." What better epitaph could any man have than this which is written of John Armstrong, the engineer of the Dry Dock stables on East Fourteenth street?—*N. Y. Evening Telegram, Nov. 6.*

Paul Synnestvedt's article on "Disease and Cure of Air-Brakes" commences next month.

## Train Running for the Confederacy.

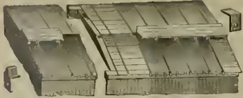
BY CARTER S. ANDERSON.

Owing to my feeling of utter incompetency to write for such a journal and to increased duties, I expected never to write again for your paper, and probably never would have attempted to do so had I not received several encouraging letters from young men of the North who read your paper, especially from one in Auburn, N.Y. I cannot imagine why young mechanical folks of to-day should take so much interest in the build of our little old scrappy engines. I should think they'd rather hear those touches of war history which I am compelled to bring in as I tell of the difficulties under which we railroaded in 1861-5.

Well, boys, here is one of my trips in the early fall of '61. Being promoted from baggage-car to conductor of troop train, I got orders to take a load of provisions from Richmond to Jackson River, the then terminus of the Virginia Central Railroad, for the Western army, which was as well as I remember under the command of General H. H. Wise. The train consisted of about twenty freight cars of provisions—no caboose. I rode sometimes on the engine and sometimes on the rear freight car loaded with hogsheads of sugar, bacon, etc. We had the engine "Staunton," and John Harton, engineer. The "Staunton" was built about 1858 or '60 by the New Jersey Locomotive Works. She was bought for a fast passenger engine. Her drivers were 5 feet 6 inches high. She set up high on her bearings. On account of our Blue Ridge and North Mountain grades, the "Staunton" did not prove satisfactory. She had a most powerful whistle, and that is the most you could say of her. She would slip her wheels on every occasion of a tight pull, and had acquired the name of "Old Spinner." But on moderate grades she could fly. The "Staunton" was, therefore, put into extra freight use. In other words she had to step down and give place to those of better build.

About the time that we left Richmond at this period of which I tell, two double-headed trains left Jackson River for Richmond heavily loaded with sick and wounded soldiers from West Virginia going to the hospitals. We got orders at Richmond to go to Gordonsville and report for orders. Gordonsville was at that time the most important military point in Virginia or the South. About noon each day there stood at Gordonsville long and crowded trains from four different and very important military points. It was a busy scene, and about the depots, for an hour or so, there was a dense crowd of officers, couriers, soldiers and sutlers going to and coming from the battle-fields.

Being an extra we had to remain there that day four hours before we could get orders to go West. The old "Staunton" had become so hot that she was blowing off loudly, and John Harton, himself, had on more steam than his boiler plates justified. We got orders, though, about 4 or 5 P. M., to go to Greenwood and "meet two troop trains, and then to go to Staunton and report for orders." When John Harton pulled up on old "Staunton," I was closely following, and—well, I was seeing how he rolled those twenty cars along the light grades and very rough track to Charlottesville. But when the "Staunton" struck the 75-foot to-the-mile-grade, she soon told Mr. Harton that she had on too many cars. So he left enough at Mechum's River to enable her to pull the train, and we soon reached Greenwood, and took the siding to await the arrival and passing of the two troop trains mentioned in the order The first train soon came through Greenwood tunnel and stopped for water. "Where's the other train?" I asked of the men. "Left it at Staunton, it is closely following and will be here soon," they answered. Sure enough, not long after the first train



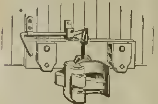
## THE MURPHY STEEL CAR ROOF.

HAS no surface nail or screw holes. It has no joints where cinders, rain or fine snow can get through. It allows for contraction and expansion, and has ample elasticity to provide for sagging, twisting, buckling and cornering of the car body. It 's as solid as the car frame itself. It has no soldered joints. It can be repaired readily, and without taking off more of the roof than is damaged. It is much cheaper than any other metallic roof now in use, and is cheaper than the double board roof, made of good lumber. It is unlike any other metallic roof for the reason that **everything is furnished to make it complete**; so that the parties buying it have no expense other than to apply it.

**This ROOF can be applied on OLD LEAKY BOARD-ROOF CARS without making any changes in the board roof; thereby saving the expense of replacing the old boards with new, and thus utilizing material that must otherwise be thrown away.**

Manufactured by the P. H. MURPHY MFG. CO., East St. Louis, Ill.

---



## THE SMILLIE COUPLER is the Strongest and Simplest M. C. B. Coupler.

**Only 4 Pieces.**

Tensile Strength (Fairbank's Test) 139,640. Drop Test, 700 lbs. hammer dropped 18 ft. 22 times failed to break the knuckle.

ALL LOCKING PARTS ARE THE BEST OF STEEL.

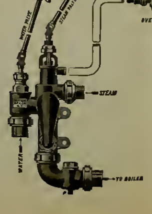
NATHAN MFG. CO., 92 & 94 Liberty St.,
NEW YORK.



had left, I heard number two, as I thought it was, coming. It soon pulled down out of Greenwood tunnel and stopped also for water. "Hello George, where's your train?" I asked of George Pelter, the engineer, who was greasing his engine, "John Timberlake," while his fireman took water.

"I could not pull my train, and left my cars at Waynesboro'. I am on my way to Richmond to get another engine," was his reply.

I, of course, considered then that the road was clear, and that my orders justified me in going ahead, having met *one* train, and the engineer of the second engine telling me that he had left his cars, which of course I concluded were those of the second troop train, at Waynesboro'. Thinking there was nothing else to come, I ordered my brakeman to change switch and told Mr. Harton to go ahead. "Why, Carter," said Mr. Harton, "that was only an empty en ine that passed. How is that?" I explained to him that George Pelter had had to leave his cars at Waynesboro' on account of his engine giving out. "Ah! All right, then," said John, and so we pulled out. As I had to see the switch locked, I pulled up on the last freight car and waved him (Mr. Harton) to go ahead.

Now, before I relate the accident—awful as it was, which soon followed—I will show your readers how we misapprehended the orders. The engine, which we met at Greenwood and whose cars had been left at Waynesboro', was *not* the train number two in our orders. There was a train at Waynesboro', which had no orders from the dispatcher to move, but as the engine was out of order, the engineer concluded himself to run under flag behind the first section of troop train and ahead of second section, thus making three trains, or at least three engines, which we would have had to meet at Greenwood had the dispatcher known that Pelter was coming in with his engine.

So tugged away the old "Staunton," and on came from Staunton, facing us, the double-headed troop train full of wounded and sick soldiers. Seth Mack, the oldest engine runner in America, now hostler in the Richmond yard, ran the front engine, "Albemarle," a fine Rogers engine. Coupled behind him was the Norris engine, "Monticello," run by John M. Kraft. When the "Staunton" turned the summit at Afton, and pitched into the dip and very severe curve, just before entering the eastern portal of Blue Ridge tunnel, the fated troop train was cautiously—thank God!—rolling down through Blue Ridge tunnel. The tunnel is straight, but curves so suddenly at eastern portal that it is impossible to see scarcely any track ahead until you are out of the tunnel. So when Seth Mack popped out of the tunnel, "Staunton's" great headlight met him full face to face, and not a hundred yards away. "Uncle Seth" says he whistled for brakes and drew her back. Mr. Kraft also reversed his engine, thus somewhat checking the very heavy train, so that when the "Staunton" dashed *her* brains out against the "Albemarle," it very slightly disabled the latter; but the old "Monticello" caught the blow as the train in her rear bursted into her tender and otherwise damaged her. What saved us from a more fearful accident was the caution which the east-bound double-headed train was taking before entering the very heavy curve on the hill overlooking the lovely Rock Fish Valley.

The curve there is so heavy that the guard rail is used there as a safety.

Although badly bruised, I was able to go to the front, and I found Mr. Harton not only not killed, as I had feared, but at work on his engine getting her in a condition to handle. The smoke from all three locomotives rolled into the tunnel as it would have been drawn up a chimney, and soon there arose howls and curses from the poor suffering soldiers who were stifling from the smoke, which had now gotten so thick that it was impossible to breathe. Fortunately no one was hurt by the collision. Only the smoke was killing them.

"Get down out of the cars, boys, and put your noses near the ground," cried out the voice of Conductor Joshua Finks, as he came along the side of his train to see what had happened to the front. The sick and suffering soldiers actually got down into the water which continually runs through this tunnel, and thus managed to get breath and get out alive. The smoke was stopped just as soon as we could put out the fires.

The crowd soon gathered. Some officers, the attendants on the sick, and some furloughed soldiers came to where we were working on the wrecked engines.

"Whose fault is this?" loudly called out an officer in a commanding voice.

"Major, here are my orders," answered Conductor Finks "'Go to Greenwood and meet one troop train; go to Charlottesville and report for orders.' This is the train I should have met at Greenwood," concluded he. Truth.

John Harton had in one hand an old-fashioned torch—black smoke and big blaze—and in the other his monkey-wrench. He realized the situation, and turning around said, with a firm and manly voice "Major, I pulled out of Greenwood side track, where my conductor had the switch changed, and gave me orders to do so. But though I am innocent, I am as well prepared to die now as I ever will be, and if you will only allow me time to get my engine back to Afton side track, so that these poor suffering soldiers can get to the hospital, you can dispose of my old body as you please, for I am nearly dead, anyway," and turning away his smutty face he went to hammering again.

"Where's the conductor of this train?" boldly asked the major.

I was about to put my nerveless fingers into my vest pocket for my orders and explain, when good and witty old Conductor Finks answered "*Dead*, sir! Mashed to death in the rear car among a lot of government supplies!"

"Yes," said John Harton. "And in hell, I hope" But John knew I was within ten feet of him as he spoke. Then, Captain Finks, turning quickly to me, said, "Henry, by the way, you must take a telegram at once to the Greenwood office. We must have two engines here at once, and the wrecking force to clear the track. These poor soldiers must be carried to the hospital, if we have to roll 'Old Spinner' down the mountain to do it." At the same time walking me off and giving me his lantern, while he pretended to be writing a telegram. As soon as he got me far enough off he gave me a sure enough message, and told me to go to Greenwood, report the accident and then keep out of sight until the soldiers' train had passed. For once in my life, I can truthfully say I took advice.

I joined my crippled train next day at Afton, but had to go to bed on account of injuries received from being caught between a hogshead and side of the car when the accident occurred. In about a week I reported to Superintendent H. D. Whitcomb, at Richmond, who said to me, "Carter, had I seen you immediately after the accident occurred I would have discharged you at once. But your absence, on account of your being hurt, has given me time for reflection, and I confess that my system of giving train orders was imperfect. I have now adopted a rule of giving in every train order the names of conductor, engineer and engine of both trains"—a rule which worked well and continued in use for twenty years Continued my honest superintendent, "You can go back on your baggage-car with Conductor Jones. I would rather not put you to running conductor now. This thing of wrecking trains crowded with soldiers is rather serious"

There happened to the troop train in the tunnel that night what may seem impossible; but I can prove it, if necessary, just by way of argument. From some cause there was in the troop train a flat. The flat was lower in body than the freight box car in rear of it, and when the collision occurred the box car jumped entirely off its truck on to the flat, and was carried, with soldiers in it, to Richmond, so nicely did it fit itself on to the flat. Of course, it just happened so.

One of your readers writes. "My old father wants to know what became of the 'Fred Harris.'" The "Fred Harris" was the smallest and oldest engine that I remember our using. Jug boiler and her steam-gauge made like a spring balance. In 1862, Superintendent Whitcomb took her to Lindsay's Station, where he had her uncoupled and swung so that he had a saw-mill attached, and John Parrott cut many thousand feet of car lumber with it. The mill and engine sat near the track. At a glance one would take it to be a short train, taking in the engine with her cab, and John, just for mischief in it, as though he were going to move. One day some one on the west-bound P. M. passenger train called out "Parrott, what time do you leave?" "Just as soon as I get 'all aboard,'" said he. When the old "Fred Harris" did get "all aboard" she was scrapped, and her cab set up on Seventeenth Street yard as a watch-house for crossing-watchmen.

SWISS RACK-RAIL ENGINE, RUNNING BETWEEN LAUTERBRUNNEN AND GRINDELWALD.

## Wants to Run 200 Miles an Hour.

One of the commonest cranks of the day is the high speed for railroad trains crank. The latest specimen hails from Buffalo and he has been making his views public in the Buffalo *Express*. His name is Kelly. He promises to be as famous as Keeley. A speed of 112 miles an hour is too slow for him, and by means of cars offering diminished resistance to the air and a wonderful locomotive, he means to make 200 miles an hour common speed. Here is his description of his locomotive

"In the common locomotive the boiler used is 56 inches in diameter by 27 inches over all, having 230 2-inch flues 12 inches long, supplying the cylinders with wet steam taken directly from top of water. Steam travels 24 inches through pipe to cylinder-head, thus wasting 40 per cent of pressure in pipe friction and turning five corners. The boiler in 'Thunderbolt' is the same length, elliptic instead of circular in form; has 502 flues instead of 231 It has a horizontal partition with super heating steam chamber, larger than a common boiler; the steam travels only 4 inches to get from boiler to cylinder instead of 24 inches, thus saving the entire 40 per cent. lost by the old boiler. All steam is super-heated, also a great advantage A common engine exhausts perpendicular up against the air at its gravity weight of 15 pounds per square inch, which is equal to a downward stroke of a 3,800-pound hammer on top of the engine every time the engine puffs at the open throttle. In the new engine the exhaust is directly back, sending the smoke and cinders out of the rear end of the train and thus forcing the train forward by a pressure of 3,800 pounds, a clear saving of nearly two tons of power.

"The engineer has a cab at the front of the boiler instead of the rear. The pilot is in the roof to his cab, he has a clear, unobstructed view on both sides and front The fireman occupies his old stand."

## Arbitration Should Prevent Strikes.

In an article on arbitration as applied to railroad corporations and their employés, contributed by Mr Edward A. Mosely to *Transportation*, the following paragraph is found

"Without venturing upon a statement in relation to the railway strikes which have occurred in our country, it is sufficient to give the result of the Scottish railway strike of 1890, when there was a complete paralysis of all industry Over 100,000 persons, other than strikers, were thrown out of employment as a consequence of the railway strike Steel works, engineering works, ship-building works and cotton mills shut down for want of coal and material. The scarcity of coal affected most seriously and bore most heavily upon the poorer people. The public loss and inconvenience was incalculable, the retail price of coal doubled. Trade left Scottish ports and merchants bought their goods elsewhere. Such a calamity might overtake our own country Can the efforts of the legislator be better directed than towards a solution of this question, towards devising some method of treating in a just, amicable and satisfactory manner these disputes so liable at any time to arise? It is for the common good, 'the general welfare,' of all interests that arbitration in matters of railway employment may be provided. May we not look forward to the time when the almost waste product of the higher abilities that are latent among railroad employés will be availed of in the directories of the corporation"

Some extraordinary ridiculous claims have been made for a smokeless coal found in the Ouchita River district of Arkansas. A daily newspaper account says that the coal is found in a large deposit, the vein being 42 inches wide. It contains 20 per cent. of oil, which has been found to be very valuable in making paint A bar of iron painted with it has been placed in a fire and submitted to an intense heat without disturbing the paint It is also claimed that one ton of this coal will produce as much steam as ten tons of ordinary coal. It is also claimed that it is much better for gas than Pittsburg coal.

The agents of the Chicago, Milwaukee & St Paul have been invited by Mr. George H Heafford, the general passenger agent, to engage in a curious competition. He wants a motto for advertising purposes that shall be striking, as catching as "You press the button and I do the rest." He offers a $25 prize for the best one, and warns all concerned to avoid sending in chestnuts. A striking, original catch phrase is worth ten times the money offered.

### An Attractive Iron Exhibit.

Ewald Iron Company, Tennessee Rolling Mills of St. Louis and Louisville, present a cut herewith of a very handsome hardwood pavilion. their exhibit at the St. Louis Exposition this year. This company displays, in a very tasteful manner, their well-known Tennessee bloom charcoal iron for stay-bolts. In their variety of tests will be found stay-bolts turned, polished and threads cut, cold and hot bent and twisted shapes, nicked tests, showing the character of the fiber, pieces of round iron tied in knots. It is a very creditable display of the Tennessee bloom iron.

### To Those Ambitious to Sail Round the Moon.

Mr. M. N. Forney writes us "In your very kind notice of *Aeronautics* in the last number of your paper, you mention the fact that the subscription price is $3.50 per year. As we are supplying it to subscribers to the *American Engineer* at 50 cents and are charging other persons $1, would it be asking too much for you to make a very brief correction in your next number? As compensation for this favor, we will promise that in the first balloon ascension which we conduct ourselves, we will send you an invitation to accompany us 'up above the little stars and all around the moon.' All prepaid subscribers will be entitled to the same privilege."

### Curious Origin of Important Inventions.

We often hear surprise expressed that invention progressed so slowly in the first years of what might be called the engineering era. Many inventions that have exercised the very greatest influence in mechanics are so simple, that it is natural to ask, why did not somebody think of that before? The application of the piston to a cylinder, was the first thing that made the steam engine a success. Yet for hundreds of years, philosophers, inventors and other wise men struggled in vain to design harness that would convert the power of steam into doing work When the piston was tried, and found successful, hundreds wondered why they had never thought of such a device.

It appears that the inventive faculty grows both among individuals and communities; and it is likely that future generations will invent appliances that will exert us much influence on industries, as anything that has been invented up to this time. They in turn will wonder that the people of the nineteenth century failed to invent things that seemed so simple. Most inventions appear simple after they have been worked out, but it requires genius to devise them. The carrying of air through a train in pipes to operate brakes is now thought a very commonplace invention, but the thought of such a plan was a stroke of genius.

It is curious the way that some of our most useful appliances were invented or discovered. We are told that some Venetian mariners built a fire on a beach, where there was sand mixed with soda, and that they were surprised to find that the sand melted and formed a transparent composition. Some reflecting man was in the party, and by this accidental melting of the sand, discovered how to make glass. Years after this, the children belonging to a Dutch spectacle-maker were playing with the glasses which their father used, and they made the discovery that, by putting one glass in front of the other, they could make the steeple of a neighboring church appear nearer. Their father had sharpness enough to use this accidental discovery in making the first telescope.

Most engineers are familiar with the story of how the steam-engine was first made automatic. In the early rude forms of the Newcommen engine, a boy was employed to open and shut the cocks which admitted steam and the condensing water. A boy named Humphrey Potter who was engaged on this work, was anxious to play, and the movement of the engine gave him very little opportunity. To increase his leisure, he devised an arrangement of strings connected with the walking-beam, which opened and shut the cocks. This was the first move towards making the engine's mechanism to perform the operations of admitting and releasing steam.

The moving of a distant signal by means of a wire, seems a very simple operation, and one which called for little ingenuity to invent. Still the earlier railroad engineers could not devise satisfactory means of operating a distant signal until a working signal man showed them the way. It is told that in 1846, an English signal man had to attend to two signals, placed some distance apart at a station. To save himself the trouble of walking to and fro between them, he procured some wire and pulleys, and made a crude arrangement, by which he was able while in his box to operate both signals An official who had been trying to devise some means of protecting trains standing at stations, happened to see this primitive arrangement, and applied it to the working of distant signals.

---

The January edition of Locomotive Engineering will be 30,000 copies. Subscriptions for 1894 can commence with that number until the over-stock is exhausted (this happened in April last year). *No back numbers beyond the current year.*

### Consolidated Car Heating Co.

A special meeting of the directors of the Consolidated Car Heating Company of Albany, N. Y., was held on Tuesday, October 31st, and the final papers were signed transferring to an English syndicate the English steam and hot water heating patents of the Consolidated Car-Heating Co. The English electric heating patents have not yet been taken by the English syndicate, although it has an option thereon until January 1, 1894. The option on the heating patents which it bought would have expired November 1st

The total sales of the Consolidated Car-Heating Co., including October complete, are slightly in excess of the sales at the same period last year. Within the last week orders for electric heaters have been received from twenty-one additional roads, making a total of fifty-one street railways in the United States and Canada which are using or are about to use the Consolidated Co.'s electric heaters.

### Meadville Shops.

One of the best managed shops we have looked through lately are those of the Erie, at Meadville, Pa., under the charge of Master Mechanic F. B. Smith, with Willard Kells as general foreman A clean, neat shop, with everything in its place and a place for everything conveys to me the information that the men in charge are looking closely after the details of their business. In going through the shop I was struck with the absence of fittings belonging to the engines undergoing repairs. They are generally to be found littering the floor or piled up in racks. There was no traces of them to be seen. On mentioning to Mr Smith the matter that was puzzling me, he led me to a large trap door, turned a valve handle and the door rose up as if by magic. It was moved by a pneumatic cylinder placed beneath The door covered recesses under the floor, where all the engine fittings where stored ready to be taken out when needed

The shop has not been well provided originally with lifting appliances, but this source of inconvenience, delay and extra labor has been successfully overcome by the use of simple air-lifts placed beside every tool that does work on heavy pieces.

They have in one end of the shop an excellent tool room, fairly supplied with small tools. Beside it there is a wall fitted up with all the appliances necessary to test brakes and gauges. In the absence of a brake instruction car, this place is used for demonstrating how the brakes operate. At the same place there is a remarkably good apparatus for applying the fittings to air and heater pipe hose. All the work is done by a simple arrangement of air-cylinders. By the aid of this device one man can fit up 250 sets of couplings in one day. When all the work had to be done by hand 35 sets was a good day's work. A. S.

---

One of the first concerns in Newark, N J., to give their employés a practical reminder that hard times had come was the Consolidated Traction Company This company has a practical monopoly of street railway transportation over about 100 square miles of valuable territory and enjoys public privileges of a most money-making character which ought to be accorded to no private corporation. Yet they quickly availed themselves of the talk of hard times to cut the wages of their employés to an unscrupulous extent. There was no falling-off of passengers riding on the cars passing over railroads costing nothing for right of way, there was no reduction of fares and ready cash continues to be the terms on which people can ride, yet the officers of the company have the effrontery to announce that the hard times make it necessary to reduce expenses.

### The Galena Oil Works.

[EDITORIAL CORRESPONDENCE.]

In the interval between the meeting of the mechanical conventions at Lakewood, last June, many of the members and their friends enjoyed a rare treat in visiting Franklin, Pa., a name familiar to most railroad men as being the location of the Galena Oil Works. It is too late now to

Galena Oil Works, Franklin, Pa.

repeat the attractions which Messrs. Miller & Sibley, of the Galena Oil Works, provided for the visiting railroad men and their friends. A magnificent display of blooded horses and prize animals of rare breeds monopolized the time of the visitors and there was no opportunity to examine the manufacture of oils, although some of us were rather more interested in that than in animals, even of highest degree. The place was attractive enough to draw the writer back a few days ago.

To many people whom I have met, "the oil regions of Pennsylvania" are sterile wastes, where all the beauties of nature are smeared with petroleum and the air is made offensive with the smells that oil sends forth. Nothing could be farther from the truth. The reality reveals a succession of verdant valleys intersected by clear running streams, and bordered by wood-clad hills where every hue of nature seems reflected in the clothing verdure. The only sign of oil is the derricks, which are dotted over the country thicker than windmills in the land of Don Quixote. Franklin is a finely situated little town, notable principally for cleanliness and well-paved streets, two characteristics by no means common to towns of less than 10,000 inhabitants. In the Galena Oil Company's office I met many familiar faces—faces that I have seen on locomotives and in other railroad positions in widely separated places. This company has followed the sagacious policy of securing railroad men as agents, and they nearly always choose the smartest men on the roads they draw from. Few railroad men visiting here would fail to meet familiar acquaintances.

Social intercourse is not, however, the object of my visit. After an hour spent in the fine offices, accompanied by Mr. Hill, one of the agents, I proceed to the works shown in the upper engraving, the place where crude petroleum oil is converted into the lubricating and signal oils so well known to our readers. The works, as will be seen, occupy a large space of ground on the bank of a creek, that in most places would be called a river. The most conspicuous things about the works are large oil tanks, where crude and refined oils are stored. Crude oil does not differ in appearance from the ordinary lubricating oils, but it proves a very poor mixture when used without the treatment which gives lubricating qualities. The operations through which the oil passes are not easily understood by a visitor. The first operation appears to be the removing of water and gritty impurities. Water is taken out by heat and solids by straining. The succeeding operations are trade secrets. Red lead and whale oil appear to be the principal ingredients mixed with the petroleum. They are put in while the oil is kept at a certain temperature, but how they succeed in putting the lead in suspension, so that it does not settle when the oil is kept quiet for years is one of the secret arts of the business.

All the valleys and hills in this region are studded with the derricks that indicate the presence of an oil well. There is a constant flow from these wells to the refining works, and from thence to the oil houses of nearly all the railroads on this continent. The output of the works is about 22,000 barrels a month. As a barrel contains about 34 gallons, it means about 750,000 gallons sent out monthly. Mr. Charles Miller, the President of the Galena

Shooting an Oil Well.—Responding to the Shot. From an Instantaneous Photograph.

Oil Company, is said to be the ablest expert in oil making in the country, and the high character of the product is due in a great measure to his skill and knowledge.

The scene shown above is the reproduction of an instantaneous photograph, and pictures a striking operation in oil production. When an oil well has been bored for a certain distance and does not produce the expected supply, or when a well begins to run dry, it is the practice to introduce a heavy charge of dynamite to the bottom and explode it for the purpose of shattering the rocks which may be preventing the oil from reaching the well. The photograph was taken when oil belched upwards after a heavy charge of dynamite was exploded. The volume of oil that responded to the charge would indicate that a good supply was still in the fountain.

These oil regions are within easy reach for any one having business in Western Pennsylvania or New York, and will well repay a visit. Here was first discovered in considerable quantities the petroleum which has become one of the greatest of the world's industries, and in this region was first solved the problem of making the product suitable for the numerous uses that it now serves. The product appeared to come when the need for it was becoming urgent, when the world could get along no longer without it. It is curious to reflect on how the myriad wheels of modern machinery could be kept running cool had petroleum oil not been found. Even more attractive to some of us is the reflection how much darkness has been dispelled by the products of petroleum. I remember when the light of the workman's house was a rush wick burning in whale oil. A good crusie, as the lamp was called in Scotland, would give light of about half a candle power, and yet this feeble glimmer had to light the family room, and by it many a student wasted his eyesight. At smaller expense, similar families now enjoy the light of a good kerosene lamp. A. S.

---

Locomotive Engineering will issue a handsome calendar next year. It will be sent to those who are subscribers to the paper for 1894 only.

### Awakening of Desire for Engineering Knowledge.

In the course of some interesting railroad shop reminiscences, written some years ago by Mr. E. P. Watson, proprietor of *The Engineer*, facts of experience are told which will be familiar to every old mechanic who has studied the science of his business. The ambitious shopman of this generation has so many well-known engineering books and publications to help him, that nothing but will is needed to obtain a knowledge of the technical part of his business. It was very different forty years ago. Writing of shop life in the early fifties, Mr. Watson says:

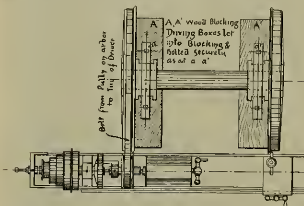
"Books and papers treating of steam and machinery were both scarce and expensive. I remember well the first technical work I ever saw. It was named 'The Mechanic's Calculator,' and belonged to the foreman of the shop. He kept it locked up in his desk, and seemingly prized it as much as though it were a precious jewel. In those days, a shop hand who was fortunate enough to know something of the theory of the trade, or if he could work out problems in screw-cutting, gearing, valve motion, and suchlike, he jealously guarded his knowledge of these things or would sell it to others at fancy prices. One dinner hour, while sauntering round the shop, I espied the foreman's treasured volume lying on the top of his desk. I glanced round to see if any one was looking, and finding the coast clear, opened the book. Glancing through it hurriedly, I found a chapter devoted to the steam-engine. Here I paused, read and re-read the rules, problems and explanations, but they were all Greek to me. I felt for the first time that I was merely an animated machine, since I was drawing lines, describing circles, and doing many other things daily without being able to give a reason why they were done. I felt abashed and humiliated, and during the remainder of the afternoon my mind was preoccupied with matters entirely foreign to the job I was working on. When I left school, I had but a very crude knowledge of arithmetic. Greater knowledge of it I felt would unlock the mystery of the signs in 'The Mechanic's Calculator' which I could not understand.

"There was an old Scotchman working in the shop at the time, an excellent machinist, who made no mystery of what he knew about the technical part of the machinist art. I spoke to this man about the foreman's book, and about my own ignorance and desire to learn all I could about the theory of the business. He advised me to go to a night school and study arithmetic and geometry. The end of it was

that I took his advice. But it was not the night school alone that helped me. That helped to impress upon me the need for more knowledge, and my daily occupation became a school. When I saw anything done which I did not understand I did not rest until I knew the why and wherefore of the operation. When a man once gets the thirst for knowledge he acquires what he wants from all quarters."

### Turning Driving-Wheel Tires on an Engine Lathe.

The annexed engraving shows a very ingenious arrangement made by Mr. Chas. H. Burgiss, master mechanic of the New Orleans, Fort Jackson & Grand Isle for turning driving-wheel tires by means of a common engine lathe. This is a case where necessity was the mother of invention. The railroad company has only got a few engines and is too poor to buy a wheel lathe, but yet the wheels had to be turned when they became worn. It was expensive sending them to a distant contract shop to have the work done, and the master mechanic in charge fell upon the arrangement shown, which has enabled him to turn his own tires although it was a slow proceeding. Two heavy blocks of wood are secured into the floor and recesses are cut in them for holding the driving-boxes. The boxes are set upside down and the wheels are placed in the boxes and are held in position by their own weight. A belt is extended from the lathe round one of the wheels which keeps it in motion while the other is being turned.



Turning Tire Without a Wheel Lathe.

### Against Overtime.

In an answer made to the Railway Commissioners of New South Wales by the president of the Locomotive Engine Drivers, Firemen and Cleaners' Association, on a charge of insubordination raised because they had agitated for redress of grievances, the following points are made:

"Overtime is being worked which the men do not desire, and consequently is keeping starving men from employment. Under all circumstances overtime is an evil, but under conditions like those at present prevailing it is materially intensified.

"The average rate of wages which you give cannot but show an increase, but it is not a real one to the men, considering that the general rule is carried out of the oldest hands retaining their positions in preference to the junior, and were it otherwise it would be decidedly unjust; but it must not be forgotten that there are now considerably less drivers than there were in 1888, although there is an increase both in the weight carried and in the mileage rate, and stronger evidence of the present sweating system, with its utter disregard of health or home comforts, cannot be given than in your own figures.

"A word as to the lodging allowances, the only alteration in this matter since you assumed office being one which was by mutual agreement shown to be in favor of the department. You quote the rule from old rule book as to preparation of engines. As you well know, this rule was not in operation, but a fair system prevailed—according to the circumstances of the depots. The rule itself, except on the Northern line, was inoperative and the whole conditions were altogether different from those of to-day. The great majority of the men ran their own engines and enjoyed the privilege of a shed day, in which they could see their engines were properly prepared. In that day engines were cleaned regularly; to-day it is very questionable whether in the whole world there are such dirty, neglected engines as in New South Wales."

### Grease for Locomotive Lubrication.

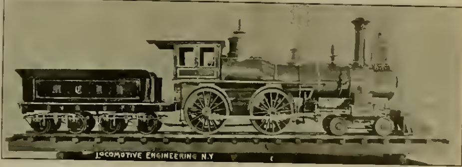
"A penny saved is a penny gained, and every penny gained helps to make both ends meet," remarked a well-known motive power man lately to the writer. The proverb was employed to justify a change to cheap lubricants, which was done to save money. The impression we received was that pressure from above had been used to induce the mechanical department to adopt the cheap material, and the head of the department was pretending to like the change. Part of the change was the introduction of grease for locomotive use. Some remarks made by Professor Denton in an address on lubricants may be edifying to those who think that pennies may be saved by the use of inferior lubricants.

The locomotive engineer, said the speaker, learning of the economy due to grease in marine work, tries it as a lubricant on the crank pins of his engine where oil-cups are available. He uses the spring-piston feed-cup, and finds the grease runs the engine fairly well. He notices that the bearing is a little warmer than with oil, but that the temperature does not increase as it does when something is wrong with the bearing surfaces and a hot pin is breeding. This fact is explained to him by the grease agent to be friction due to a little viscosity, but the viscosity is called "body," and a lubricant possessing more body than lard oil or engine oil common to locomotives is an idea which seems to the engineer an improvement, especially if the grease is going to save on the quantity of lubricant used. So he makes a faithful trial of the grease without any overheating occurrences. But he finds little or no saving over oil in the consumption.

When he used oil with a needle-feed oil-cup adjusted carefully, as he has long since learned to regulate it, he could run a thousand miles without exhausting the small-sized oil-cup used on the crank-pins. He finds that he cannot do sensibly better with the grease. Also, that in the long run about as many cases of overheating occur. Again, when the overheating occurs, although the grease flows from the cup with a sudden abundance, it is too late to save the overheating, while the increase of consumption over the oil is then unquestionable, especially if he must smooth the journal by a temporary use of oil.

### The Very Smallest Locomotive.

We have several times within the last few years given illustrations of extremely small locomotives that were complete in all parts, but that shown in the annexed engraving is the very smallest working locomotive that we have heard about. It was built by a jeweler, and is the property of



The Very Smallest Yet.

Mr. W. E. Gallant, Chicago. This elaborate toy is built to run on a track ⅞ inch wide and has a total length of 9½ inches with tender included. The cylinders are ¼ x ⅜ inch, the driving-wheels are 11/16-inch diameter. The boiler is ¾ x 3 inches. The total weight of engine and tender is 9½ ounces. Gold, brass, steel and nickel are the materials of which the engine is made and the pilot is of wood. It is a real working model and spins along in good shape with its own steam, a spirit lamp supplying the required heat.

### 16-Spindle Drill.

The annexed engraving is made from the photograph of a novel form of drill which was in the Pratt & Whitney exhibit at the World's Fair. Beside it is a specimen of the work done by this drill. The machine is so made that it will drill holes arranged in any form, regular or irregular. This is the first tool of the kind, but it has been so useful and popular that

A New Multiple Spindle Drill.

there is likely to be a lively demand for it. The company have also decided to make similar drills with the shafts set vertically. In this form the tool will be very useful for drilling flue sheets and other articles where many holes can be drilled at the same time. This tool can drill one to sixteen holes of ½ to 1¼ in. diameter, 2½ in. or more apart in circles, or arranged in any shape. The power feed is 1 to 3 in. per minute. The tool is made exclusively by the Pratt & Whitney Co., Hartford, Conn.

Firms that deal with railroad companies would do well to have their catalogues made of the standard size recommended by a committee of the M. C. B. Association. Nearly all railroad officers who require to consult catalogues are having cases made specially adapted to the holding of standard sizes, and the likelihood is that odd sizes will find their way into the waste-basket.

The following is an extract from a Detroit paper: "The gold medal awarded as evidence of the highest merit in lubricator cups was very appropriately given to the Detroit Lubricator Co.'s line of goods known as 'The Detroit.' We are pleased at this, not because it was essential to the success of these particular lubricators—for they certainly are already known as well, or even better, than any similar line in the market—but because it confirms the verdict previously given by the most practical and reliable engineers all over the country, and furthermore, because it will undoubtedly settle the question in the minds of doubters and be a reliable guide to others not conversant with the comparative merits of the goods hitherto presented."

The legislature of Ohio passed a law some time ago making ten hours a legal working day. Most people thought the law was one of those ornamental enactments designed as a sop to labor interests without hurting exacting employers of labor, or benefiting the unfortunates whose hours of work are scarcely kept within the bounds of physical endurance. A telegraph operator who worked for the Bridge & Terminal Railroad Co., at Martin's Ferry, and a jury have reduced the terms of the law to practice. He had been kept at work from fourteen to eighteen hours a day and sued the company for $523 overtime and a verdict was returned in his favor.

The Great Northern people are erecting very fine shops at Hillyard, on the Pacific division. It is intended that all repairs of locomotives and cars running west of the mountains shall be done in these shops. First-class machinery will be provided for doing the work, and the most approved methods will be followed.

# Car Shops and Car Builders.

## Reduce the Shocks of Passenger Trains.

The hydrostatic buffers used on the cars composing the trains that formed the New York and Chicago Exposition Flyer did a great deal to make the train popular, for nearly every passenger who traveled on the train testified to its remarkable steadiness. We hope to see the buffer applied to all the passenger equipment of the country. It is an improvement greatly needed, and will rank in the line of progress with the Miller platform and coupler, which was the first great step towards making a train run steady. The traveling public have the right to demand the introduction of every practical improvement that will increase the comfort and secure greater safety to those who ride in trains. It is not so very long ago that railroad men objected to close coupled cars because they made a train hard to start. The putting of wedges into the links to hold the slack was considered an important improvement before the Miller coupler made people aware that wedged couplers were not all that could be desired.

The wedged coupler was as good, comparatively, as the common vertical plane coupler with springs is compared to a car that is bound to the next one by the hydrostatic buffers. The beauty of this device is that it never lets the springs get loose. In ordinary passenger car draft gear, the springs are constantly losing their resisting power, and the cars get jammed together in a way that is extremely uncomfortable and in some cases dangerous. The road that first adopts for all its through passenger cars a buffer that prevents the common shocks due to sudden braking and to quick starting, will gain in popularity much more than will pay for the expense of applying this much needed improvement.

## Redwood as Car Building Material.

Nearly every person acquainted with American products is familiar with the fact that in California there grows immense trees which are called "redwood," from the color of the wood, and that the trees sometime attain an altitude of 300 feet, with a diameter on which could be built a large house. Interesting particulars about this wood were given by Mr. Benjamin Welch, the well-known master car builder of the Southern Pacific, in an article contributed to the *Railroad Car Journal*. We abstract the following points.

"Redwood is extremely light in weight, but durable. It is of a handsome red hue, very closely grained and straight, and may be split with remarkable facility, it may also be very readily and beautifully polished.

"From a tree 35 ft. in diameter and 300 ft. high, was taken a plank 16 ft. 3 in. wide, 12 ft. 9 in. long and 5 in. thick, and was about 20 per cent. clear. According to its rings the tree must have been at least 1,500 years old. The tree was cut 28 ft. from the ground, and the plank was hewed out of the stump, representing a section taken from near the heart to the bark. After it was displaced, it was lowered by block and tackle, with a locomotive for power. In the way of labor, its cost represented the time of two men for a month, simply to prepare it in the rough for shipment.

"Redwood is unquestionably the most durable wood of its kind grown in California for car and house building, it being much preferred to pine or other soft woods, though the cost is of no material difference. Redwood will shrink a little in length but in width this is scarcely perceptible, and when seasoned is not affected by climatic changes. It has also been demonstrated by actual occurrences that redwood has wonderful fire-resisting qualities.

"The uses of redwood are varied. It is adopted in California almost exclusively for railroad ties, car sheathing, roofing, lining, inside finishing, pickets, rustic shingles, and other classes of work subject to dampness and where strength is not required. Rock redwood is used for underground work, is harder and darker than that used for purposes above named, and on account of the greater amount of pyroligneous acid therein contained, is not so easily subject to decay.

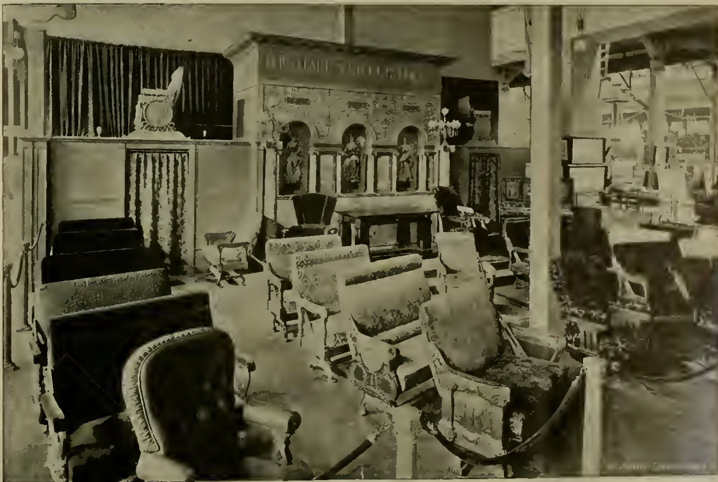
"The adoption of redwood for car building was brought on wholly through practical tests, and we have yet to discover the first species of another similar variety which could be successfully used as an auxiliary to it.

"This has been fully demonstrated on some cars built by the Central Pacific Railroad in 1875, which were finished inside with redwood. Some of the panels were oiled in part, leaving the other part to be shellaced and varnished without oil. To-day the parts of the panels not oiled are of a dull reddish yellow, while the parts oiled present a strikingly rich red.

"Redwood should be perfectly dry before painting, if not, it is quite impossible to keep the paint from blistering on it. In its natural state it contains much more sap and acid than white wood, ash or poplar, and if it is wet to any great extent the paint will not dry, no matter how much Japan dryer it contains. There is but one dryer that I know of that will dry paint on wet redwood, and that is 'litharge.' This will dry the paint no matter how wet the wood may be. This will do very well for freight cars and other rough painting, where but two or three coats are applied and not varnished, but if sealed with varnish it will invariably blister. Absolute dryness of the wood in passenger car painting is very essential, and especially so if the paint to be used is of a dark color."

## Exhibit of the Hale & Kilburn Mfg. Co.

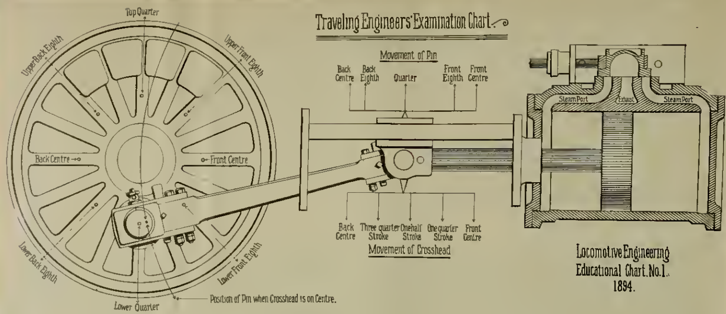
One of the most attractive exhibits witnessed in the Transportation Building of the World's Fair was the fine display of car seats made by the Hale & Kilburn Mfg. Co., of Philadelphia, an illustration of which is here shown. A great variety of car seats was exhibited, all being remarkable for artistic design and perfect workmanship. To those who were not fortunate enough to have the opportunity of examining the exhibit in person, the picture will convey a good idea of how the exhibit looked, and what kind of seats were shown. But we cannot reproduce the rich hues of the silk and the plush and the embossed leather. The exhibit attracted the attention of so many railroad men that the company, no doubt, see a future return for the great expense involved in adding that very interesting display to the beauties of transportation comforts. An examination of the car seats, some form of which is used by nearly all railroad travelers, was sufficient to rob a long journey of the terrors of prospective fatigue.



Car Seat Exhibit of Hale & Kilburn Manufacturing Co. at World's Fair.

## New Form of Sleeping-Car.

There was exhibited at the World's Fair by the Krabel Palace Car Company three cars of a very peculiar arrangement of seating, and the means of converting the cars from day coaches to sleepers. The seats, which are noted for their splendid cushions and fine upholstery, look like very wide arm chairs that are capable of being turned in any direction. The seats are so constructed that they form an excellent seat during the day, and have all the parts necessary to make up both upper and lower sleeping berths at night. Each seat or chair rests on four double casters, in the center it is securely fastened to the floor with 1-inch steel king-bolt, the head of which moves in a slot in the floor, which slot extends across the car. The bolt passes through the bottom of the



# The Angularity of the Main Rod

Is one of the things few men fully understand. Our **Educational Chart No. 1** explains it better than anything else. The above picture gives some idea of this Chart. The piston, piston-rod and cross-head, as well as the valve are made of celluloid and move back and forth in slots. On the back of this Chart there is a short, plain explanation of the angularity of the rod and its effect on the piston and the valve. Then there are thirty-six questions to be answered, by placing the valve and piston in the proper positions—if a man can answer all these questions in this way he must know something about the **subject.** The answers to these questions cannot be learned parrot fashion, the student must know **why.**

# The Names of All Parts.

**Educational Chart No. 2** will be a fine, transparent picture of a modern locomotive, with the name of every part given. This will be as fine as steel and worthy of a frame in the home of any man who knows a locomotive from a sausage mill.

# The Triple Valve

Is another **Educational Model, No. 3,** with moving celluloid parts, on the same plan as the first one. This will show just what takes place in the triple valve when re-charging in service application and in emergency, and with the "few well chosen words" on the back will make this subject clearer to any train man than fourteen pages of explanation in type.

These three models will be sent free to every subscriber to **Locomotive Engineering** for 1894. The paper will come out in a new dress and a cover on January 1st, and we are spending a lot of money for articles from the best writers on mechanical subjects in this country. Some special articles on Block Signals will be very interesting.

# The Prize Designs.

In the past ten years there have been 796 engineers and firemen cooked to death under engines! This year we are offering prizes of $350 cash for the best designed cab fittings for an eight-wheeler and a consolidation engine. We furnish drawings of the engine and boiler, all the designing we want is the arrangement of throttle, lever, all the gauges, injectors, lubricators, pipes, cocks, hose, draft-rig, etc. The design must aim at: 1st. The safety of the engineer and fireman; 2d. Convenience in handling; 3d. Accessibility and economy in keeping up running repairs. $100 for first prize for each class of engine; $50 for second prize, and $25 for third. We will also pay $5 each for all designs not winning prizes which we consider worth publishing. This contest is open to the world. Readers of Locomotive Engineering get the benefit of it. A competent board of railroad men and locomotive builders will award the prizes in June, 1894, and we will pay them by July 4th. See other posters for particulars. Here is a chance for engineers, firemen and shop men.

# The Dull Times

Are not worrying us—we have spent over $3,000 per month on the paper in the last year, and will spend more next. New features will be added and the best of everything in our line will be captured at any cost. We don't propose to give our worst enemy the least excuse to say that the words on our seal are not the truth, the whole truth, and nothing but the truth.

Everybody "Most Interesting Railroad Paper Published" Says So!

If there is anybody getting up a club in your district, give him $2.00 and your name if not, send direct to us. We pay a cash commission to club raisers or give watches or other premiums—you can make the price of a $100 gold watch or get yourself a new overcoat by a little overtime. Send for terms to club raisers.

ANGUS SINCLAIR, JOHN A. HILL, Editors.

**LOCOMOTIVE ENGINEERING,**
NEW YORK.

seat, which is made of 3 inches of oak, there is then a very ingenious device for securely locking the seats when made up in berths for the night. By means of this slot in the floor the chairs can be moved to

End Framing, Pullman Coach

either side of the car and the entire car made up into staterooms, containing upper and lower berths, and two sections, with a 2-foot aisle on one side. In order that the chairs may be moved in the daytime without obstructing the center aisle, the bottom of the seats also has a 6-inch slot, by which means the chairs may be moved.

By this means, when the seats are facing each other, they can be moved back until they strike the next section, and when the front of the seat is opened and locked to the half of the corresponding seat, it makes all the sleeping berths rigid throughout the train. These two seats or parlor chairs contain all the material for upper and lower berths, thus dispensing with the great weight usually carried in the top of the car. This plan makes the cars ride very smoothly, and they do not sway under rapid motion. To make up the berths, the cushions are removed, and each back is hung at the upper edge and locked by a brace; one cushion is then inserted between the ends on a projecting shelf, this forms the upper berth. The front of each seat is divided vertically and hung at the corners; a lift is raised and each half is swung around to meet the corresponding half of the other seat and locked. The second cushion, with two mattresses on the seat, are then drawn together to form the lower berth. By this arrangement, the upper berth is one foot lower than in any other sleeper, and the lower berth, by being lower, gives four inches more between the upper and lower berths than any other sleeper. As these chairs meet at the top, it leaves a sixteen-inch space at the end of each berth for baggage and full depth of the berth. As the chairs revolve on a center, when made up they are six inches from the wall, thus giving a good circulation of air through the car. The berths are one foot and four inches longer than the Pullman, and the upper berth is six inches wider. Although each berth is one foot and four inches longer than the Pullman, the same number of berths can be put in a Krabel car of the same length, on account of the smoking-room in the latter being on the platform.

### The Krabel Vestibule.

A train of cars which was exhibited at the World's Fair by the Krabel Car Co., presented a decided novelty in the platform being covered in, making the train look like a continuous car.

All vestibules heretofore used have been an integral part of the car, and rigid to it. The construction of the Krabel vestibule differs from all others; the two halves of the vestibule are locked solidly together, forming a room rounded at the opposite ends, and resting on the two platforms, secured by means of a king-bolt in a longitudinal slot in each platform. At this king-bolt the vestibule is slightly convex and there are iron boxes bolted to the corners of the regular car platform, in which are coiled springs with an iron plunger or piston resting on the spring, in which the rounded end of each vestibule floor, covered by an iron plate, rides. By this arrangement the section, or smoking room, can be built the full width of the car, thus overcoming the usual wind friction between the cars, and as it is not rigid to the platforms, but connected to them on the same principle as the coach on the truck, excepting that the king-bolt is in a slot to permit of the cars taking up the slack, otherwise the vestibule would tear in two at the center when making a curve. When in the normal position, the king-bolt stands in the center of the slot and the rounded end of the vestibule is cushioned between the sill of the car with a 6-inch rubber cushion.

On account of the vestibule at the point of contact being slightly rounded, and attached by a king-bolt in a slot, the cars readily move to and fro and all concussion is received by the regular buffer heads and car platforms, the vestibule being six inches from the car sill. A provision is also made to provide against the cars uncoupling. If the cars should uncouple and the safety chains part, the vestibule floor coupler, a secondary coupler which couples the vestibules together, would prevent the train from parting and the entire train could be hauled in this manner. By this arrangement, the opposing motion of the cars is not imparted to the vestibules, and on undulating track no matter how much the cars fall from the level, this vestibule remains level on account of the two springs on each side. To cover the distance between the opposing ends of the vestibule and the car threshold, an iron plate is fitted in the center of one side and the sill of the car, which slides over the vestibule floor as the car moves when making a curve. The steps on these cars also close up when cars are in motion, and when closed the upper edge cannot be pushed out, thus avoiding all danger to passengers. When lowered it is pushed down by the foot by means of the lower step, when it moves out and assumes a level position at the instant of locking. As the steps descend the weight increases the tension on a coiled spring, by which means, when released, its action throws the steps back again.

### Most Advanced Features in Car Design.

It may be taken as a fact that the most advanced ideas in car construction were embraced in the cars exhibited at the World's Fair. Accepting this as true, we must conclude that the freight car used on American railroads has reached a standard form which is susceptible of very little improvement. Invention is still devoted to improving the attachments of the car, such as trucks, draft gear, doors and roof, but the body of the car has reached the form in which it is best adapted to the work intended. This would seem to offer a very strong argument in favor of the Master Car Builders' Association establishing a standard form of body for a box car.

Ordinary day coaches appear, like box cars, to have reached an established form, the only room for improvement being in the arrangement of lavatory apartments and in conveniences for depositing small articles of baggage. The ordinary rack used for the latter purpose is ridiculously inadequate. It is not only too small to be of utility, but most of the racks used are unsightly protuberances, with projections in the way of ornamentation that are dangerous to people thrown against them in case of the car being overturned from any cause. The extended baggage rack used by the New York, New Haven & Hartford is much more convenient than the ordinary short forms, and it makes a more harmonious looking inside. Why this kind of rack is not generally used is one of the mysteries that common-sense people cannot understand.

Side Framing, Pullman Coach

There was apparent among the cars shown at the Fair an inclination to utilize the platform or the open space usually wasted by the platform. Of course the vestibule was a move in this direction,

but that has merely taken possession of a passage-way over the platforms. Some designers have taken a more radical position and taken in the whole platform. We consider this to be a move in the right direction. The original purpose of the platform was to provide a convenient place for the admission of passengers, and after that it was utilized as a good place for the brake-wheel and the coupling levers. When cars have to be coupled and uncoupled frequently, a platform is a necessary convenience. In the case of through trains the platform is no longer needed for brake and coupling devices, and the passengers might as well mount direct into the car. The closing of the openings now made for the platforms would make a much better looking train and it would greatly reduce the resistance due to wind pressure.

Those who are familiar with the increased power necessary to haul a freight train when a few car doors are open will readily appreciate how much harder a passenger train is to haul with the front of every car acting as a huge wind cup, than it would be to haul the same train with a continuous smooth side. With closed platforms the train would be so much lighter to haul and so much easier kept warm in winter that a material saving in fuel would result from the adoption of the improvement.

There may be practical objections against the Krabel car arrangement, which converts the platforms into an articulated section separate from the rest of the car, but it seems to us that a modification of that form could be used successfully on roads that are not very rough. If the car designers of this country will devote their abilities to designing cars that will have the platforms covered, we have no fear but what the problem will be worked out successfully.

### Compressed Air for Car Cleaning.

About a year ago a representative of LOCOMOTIVE ENGINEERING, while on a visit to the Pacific Coast, found several railroad companies in the West using compressed air for cleaning passenger cars. Particulars of the process were published, and we received many private inquiries for detailed particulars as to how the work was done. We now find that the system has been adopted by several of the trunk railroads, and that the Pullman Car Company is introducing the practice wherever they can obtain air pressure conveniently.

In conversation with men engaged cleaning cars by air in the Erie yards, at Jersey City, we learned that a strong jet of air searches out dust and impurities which hand work fails to reach. They say that cushions and upholstery generally can be much better cleaned by air than by caning. Consideration for the health of the people who ride in passenger cars demands that the cars should be thoroughly cleaned. Compressed air is the latest auxiliary to thoroughly doing the work, it makes a better job than hand, and reduces the cost of labor. The use of air for car cleaning ought to become general.

### Excessively Decorated Cars.

At a recent meeting of the Western Railway Club, Mr. George Gibbs, of the Chicago, Milwaukee & St. Paul, read a paper on the "Passenger Train Equipment at the Columbian Exposition." Mr. Gibbs was one of the judges of train equipment, so that he had peculiarly good opportunities to make himself familiar with the cars exhibited. The greater portion of the paper was devoted to a description of the various cars, but he gives the following opinions, which we consider pungent and well worthy of serious attention

"I have space for but a few of the conclusions which might be profitably drawn from the collection of cars here briefly described. As examples of perfection of the car builders' art, the trains exhibited are truly representative, as examples of the decorators' art, they have never before been equaled, and it is to be hoped will not in this respect prove representative in the near future, this latter refers especially to the Pullman and Wagner trains. These cars should have been entered in the catalogue as two separate classes of exhibits, first, as excellently designed railway equipment: second, as fine examples of the decorators' and house-furnishers' art; but the latter is absurd and execrable taste in connection with the former.

"It has for some time become apparent to railway men that it was time to call a halt upon the expensiveness and over-elaboration of detail found in the equipment of sleeping car companies. I have heard, however, the plea gravely advanced by men who should know better, that the sleeping car companies and not the railways pay for these luxuries. It seems hardly necessary to advance an argument to refute this statement, but it may be asked, who pays for hauling the increased dead weight around the country? In the Wagner compartment car, for instance, but twelve passengers are comfortably accommodated, whereas, in the ordinary twelve section sleeper, with drawing-room, twenty-seven will have a berth apiece. Again, it is the rule to base contracts between car and railway companies upon the net earning power of the equipment to the former, including, of course, interest charges on investment and cost of maintaining, and the higher these latter charges, the less favorable the terms to the railway companies. It is possible, however, that these companies do not intend to put their trains into regular service in exhibition order, and we will rest in that hope.

The Westinghouse Air-Brake Company have been experimenting for some time with an attachment to the air-brake, which enables the brake to exert greatly increased power when the train is running at a high rate of speed. The principal novelty about the improvement is a valve which regulates the pressure to correspond with the speed of the wheels. As the velocity gets reduced, the cylinder pressure is reduced. Some experiments were made last month with this improved brake on the Pennsylvania Railroad, and the performance was highly satisfactory. A train was stopped in 971 feet from a speed of sixty miles an hour. The ordinary emergency brake required 1,235 feet in which to stop the same train. This is a very important gain, and in a great many cases would mean the difference between a safe stop and a collision.

We have received a document in parti-colored ink addressed to the railroad managers throughout the world, and headed "Preamble and Resolution," followed by various whereases and graced in the bottom by a blazing seal. This imposing paper is a circular issued by the Railroad Lighting and Manufacturing Co., Philadelphia. We received the same circular nearly a year ago, but consigned it to the waste-paper basket without notice. From its being sent out a second time, we conclude that it was not found effective enough in the first instance. The purpose of the circular is to tell that the Pennsylvania Railroad Co. have adopted the Frost Carburetor system of car lighting because it is the best lighting system in use. We do not think that in the present state of the art of train lighting the gasoline device has much show. It is well known that the system is used upon the Pennsylvania Railroad, because one of the most influential officers in the company is a stockholder in the lighting company.

### No Spark Arresters Are Best.

*Editors*:

Having read your article in the June number of LOCOMOTIVE ENGINEERING headed, "No Spark Arrester the Best," I wish to add my testimony in the same direction. That is certainly right, provided the engine is properly constructed and proportioned. I have run engines which never threw fire, although they had no spark arresters. I may mention those designed by Mr Fletcher for the North-eastern of England as good examples for they ran the fastest trains of their day without fire throwing, no matter how heavy they might be worked. On the other hand, the engines under the charge of Mr. P. Sterling, of the Great Northern Railway of England, are noted for spark throwing, but this is due in a great measure to the inferior quality of coal used and to the heavy work the engines have to perform. The arrangement of the blast-pipe has much to do with the quantity of sparks sent through the chimney. The last engine I ran in England had the Adams variable blast-pipe. When it was put in right the engine would work without throwing sparks, but it had to be just right. The eight-wheel engines that were engaged working fast freight, fast passenger and cattle trains used from seventeen to twenty-four pounds of coal to the train mile. Before the Adams blast-pipe was put in and when a spark arrester was in use, they used from thirty to forty-seven pounds of coal to the train mile. With one of these engines I have run twenty-one miles in nineteen minutes, and reduced the speed four time.

On this road where I am now the engines were throwing fire when I came, but they do not throw any now, and we have 3½ miles of a grade varying from 1 in 21 to 1 in 30 feet (251 to 179 feet to the mile). The engines are all worked by Chinese engineers and they steamed badly at first but they are all right now. Good steaming and absence of sparks often go together, and the reverse also holds good.

### What a Patent is Worth.

*Editors*:

On page 407 of the November number, you publish a letter from J. B. Michael, asking certain questions about patent law. Instead of answering your correspondent's questions in an intelligent manner, you turn him off with a few sneering remarks about patent attorneys. (?) whom you represent as ignorant and grasping, anxious only to pocket their fees.

Of course, there are rascally patent attorneys, just as there are scamps in every trade and profession; but the great majority of them are honorable men, and it would not hurt you to recognize that fact. I notice that you are quite willing to publish their advertisements and to take their money for such services. Now, since you tacitly confess your inability to answer Mr. Michael's questions, will you permit me to say a word or two to him, because he is perplexed about a matter which troubles a great many intelligent inventors.

His patent was on the face of it, a valid one, and I presume it was actually so. Such being the case, he cannot understand why the Court should have decided that it infringed a prior patent, and why the Commissioner of Patents should not have informed him of that prior patent.

In the first place, nearly every patent that is granted now-a-days—and they are issued at the rate of about 500 a week—is an infringement on one or more prior patents. A patent covers only what its claims point out. Jones invents an improved throttle-valve. It has some new and valuable features but it is an improvement on Smith's old throttle-valve, and contains several of the features of Smith's old valve, which Smith has covered by the claims in his patent Jones cannot make his valve without using the old parts of Smith's valve, and consequently Jones infringes Smith's patent, yet the Patent Office will grant Jones a valid patent for all the new features which he himself has invented, and might not say a word about Smith's patent, because Jones is, in law, presumed to know all about not only Smith's patent but all the other patents which have been granted.

This is a violent presumption, to be sure, because nobody really knows all about the prior patents. But the Patent Office merely says "Here is your patent. The claims are good, so far as we can find out," and leaves the patentee to make his own investigation to determine what prior patents he will infringe if he goes to manufacturing As a matter of fact, no shrewd business man begins to manufacture a patented article without first employing an expert to make a thorough search for all the prior patents which have claims covering any part of that article.

He then either buys those prior patents, or he gets a license from the patentees to use their patents. Such a search takes lots of time and study, and the Patent Office has neither men enough nor time enough to make such a search on every patent issued.

The fact that a patent may be valid, and give full protection for all that is new and patentable in an invention, and yet the invention may infringe prior patents, is one which all patent attorneys find it very hard to explain to inventors.

Suppose a man is put in charge of a locomotive, and is told that she is all in good shape and ready to run on the track that he sees stretching away across the country. Suppose he pulls open the throttle and starts off, and running past danger signals and flagmen he swings round a curve bang into the tail end of another train. You would say he ought to have kept a lookout, and not have run against his signals. In other words, *he must have a regard for the rights of those who are ahead of him on the same track.* The same rule applies to patents.

A patent is good for so much of what it shows and describes as is covered by its claims. The claims, when properly drawn, cover everything in the invention that has not been previously patented or described in some printed publication. Any good patent attorney can ascertain with reasonable certainty what prior patents will be infringed by making the invention. But the search is frequently long and expensive, and the Patent Office has neither the time, money, nor ability to make such a search. Nor does the law require it.

GEO. P WHITTLESEY,
Patent Attorney.

### That Defective Engineer's Valve.

*Editors*:

E. P. Bishop, of Birmingham, Ala., has answered my article about engineer's valve very correctly, in fact, almost word for

# Some New Features!!

# LOCOMOTIVE ENGINEERING will have quite a number of entirely NEW FEATURES for 1894. New Dress! New Cover! New Ideas!

## Prize Locomotive Designs.

### $350 CASH IN PRIZES

For the Best Plan of Arranging Cab and Boiler Fittings on a Locomotive for the safety of the crew, comfort in handling the engine, and economy of repairs. The prize-winning designs will be published during the year.

## PROMINENT AMONG THEM WILL BE THE INTERESTING:

**Block Signals.** We have secured from the pen of D. B. McCoy, Signal Engineer of the N. Y. C. & H. R. R. R., a Series of able Articles on Block Signals. The writer tells "What a Block Signal is," "What it Does," and "How it Does it." If you want to post up on block signals, just read these articles.

**Air-Brake Doctors** will be interested in the Series of Articles commencing in the January issue, written by Paul Synnestvedt, and entitled "Diseases of the Air Brake System; their Causes, Symptoms and Cure." These brake articles tell what to expect when any part of the brake acts in a certain way, and then what to do to remedy it. There will be a complete, illustrated chapter on each vital part of the brake mechanism. There will be a chapter each under the following headings: Pumps, Governors, Main Drum, Engineer's Brake Valve, Train Pipe, Auxiliary Reservoir, Brake Cylinder, Triple Valve, Pressure-Retaining Valve, Foundation Brakes, and Miscellaneous. This series of articles will be something new in a new line, and is destined to be of great benefit to all who work with or on air-brakes.

## Profit-Sharing for Railroad Employes.

A Plan of Settlement of the Capital and Labor Controversy, by M. E. Ingalls, President of the C. C. C. & St. L. and the C. & O. Railroads. A live subject by a live man.

## The Injector,

An Ever Interesting and Instructive Subject. A series of articles on Injectors will appear during the year. These are from the pen of an Injector-maker, who has used them on a locomotive as well as made them. They will tell all the flow, when and why about Injectors.

## The Commercial Value of Compound Locomotives.

An Opinion on Compounds from the Financial Side of the House will be contributed by Mr. S. M. Felton, President and Receiver of the Queen & Crescent Road.

## Discipline Without Punishment.

One of the Most Successful General Superintendents in Railroad Work will explain how he keeps up discipline of train and enginemen, and he never lays a man off or fines him.

## Keeping Shop Accounts.

A System of Keeping Accounts of Material and Work in Railroad Repair Shops. These articles are by a well-known railroad officer and describe a system with which he is thoroughly familiar, if not the originator of most of it.

## Railroad Coppersmithing.

By JOHN FULLER, Sr.

Already commenced, will be continued and finished—these articles are a school for sheet-metal workers.

## Economy in Compressing Air for Shop Use.

Will be the Title of a Paper by R. M. Dixon, Engineer of the Safety Car Heating and Lighting Co. No engineer of his country has a more varied experience than Mr. Dixon in pumping air, gas and other vapors.

## Locomotive Tenders.

A Comparison of the Weight, Cost, Repairs and Capacities of the American Eight-Wheeled and the European Six-Wheeled Designs. An interesting subject by a man who knows something about both kinds.—Mr. W. F. Dixon, Chief Draftsman of the Rogers Locomotive Company.

## Sampson Fox,

the Great English Steel-maker, the father of the Pressed Steel Industry, has promised us an article on Boiler Steel, its Manufacture, Inspection, Test and Care. Mr. Fox writes and talks on steel in the most entertaining way—because he is the master of the business.

THESE ARE A FEW OF THE MANY INTERESTING ARTICLES WE HAVE LAID PIPES TO.

WATCH THE PAPER.

1894

DON'T FORGET that we send **THREE EDUCATIONAL CHARTS** to every subscriber whose name is on the list to December, 1894—and to no one else.

YOU DON'T want to miss a chance at those Prize Designs. If you don't compete you want to see what schemes are proposed.

LOCOMOTIVE ENGINEERING will be made so interesting for 1894 that every subscriber will be ashamed that he took so much for the money.

**Blessings are scarce this year! Are you one of the Anointed?**

word as I had intended to have answered it myself. The gasket was burned and cracked between supply port and chamber *D*, as he said. This same thing has occurred several times on some of our engines, because the valves are too near the boiler-head.

I had occasion to examine an engineer's valve a short time ago, that had but recently been overhauled in the shop. The engineer said that an unusual amount of air would escape through preliminary exhaust port before brakes would take hold. On examination I found that a new ring had been put in piston 17, and it was so tight that I could hardly pull it out. The ring was made in the shop and was much heavier than the rings put in by the Westinghouse people. Now, this is wrong, and ought not to be allowed to be done; because it is liable to get some one into trouble. Piston 17 ought to move with as little friction as possible to do good braking. I don't approve of making anything pertaining to the Westinghouse air-brake, because several years' of experience has convinced me that it is cheaper to buy than to make the different parts needed for repairs.

*Syracuse, N. Y.* W. F. RELYEA

### Why Do We Lag Air End of Pump or Driver-Brake Cylinders?

*Editors*:

There seems to be a great complaint about the packing leather in the driver-brake cylinder drying or burning up, also about air cylinders heating, and yet in the face of all this we go right along lagging these cylinders—acting on the supposition that there is condensation to guard against—in fact, keeping them hot when we want them cool. What is the matter with drilling holes through the bottom flange and head between each bolt, and then, instead of lagging for driver-brake cylinder, put on a perforated sheet-iron casing to allow the air to circulate. For the air cylinder, put on a backing of wire netting covered with perforated Russia iron; or for the air cylinder, instead of a perforated casing, make it tight, and connect the air inlet with the space, but drilling the holes mentioned, thereby pulling a current of cold air in about the cylinder.

*Indianapolis, Ind.* W. DE SANNO.

### A Few Suggestions to Those Interested in Learning Mechanical Drawing.

*Editors*:

No doubt there are many of the readers of your paper who have a desire to study some of the "technicals," and mechanical drawing especially. I have had the pleasure of giving lessons in that branch in the last few years, and feel competent to give a little advice. The first question generally asked by the would-be student is "What instruments must I buy, and what will they cost?" An answer has been given to the latter clause of the above by saying buy the best you can afford, which, to say the least, is rather confusing when dealers in such advertise "sets" from one dollar to ninety. It is not my intention to advocate one maker's goods more than another, but would say, first, the list is as follows:

One pair of plain dividers 5 inches long.

One pair of dividers 5 inches long with changeable points.

One spring-bow pen for very small circles.

One drawing or lining pen.

One No. 6 B, or H H H H H H drawing pencil.

Half dozen of fastening tacks.

One drawing board of pine, size 14 x 20 inches.

One T square "blade," 20 inches long, plus the width of "stock."

One triangle of 30, 60 and 90, or equilateral triangle cut in half.

One triangle of 45, 45 and 90, or one half square cut across corners.

A piece of velvet india rubber, for erasing individual lines.

A piece of sponge rubber, for cleaning drawing.

Use a common 2-ft. rule for scale to commence with.

In purchasing, see that the joints of dividers are stiff and do not move with a jerk, choose those with round points and see that the pencil leg is made to receive the small leads that are sold without wood on them. Also have a needle-point attachment to the same dividers.

The triangles should be of hard rubber, and the T-square of any close-grained hard wood, that will keep straight and a smooth edge. For paper I advise printers' blank, 17 x 22 inches, of such quality as this paper is printed on. The cost of the above set should be from seven to ten dollars, and if bought from a reliable firm they should give good satisfaction, generally the pens are sharpened ready to use, which is not the case with the poorer grades.

In addition to the above, I should advise the student to purchase a protractor for laying off angles, but not until he is somewhat advanced. I believe it is much the best to take lessons of some one competent to teach, but if a boy is "too poor" to do that, let him buy some reliable book to learn the rudiments from, and study the different illustrations that appear in LOCOMOTIVE ENGINEERING or other mechanical papers, and don't be afraid to ask all the questions you want to of any one that you see knows something you want to know, never mind being stared at. Of course, it is necessary to know something of geometry and other kindred studies to become an expert, but don't try too much, remembering the maxim, "One thing at a time, and that done well." Would say in closing, that it is better to school the hand to make proper lines and curves rather than close measurements at first.

*Oneonta, N. Y.* WM. NEWTON.

### Defective Piston Attachments.

*Editors*:

The practice of leaving a shoulder on piston-rod crosshead fits is a relic of the barbarous era of mechanics, and should go the way of all barbarism and relics. Without grinding the crosshead on, it is extremely difficult to tell when the rod is drawn solidly into the fit, and unless it is solid, there is no certainty of its staying there. Then, too, the man in a hurry is liable to say, "That ain't very good, but she will go another trip," and sometimes with disastrous results. On the other hand only the worst ignoramus could drive a crosshead key without knowing when the rod was home, when there was no shoulder; and if from any cause the rod should get to working in the fit, the engineer would have a chance to see it.

We used to think the cracks that started in the corners of the shouldered rod, were because of the sharp corner; but I have noticed that rods without a shoulder crack in relatively the same place, *i. e.*, just outside the crosshead. Can some one explain?

While seeking an explanation for that let him think a little on these also. Why are spiders keyed on when nuts are cheaper and better? Why do we take so much pains to keep guides closed when the business end of the piston-rod is often a quarter of an inch too small for the cylinder? Why is not the solid piston-head and snap ring in more general use when it is both lighter and cheaper and just as effective?

*Boone, Ia.* F. W. PETERSON.

### How to Make a Good Rod-Strap.

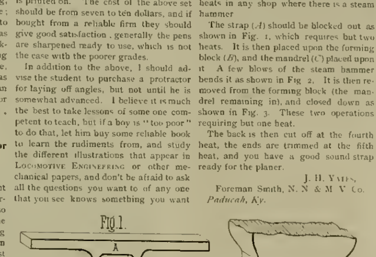
*Editors*:

The inclosed sketch illustrates how a locomotive rod-strap can be made in five heats in any shop where there is a steam hammer.

The strap (*A*) should be blocked out as shown in Fig. 1, which requires but two heats. It is then placed upon the forming block (*B*), and the mandrel (*C*) placed upon it. A few blows of the steam hammer bends it as shown in Fig. 2. It is then removed from the forming block (the mandrel remaining in), and closed down as shown in Fig. 3. These two operations requiring but one heat.

The back is then cut off at the fourth heat, the ends are trimmed at the fifth heat, and you have a good sound strap ready for the planer.

J. H. YATES,
Foreman Smith, N. N. & M. V. Co.
*Paducah, Ky.*



### Has Faith in the Engineer's Valve.

*Editors*:

Was pleased with Mr. W. R. Scott's article in regard to the equalizing discharge valve. I fully coincide with Mr. Scott, and think that the only thing wrong with the valve in most cases is a lack of confidence in it on the part of the engineer. Having had considerable experience with valve and maintenance of same, I find that when valve is in proper condition, 20 pounds excess can be maintained, no matter how leaky your train-pipe. For example, have met with train, that, owing to leaks in train-pipe, pump would not supply more than 40 pounds train-pipe pressure, with this train and equalizing discharge-valve in proper condition have maintained 60 pounds reservoir pressure.

I find the greatest trouble arises from engineers having been used to old style brake-valve. Through force of habit they allow handle of valve to remain in release position after releasing brake, which causes valve to become seated to that one particular position, then after having used the valve in that position for some time, should you endeavor to carry valve in running position, you will find it cannot be done, on account of air escaping between valve and seat, causing the gradual application or sticking of brakes. But could engineers be made to see this, and carry valve in running position at all times, it would naturally seat there, and excess might easily be maintained.

*Wellington, Kan.* J. D. MCKEWN

### Air-Brake Questions.

Grief with Driver Brake-Cylinder Packing. Quick-Action on Engines and Tenders. Gable's Leaky Engineer's Valve. Sweeney's Automatic Pressure Rotary-Valve. A Hardened Scraper for Valve Work. The Other Air-Brake Puzzles. A Remedy for Self-Closing Angle Cocks.

*Editors*:

Some time before the question of pistons on driving-brake cylinders came up in the August number, I heard that the R. & D. men were using water as a remedy, and we proceeded to try it on a particularly bad case—one in which the packing would be ruined in a couple of trips. It was a complete cure in this case, but in a few weeks one of them dried out, and immediately burned so as to be useless. Since this leather was renewed it has given no trouble, there is reason to believe that in the last three months, where this practice has been followed on our mountain divisions, the driving-brakes have been made more reliable, and not only has the life of the packing leathers been increased, but less than half as much time per trip is required to keep these brakes in order than formerly. We are now trying water from the steam lubricator in them, on a hint from an old runner. I am still of the opinion, however, that, if whoever was at fault in placing these cylinders where the leather was so readily burned or overheated, was required to do the repair work on them for a couple of months, there would be no more trouble with that kind of brakes. or if some one who is looking for a place to save money in little things could be brought to realize the amount of labor and air that is wasted in trying to keep up what may be a brake in name, but frequently is not so in fact, perhaps things might work a little better than they do now.

In the September number Brother Synnestvedt wishes to learn what is the opinion of air men as to using a quick-action triple on engines and tender. There may be something that would perhaps interfere with such practice, but if so I have been unable to find it, and believe it should be given a trial on some road that is prepared for such things. It looks as though the Plate D 20 triple-valve has been left on when engines were not so heavy as now, and the blow a heavier non-quick-action engine would strike on a train with these valves in operation not all [illegible] for, and at present it seems to me as though in an emergency all brakes should go on alike, from pilot to rear of train. If there was any trouble, it could be overcome in a special valve working in accordance with its proximity to fountain head. While I may be considered a heretic in this matter, I am personally in favor of straight air for switch engines and quick action for train service.

In same number, page 415, friend Gable mentions rotary valve as setting brakes on service application without letting air out of service exhaust port, and which was in good order, with the exception of some small holes drilled in rotary-valve. Would suggest that he take a piece of paper, cut a hole in it for center pin in rotary-valve to go through, then, after cutting out all ports and drilled holes, place it on that valve-seat in service stop, and see if some of these holes do not just hit the edge of emergency port, or are very close to it, and leak either in the valve or seat from recess c, Fig. 4, Plate D 5, to emergency port. That is where the trouble is likely to be.

The automatic pressure-retaining valve in October number is very interesting, but it looks as if there would be some difficulty in getting prompt and certain release, unless the valve was large enough to work in unison with the triple-valve pistons and when brakes were applied would there not be a considerable leakage from the auxiliary reservoir out by this valve.

As for Mr. Armstrong's brake-valve, would state that here we scrape them in, and use usually the oil and grit off a soft

oil-stone to set the grain. My style is to get a pair of templates, one for the valve-seat and one for the rotary-valve; use a scraper made out of tool steel dipped in a can of bromide of potash and black oil when cherry red; do not draw the temper; and it sometimes improves them to reheat and dip again in the same medicine. To sharpen, use one of those ordinary razor hones, called petrified hickory, that costs 40 cents in hardware stores, one side is black, the other white—the grit from either side will finish the valve after scraping. Before this was used I tried everything I could hear of, found grindstone grit embedded itself in the brass, then, when pressure was applied, caused the valve to hang or drag; also find after a brake-valve is in use awhile the top cap No. 2 Plate D 8, will wear off on one side, as the engineer usually bears on handle when using it, and in that case if the top cap is trued up in a lathe it will help matters. This road does not use the oil in air pumps recommended by the W. A. B. Co., and sometimes on account of boiler heat, oil will gum on seat and make valve stick; as to washer No. 12, Plate D 8, getting so thin as to let the key No. 11 drag, as our Kansas friend points out, a piece of old bacon rind made into washer No. 12, and put in with meat side next to top cap No. 2 will relieve the engineer's mind to a large degree, and Mr. Wescott must have had something wrong with the air space above piston 17, perhaps the small reservoir under running board had a cock in it that had been left open.

As to the brake valve Plate D 5 not setting in service stop, last month something a little different made its appearance here. An engine came in on a train with only 40 lbs. of air, but when brought to roundhouse showed 70 lbs. Now, as all were, I thought, posted in the repair shops, as to all the tricks this valve could play, and as it had been worked on and not benefited, I concluded to go over the valve myself. I examined gasket No. 61, Plate D 5; not very good; put in new one, looked at rotary valve, it was O. K. Had the gasket been leaking, the black hand would have crept up with the handle on lap. Feed valve case gasket was not very good; put in new one; found feed-valve No. 63 had been leaking; unscrewed spring-box No. 69, and with a feed-valve cap nut No. 65 with hole drilled through top (which is used to set air gauges with, the space occupied by spring 64 being filled with solder to keep center true) scraped this valve to its seat; put it together and told the man taking instructions, to see how the valve cut off, and the black hand stopped at the pressure the piston spring No. 68 was set at; he saw that the valve cut off all right, also saw black hand creep round just as it did before, and I saw there was more in the valve than was dreamed of.

After some time lost in fooling around, the adjusting nut No. 70 was run down till it was free, and I found the pin on lower end of feed-valve was resting on top of piston 66, and could not shut off the air from main reservoir entirely; investigation revealed the fact that the piston barely cleared the end of feed-valve when both were down, and everything in order, and that the gum diaphragm No. 72 had become swollen or thickened with age and would not let piston No. 66 seat on spring box No. 69, which it should do to clear feed-valve stem. After putting in new diaphragms once more, I told the man to see if the black hand stopped, and it did so. In case this trouble occurs on the road, if the spring box is unscrewed a little it will help matters till the trip is finished, but keep an eye on it when you screw it up; on long trains this valve may possibly be a disadvantage, but it is in great favor among the engineers here for the reason that it does not pump up with handle on lap.

In Mr. Pratt's case, if the drivers had not slid, and the brakes were holding as they should (which is not always the case), the train should have stopped before it did, but it should be ascertained if the driving-brakes were reliable, and the man posted. I usually find discipline needed at the other end of the string. Could you have done with this brake what the man in charge failed to do? I believe all engineers should be thoroughly posted on the brakes; then, if he is a competent engineer, as he should be, and knows the engine, his judgment certainly ought to go for something, especially as his is the life at stake in a crisis.

The disease our Scranton friend mentions is apparently universal, costs lots of money and would apply in the following: Since I heard Mr. Hedendahl point out the danger of angle-cocks closing automatically, as mentioned in the editorial on page 480, I have been experimenting, and find by striking short, sharp blows with a hammer on top of handle or key No. 2, Fig 7, Plate D 24, every angle-cock could be closed in a train, also found every one that closed had the spring No. 4 wound right handed, the same as a screw, in one old cock I found a left hand spring, which was put in on a cock at rear of tender, and securing a man who knew nothing of what was wanted, had him use the hammer on the cock which was half closed; it gradually *opened*; then took out the left hand spring and put in a right hand one, and as soon as he began to hammer, the cock began to *close* again. This was repeated on another engine with the same results. Also found if the hose-clamp presented the proper angle to the handle, if loose, would ride and have a tendency to close the cock. Am now satisfied that a right handed spring in an angle cock is an element of danger that cannot be removed too speedily.

I once planned a valve or cock in place of the angle-cock, which I yet believe would overcome the difficulties under consideration; but seeing that it would look very clumsy and probably cost more than the angle-cock, besides being reluctant to believe that cocks would be closed purposely, I let it drop. The present outcry against tramps, accusing them of closing angle-cocks, appears to me to be largely sentimental, and I believe no more of it is done (if as much) than other attempts to wreck trains by placing obstructions on track, and if an impartial investigation were made in cases where angle-cocks were closed, nearly every case could be traced to improper inspection or defective apparatus, and the tramp cry used as a loophole. Meantime, if the springs under the key in angle-cock are changed to left-hand ones, and the holes drilled in angle-cocks, as recommended on page 411, September number, the danger will be lessened to such an extent that it will pay to wait for the remedy that always turns up in the course of time.

*Roanoke, Va.* GEORGE HOLMES.

## Another Signal Whistle Puzzle.

*Editors:*

Here is a report of defect in air-whistle from one of our engineers "Can't blow air-whistle only once" I put on my "tester" and found that the pressure was about right, and then opened the little cock on the end of the "tester" to blow the whistle. Well, it did blow, but it took a long time for the pipe to recharge. I knew right away there must be something wrong with the reducing valve, so I took off the cap and found that a new diaphragm had recently been put in. I then pressed on the feed-valve and turned it around with a screw-driver and found that air got through it all right. I put it together again, but it worked just the same as before. Now, all air passages were open full, and there was no obstruction in the pipes and the same pressure-reducing valve had been on the drum since the engine was built, still the trouble was in the pressure-reducing valve. What was it?

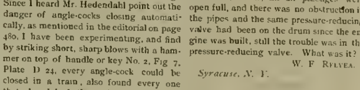
W. F. RELYEA.

*Syracuse, N. Y.*

## Painter's Portable Platform.

*Editors:*

Any one who has been obliged to work on locomotives while on blocking in the back shop at the same time the painters are trying to *get there* with all of their paraphernalia, such as high horses, ladders, empty oil barrels, long planks, and a host of blocking, with which to elevate themselves high enough to paint, sand-paper or varnish a cab, will appreciate the platform shown in sketch.



Some six years ago the writer conceived the idea that a platform of this kind would be a good thing to have, and forthwith had one made at a trifling cost, and it proved to be a very useful appliance. When the platform is in position it leaves the floor space around the locomotive clear of obstructions permitting free access to all parts below the running boards, so that machinists can work on frames, shoes and wedges and spring rigging, and the boiler-makers can get at the bottom of firebox to do their work.

The platform can be carried by one man, and put up in position in a few minutes. It will suit any ordinary cab, and permits the painter to reach all parts of a cab to be painted. The details show the number of parts required.

This platform has been in the C., M. & St. P. Dubuque shops for the past six years, and is still in good condition, being in use a great share of the time and is highly appreciated. J. C. MILLER,

*Dubuque, Ia.* General Foreman.

## The Invention of the Link Motion.

*Editors:*

With reference to the letter of Mr. James Hedley and the editorial note, page 493, I may point out that the question of Howe *versus* Williams is quite a side issue. The main question which is engaging so much attention over here is the "invention of the link." Does it belong to England or America?

Of course, Englishmen have believed that it was an English invention, but from the most careful and impartial examination of facts I can come to no other conclusion but that it was invented by James, of New York, in 1832. In the year 1833 details of the James gear were sent over to Forrester & Co., engineers, of Liverpool, and they, in 1834, adopted the "four eccentrics," which was an important part of the James invention.

Since seeing the model at the World's Fair, and investigating the matter most carefully upon my return home, I am convinced that the link was invented by James, and the fact that drawings were sent over to England in 1833 must prove to all impartial minds that the credit for this important invention belongs to America. CLEMENT E. STRETTON, C. E.

*Leicester, Eng., Nov. 10, '93.*

## Mr. Wescott's Problem.

*Editors:*

In reading November LOCOMOTIVE ENGINEERING, I came across Mr. Wescott's statement. I happened to be in the same predicament, and I found that the cause of the air blowing through the train-pipe exhaust port was due to a hole being in the small reservoir right under the running board. The reason it would not show any pressure is because there wasn't sufficient compressed air to hold piston 17 on its seat. ROBERT HENNINGS,

*Algiers, La.* South Pac. Shops.

*Editors:*

The trouble complained of by W. C. Wescott air blowing through train-pipe exhaust port while handle was on release or running position, and could get no pressure, will say that cock in small air-drum under cab was open.

*Aurora, Neb.* L. F. WESSMAN.

*Editors:*

In answer to W. C. Wescott's air-brake problem in November number of LOCOMOTIVE ENGINEERING, will say if friend Wescott had examined drain-cock on small reservoir before taking down his engineer's valve he would have saved himself quite a job, saying nothing about the detention to his train, as he undoubtedly found it open when he located the trouble.

*Elmira, N. Y.* T. H. GOSWARD.

*Editors:*

In Vol. VI, No. 11, page 499, I notice inquiry of W. C. Wescott (Where did Air Come From?). He states upon arriving at engine he found air-pump running, and air escaping through train-pipe exhaust port, and said he could stop it only by putting valve on lap. Examined piston No. 17, and found it O. K. What was the matter? Will say there could be but one thing, which was a lack of pressure on top of equalizing-valve or piston No. 17, caused by drain-cock in equalizing cylinder being open, or leak in some of connections to cylinder. J. D. MEKEMS.

*Wellington, Kansas.*

THE ANSWER.

*Editors:*

Drain cock was open in equalizing drum, which would prevent pressure accumulating above piston 17 to keep it to its seat. W. C. WESCOTT.

*Albert Lea, Minn.*

## An Improvement in Case-Hardening Furnaces.

*Editors:*

In a letter published in your September issue I described some cheap furnaces for case-hardening and tempering—railroads think they must have everything cheap.

Once in a while you run across a shop where they appreciate a first-class thing, even if the first cost is higher. Here is a furnace of that kind, and I venture to say that 25 per cent. more work can be done with it, besides that it requires less fuel and less labor and insures even heating and prevents burning.

You can see by Fig. 1, which is a sec-

…tional view, that the usual form is used, but that the table where material is laid is arranged to be revolved about six turns per minute.

You cannot help getting a uniform heat, the fire being on one side of the furnace the heat has got to travel over the table and down the flue on the other side.

In opening the valve at *B*, you can regulate your fire, as you have to have a stronger blast to start your fire and get

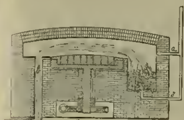


Fig 1

your furnace hot than you will need after you get the furnace to the proper temperature for the class of work you are going to do.

The valve at *A* is used to force the heat over the table, and takes the place of a hot blast to a certain extent. You can get a welding heat, if necessary, by the use of this valve.

C, Fig. 2, represents the firebox door, and *D* the door that opens in line with the center of your table, and is used to put in and take out your material, *e*, the

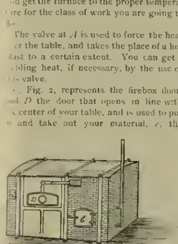

Fig 2

little door to the left is used in cases where some of your material is crowded off from the table and drops down the flue *b*.

This furnace can be built of ordinary brick and lined with fire brick. You can also use different kinds of fuel for tempering. The scrap wood from the wood-shop does very well, especially for shaping such things as spring leaves, as there is little danger of overheating.

*Rochester, Minn.* W. G. Lottes.

## Some Dimensions of Those Swiss Engines.

*Editors*:

I write to give you a little information about the general dimensions of the Swiss locomotives illustrated on pages 476 and 477 of your November number. The six-wheel connected engine, No 108, is a compound engine with a hand-brake operating on the tender wheels and the Westinghouse on the drivers. She has driving-wheels 5 ft. 3⅛ in. in diameter, cylinders 17¾ and 25¼ in., and 25⅝ in. stroke. Her boiler carries a steam pressure of 180 pounds. She has a firebox heating surface of 84 square feet, and a total heating surface of 1,489 square feet. There are 184 tubes 14 ft 7¼ in. long, and a grate area of 18 4/10 square feet.

The total weight of engine, empty, is 98,100 pounds, and ready for service, 108,170 pounds. The weight on the drivers is 82,000 pounds. The empty tender weighs 23,400 pounds, and has a water capacity of 2,100 gallons, and 7,500 pounds of coal. The engine and tender are 43 ft 10½ in. in length over all, and the top of the smokestack is 14 ft. 7¼ in. above the rail, the fixed wheel base being 11 ft. 6½ in. The total wheel base of engine is 19 ft. 8¼ in., while the total wheel base of engine and tender is 34 ft. 10⅞ in. The engine was designed for a maximum speed of 46.5 miles per hour.

The four-coupled engine, No 52, is a simple engine also designed for passenger service, having driving-wheels 5 feet 2¾ inches in diameter, with cylinders 15¾ x 23⅝ inches. Her boiler carries a steam pressure of 165 pounds. She has a firebox heating surface of 70 square feet, and a total heating surface of 1,054 square feet. There are 159 tubes, 12 feet in length, and a grate area of 16.1 square feet. Total weight of engine, empty, is 69,526, and ready for service 78,000 pounds. The empty tender weighs 19,400 pounds, and has a water capacity of 1,980 gallons and a coal capacity of 6,600 pounds. The engine and tender is 42 feet 10¼ inches over all, and the top of the smokestack is 13 feet 7¼ inches above the rail. The fixed wheel base is 9 feet 2⅜ inches, the total wheel base of the engine being 17 feet 4⅝ inches, and of the engine and tender 32 feet 4⅞ inches. This engine was also designed for a maximum speed of 46.5 miles per hour.

Both engines are equipped with steam-heating apparatus, Westinghouse air-brakes, with hand-brakes for engine and tender. Henry Gretner.

*Philadelphia, Pa.*

## Testing for Leaks in Engineer's Valve.

*Editors*:

For the benefit of your numberless readers, please let me give my views of what I think is a good way to test for a leak in rotary-valve. First turn stop-cock in train line under brake-valve, place handle in lap position, then start pump. If there is a leak in rotary-valve, air must leak in train line above stop-cock. After red hand has reached the point it is intended to stop at, and pump has stopped, turn stop-cock back and you can hear the air above cock rush in train line below. Another way: If your brakes are leaking off, and you are in doubt if it is caused by leak in rotary-valve or leak in brake-cylinder, after train line is charged and brakes are ready for operation, reduce the pressure in train line, place handle in lap position, and if the brakes leak off put handle in release position again and charge train line, then reduce pressure and turn stop-cock; if the brakes don't release blame it to rotary, if they do, blame it to something below the stop cock.

C. Reilleis.

*East Albany, N. Y.*

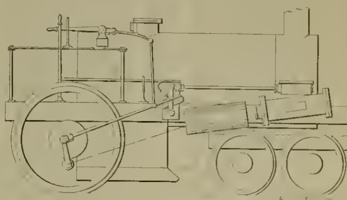
## The Seth Boyden Locomotive "Orange."

*Editors*:

In the descriptive article of the Boyden locomotive, illustrated in the October issue of your paper, you say the engraving was made from the original drawing. I do not think the original drawing was strictly adhered to, as I can see where changes must have been made, as I remember the engine. You say the wheels were cast with flanges, no tires. My father, the late Samuel D. Harris, who did the forging for all the locomotives built by Boyden, told me that when he made the tires that Mr. Boyden came in the shop, and, taking a travel, ran it around the inside of one of the tires, and said "Damn it! Sam, you have spoilt it," thinking that there was not sufficient stock to turn out to make a fit to the wheel. On being told to run the travel around the other way, it showed the tire was right. The truck wheels, as well as drivers, had tires. During my school days, which ended in 1855, I was one day around the engine-house and heard a sharp report. On going to where the workmen had congregated, I saw that a tire while being shrunk on her right hand driver had burst, leaving a crack of not less than ¼ inch wide. The truck wheels were also tired, one pair of which were under the engine as long as she was in use.

On one of her trial trips, after having run to the top of the Newark hill, with Mr. Boyden acting as engineer, he stopped to take aboard some of the officials of the road, and while talking to them he placed his hand on the safety-valve to stop the noise of escaping steam, and, as father described it, there was a sudden shock and tremor to the boiler, after which, on starting, she would hardly move. Taking her back to the shop, it was found the dry-pipe had collapsed, leaving only space on each side to insert a pencil. The "Orange" was in passenger service at the time of being burned, February, 1863.

The *American Machinist* of October —, 1883, gives an account of a twist drill made by Mr. Harris, and used for drilling the stub ends of the rods of the "Orange," which is the earliest history of that indispensable tool.



Seth Boyden's "Orange."

There were three engines built by Boyden. The "Comet" was built for a Cuban

Hook Blocks of the "Orange."

railroad, the man who took her out having lived until about two years ago.

The "Essex" was sold to some road in Ohio early in the fifties, and was lost overboard crossing Lake Erie. I never heard that she was raised.

D. M. Harris.

*Newark, N. J.*

## What to Do in Case a Rear End Looms Up.

*Editors*:

In the November issue I notice an article in regard to handling driver-brakes in case of an emergency from Mr. Pratt, of the C. & N. W.

In the case engineer applied brakes on engine and train, and as he was about to have an accident, reversed engine, which caused drivers to slide flat. If the engineer had released brakes and cut driving-brakes out, then applied air and reversed engine on sand, he would not have slid driving-wheels, but undoubtedly would have struck caboose harder and made accident more serious, blocking main line longer. In an emergency, all engineers do everything in their power to avert an accident; that is perfectly natural and right. This engineer did his duty by reversing engine.

The gentleman in charge of air-brakes on the C. & N. W. is partly to blame for the flat spots on those driving-wheels. Suppose the air-brake man would have a pipe connected to air-pipe which leads to driver-brake cylinders, and this pipe run up in cab where engineer could reach it, and in the top end of this pipe have a plug-cock. When engineer saw drivers about to slide, he could turn plug and allow all air in driving-brake cylinders to escape and still hold brakes on train. An engine in back motion on sand will hold more and quicker and stop sooner. I have seen a 6-wheel connected engine stop a train of sixteen cars of stock running thirty miles an hour in 400 yards, no brakes set, sand running on both sides. All driving-brakes on engines should have a pipe to release them by. There are a great many times when wheels are liable to slide, when it would be dangerous to release all brakes. I have had drivers slide with 10 pounds application down hill, and would have to release and cut them out. As sand pipes are liable to stop up in five minutes in a wet night, would like to ask some of the older engineers what they would do if they were to apply brakes and drivers would slide in a close place when to release would cause accident. I notice the argument in regard to handling brakes in an emergency. One correspondent, and also Locomotive Engineering, recommend to go immediately to emergency position if you are flagged or want to stop quick.

Well, suppose you had a train, all air, with long piston travel and not in good shape—as a great many are—you are coming down a long, steep hill, you commence to make a stop, and altogether draw off twenty or twenty-five pounds in service position, and then you want to stop quick and throw valve in emergency position, what do you gain? Suppose train-line pressure is less than brake cylinder pressure, when you go into emergency position you may get the quick-action valve to move; if so, what is to keep the highest pressure in cylinders from flowing back in train-line until it equalizes, which weakens or releases brakes. If I am wrong correct me. I am here to learn.

Wald. M. Perkins,

*Dennison, Tex.* M. K. & T.

[We fear our correspondent would have a hard time to get the quick action valve to work under the circumstances he states, and a harder time yet to get air from the brake-cylinder to get back into train-pipe through emergency-valve and check. It could not be done.]

When the New York Central twenty-hour flyer was put on between New York and Chicago, it was expected that the train would prove so popular that it would be continued permanently. It has been popular and a great public convenience, but the opposition of rival lines has been too great. The train made its last run on November 18.

A very sensible suggestion is made by Mr. De Sanno in a letter published in another part of this paper in regard to making provisions for cooling the air end of air-pumps instead of lagging them to keep in the heat, the present practice. Compressing the air heats it up considerably, and to this is added the heat that comes from the boiler to which the pump is attached. The volume of air increases very much by rise of temperature, so that there is less effective braking power in air that is heated in passing through the air-pump than there would be if it was kept near the temperature of the atmosphere. We heartily commend the suggestions for keeping air-pumps cool to all persons interested in the efficiency of air-brake apparatus.

# ? A. What You Want to Know. ? A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(106) Robt. Flodo, City of Mexico, writes

Kindly inform me through the columns of your valuable paper, the best and most accurate manner of setting eccentrics on a locomotive before wheels are put under engine. *A.*—See LOCOMOTIVE ENGINEERING for March of this year.

(107) Shopman, Topeka, Kan., writes

Has anything ever been done to apply power to the calking tool? Do you think it would pay to take out a patent on a way of using air or steam to work a calking tool? *A.*—There is a power-calking tool on the market, but the proprietors have so little to say about it, that they seem afraid the public will hear about it. We believe it would pay to patent a new invention of this kind.

(108) R. J. H., Helensville, Australia, writes

Can you give me some information through your columns about capillary attraction, so far as it applies to the locomotive? *A.*—Capillary attraction figures very little in American locomotives, but in the locomotives used in Australia the bearings are nearly all lubricated by means of worsted feeders. In that case the oil passes up the worsted by capillary attraction. The packing in an oil cellar also carries the oil to the journals by the same force.

(109) W. B. M., Boston, writes

In figuring up heating surface of a boiler, which is the proper way to calculate, the inside or the outside surface of the flue? *A.*—The rule is to figure the outside surface of the flue. We understand that the inside surface is sometimes made the basis of measurement, which makes a boiler appear to have smaller heating surface than it actually has when compared with others. The practice ought to be uniform, and figuring the outside surface has enough adherents to entitle it to be considered the rule.

(110) Inspector, Bombay, India, writes:

I see frequent reference in your paper to the standard train rules. What are they? Who has made them standard? Where can they be procured? What do they cost? *A.*—1. They are rules for controlling the safe movement of trains. They define the kind of signals to be used and the form of order for train movement to be given. 2. They were made standard by the American Railway Association, which is composed of the leading railroad managers in America. 3. From the Engineering Literature Co., East Orange, N. J., price, $1.00.

(111) R. C., Sedalia, Mo., writes:

There have been some disputes among the men in the shop about the weight of locomotives and their parts. We have decided to refer the thing to you. We want to know: 1. How many engines were there in the World's Fair over one hundred tons weight? *A.*—None. 2. Where is the heaviest engine ever built, how heavy is she, and who was the builder? *A.*—Working the Grand Trunk business in the tunnel under the St. Clair River, near Detroit. About one hundred tons. Baldwin Locomotive Works. 3. What is the weight of a boiler with say 230 2-inch flues? *A.*—From 23,000 to 25,000 pounds.

(112) J. C. B., Memphis, Tenn., writes

I have often seen mention of steel made by the Coffin process, but no explanation of what the process is. You would favor several readers by explaining the process. *A.*—The Coffin treatment is a process to which steel is subjected after being made for toughening the material. The piece to be treated is heated uniformly to a cherry red and then it is dipped in cold depending upon the size of the article. It is then taken out of the water, and the water for a few seconds, the length of time internal heat of the article is sufficient to bring it back to a low red heat. From this temperature it is permitted to cool gradually. The process is said to cause a molecular change in the steel which makes it exceedingly tough.

(113) S. W., Portland, Me., asks

1. Will you please tell me what an intercepting valve is for. *A.*—An intercepting valve is used only on two-cylinder compound locomotives. It is a valve that automatically shuts off live steam from the low-pressure chest and opens it to the exhaust steam from the high-pressure cylinder. 2. What is the best way to cramp a valve-stem where metallic packing is used? *A.*—You cannot "cramp" the gland on valve-stem of an engine equipped with metallic packing. The Jerome has a set screw through the side, take this out and remove the washer under head and screw it down on to the stem. With the other kinds always carry a piece of sheet metal that can be fastened to one of the studs and reach back to the keyway in the stem, having a slot to match this keyway.

(114) D. McInnes, Philadelphia, Pa., writes:

A friend of mine (a marine engineer) and myself, had an argument lately, and the subject was, "The bevel on locomotive wheels." This subject was brought up by one asking the question, why was it, if a locomotive was set on a circular track, at a certain part, and started to go right around to the starting place, why was it that the wheels came to the same place and position as when they were started, the inside rail being so much shorter than the outside one? His argument was that the inside wheel slipped or skidded on the rail, and I, failing to convince him that the bevel on the wheel was for the purpose of allowing locomotives and cars to round curves, would like you to explain the matter in your December number. *A.*—When wheels are beveled, there is no doubt that it helps on a curve, but after short service they are often beveled the wrong way, yet they curve with little trouble. In this case the wheels on one rail must slip.

(115) No One, Erie, Pa., says

There is a dispute among men here as to who holds the more responsible position—the engineer of a locomotive, or the engineer in charge of a marine engine? We want you to settle the question. *A.*—That depends upon circumstances. The engineers on a passenger steamer must be able to do machinist, blacksmith and boilermaker work in case of necessity; they must know something about electrical machinery, a great deal about pumps of various kinds, and be familiar with the working of complex marine engines. Men for this position must have a good mechanical training. Many of the best locomotive engineers could not do any work on their engines requiring mechanical skill. Their knowledge is confined mostly to the handling of the engine. The marine engineer has a particularly responsible position when anything unusual happens to the machinery, and he must have knowledge and training to deal with emergencies. The locomotive engineer has a more responsible position than the marine engineer in the ordinary routine of his duties. He is responsible for the safety of his train as well as for the working of his engine.

(116) C. R., Little Rock, Ark., says

A discussion took place at the dinner hour yesterday about steam. P said that a locomotive used saturated steam. B said that saturated steam was mixed with water, and that the engine was priming when that kind of steam was going from the boiler. C, who pretends to know more things than other people, tried to ridicule what was said, and talked about anhydrous, saturated and dry steam till my mind was muddled. Please say who was right about saturated steam, and explain the meaning of the terms used. *A.*—Saturated steam is the kind of steam used by most engines, and it does not contain water in the shape that causes priming. If any heat is taken away from it, part of the steam will instantly turn to water. Saturated steam is sometimes called dry steam and sometimes anhydrous steam. Steam is called saturated when it exists in the presence of the water from which it was evaporated. It represents the amount of steam that can be held in a given space at a given pressure. If more steam is evaporated the pressure will increase, if any heat is taken away from the steam, part of it will return to water and the pressure will fall. When steam, not in presence of water, receives additional heat it becomes superheated, which increases the temperature and the pressure.

### Another.

The speed of railway traveling is to be nearly doubled when the new express locomotive, now in course of construction at Wolverhampton, is placed upon the track. The horse-power is 2,000, and the speed 100 miles per hour, the driving-wheels are 12 feet in diameter, and there are three cylinders of 40, 28 and 18 inches in diameter, with a 30-inch stroke. The boiler pressure is 200 pounds. It is proposed to run from London to Edinburgh in six hours.—*English paper.*

### A Jury on the Battle Creek Wreck.

On Nov. 15th the Grand Jury empaneled to inquire into the causes of the disastrous wreck at Battle Creek, on the Chicago & Grand Trunk, on Oct. 20th, rendered the following verdict:

"We find that the said collision was caused by gross disobedience of orders given by train despatchers. We also find that Engineer Harry Wooley, of train No. 6, eastbound, and Conductor Bertram N. Scott, are guilty of criminal negligence in running past their meeting point, at which they had positive orders to stop."

The jury reported that the Grand Trunk Railroad Company had done all that could be done in the way of first-class equipments for the safety of its patrons, and the road was exonerated from all blame.

The latter statement is doubted by many men who know, as the equipment of this train was not of the best, but the verdict among railroad men seems to be that the crews were to blame, as stated in the indictment.

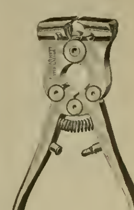
Our neighbor Van is disgusted with our Ananias Column. This is hard on us, but the yarns which our correspondents tell do not violate the spirit of truth half so much as Van's claim of having got 8,000 subscribers in one year, without intimating that this was in 1883, and that he lost the last one of them the following year—which is a fact.

In a performance sheet summary of the work done by locomotives on the Santa Fé for the month of September, we note that the average mileage was 3,329 which does not indicate greatly depressed business. From other sources, we now learn that they are very busy on the road and complaints are heard of shortness of power, and scarcity of cars.

### A New Adjustable Jaw Cutnipper.

This tool was designed to supply the demand for a better thing in its line than has been heretofore obtainable. A brief examination will convince any mechanic that it does so.

The jaws are detachable, so that they can be removed, ground and adjusted when they have become worn. Each jaw can be ground away to the extent of ¼



No.1.

inch, remaining as good as new for practical use, and when used up, if ever, new jaws can be procured.

These jaws have a dovetailed slot in their under side to receive a spline which extends into a slot in the frame. A tapering screw through the frame and spline draws the jaw firmly down to a toothed seat in the frame, holding it securely.

Another improved feature in this cutnipper is a flat spring below the cutting edges, and over the joint, forming a yielding seat for the end of the wire to press against while being cut. This obviates the danger of breaking the jaws as often happens with the other styles of cutnippers which allow the wire to be inserted against a solid surface, thereby creating a pushing out strain on the jaws when they are pressed together.

The head and handles are of drop forged steel, finely finished. All the parts are case-hardened except the jaws, which are made from a high grade of steel, nicely tempered. They are made by L. S. Starrett, Athol, Mass.

### Kiley's Automatic Relief Valve.

The illustration herewith shows the valve invented by Mr. Daniel Kiley, a locomotive engineer on one of the Brooklyn

Fig: 1.

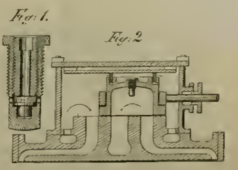


Fig: 2

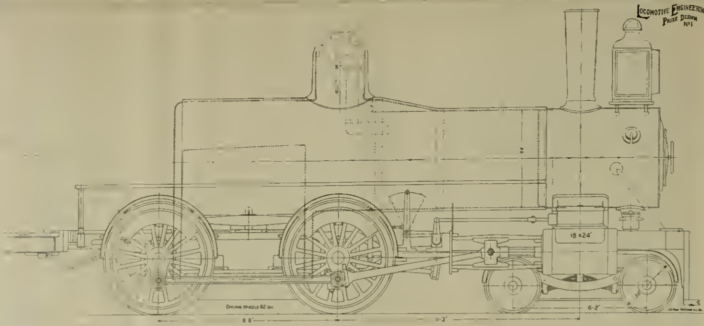
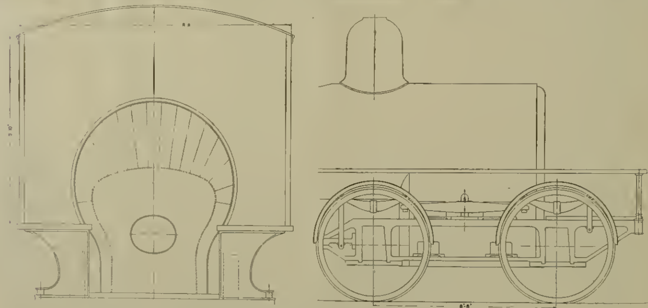
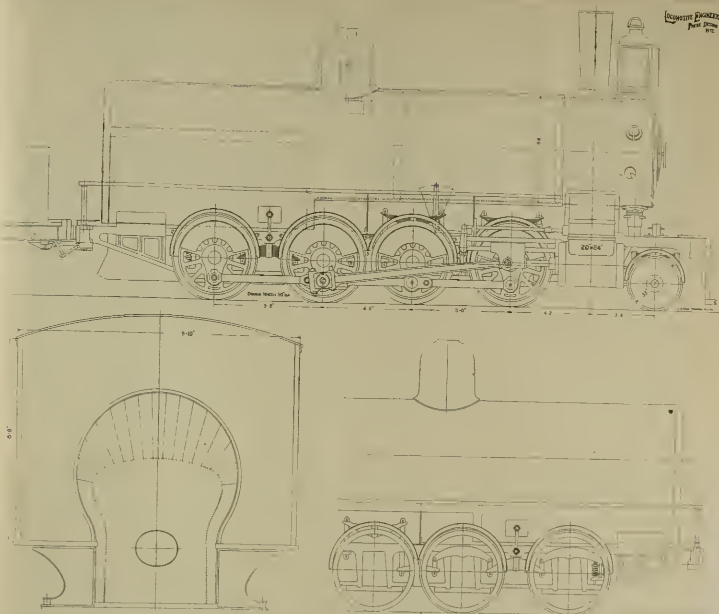
elevated roads. He does away with relief valves in the chest and puts a small relief valve in the top of the valve, taking the place of the vent or leakage hole in ordinary balanced valves. The B. & O., the D., L. & W. and several other roads are using this device and report good results. The inventor claims that by the use of this valve all the advantages of the balanced slide valve is had as long as steam is used, but that when steam is shut off the valve practically becomes a plain D valve.





Chance to Earn $100, $50 or $25. See Particulars on Page 557.



$175.00 in Prizes to Finish this Design. See page 557.

# THE WESTINGHOUSE AIR-BRAKE CO.

# LOCOMOTIVE ENGINEERING PRIZE DESIGNS.

# $350

## In Rewards for Best Designs in Cab and Boiler Fittings.

SEE DRAWINGS ON PAGES 554 AND 555.

THE number of men scalded and cooked to death in wrecks is so great that little notice is taken of it. Practically nothing at all has been done, or attempted, to make Locomotive Boiler Fittings safer for those who handle them. The details of some of these wrecks are heart-rending. Instances are on record, and are common, where men have been held down by wreckage, but uninjured, until slowly cooked by escaping steam—one fireman was found with steam pouring out of his mouth and nose, the small pipe to the steam gauge had broken off and the end had partly penetrated his side (a wound of little consequences had there been no steam there). This is only a sample.

Nor does this danger exist for enginemen alone. Only last year a locomotive on the Colorado Midland Road struck the side of a loaded passenger car. The check broke off and killed the passengers—the force of the collision was not enough in itself to overturn the car. The Quincy wreck on the Old Colony was so frightful because the victims were imprisoned in a car crushed over the wrecked locomotive. Half the fatalities of railroad wrecks, and more than half the tortures can be prevented if the steam can be kept in the boiler.

Many locomotives are extremely uncomfortable and unhandy: boiler fittings are located in places where they are liable to be broken, are hard to handle or to pack; seats are poor and located where men cannot use them and handle the engine properly. Brake valves are located where they get hot and stick: where they are hard to reach, etc. Those who ride the engines day after day know how uncomfortable many of them are. All this can be made better.

The running repairs are troublesome and expensive. Grinding in valves takes time; takes the engine out of service, and is long neglected on that account. Is it necessary to grind in valves? Half the repairs of injectors is to the priming apparatus. Are primers necessary? Half the steam pipes in a cab are where they will be touched in handling some valve, where some of them are sure to be broken off in a wreck, and are in the way of the crew. Are they all necessary or can't they be shortened? There are a thousand reasons for improvement—life-saving reasons, comfort-promoting reasons; time-saving and money-saving reasons.

For all of these reasons LOCOMOTIVE ENGINEERING opens a **prize contest** to see if the brains of American railroad men can't be employed to make a bad thing better than it is.

### THE ENDS SOUGHT.

The above amount, $350, will be paid in prizes for the best design of Boiler and Cab Fittings for two classes of Locomotives — freight and passenger — showing the greatest improvement over present practice, tending to:
1st. Greater safety for the lives of the engine crews under any and all circumstances—especially in wrecks.
2d. Convenience in handling the locomotive, comfort of crew—consistent with best road service.
3d. Economy of time and money in keeping up running repairs.

### THE PRIZES.

**Design No. 1.** One Hundred Dollars ($100) cash for the best design for the Eight-Wheeled Passenger Engine. Fifty Dollars ($50) cash for the second best design. Twenty-five Dollars ($25) cash for the third best design.

**Design No. 2.** One Hundred Dollars ($100) cash for the best design for the Consolidation Freight Engine. Fifty Dollars ($50) cash for the second best design. Twenty-five Dollars ($25) cash for the third best design. Five Dollars ($5) cash to be paid for each design published that has not taken a prize.

### THE JUDGES

will be selected by lot from the following callings. One Superintendent of a Locomotive Works, One Superintendent of Motive Power, from a road having over 300 locomotives; One Chief Draughtsman of a locomotive works or general railroad shop; One Traveling Engineer, selected from the membership of the Traveling Engineers' Association; One Locomotive Engineer in actual service, from a list of the most prominent B. of L. E. men in this country. The names of the members of this Committee will be announced in the January number of LOCOMOTIVE ENGINEERING. They will meet at the Master Mechanics' Convention at Saratoga Springs, N. Y., in June and award the prizes, and the cash will be paid on or before July 4th. In case there is an absentee in the Committee, the remainder of them will elect a man from the same employment, if possible, as the absentee.

### CONDITIONS.

Separate designs and written descriptions must be submitted for each class of engine. Persons submitting design must place on the drawing some distinguishing mark (such as initials, *nom de plume* or device), and no name must appear on the drawings or in the written description of same. Drawings for one class only, together with written description, must be sent in one package and a sealed letter stating the name of the person or persons who submit the drawings marked as described. This letter will not be opened until after the judges have made the awards — they will judge on the merits of the designs alone. Nicety of drawing will not secure the reward, though it is to be commended: it is the *idea* that is wanted—the suggestion that can be used by railroads and by locomotive builders for the improvement of locomotives in the three lines we have laid down, namely safety of crew under all circumstances; convenience in handling, and economy in keeping up running repairs.

One person may submit as many designs as he cares to, but each must be separate, and use a different distinguishing mark. More than one person can have an interest in one design if desired. Drawings must be on white paper with black ink — no other will be considered. The printed drawings may be finished out, or new and larger ones submitted, but in each case they must be complete, and the same as printed design. Written description must briefly point out the intended improvement in each device and explain the working of same, but the intention is that the drawings shall tell the whole story. Unusual or new devices may be shown in sectional sketches on margin of drawings, but be it remembered that this is not a contest of merits of engine devices; the rewards will be given on the merits of the whole arrangement. The cab must be limited in width to the height and width marked on drawings. It can be made as long as desired and placed on engine in any position wanted.

### WHAT WILL BE FURNISHED.

Drawings of a complete locomotive, except cab and operating handles, lubricators, injectors, air brakes, etc. The throttle valve stem is left ready to connect. Designer can put on any kind of a throttle he thinks best and bring it out wherever he likes.

The tumbling shaft arm extends up the usual height ready to connect to the reach rod.

### WHAT TO DO.

Take either of the incomplete drawings and finish them. Put on everything necessary that is not shown. Everything above the running boards.

The passenger locomotive must be equipped with automatic air brakes, sight feed lubricators, steam heat connection and whistle signals.

The freight locomotive will have air brakes, sight feed lubricators and all modern improvements.

Locate and draw in the main drum, engine air brake equipment complete, throttle, reverse lever, gauge cocks, steam and air gauges, blower, cab light, etc. Decide on kind of injector and valves and locate all of them, arrange all hose connections between engine and tender. Locate whistle lever or cord, lay out windows of cab and arrange to handle and fasten them, choose design of check valves and all piping and boiler connections. Locate tank hand brake, either in sketch or description, locate shake levers, dampers and slide pullers, sand lever, cylinder cock lever, seats, arm rests, etc.—in fact, everything used to handle the locomotive.

### WHO MAY SUBMIT DESIGNS.

This contest is open to the world. There is absolutely no limit as to who may take part. Large prints of the drawings, in tubes (not folded), will be sent free, on request to any regular subscriber of LOCOMOTIVE ENGINEERING, or those who send subscriptions for a year with the request. We will have to ask others to send 20 cents for postage.

**All the Announcements as to Prize Winners and Engravings of Successful Designs will be printed only in LOCOMOTIVE ENGINEERING.**
