## A Case of Doubt.

Here is a picture familiar to all railroad men of experience. This is no fancy sketch, but was taken from a photograph of a little circumstance on a New England road not very long ago. The graveyard in the background is very suggestive. The N. Y., W. S. & B. car was away from its home road,

It is doubtful if anybody was indicted for the casualty.

It is doubtful if the operating officer did not discharge some one to shield his office, and officially locate the responsibility—off of himself.

It is doubtful if the company allowed its employés to telegraph any particulars home.

It is doubtful if the brakeman didn't say

It is doubtful if he was really asleep after it happened.

It is doubtful if block signals would not have entirely prevented the mishap.

It is doubtful if this road don't have enough of this every year to pay for signals for a good part of the road.

It is doubtful if you can get the management to see this.

paper statement that the dear ones died a the post of duty—perchance with a han on the throttle.

It is doubtful if you don't get into a cas like this some time yourself.

It is doubtful if the same thing don happen again to-night or to-morrow.

It is doubtful if anything is done abou it if it does happen.

"IN CASE OF DOUBT TAKE THE SAFE SIDE."

laden with grain, but when it came to a case of doubt it took the safe side—in this case, the top side.

How many, many of these cases there are! Very often the engineer and fireman are killed; that's to be expected. It is doubtful if they escaped in this instance.

It is doubtful if this train had automatic power brakes.

It is doubtful if the brakeman of the first train was out the proper distance with a flag.

he was real sorry that the boys got killed, and that they ought to have jumped.

It is doubtful if he said he was not out far enough.

It is doubtful if all hands told the truth about speeds and distances.

It is doubtful if the conductor didn't swear that he ordered the flagman out more than the regulation distance.

It is doubtful if the conductor was really awake when it happened.

It is doubtful if the railroad commissioners did anything about it.

It is doubtful if the Legislature does anything to prevent accidents of this class.

It is doubtful if there won't be thousands more men murdered in these wrecks before legislation compels brakes, blocks and couplers.

It is doubtful if the families of the butchered men find any consolation in the news-

To clean your headlight keep a bottle of lamp-black and alcohol on your engine. Common wood alcohol is good enough. Mix about as thick as paint and apply with a small piece of waste. The alcohol evaporates at once and leaves the lamp-black dry, which, when wiped out, leaves a clean reflector without hard work.

Preserve this paper; the premium list will not appear again.

1635

iow many of the younger machinists and machinists' apprentices who read LOCOMOTIVE ENGINEERING, have, I wonder, thought how they would proceed, if given the task of laying out, drilling and putting in place a back cylinder head. Of course this would not be so difficult a job to do if jigs were available, to which the head could be drilled. But all shops do not have jigs, and a machinist may often be called upon to do work of this kind when very few tools are provided.

We will assume that we are working in the roundhouse at some division terminal, where the only machine tools provided are

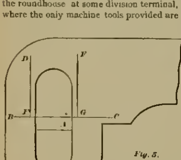

Fig. 5.

a drill press, a small lathe and planer, and that an engine comes in with the right back cylinder head badly broken. One is sent to us from the main shops, but it is only finished in the lathe and is not drilled for the studs or guide-blocks. How shall we lay it out properly?

Some one may say, "lay it out from the old head," but this is not possible to do in all cases. The old head may have been broken too badly, then too, the old head may not have been properly put up in the first place. The best way I think, is to have ideas of our own relative to these matters; then we are independent.

Now we know that the joints will have to be ground, so we will first remove all of the studs which fastened the head to the cylinder, then with two pieces of wood and two bolts make a clamp, like Fig. 1, and fasten it around the neck of the cylinder head. Then thread each end of a rod or use a bolt long enough to pass through the cylinder and head, when the head is in place. After applying oil and emery to the joints, fasten the head to place by passing the rod or bolt through a plate of iron, long enough to span the front end of the cylinder, then pass the rod through the cylinder and head, fasten it at the back end by passing it through a plate of iron, of sufficient length to span the stuffing-box in the head. The head can then be turned and ground by the use of the wooden clamp, previously adjusted. The necessary pressure can be given by tightening the nut on back end of rod.

After the joint is perfect we can easily determine which part of the head should go to the top of the cylinder by the position of the clearance space cast in it, for, with the head in place, this space should conform with the steam port in the cylinder.

Now dampen some lamp black with oil, (do not have it too thin) and apply a very light coat of the mixture all around the inner edge of the joint on the cylinder, also around each stud-hole and outer edge of the flange, and with the lamp black also make two fine lines, A B, Fig. 2, across the face of the flange, one at each end of the steam port. Now take a piece of stiff wrapping paper large enough to cover the end of the cylinder, and having the helper hold it firmly to place, rub the surface of the paper with your hand over all points where it touches the flange; this will give you on the paper a clear impression of all stud-holes, marks A B, etc.

Remove the paper now and cut out the center and outer circumference, being careful to cut close to the lines, then with a lead pencil make a dot in the center of each stud-hole impression. Now lay the template on the head, being careful to lay the side with marks on toward you, and

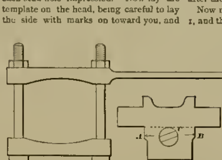

Fig 1.
Fig. 4

having the lines A B, one at each end of clearance space; then have the template held firmly to place while you with a fine center-punch, mark over each pencil dot a punch mark through the template into the head; remove the template and from the punch marks lay out the stud-hole .02" larger than the studs. Now drill them to the marks, replace the studs and you will find on trial that the head will slip to place nicely.

Fasten it to place with a nut at the top, bottom and each side, then on a stick or piece of flattened copper wire, driven firmly into the stuffing-box, get the center of same. Now place a straight-edge on top of the frames just back of the cylinder, of sufficient length to reach from frame to frame, and to this adjust a level; it does not matter if the engine is not exactly level, if care is taken to adjust the level to the straight-edge.

Fasten the level now on the top of a shorter straight-edge (being very careful not to reverse the level from its former position when adjusted to the long straight edge), and place the short straight-edge with the level on it against the face of cylinder-head flange to which the guides are attached, adjust the straight-edge until the level is correct, and along its top edge, through the center of the stuffing-box, scribe line A B, Fig. 3, and also through the center scribe line, C D, at right angles to line A B. These lines now form the foundation from which we will work, for we know that line A B is level with the engine and that line, C D is plumb with it.

Now the distance that the guide-blocks should be apart on the head might be determined from the position of those in the guide-yoke, but the yoke might also be broken, and we will consider such to be the case in the present instance, and that the entire head has been renewed, planed up and sent to us without having the holes drilled for the blocks.

We will now turn our attention to the crosshead and must bear in mind that when all parts are in place the center of the hole into which the piston-rod fits in the crosshead, must be exactly in line with the center of the stuffing-box in cylinder-head. So after centering the hole in crosshead we will span with our dividers from this center point to point A, Fig. 4, and from center of stuffing-box, Fig. 3, mark this distance to the *right* of center on line A B; then from this mark scribe line E F, parallel with line C D; now do likewise with distance from center point in crosshead to point B, Fig. 4, and scribe line G H, Fig. 3, parallel with line C D; then across the end of the crosshead and just flush with the lower bearing surfaces of each lug scribe dotted line C, Fig. 4, and from the center of hole set the dividers 1/16" *above* line C. This is to allow for a 1/16" liner between each bottom guide and block.

Now from points F and H, on line A B, Fig. 3, mark this distance on lines E F, and G H, and from the marks thus made, scribe lines I J and K L, parallel with line A B.

When the blocks are in place their inner edges should be flush with lines E F and G H, and their lower faces flush with lines I J and K L. All of the lines should be scribed lightly so they can be filed out after the holes are drilled.

Now mark the top of the outer block, No. 1, and the top of the inner block, No. 2, and from the inner edge of block No. 1, space the distance to the center of the lug by which it was secured to the head, and to the right of line E F, and parallel with it, mark this distance. Now get the distance from the bottom surface of the block to center of lug and above and parallel with line K L, mark the latter distance on the head. Proceed in like manner with block No. 2, only scribe to the left of line G H and above line I J. The points of intersection of the four lines last made are the points for the center of the holes for the block lugs, and the holes should be drilled and reamed to warrant a snug driving fit of the block-lugs.

The holes over the piston gland studs can now be located on line A B or C D, as the case may require, the head will then be ready to drill; but before removing it we will remove the center stick of the stuffing-box, bolt the yoke to place and run a fine line or wire through the cylinder and secure it to the yoke by hanging a weight to it after passing it over the stick A, Fig. 5, driven firmly into the slot through which the main rod plays; now center the line from the counter-bore in front end of cylinder and stuffing-box in back-head; then with the short straight-edge, with level on it, we will scribe on the forward side of the yoke, line B C, just flush with the line through the cylinder; then mark

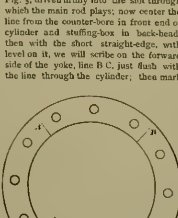

Fig. 2.

on stick A a point at which the line through cylinder rests on it; remove the line or wire and proceed to lay out the holes for the back blocks, in exactly the same manner as we did those for the forward blocks on the head, after which both yoke and head can be removed and drilled, and before replacing them, after the drilling is done, each block should be fitted to place, for when again put up they should remain in place. When both are finished and bolted to place we are ready to line up the guides, and upon this subject, perchance we will have something to say in the near future.

## The Life and Services of Isaac Dripps, the First Superintendent of Motive Power in America.

There are, perhaps, a hundred men in the United States, who bear the official title of Superintendent of Motive Power, and not less than five hundred who are Railway Master Mechanics, having in charge the thirty-odd thousand locomotives of our land and the crews that man them.

To all of these, we are sure, a brief outline of the life of the first man who bore the title of Chief of the Motive Power department of a railroad in this country will be interesting.

This man is Mr. Isaac Dripps, who still lives and watches the progress of locomotive engineering with interest, as he has watched it from its birth, now more than sixty years.

Mr. Dripps was born April 17th, 1810. When living in Philadelphia, while quite a young lad, he used often to visit the city water works and sit for hours, watching the pumping engines, especially the English engine with its large walking-beam, moving up and down, to him without any apparent cause. It was during these visits that the desire to know how to make and operate such machines, took forcible possession of his youthful mind.

At sixteen years of age, he apprenticed himself to Mr. Thos. Holloway, who at that time had the largest establishment in the city of Philadelphia for building machinery for steamboats.

During Mr. Dripps' apprenticeship, Mr. Holloway built the engines and machinery for quite a number of steamboats, both large and small. Among the number were the "Albany" and "New Philadelphia" for the Stevens New York and Albany line; the "New Castle," "William Penn," "Wilmington" and "Robert Morris" for the Delaware River lines, and a number of ferry-boats for the ferry between Camden and Philadelphia.

Mr. Dripps had full charge of fitting up and erecting the machinery of the "Wilmington" and "Robert Morris."

He had also charge of the erection of the machinery of the steamboat "Kensington," and of its management before and during the trial trip of the boat. Steam was raised in the boilers and the engine revolved under his direction while yet the steamboat was on the ways, and, as soon as launched, she made her trial trip, under steam, up the river. It is believed that this is the first time such an occurrence ever took place.

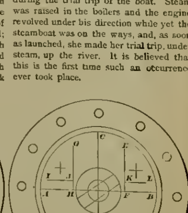

Fig. 3.

The last work done by Mr. D. as an apprentice was in New York, in charge of extensive repairs to the machinery of the steamboat "Swan." Upon the completion of this work in April, 1821, he was twenty-one years old.

In the month of August, 1831, Mr. Robert L. Stevens, President of the Camden & Amboy R. R. Co., engaged him to take charge of the locomotive "John Bull," which had just arrived at Philadelphia from England. Mr. Dripps had the locomotive put on board a sloop, taken to Bordentown, N. J., and then hauled by wagon to a piece of railroad track, about three-fourths of a mile long, near Bordentown. Here the locomotive was placed beside the track and a shed built over her.

Here Mr Dripps put the machinery of the old "Johnny Bull," together." He had never before seen a locomotive and had no drawings or other directions to guide him, but he studied the details out successfully

The engine was not provided with a tender, and for this purpose our mechanic found a small four-wheeled car. To the platform of this car he fastened a small whisky cask, that he had purchased at a Bordentown grocery. For a hose to connect the tank and engine, he called in the services of a shoemaker, who made a leather pipe for this purpose. Thus equipped, the little engine was ready for service.

In November, 1831, the members of the Legislature of New Jersey were invited to Bordentown to be convinced that a locomotive would actually pull cars on a rail.

They accepted, and on November 12th, 1831, Mr. Dripps had the cars and engine ready, and ran back and forth on the track built, carrying the Solons of the State and many interested citizens. This was the first time that a train of cars had been moved by steam in New Jersey, and the event was celebrated on November 12th, 1891, by the unveiling of a monument on the spot where Mr Dripps and the "John Bull" first started on their careers—60 long years before.

The following winter Mr. Dripps went to the company's shops at Hoboken to take charge of the building of new locomotives. During the summer and winter of 1832-33 they built three locomotives, and in March, 1833, Mr. Dripps took these locomotives to South Amboy, where a portion of the road was completed. During the summer these engines were used to haul materials, and as a school to teach men to run and care for them. Firemen runners hadn't been made then.

During the latter part of the year four more locomotives were turned out of the New York and Hoboken shops, and were put upon the rails at South Amboy, making eight engines that the road owned. Late in the fall of 1833 the company commenced to haul passenger trains by steam; previous to this they were hauled between Bordentown and South Amboy, a distance of thirty-five miles, by horses. From this time on Mr. Dripps was superintendent of machinery of the Camden & Amboy road, and also had charge of all repairs to the steamboats of the company on the Delaware river. He also made most of the experiments for the famous Stevens' Steam Battery, and was generally in the confidence and mechanical adviser of Mr. R. L Stevens.

One of the locomotives sent out from the New York shops was the "Monster" (fully illustrated in our issue of February, 1890). This engine had a boiler designed for burning anthracite coal, but she was a poor steamer. Mr. Dripps rebuilt her, raised her grates, put grates in her combustion chamber, firing it from the side, he used a circular box exhaust; this box was full of small jets, designed to fill the stack, and a tapered open stack was adopted; this arrangement increased the steaming capacity of the engine very satisfactorily.

In 1845 Robt. L. Stevens, president of the C. & A. R.R. Co., visited England and there saw locomotives with very large driving wheels; on his return home he ordered Mr. Dripps to design a locomotive with driving wheels eight feet in diameter, with a boiler burning anthracite coal and capable of making forty miles per hour.

The drawings were completed and approved in 1847, and the engine was built by Richard Norris & Sons, of Philadelphia. The cylinders were 13 inches in diameter and the stroke 34 inches, the single pair of drivers were eight feet in diameter and located behind the fire-box. This was the first time that hard coal was used for high speed engines. This engine had a six-wheeled truck in front. (Illustrated in our issue of February, 1889.)

When this locomotive had been in use for some time Mr. Dripps saw very clearly that one pair of wheels with the light load carried did not give sufficient adhesion to haul the heavy passenger trains then running, and opposed the further use of the class, but was overruled, and several more of the class were built.

In 1852 Mr Dripps designed a boiler for one of these eight-footers, with cylinder 14 x 38 inches, which had a device under the throttle in the dome to prevent carrying water over into the cylinders; this was very similar in its operation to the modern centrifugal separator, the water was thrown off a curved plate or deflector and returned to the boiler.

This boiler also had two sets of tubes with a combustion chamber between them, almost identical with the very latest boiler turned out by Mr. Webb, of the London & Northwestern. The smoke box of this engine also had a modern deflecting plate and a high nozzle, designed by Mr. Dripps.

Mr. Dripps designed, built and used, on engine No. 2, in June, 1833, the enlarged stack, with a cone and inside pipe.

To Mr. Dripps, also, belongs the credit of designing and making the first successful single screw for propelling vessels. This screw was put in place of a double screw made by John Ericsson, in England, in 1839, and imported by Commodore Stockton This single screw of Mr Dripps had six blades. It was used with entire success for many years, and was, practically, the screw now in use This screw was shown and its history was told in these columns in January, 1891

In 1853, Mr. Dripps resigned as Superintendent of Motive Power and Machinery of the road, a position he had held for twenty-two years, and became one of the partners in the Trenton Locomotive and Machine Works, at Trenton, N. J., but in 1858 the company dissolved owing to financial difficulties.

In 1856, while at Trenton, Mr. Dripps designed for the Belvidere & Delaware R. R Co., the wide-tread wheel for running on tracks of either 4 feet 8½ inches or 4 feet 10-inch guage

In 1857, at the same works, he designed and built for the Lehigh Valley R. R Co., an iron freight-car truck, the first of the well-known diamond-framed trucks, now almost universally used on freight cars in this country.

In January, 1859, J. Edgar Thompson, President of the Pennsylvania Railroad, offered Mr Dripps the position of Superintendent of Motive Power and Machinery of the P., Ft. W & C. Ry. Co., and he took charge the following month.

The road at that time was, financially, in a very bad condition, and soon after went into the hands of a receiver. Upon its reorganization it was determined to operate the mechanical department in two divisions, and Mr. Dripps was given the Western Division with headquarters at Ft. Wayne, Ind.

No man ever took charge under more adverse circumstances, the road was not earning operating expenses, the shops were old and full of dilapidated tools from an old car shop; the road had been laid with mud sills on prairie soil without ballast, and the locomotives were of old style and pretty well worn out.

After the reorganization, affairs brightened gradually and better facilities were provided accordingly. Subsequently, new shops and a large roundhouse, all of Mr. Dripps' designs were built at Fort Wayne. These shops were fitted out with the best and most modern of tools, especially in the car shops, where the frames of cars were finished by machinery so perfectly as to be interchangeable. The tools for this purpose were all of Mr Dripps' design and were built in the shops there These shops had the reputation at that time, far and near, as being far in advance of anything in the country—the model shops

In 1869, after a service of ten years, Mr Dripps retired from the position on full pay. When the Pennsylvania R R. Co. leased the Fort Wayne road, President Thompson appointed Mr Dripps "Inspector of Shops, Tools and Machinery of the Main Line and Branches of the P R R System, and all lines owned, operated and leased by it."

Mr Dripps made many minor changes in the shops and in shop methods, so as to bring the same system and the same uniformity of work into practice in the shops He closed up the shops at Mifflin, Pa, as unnecessary, and removed the tools to other shops, and generally concentrated the work

He had charge of erecting the new car shops and iron foundry at Altoona and in selecting the tools, these were then the most extensive railroad shops in the coun-

try On the Panhandle system he equipped the new shops at Logansport, Ind, with new tools.

When Mr A J. Cassatt became General Superintendent of the P. R R, Mr. Dripps was appointed General Superintendent of the M P & M, with headquarters at Altoona The arduous duties of this office, combined with that of superintending the erecting of the new shops, very seriously im- ed his health and caused his resignation resident Thompson, not wishing to his services, gave him lighter work perform, and sent him to the Northern Central to assist J N Du Barry, General Superintendent, in erecting new shops at Baltimore

While in this service Mr Dripps made some very valuable experiments, at the request of President Thompson, with three classes of locomotives—eight-wheeled, ten-wheeled and consolidation to ascertain the amount of frictional resistance of each class in passing around a curve The dynomometer used in making these experiments was designed by Mr Dripps The final experiments were made with engines belonging to the Philadelphia & Erie Road, upon the Shintown curve, near Renovo, Pa., this is a 4-degree curve, 1,432-foot radius.

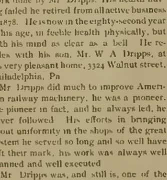
These engines are now the standard freight locomotive of the P R R., and are known as class *R*.

These experiments constituted the last work done by Mr Dripps. His health having failed he retired from all active business in 1878. He is now in the eighty-second year of his age, in feeble health physically, but with his mind as clear as a bell He resides with his son, Mr. W A Dripps, at his very pleasant home, 3324 Walnut street, hiladelphia, Pa

Mr Dripps did much to improve American railway machinery. he was a pioneer. e pioneer in fact, and he always led, he never followed His efforts in bringing about uniformity in the shops of the great system he served so long and so well have left their mark, his work was always well planned and well executed

Mr Dripps was, and still is, one of the most modest and retiring of men, claiming nothing for himself Had he taken out patents for his numerous inventions, for both locomotives and steamboats, he might have made an immense fortune

All over the land there are old railroaders who served under Isaac Dripps, and we are sure that one and all of them will be glad to see his face here and join us in wishing the grand old mechanic a merry Christmas and a happy New Year, and in expressing the wish that he may live to see a round hundred of them



No. 1.

## Stuck Inside a Boiler.

The story is told of a misanthrope who confessed on his deathbed that life to him had been a failure, because his hopes of seeing a great train wreck were never realized He dwelt beside a railroad where there was a sharp curve over a deep ravine, and day after day he spent watching for the passenger train that would jump the track on that curve and make devastation in the chasm. The train never jumped the track and the old man went to his grave disappointed.

"I must confess to a feeling something akin to that of the man of that story," said John Pastor the other day, while paying a visit to this office. "I once spent a night in a boiler because the hole seemed to get smaller after I got in, and I have been waiting to hear of some unfortunate getting incarcerated for life in one of those iron prisons. I have just heard of a case which is likely to be as near what I have been waiting for as anything is likely to be

"The experience came to Daniel Donlin, engineer of the Colonnade Hotel, New York City, who went into the boiler to do some work He fattened on the job, and when he tried to come out he stuck. The people tried to pull him out, but he could not come, except by pieces. The end was that boilermakers had to be sent for, and they cut a strip out of the manhole, making it large enough to let Donlin slip through."

## Testing Car Roofs.

There is now being conducted at the C B & Q Laboratory, at Aurora, tests of the several plastic car roofs in the market

There are two samples of each, about 4 feet square These have been weighed and been put down on the roof of the building One piece exposed to rain and shine, the other with a covering of boards the same as in service These pieces will again be weighed when taken up

Another way of testing is this They have taken a small section of each roofing material, weighed it, and put it in a jar of water separately, where it will be kept and any action will be noted. These will also be weighed when taken out.

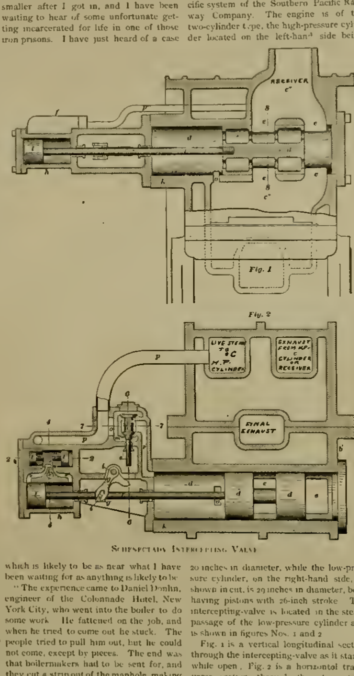
Their engineer of tests is also by chemical analysis determining just how much pure asphalt or coal tar there may be in the material

This test was instituted November 1st, and it is not known just when it will be concluded, but not until superior merit is demonstrated

About six or seven manufacturers have contributed to this test.

## Schenectady Compound Twelve-Wheeler.

The accompanying engraving illustrates a heavy twelve-wheel compound locomotive recently built by the Schenectady Locomotive Works for service on the Pacific system of the Southern Pacific Railway Company. The engine is of the two-cylinder type, the high-pressure cylinder located on the left-hand side being



SCHENECTADY INTERCEPTING VALVE

20 inches in diameter, while the low-pressure cylinder, on the right-hand side, as shown in cut, is 29 inches in diameter, both having pistons with 26-inch stroke The intercepting-valve is located in the steam passage of the low-pressure cylinder and is shown in figures Nos. 1 and 2

Fig. 1 is a vertical longitudinal section through the intercepting-valve as it stands while open, Fig. 2 is a horizontal transverse section through the intercepting-valve, and showing also the auxiliary mechanism employed for operating the valve and for regulating the admission of high-pressure steam to the low-pressure cylinder. The intercepting-valve D D is operated direct by the piston valve L. In both the figures the intercepting-valve is shown open, with the steam passages E E unobstructed, and therefore in the position it occupies when the engine is working compound. When the valve is in this position there are no means for live steam to pass into the low-pressure cylinder.

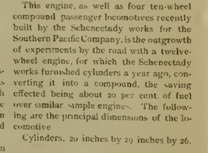
In starting, the operation is as follows The pipe P is connected at C with the steam-pipe leading from the boiler to the high-pressure steam chest On the throttle valve being opened, steam passes through the pipe P into a small supplementary steam chest, which leads it into the auxiliary steam chest N between the pistons T T. The piston T in this steam chest, being of greater area than the piston T, the valve V is moved to the right, opening the left port X The steam passing through that port pushes the piston L to the right, moving in the same direction the intercepting-valve D D, and closing the steam passages E E In moving to the right, the piston-rod of the intercepting-valve operates the elbow-lever G, which strikes the rod of the puppet-valve V and admits live steam through the port O and passage P into the cylinder D', and hence through the port O to the steam chest of the low-pressure cylinder. The intercepting-valve, as before stated, being now closed, the tendency of the live steam is to push it up against the seat, closing the receiver.

The changing from simple to compound working is done automatically. When a certain pressure is attained in the pipe that leads the exhaust steam from the high-pressure to the low-pressure cylinders (that is in the receiver), the steam passes through the pipe P (fig. 1) to the supplementary valve already mentioned, and being sufficient to overcome the force exerted by the high-pressure steam on a smaller surface, moves the valve back and opens the passage that admits steam to the right of piston-head T of the auxiliary valve This is forced to the left, admitting steam to the right of the piston L, which is moved to the position shown in the illustrations. At the instant the intercepting-valve and its connections move to the right the elbow-lever G lets the puppet-valve V drop, and direct steam is cut off from the intercepting-valve and the low-pressure cylinder. The actual operation is much simpler than the description.

Two, from a number of indicator cards taken from the engine while pushing trains up a sixty-foot grade on the New York Central Railroad out of Schenectady, are given, showing a very even distribution of power in the two cylinders. The cut-off is somewhat earlier in the high-pressure cylinder than in the low-pressure cylinder, the proportion of cut-off being as 40 to 50 at half-stroke. Card No. 1 was taken when the engine was making one hundred and thirty-six revolutions per minute, representing a piston speed of 589.3 feet. The boiler pressure was 195 pounds and the horse-power developed was 820. The other card was taken at 96 revolutions, boiler pressure 145 pounds. The cards show a remarkably good distribution of steam

This engine, as well as four ten-wheel compound passenger locomotives recently built by the Schenectady works for the Southern Pacific Company, is the outgrowth of experiments by the road with a twelve-wheel engine, for which the Schenectady works furnished cylinders a year ago, converting it into a compound, the saving effected being about 20 per cent. of fuel over similar simple engines. The following are the principal dimensions of the locomotive

Cylinders, 20 inches by 29 inches by 26.



No. 2

Valves (Richardson-Allen), $5\frac{1}{2}$ inches travel

Steam port, high-pressure, 2x18 low-pressure, 2x20

Exhaust ports, high-pressure, $3\frac{1}{2}$x18; low-pressure, $3\frac{1}{2}$x20

Bridge, high-pressure, $1\frac{1}{4}$, low-pressure, $1\frac{1}{4}$.

Outsid [illegible] n-pressure, $\frac{7}{8}$-inch, low-pressure [illegible]

Inside [illegible], high-pressure, $\frac{1}{4}$-inch, low-pres [illegible] inch

Boiler—Wagon-top, 60 inches diameter at smoke-box end; shell, 9-16-inch steel; fire-box, 104 inches long, 43 inches wide, 61 inches deep, tubes, 270, 2 inches diameter, 12 feet 8 inches long.

Heating surface—Tubes, 1,779 sq. feet, fire-box, 156 square feet, water tubes, 12 square feet, total, 1,947 square feet. Grate surface, 31 square feet.

Working pressure, 180 pounds of steam per square inch.

The engine has swing-bolster truck, with journals 5 inches by 9 inches, drivers, eight-coupled, 51 inches diameter, outside of tire, the second and fourth pair being flanged, while the first and third pair are plain. The driving-journals are 7½ inches by 8½ inches. Total wheel-base of engine is 23 feet 7 inches; driving-wheel base, 13 feet 9 inches, rigid-wheel base, 9 feet 2 inches, total wheel-base of engine and tender, 49 feet 1 inch. Tank capacity for 4,000 gallons of water. Weight of locomotive in working order, 138,800 pounds of which 116,800 pounds is on the drivers.

If the superintendent of each locomotive shop in this country was obliged to get on to one of his own locomotives, going at the rate of ten miles per hour on a dark night, it would result in the immediate adoption of larger and better designed steps—or some funerals. The little, oval, cast-iron, pad on the end of a rod, often loose, stuck under the tank frame, made in such shape as to collect ice and coal, is a trap. The usual step hung on the tail piece of the engine frame is only useful to strike something and get bent. Little, cast, cab handles such as would be put on a barn door are not big enough or good enough for cabs—too much depends on them. All handles should be long, at least four inches from the cab and extending below the corner of it. Steps should be located on the tender frame, have double supports and be at least two feet long; have a back to prevent the foot from going over it and the bottom of open work to prevent the collection of snow, ice or coal. Men's lives depend upon these little things. A bent pancake turner don't make a good step for a locomotive.

For the first six months of 1891, there were 583 persons killed and 5,656 injured on British railroads, but of this number, 36 were killed and 3,280 injured by other causes than moving trains.

Compound Twelve-wheeler, for the Southern Pacific.

## The Purification of Water for Locomotives.

BY GEORGE GIBBS.

That this question comes up periodically for discussion by those interested in railway motive power is testimony to the vitality of the causes, at least, if not to the value of the results obtained from the numberless "processes" advanced. Each time the subject is before a railway club or master mechanics' association more or less desultory discussion is indulged in and stories told of hard times with the "worst water in the country," samples of scale exhibited. It is difficult to understand, from all accounts, how their locomotives are kept in condition to pull trains and yet, when remedies in the form of "purges," "scale-looseners" or "compounds" are proposed, interest in the subject flags and the man who advocated the deadly (?) "chemicals" feels that he has been sat upon.

Now, master mechanics are thoroughly alive, as a rule, to opportunities for saving a small portion of the coal and repair bills, and there seems to be a pretty general impression that these items are not a little increased by the use of bad water, how then, does it happen that all hesitate to take up some of the rational processes proposed for the purpose? The reason seems to be in the somewhat mysterious action of the device, and a doubt, arising from unintelligent trial, whether it will accomplish the purpose. The question of cost is not discussed, as a rule, few being able to place the value of a clean boiler in actual figures.

There seems to be two legitimate headings under which to consider the subject. First, Will the process accomplish its purpose? Second, Will it result in a net saving to the road?

It is impossible, in this short article, to fully enter into the complicated chemical reactions involved in water purification. It will suffice for an understanding of the theory to say that the trouble most generally complained of is scaling tendencies. This scale is formed by the depositing, in a crystalline form of lime compounds, which are present in solution, in a greater or less degree, in all waters. This deposition takes place from the destruction of the solubility of the compounds by the heat in the boiler. Certain chemicals may, however, be introduced into the water, which will act upon the lime to form other and non-crystalline precipitates. It is these chemicals which constitute the so-called "purges" or boiler compounds. The lime is precipitated by their action in a granular or mud-like form, which does not adhere to the sheets, unless baked on by carelessness in drawing off the water while the sheets are hot, and which may be readily blown or washed out as a slime.

Now, as to the first point in the efficiency of the "compounds." Will they accomplish their purpose? This can be definitely answered in the affirmative. There are many cheap and harmless chemicals which thus act upon lime-salts in water, and always in known and calculable proportions. The precipitate is further formed, as above, as a sludge, and not as a scale. It is also beyond question that a boiler may be kept perfectly clean by the proper use of these agents.

As to the second heading of the problem, will the treatment pay? It would seem that this offers the rational point of attack for opponents of experiment in this direction.

The expense of the cleaning process is made up of several items, and may be quite definitely ascertained. Thus, we have, first, cost of chemicals for engine mile, including all expenses of making up and handling, second, cost of extra washing-out entailed, third, cost of fuel wasted by reason of frequent washing-out and the blowing-off on road. All of the above are on the wrong side of the ledger. Against these we have the saving effected. This is likewise made up of several items, but unfortunately their money value is seldom definitely, or quickly, at least, ascertainable. They are: First, saving in coal on account of better evaporation in boiler uncoated with scale, second, saving in boiler repairs, third, saving in delays on the road from leaking flues, etc.; fourth, obtaining increased hauling capacity by reason of better condition of boiler and the increased evaporation resulting from clean sheets, fifth, fewer days per year in shop for repairs—the monetary value of which is at times very great, sixth, absence of obstruction to careful interior examination of boiler as to the condition of its plates. It is not my purpose to work out this equation of expenditure and saving. To be applicable, it must be done for each individual case with the data best at hand. I have merely attempted to point out the elements to be considered, and attack the position which has been heretofore almost exclusively taken by master mechanics, that it does not pay to consider these processes, because they will not effect the object of keeping the boiler clean.

While it may be gathered from my remarks, here and elsewhere published, that I favor the intelligent use of a "boiler compound," I am not sanguine that we shall be able to show much or any coal saving through it. Many attempts have been made to figure the loss in evaporation caused by incrustation on the surface of the plates. "Wilson" cites one observer as stating that 15 per cent. more fuel is required with 1-16 inch scale than with clean sheets, 60 per cent more with ¼ inch and 150 per cent more with ½ inch scale. These results have the appearance of being arrived at from the relative heat conductivity of metal and scale, or if from a test at all, they are certainly absurd for locomotive practice.

If specific conductivity of different substances, within reasonable limits, has much meaning in boiler practice, we should certainly expect a very large increase in coal economy by the use of copper instead of iron or steel fire-boxes. Yet who has heard of a serious attempt to prove this the case? Poorer conductivity means simply raising the plates to a higher temperature in order to transmit a given quantity of heat, and consequently a rejection of the smoke-box gases at a somewhat greater temperature and with some resulting loss.

They tell a laughable story on two freight handlers on the Central Road in this city. They were sent up in the yard to get out "one roan horse," and boldly breaking open the seal and throwing the door back one of them climbed in, but fell out in a hurry and broke for high ground. His partner hurriedly shut the door and then went and "pecked" in the end grating to find that the occupant of the car was a rhinoceros, consigned to Barnum's circus. They had a four-horse van come up for the critter, and then found out that it was stuffed.

There is a very simple form of tool-grinding machine made by the Gisholt Machine Co., Madison, Wis., which is highly spoken of by those who use it.

[When you are reading articles of especial merit from the pen of a co-worker, it adds to the interest to know something about the man

Harris Tabor was born near the city of Buffalo, N. Y., in 1843

At the age of sixteen he entered a machine shop at Tioga, Pa., as an apprentice, where he worked a year.

On the breaking out of the Civil War he enlisted, May, 1861, and served through the struggle.

After the war he went into the machine shop of S W Payne, Troy, Pa., where he worked one year under instructions In 1867, he went into the shops of B W Payne & Sons, of Corning, N. Y., now of Elmira, as journeyman, and remained with this concern for some fourteen years, having in the last years served as general foreman This firm built steam engines of all sizes, especially small ones, and have probably turned out as many as any concern in the country

In 1876, in conducting experiments with steam engines, Mr Tabor saw the need of a better indicator than was then made for high speed engines, and made the first of the now well-known Tabor indicators, these instruments are made in this country by the Ashcroft Mfg Co at Bridgeport, Conn and in Europe by John Musgrove & Sons, Manchester, Eng

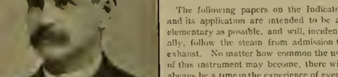
In 1883, Mr Tabor accepted the position of Superintendent of the new shops of the Westinghouse Machine Co then perfecting the inclosed, single action Westinghouse engine This position Mr. Tabor held for two years.

Since that time he has been with the Tabor Mfg. Co., who make a specialty of sand-molding machines for metal castings. He is the inventor of the molding machine illustrated in our November paper The machines are manufactured at Elizabeth, where Mr. Tabor resides.—Eds ]

---

The following papers on the Indicator and its application are intended to be as elementary as possible, and will, incidentally, follow the steam from admission to exhaust. No matter how common the use of this instrument may become, there will always be a time in the experience of every man, when its mechanism and purpose will be new, it is to this period these papers are addressed.

As its name would suggest, its office is to determine the action of steam, doing work in the cylinder of a steam engine, or, in other words, to outline on a piece of paper, called the "card" or "diagram," a map of the various pressures exerted against the piston throughout the entire revolution An indicator card may be compared to the surveyors' profile or map of a railroad in its manner of conveying information. each has its base line from which calculations are made, and in each case the base line may be called zero. On the surveyors' profile, the zero or base line is a line representing sea level, or no altitude, and from this line all grades and elevations are estimated This map is drawn to a reduced scale, whereon an inch represents a much greater distance, perhaps miles, which is marked on the drawing so that one may take an ordinary rule and by measuring from the base line to the grade or elevation, readily find the exact height of any point on the road



The base line on an indicator card is called the vacuum line, or line of no pressure, which, at sea level, is 14 7 below the average pressure or weight of the atmosphere At greater elevations the air is lighter, and consequently the vacuum line is a trifle higher, but 14 7 lbs., is ordinarily used In analyzing an indicator card, this line must be considered, especially in dealing with a card from a non-condensing engine, where the pressure of the air is largely reduced by the condenser There is still another line on the indicator card which may also be considered as a base line, and which is quite as important as the vacuum line this is called the air or atmospheric line, and represents no effective pressure on a card from a non-condensing engine this line on the card is traced by the indicator pencil when air is on both sides of the indicator piston, and the spring in the indicator is under no tension

All the indicator springs are made to a known scale, that is, they are made so as to allow the pencil of the indicator to represent a given number of pounds of steam pressure for each inch of vertical movement, and, as in the case of the surveyors' map, one may put a scale on the card and accurately measure the pressure on the engine piston at any point in the stroke. He may also measure the back pressure or resistance due to the atmosphere. The air and vacuum lines are independent of any lines made by the indicator, and the condition of the engine or steam pressure has no influence on them

The lines on the diagram which are made by the steam are

First The admission line (sometimes called the lead line because it is the steam which passes through the valve lead which makes it) which is made by the upward movement of the pencil when steam is admitted to the cylinder through the opening of the main valve at the beginning of the stroke, when the valve has so much lead that it opens the port before the piston has reached the end of its stroke, the admission line will not be vertical, but will incline slightly outward; if the valve have lap, or negative lead, when the piston is on the center or at the end of its stroke, the admission line will incline inward, but if the main valve opens just as the piston begins its movement, the admission line will be vertical

Second The steam line is that line marked by the pencil after the piston has commenced its stroke and the steam is passing through the port; this line leaves at nearly a right angle from the admission line, and continues along the card until the cut-off takes place, that is, when the main valve has moved across the port and back again, shutting off the steam from the cylinder during the remainder of the piston's stroke; this line depends largely upon port opening and steam-pipe connections, and the velocity of the piston, when the port and pipes are ample, and the piston velocity not too great, the steam line is parallel to the air line, but in the majority of cases these conditions do not exist and this line falls off perceptibly, so much in some cases that the point of cut-off is hardly discernible on the card.

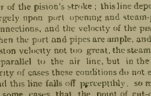
Third The expansion line is what its name would suggest, viz that line which is made by the indicator, after the cut-off has taken place, and the steam is doing work expanding, this line takes the form of a hyperbolic curve, and falls to a lower pressure, just in the ratio that the steam is expanded. (Cuts 1 and 2 illustrate the hyperbolic curve ) There is no line on the indicator card that posesses the interest of the expansion curve, it is the index of steam economy, and represents work done by the piston after the steam has been shut off, when compared with an engine that takes steam throughout its entire stroke, it means work done without cost It should be well studied, for it indicates good or bad performance in a steam engine

Fourth The release or exhaust line (often called the back pressure line,) follows the expansion line, in fact the expansion line runs into it the same as the steam line runs into the expansion line It is formed by the opening of the exhaust port and the flow of steam to the atmosphere in a non-condensing engine, and to the condenser in a condensing engine It takes a rounded form while the engine is passing the center, then makes a line nearly straight, and nearly parallel to the air line, until it is lost in the compression line or curve; its proximity to the air line depends upon pipe and port openings and piston velocity. This is also an important line showing loss of power It is always well to have this line approach the air line as nearly as possible, as the greater the distance between the two makes the loss greater.

Fifth When the exhaust valve is closed on the return stroke the steam remaining in the cylinder cannot escape, and the movement of the piston forces it into a smaller space, compressing it to a higher pressure; in some cases, where an engine is linked up, or the clearance is very small, even higher than the pressure in the boiler. This line runs into the admission line and it is sometimes difficult to tell where the compression line ends and the admission begins.

Fig No 3 is an indicator card showing very clearly all the lines on the diagram In considering this it must be kept in mind that the air and vacuum lines are not a part of the diagram made by the steam pressure

The pressure of a perfect gas, when confined, varies inversely with its volume, that is, its pressure decreases in direct proportion as its volume increases. This may be graphically illustrated by the cylinders, fitted with air-tight pistons, shown in sketch. If we could get a piston that had neither weight nor friction and put it in cylinder No. 1, it would remain in the position shown, because it has air above and below it. If we put a weight on the piston, it will go down in the cylinder until it has compressed the confined air equal to the weight, and a balance between the two forces has been established; if we again put a weight on the piston, there will be another downward movement, but less than the first, because the air beneath the piston is under greater pressure due to the first weight; we may continue to add weights and we will find that each succeeding weight will force the piston down less When the piston has reached the position shown in number two, it has passed through $\frac{4}{5}$ of the volume and has compressed the air five times, or atmospheres, making the pressure 90 lbs above vacuum and 75 above atmosphere; its volume has been decreased five times and its pressure multiplied by that number. If we now take off the weights the piston will take an upward movement corresponding to the downward If an indicator had been attached to the cylinder before the weight was taken off, and a piece of paper put on the drum, the pencil would have marked on the paper a line representing the pressure throughout the whole movement of the piston, and this line of pressures would have been the curve marked hyperbola An examination of the curve will show that the increase in pressure is precisely the reverse of the decrease in volume This diagram resembles a card from an engine without clearance or



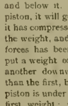


FIG. 1

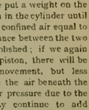

FIG 2

compression, cutting-off at ⅛ of the stroke, with an initial pressure of 75 lbs. above atmosphere.

This law of expansion is commonly known as Marriotte's, from the fact that it was discovered and published by him. The hyperbolic, or expansion line, is sometimes called Marriotte's curve

Steam is not a perfect gas, but is nearly so. When steam expands, doing work, it parts with a portion of its heat, causing condensation and loss of pressure For the sake of convenience and simplicity it will be treated as a perfect gas in these papers. For the same reason the pressure of the atmosphere was assumed to be 15 lbs. in plotting the accompanying pressure curve

Harris Tabor

## Passenger Trains for Passengers Only.

The article on "How to Accelerate Passenger Trains," from Mr John Player, Superintendent of Motive Power of the Atchison, Topeka & Santa Fé, which we publish this month, contains some suggestions that ought to receive serious attention from the railroad managers who contemplate increasing the speed of their passenger trains. Never in the history of the country was there such a tendency to accelerate trains as exists at present. Passenger business is increasing everywhere, and in all quarters preference is shown for the road that runs its trains through on the shortest time. The Empire Express on the New York Central and the special run made on that railroad, when the 436 miles between New York and Buffalo were passed over at the rate of a mile a minute, have demonstrated that exceptionally high speed can be maintained successfully on our lines, and has roused the craving of the public for faster trains. During the Columbian Exposition there will be great competition among railroads to secure the enormous passenger business to and from Chicago, and every effort will be made to offer superior inducements. The attractions of luxurious finish of cars, vestibule trains, barber shops and bath rooms in cars are losing their novelty, and nothing will equal the offer to consume the shortest time on the journey.

Mr. Player, recognizing the fact that there is great loss of time at every stopping place by handling the mail, express and baggage carried on most passenger trains, proposes to carry these loads on separate trains and confine passenger trains to cars carrying passengers only. The change seems a radical one at first, but on reflection and consideration it will be found that there is no absolute necessity for adding baggage, express and mail cars to those carrying passengers. This arrangement has been a convenient one, and on that account has been adhered to; but the passenger-carrying business of the country has now gone beyond this on a great many roads. There is a great deal of freight, such as fruit and other perishable material, that has to be pushed through as rapidly as express matter, and there is no reason why fast-freight trains, composed of the dead-weight impedimenta usually hung upon passenger trains, and perishable or other urgent goods, should not be formed into separate trains, permitting those carrying passengers to go on without delay.

Locomotive Engineering has received a nice club from Engineer Alexander S. Steele, engineer on the Government railway at Jamaica The men on this road are keeping up with the times, and intend to be posted on current events, even if they are isolated.

The Mexican government have issued an order that no passenger trains shall cross the border after ten o'clock at night.

## Mechanical and Other Conditions of our Time.

[James E. Phelan was born in Michigan in 1857, and at the age of 16 went firing on the Lake Shore Road, continuing in this service some three years At an early day, on the Northern Pacific, he took service there as a fireman and was promoted at the age of 23. He ran on the road for some seven years and was then made road foreman of engines for the whole system In December, 1889, he was made division master mechanic at Mandan, N. D., and a year later was selected as Superintendent of the Missouri Division of the great road, a position that he holds to-day J. E. Phelan always took an active part in the affairs of the Brotherhood of Locomotive Engineers, of which body he is still an honorary member. He represented his division in the Chicago convention In 1888, Mr. Phelan commenced a series of articles on "Air-brake Practice" in *The Locomotive Engineer*, that attracted the attention of the railroad world. These articles were afterward published in book form, and to show how they appreciated the work, the Westinghouse Co. took one thousand copies of the first edition. The work is now in the fourth edition, several hundred copies have been sold in Australia, where the air-brake is used. Mr Phelan resides at Dickinson, N. D., and has under his charge a long and difficult divison of road, across the bad lands of Dakota and Montana. J. E. Phelan is a typical American locomotive engineer; keen, bright, studious, he went up because he tried to better the condition of himself and his fellows, he was confident that his study of brakes, etc., could benefit other enginemen if known, and he made it known. The Northern Pacific saw that he was a leader, an educator, and promoted him. If they had not, some other road would.—Eds.]

Who in this age is to become famous by writing a history of mechanics pertaining to railroad service?

Who will "rise and explain" in simple and sensible language the evolution of railway appliances, condensed and boiled down, in a way to catch the eye and inoculate the senses of the busy railroad man, with undying principles pertaining to practical operation without occupying too much time with the process of inoculation?

Among the rank and file of railway employés, is it not a fact that the most urgent demand for reading matter, pertaining to railroading, comes from the small systems where men have time for labor, time for recreation and study, and time for sleep?

Is it not a fact that very little demand for reading matter, pertaining to railroading, in comparison to the number employed, comes from the great railroad systems of this age, especially when such systems are rushed with business, and every individual in the chase after the mighty dollar, regardless of sleep and the other luxuries and minor necessities of a well proportioned existence?

In the magnitude of present railroading master-minds find more scope in governing conditions and accomplishing results than was ever comprehended by the ordinary political Governors or Kings.

In our school days the gleaming of historical knowledge nearly all pertains to political conditions, Presidents, Governors, Generals, and the like.

A scepter of knighthood awaits the genius who will write entertainingly of industrial science and development, as some of our noble and noted historians have written of political events.

In this month of January, eighteen hundred and ninety-two, Locomotive Engineering takes a fresh start into this field, to be cultivated by the furrowing pens of genius, in energetic development of proper principles, designed for the upbuilding and preservation of railroad property, to the end that railroad property may first pay dividends to the owners of the property, with corresponding prosperity—sharing, by all employés, great or small, to the edification and satisfaction of the patrons of railroad interests. Then the Millenium—Paradise found forevermore.

The volumes yet to be produced by Locomotive Engineering will stand as garnered crops—results and experience to assist our future *great* historian

Various conditions now existing must be helped to favorable results or left in the by-way of progress

Recently we rode in a train on a railroad where the train was heated by the steam from the locomotive The weather outside ranged about thirty-five degrees above zero. The state of the weather within the car would have delighted an inhabitant of Africa wearing summer clothes We slept with the window up all night. Later, on the same railroad, we rode on the train having all pipe connections for heating from the locomotive Weather outside zero or lower, steam was not turned on from the locomotive, excepting for the cylinders, where it was evidently all required for pulling the train. We slept comfortably with the windows closed; less ventilation, but enough, no waste of heat.

Heat in the winter time costs money This is an unsettled problem, we leave its development to be recorded by the future historian.

Power brakes, yet in the field of development, but who can gainsay the splendid success achieved in this direction. History unrecorded, unwritten statements without number, testify to the wealth saved to the owners of railroad property by prevention of wrecks, and expedited passenger and freight service. But one necessary condition in this direction railroads nearly complete in this line should hasten to full equipment of all rolling stock with power brakes. Railroads behind the times, and backward about applying power brakes to all equipment, should hasten in this direction as far as consistent with funds available.

Automatic couplers are gaining ground rapidly, considering all hampering conditions. That was an interesting report emanating from proceedings before the political commission somewhere in the East recently, reading between the lines the story reads like this

The seers among the managers, car builders and mechanics, who have been able to look into the future and comprehend conditions in advance of the average mind, have taken strides in this direction beyond the anticipation of the many. As the snow flakes descend in quiet atmosphere, so have the automatic couplers appeared along the railroad landscape, until we are confronted with a mixing of the beautiful with the unrefined, annoying to many discouraging to some, but freighted with evidence of results accomplished and yet to come, we must have considerable more snow before we can enjoy smooth sleighing.

Was ever a period of transition not laden with hope and fear, anticipation clouded by ungainly facts?

The representatives of the switchmen, regarding the coupler question, while apparently unreasonable are fair in their desires, they either want good wheeling or smooth sleighing. Who can blame them for objecting to a mire of slush?

The seers and advance guard doing battle for correct principles can hold courage in this direction, close automatic couplers are as inevitably necessary in economical operation—as indispensable as power brakes.

The compound locomotive has made its share of noise in the mechanical world recently, notwithstanding the reduced echo from low pressure in the exhaust; while the compound is in progress of development, indications of economy are as sure as the fact that a given amount of energy, once generated and nearly all utilized, produces better results than when half wasted The development of compound locomotives should not be stayed while waiting on electricity to revolutionize motive power.

Electricity—the word has a charm for hopeful minds, as our imagination shapes our faith in the hereafter by that which we most hope for, so our intelligence is guided in judgment and anticipation for the future by all that has been accomplished to date It all depends on what returns may surely be expected from money invested The mighty dollar rules the destiny of electricity, may the field be fruitful

There must come a time when direct principles of railroading will be as irrevocable as the rules of war or the science of government While successful government comes from an intelligent discernment of the will of the people, successful railroading must come from an intelligent discernment of conditions and appliances best suited to produce revenue and favor economical practice

For the benefit of all branches of railroading, more students are necessary, else more time allowed the studious officers and employés in service to demonstrate principles. The most valuable lessons are not learned from books.

Phelan

## The Baldwin Compounds.

The Baldwin compound locomotives now in use on the Pennsylvania Railroad are said to be doing the same work as the simple locomotives of the same size with perfect ease and with a material saving in fuel The very heavy loads are pulled through the long, slow drags of mountain service with eminent success.

About half of the work now going on in the Baldwin Locomotive Works is on compound locomotives.

The boilers for compound locomotives are all made with a factor of safety of 4½ when carrying a pressure of 200 pounds to the square inch. This is done to inspire confidence in the high pressures and to insure the use of at least 180 pounds working pressure, thereby obviating the use of larger cylinders to do the necessary work.

These compounds are becoming noted as successful spark-preventers, and some of the railroad officers, who care little about fuel-saving, and therefore have no interest in the compound principle, are greatly pleased with the habit the engines have of leaving the sparks in the fire-box instead of throwing them around to burn up the country.

All the engineers, hostlers and firemen on the Staten Island Rapid Transit Railroad receive Locomotive Engineering, and the company pay for it General Superintendent Frank S. Gannon says it is a paying investment.

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

## The Air-Brake Situation.

American railway companies have always placed great reliance upon brakes as a means for securing the safe operating of trains. About fifteen years ago, when the air-brake had become a recognized necessity for all passenger trains, railroad men interested in the faster movement of freight began to recognize the fact that before long power-brakes would become as much a necessity for freight trains as air-brakes were for passenger trains. Few of the persons most in favor of power-brakes for freight trains contemplated that railroad companies would ever decide to incur the enormous expense of equipping all cars with air-brakes. A few companies had applied the Westinghouse Automatic Air-brake to all or a portion of their freight-car equipment, but these were regarded as exceptional cases.

There were several forms of mechanical brakes coming into service, mostly operated by compression of the buffer-springs, and some of them worked fairly well. The strongest recommendation possessed by this form of brake was that it could be put on cheap.

If brakes of this character were to be the freight brakes of the future, it was of the utmost importance to railroad companies that uniformity should be secured to the extent of all the brakes working together when mixed in a train. The discussion of this subject, in the technical press, cultivated railroad opinion rapidly. The result was that in 1883 a committee of the Master Car Builders' Association was appointed to investigate and report on the subject of automatic freight-car brakes. The first report made was very discouraging, but the following year a new committee was appointed and a disposition was shown to settle the question permanently. Mr. G. W. Rhodes, who was a member of this committee, eventually took the lead in arranging for and carrying out the most thorough tests of air-brakes that ever has been made—a test that has supplied reliable information on brakes to all the railroad companies in the world.

The first report of this committee was made in 1885. Although the members were evidently appalled at the expense of air-brakes for freight cars, they had learned something about buffer-brakes in the course of their investigations that deterred them from advocating that form. They recommended that a series of comparative tests should be carried out to demonstrate the value of the different brakes. This recommendation was adopted.

The fact had become apparent by this time that a brake to be satisfactory for controlling freight trains must be capable of working smoothly on very long trains. Acting on this knowledge the committee in arranging the terms of the competitive tests made the condition that all the brakes should be used on trains of fifty cars. The trials took place in July, 1886, at Burlington, Ia. It is needless to go into the particulars of these well known tests. There were many surprises both to brake companies and to railroad men. Air, vacuum and compression brakes were tried. It was shown conclusively that compression brakes were worthless as a means of controlling long trains. The old Westinghouse automatic and the vacuum brakes did fairly well in controlling the long trains when time was given so that they could be applied slowly, but if they were thrown on suddenly, violent and dangerous shocks were experienced at the back end of the train. With the old triple valve it took 17 seconds to apply the brakes on the last car of a fifty-car train, and the vacuum brake was even slower. The committee reported that the performance of all the brakes was unsatisfactory and the brake companies were recommended to make improvements and try again. A second trial was arranged to be made in May, 1887.

The vital question now to be settled was a brake that would act so quickly in cases of emergency that the brakes in the hind part of the train would be applied in time to prevent the cars from crashing upon those in front. Most of the brakes presented for competition at the second test were provided with electrical apparatus that in emergency stops applied all the brakes simultaneously. When this was done a fifty-car train could be stopped without any shocks. The Westinghouse Company had effected improvements on their brake that reduced the time of application to the last car of a fifty-car train from 17 to 6 seconds, but that increased velocity of action was not sufficient to make a satisfactory emergency stop. In the report made on these trials the committee favored the use of electricity as an auxiliary for making emergency stops. Air alone did not seem to admit of sufficiently rapid action.

Electricity had been found so unreliable for all purposes connected with trains that railroad men were extremely reluctant to employ it for braking purposes, and great disappointment was experienced with the result of the brake trials. Shortly after the second trial the Westinghouse Air-Brake Company affected another improvement on their air-brake, by which the time of reaching the last brake in a fifty-car train was reduced to two and one-quarter seconds. It was found that the brake thus improved made emergency stops as smoothly as brakes applied by electricity. The committee, reporting on the performance of this brake, said that "it could be relied on for any condition of train service, that brakes can be simultaneously applied without electricity throughout a train of fifty cars. Among conditions which the Master Car Builders' committee prescribed for a freight-train brake were, "that it shall work without shock on a train of fifty cars, and that it shall stop a train of fifty empty cars, running twenty miles an hour, within two hundred feet on a level."

It was demonstrated by numerous public tests that the Westinghouse improved brake fulfilled these conditions, and many railroad companies proceeded to equip their freight cars with this brake. Competitors have lately entered the field, and three or four other air-brakes are now offered to railroads, with the claim that they are quick-acting brakes, capable of meeting the Master Car Builders' requirements, and interchangeable with the Westinghouse brake. The mere assertion of parties interested in a brake ought not to be accepted as conclusive. Tests of the brakes on fifty-car trains should be required before railroad companies begin putting upon their cars brakes of doubtful efficiency. If a brake meets the requirements it is no hardship to require the company owning it to demonstrate the value of the brake in actual service. A shop-test or a test on a short train of cars proves nothing. Let brakes offered to handle fifty-car trains under all conditions of service be tried on trains of that size.

## Inspection as a Preventive of Accidents.

The people in Great Britain are ahead of us in the systematic inspection of every appliance used that is liable to jeopardize human life. Mines and railroads and factories and steamers and boilers are all subject to very rigid inspection by experts. The system no doubt greatly reduces the number of dangerous accidents, yet, with the greatest care casualties of a serious nature happen occasionally in all the departments named. One of the most valuable features about the inspection system is that when an accident does happen, experts are required to make a thorough investigation and the true cause of the accident is made public. This publishing of all the facts connected with railroad accidents has had a powerful influence in causing railroad companies to adopt the best appliances for the promoting of safety.

Railroad accidents have been unusually numerous in this country during the last month and nearly all the loss of life, injury to persons and destruction of property could have been prevented had the proper appliances for promoting safety been employed. If officials thoroughly familiar with railroad operating were required to investigate these accidents and report plainly on the cause, public sentiment would gradually work round to the demanding of remedies. There is great need for the imparting to the public of exact information as to the cause of accidents. Where there is so much material and mechanism subject to the severe service of heavy fast train operating there are many links in the chain of mechanism liable to break and cause accidents, so that safety can be maintained only by constant vigilance in watching the gradually weakening or wear that ends in breakage. But by far the most common and most disastrous accident of to-day is the collision. Collisions happen because proper means are not employed to keep the trains apart. There has been too much dependence put upon the means of stopping a train after the engineer sees an obstruction on the track. Good brakes are a great auxiliary in preventing accidents, and they can safely be depended on in the hands of careful men where trains are few, but many railroads are becoming too much crowded with trains to be operated safely without a system of signals that keeps trains a certain distance apart. If competent Government inspectors had investigated all the collisions that happened during the month, and reported the truth in most cases that the accidents happened because signalling systems capable of preventing the trains from coming together were not in use, a valuable educational work would have been done.

## Doctoring Feed Water.

When a man is sick with any complaint that is difficult to cure, he is very liable to fall into the hands of pretentious quacks, who presume to have a cure for everything.

We have often thought of this when listening to the list of compounds that have been tried for softening feed-water for locomotive boilers. A locomotive boiler uses such an enormous quantity of water that a small percentage of solid matter forms a big deposit at the end of a month. This soon gives trouble and raises the demand for a remedy. The proper remedy calls for some knowledge of chemistry, and that is a science little studied by the ordinary railroad man.

Under these circumstances the man responsible for keeping boilers in running order is a ready victim of quacks in doctoring feed water. The man having a compound that acts to precipitate lime is the least dangerous of the large tribe that tell of remedies for prevention of scale in boilers. All kinds of vegetable substances and many mineral compounds have been put into boilers with little success. Some of the ingredients used do some good, others are hurtful. Corn, starch, potatoes, sorghum, bran and compounds of petroleum are a few of the ingredients used on some roads. All these substances act on the scale and tend to soften it, but they form a sort of mild homeopathic remedy that is permissible because it is not likely to do much harm. It is safe to say that a few pounds of caustic soda would be much more efficient than any of the compounds mentioned.

Some of the companies that sell boiler compounds prepare their mixtures to suit the water to be treated. Where this practice is followed it indicates intelligent dealing with a difficult malady. If a railroad company has an analysis made of the water on each division, and gets a chemist or manufacturer of boiler-purge to prepare a mixture to suit the water, benefit is certain to result from the treatment. But it is of the utmost importance that the medicine should be taken regularly. The leading cause of the failure of good compounds has been neglecting to put them in the feed water.

## The Indicator Articles.

We doubt not that the A, B, C articles on indicating locomotives that commence in this issue will be appreciated by many men who want to be able to read a card, but who do not expect to take them. Plainly put, an indicator card is a photograph of the work done in one end of a steam engine cylinder—a picture—and when one gets the idea into his head of just what causes the different parts to be drawn, a card tells the whole story—admission, point of cut-off, expansion, exhaust-opening, back pressure, compression, lead, pressure, etc., etc. It is the language of the steam engine; learn it.

If you remember that all the lines made vertical, or *up and down*, are caused by the steam pressure in the cylinder raising and lowering the pencil, and all the lines made horizontal, or *back and forth*, are caused by the drum moving the paper under the pencil, and that this drum represents on a reduced scale the movement of the piston, you have gone a long way toward understanding the card. Harris Tabor, the inventor of the Tabor Indicator, and one of the most expert steam engineers in the country, will make the matter plain to you if you follow his articles. He is not going to write for experts, but for men who do not understand the instrument at all. He is going to confine himself entirely to locomotive indicating, in which he has had long years of experience. He will make a card for you, line by line, showing the exact location of the piston and valve for each line, and will give many object lessons on cards actually taken from locomotives in different kinds of service and under different conditions, ending up with cards from compound locomotives.

One of the best and most reliable mechanical papers that comes to this office is the journal *Industry*, published at San Francisco, Cal. It is edited by John Richards, a mechanic who has made his name known at home and abroad. The paper is valuable, because it is published to give value received to subscribers, and not solely for advertising. Next year it will be issued in magazine form.

## Train Accidents.

Some of the Eastern railroads have been noted during the last month for the number of train accidents. The New York & New England has been peculiarly unfortunate in smashing trains. The New York Central had two bad wrecks by express trains running into trains at stations, and the Philadelphia & Reading killed three persons through an express train running into a gravel train. In all cases, the usual excuses were made that the accidents were caused by the carelessness of the trainmen. We think that all the accidents were due to inexcusable looseness in the methods of operating, and to the lack of proper appliances for protecting trains.

When an express train runs into a train standing on the main line, it may safely be concluded that it is a common thing for stray trains to be on the track when an express train is due. The system that permits this dangerous method of train operating has no right to run trains at a speed greater than twenty-five miles an hour. The way to prevent accidents to fast passenger trains is to have no excuse for any train intruding upon the track when an express train is due. Strict discipline is necessary to make all concerned understand that taking chances will be considered as serious when nothing happens as when an accident results. We are aware that this is not the usual way of looking at the matter. When a conductor of a freight train or a train dispatcher saves a few minutes by running dangerously close to an express or other fast train, he is excused and considered zealous. It is only when the smash comes which is brought about by this kind of operating, that the delinquent is blamed for reckless conduct. Railroad men do not properly recognize the fact that it takes 1,000 feet under the best conditions to stop a train running 60 miles an hour, and that it takes twice that distance with defectively braked trains and bad rails.

The first reform necessary is to make all concerned understand that fast trains must have clear track. The next one is the providing of a signal system that will keep trains apart. All our railroad companies are slow to perceive that good management requires the most perfected appliances for operating trains safely, and that a block signal system is as urgently wanted on many of our crowded lines to-day as good brakes were needed twenty years ago. The expense of one bad accident would go a long way toward equipping a road with good block signals. To neglect this is like neglecting insurance, with the added objection that it is subjecting the traveling public and trainmen to dangers that are criminal.

## Power of Knowing Things.

A general manager who rose by the line of the scoop, throttle and master mechanic's office to the exalted office he now holds with dignity and ability, lately remarked to the writer: "There is no mistake but the engineer is every day becoming a more important person.

"When I was on the road the engineer received no consideration compared to that extended to the conductor. If there was a very important train to be run, where the making of time was of unusual consequence, the best conductor on the road was selected and upon him devolved the responsibility of getting the train along. If the weather was bad or snow deep and unusual difficulties were looked for in getting trains over a division, the conductor was regarded as the man who would do the most in getting there.

"Since there came to be so much mechanism on locomotives and cars that the engineer alone is likely to understand, he is getting to be looked upon as the man responsible for everything connected with the safe and prompt movement of the trains. When there is anxiety to get a train through under difficulties nowadays, we never concern ourselves about who is conductor. If the engineer is a man whose record gives confidence, we know that everything will be done that knowledge, judgment and ability can accomplish.

"We have two or three conductors who know more about air-brakes, heating pipes and valves, signals, etc., than the average engineer, and these men are valued accordingly. Knowledge is power, and to no class does this apply more practically than to railroad trainmen. A significant sign of the times is that you can hear young trainmen making fun of the engineer who does not understand all the details of train mechanism."

## Strength and Weakness of Boilers.

It is almost impossible to make the ordinary boiler user realize that a boiler which has been worked for years with safety is gradually or rapidly approaching a condition when it will be dangerous to be near. When a man first gets a boiler into his premises, he is nervous every time he hears the steam blow off lest the noise means a coming explosion, but familiarity gets him over that feeling, and then it breeds the contempt which ignorance is ever so ready to embrace. Most of our States are painfully in want of laws to regulate the control and inspection of steam boilers; but public opinion is slow in making the demand that leads to the necessary lawmaking, although the examples of killed and wounded from boiler explosions are sufficiently numerous to stir people with feelings of humanity to demand a remedy.

Laws requiring a thorough investigation of all boiler explosions by expert inspectors, and the publication of the facts, would do a great deal to prepare the way for effectual remedies. It is not necessary that expert inspectors are men who must be brought from outside the works where a boiler is stationed or is cleaned. A boiler maker employed by a firm on other work may acceptably act as an inspector when boilers have to be examined. The Railroad Commissioners of the State of Massachusetts, who are noted for the conscientious way they perform their duties, recommended some years ago the enactment of a law requiring all locomotive boilers to be periodically inspected and tested. Most of the railroad companies considered this law a hardship at first, but most of them now recognize that it was a blessing in disguise. The boilers are inspected regularly at trifling expense, and defects of a dangerous character are frequently discovered. The mechanical head of one of the railroads in Massachusetts made the public statement after the inspection law was in force for some time, that he would rather quit the road than return to the loose practices that prevailed before rigid and systematic inspection became imperative. If the system enforced in Massachusetts were practiced in all States of the Union, there would be fewer explosions of locomotive and other boilers.

There are many people who still cling to the delusion that there is some kind of mysterious force at work that causes boilers to explode. This belief is held with child-like faith especially among people who are using boilers and have ignorant and unskillful men in charge. It is their interest to make believe that accidents to boilers are mysterious dispensations of Providence.

Two well-known facts give strong testimony in favor of the value of inspection. One of the weakest forms of boilers, owing to its awkward shape, is the Scotch marine boiler; one of the strongest forms of boiler naturally is the locomotive. Although the Scotch boiler is used in nearly all the ocean steamers carrying high pressures, no boiler of that type, inspected under the rules of the British Government, has ever exploded. The boiler that explodes most frequently in this country is the portable locomotive boiler, used with threshing machines. Inspectors never disturb the comfort of the owners of the latter boilers.

Boilers explode only when the pressure of the steam inside is too great for the strength of the material holding in the pressure, just the same as an elevator falls when the weight is too heavy for the strength of the cable doing the lifting. The greater portion of a cable or a chain used in lifting may be strong enough to raise four or five times the weight successfully, but there happens to be one weak spot which gives way and disaster follows. The same is the case with boilers. A boiler is not safe unless it has strength to bear four or five times the amount of working pressure. This is called the "factor" of safety. If any spot of a boiler is weak, that spot is the measure of the safety of the boiler, for if it causes a sudden rupture, the effect is as bad as if the whole of the boiler was weak. The weak spots in locomotive boilers are generally broken stay-bolts or corroded sheets. Systematic, regular and thorough inspection is the only means of preventing this weak spot from becoming a source of danger. If you take a piece of wire and keep bending it to and fro, it will soon break. Certain stay-bolts of a locomotive fire-box are constantly subjected to a bending action, and it is only a matter of repeating the bending often enough till the bolt breaks. The means of detecting breakage ought always to be as active as the agencies at work to cause accident.

We have completed arrangements that will enable us to offer ambitious young men a chance to get almost any tool, instrument, book or model they may want, for getting us a few subscribers. The best papers in the world do this, and we will be among the best. There will be no prizes or fakes of any kind, but drawing instruments, fine tools, valve-motion models and books will be given for certain numbers of subscribers, not to one, but to as many as want them. These goods will be shipped direct to the men from the makers just as if cash had been paid for them. Don't fail to preserve our premium list sent out with the January number.

## NEW BOOKS.

THE ENGINE RUNNER'S CATECHISM. By Robt. Grimshaw. John Wiley & Sons, New York. Price $1.50.

This is the most useful of all the Grimshaw Catechisms; there is little if anything new in it, but it illustrates, describes and explains the peculiarities of all the well known stationary engines used in this country. For young engineers or men in charge of strange designs of engines or isolated plants, it contains a great deal of useful information about the adjustment of the valve, gear, etc., and the care of the engine. It is something better than a bound and indexed collection of engine builders' catalogues, for it treats more of the things the man in charge wants to know, instead of what the buyer wants to know. It is handsomely bound and of a handy size, 4 by 6 inches.

THE HISTORY AND DEVELOPMENT OF STEAM LOCOMOTION ON COMMON ROADS. By Wm. Fletcher. E. & F. N. Spon, 12 Cortlandt St., New York. Price $3.00.

This work is on the present locomotives in use on the common roads of England. The work is divided into six parts as follows: Period of Speculation, Period of Experiment, Period of Successful Application, The Modern Period, Practical Notes on the Design and Construction of Road Locomotives and Traction Engine Low. The road locomotive has reached a high development in England, but the roads of that little country have reached a higher development, that has made the road locomotive possible. The book is profusely illustrated, and we notice that almost every builder's latest effort is a compound engine. The work is very useful and complete.

## WHAT'S GOING ON.

The New Jersey & New York are in the market for three passenger cars.

The Minneapolis and St. Louis Railroad are in the market for some new locomotives.

An order for 500 freight cars has just been placed for the Savannah, Florida & Western.

The Chicago & Northwestern have just ordered from Schenectady, 25 ten-wheel locomotives.

The Cleveland, Cincinnati, Chicago & St. Louis have finally decided to order the passenger cars that have been talked of so long.

The West Shore have ordered 25 mogul locomotives from Schenectady, of the same pattern as those used for freight on the New York Central. They have also ordered 650 new freight cars.

The Richmond Locomotive Works are busy on orders for different Southern roads. The Chesapeake & Ohio have recently ordered more heavy 19 x 24 inch engines. Those previously built are reported to be giving perfect satisfaction.

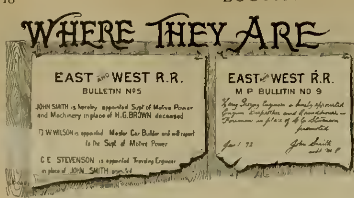
The Baltimore & Ohio Railroad shops at Mt. Clare, Baltimore, are turning out a few new baggage, express and caboose cars to take the place of cars destroyed. An earnest effort is making at all the shops on the system to get the passenger equipment into first-class shape.

The Mexican National is getting ten new engines. Six of them will be plain ten-wheelers and four Vauclain compounds. This is a narrow-guage road, and the standard engines have the wheels inside of the frames and cranks on the ends of the axles. This admits of the use of a wide fire-box.

The Pennsylvania & Northwestern Railroad Company has contracted with the Baldwin Locomotive Works for ten locomotives to be used in hauling coal. All are to be of the consolidation type and of the four-cylinder Vauclain compound pattern. The line on which they are to work has maximum grades of 158 feet per mile and curves of 18 and 22 degrees.

During a recent visit to the Baldwin Locomotive Works we found the place full of compound locomotives of all sorts and sizes. Over half the orders now on the books are said to be for compounds. Several of the compound decapods for the Erie were in the erecting shop, and they are huge machines, the heaviest road engines ever built. Business is supposed to be a little dull, but these works are turning out two big locomotives every day.

The Pullman Palace Car Company have recently received orders for the following equipment: One passenger coach for the Wichita Valley Railway Company, one baggage car for the Denver & Rio Grande Railway Company, twenty chair cars for the Chicago, Burlington & Quincy Railroad Company, one combination passenger and baggage car for the New York, Lake Erie & Western Railroad Company; ten first-class passenger and ten suburban coaches for the Chicago & Eastern Illinois Railroad Company; one vestibuled combination passenger and baggage car for the Old Colony Railroad Company; one narrow guage passenger and baggage car for the Fremont, Elkhorn & Missouri Valley Railway Company; one hundred Pullman standard twenty-five-ton coal cars for the Du Quoin Transportation Company, one combination baggage and mail car for the Toledo, Columbus & Cincinnati Railway Company, two passenger coaches for the Toledo & Ohio Central Railway, ten first-class passenger coaches (five of which are to be equipped with vestibules) for the Chicago, Rock Island & Pacific Railroad Company,



At the January meeting of the New England Railroad club, the subject of locomotive boilers and their attachments will be discussed

The General Manager of the Fall Brook Coal Co , has made the request to the directors, for permission to buy six new consolidation locomotives

Mr R C Blackall, Superintendent of Motive Power of the Delaware & Hudson Canal has been elected president of the New York Railroad Club

Mr Geo E. Stevens has been appointed purchasing agent of the East Tennessee, Virginia & Georgia, in place of Mr J E Wilcox, resigned. Mr Stevens has been for several years with the Ohio & Mississippi.

Rumors are current that General Manager Saul, of the Chicago & Eastern Illinois, is about to resign Resignations have been so common on that road since Mr. Saul took hold that it is about time his own turn was come

The announcement has been made that Mr James McNaughton, Superintendent of Motive Power of the Wisconsin Central, will have his jurisdiction extended over the Northern Pacific and Chicago & Calumet Terminal Co.'s motive power.

Some of the Cincinnati papers circulated report that Mr C H Hudson, General Manager of the East Tennessee, Virginia & Georgia was about to resign, and that numerous official changes on the system would follow. We are authorized to say that these reports are without foundation.

L. W Rogers, the soul of the *Railroad Trainmen's Journal* has retired from the editorship and will establish the *Age of Labor* Rogers is able, honest and consistent He suffered being frozen out of a $2,000 job rather than indorse a wrong because his order had committed it.

In his annual report Mr G R Brown, of the Fall Brook Railroad, mentions that when men and derrick cars are required for a wreck, the shop whistle is blown three sharp toots four times. They find that this practice enables them to start off the wrecking outfit very promptly.

There is no class of people in America so poorly paid as division master mechanics and the master mechanics of small roads. An engineer who is a machinist is very often the man selected for such a position, yet he is expected to accept increased responsibility with less pay Curious line of promotion

Superintendent Reasoner, of the Delaware, Lackawanna & Western, has been under the weather lately and has not been able to leave his room "Pap," as the boys call him, is an unbending type of the old school of railroad men. But few railroad officers have a firmer hold on the affections of the men under them

Mr A M Waitt, Assistant General Master Car Builder of the Lake Shore Railway, who contributes an article in this issue, was raised on the locomotive side of the fence, and still retains a lively interest in everything relating to engines He worked out the designs of the first successful extension smoke-box applied to a locomotive.

Mr J. W Allen, of the Hartford Steam Boiler Insurance Co., who is one of the best authorities in this country on boilers, has been lecturing lately on riveted joints, and intends taking up the subject again. He believes that great ignorance prevails about the designing of boiler seams and that danger results often from faulty design.

It was noticed that an engineer running one of the Baldwin compound locomotives ran the engine with direct steam a great part of the time On being questioned about his reason for doing this, he said that she spoke out with better voice when working that way. Some men think an engine cannot be doing anything unless she is making great noise. This is a decided case of great cry and little wool

No improvement lately applied to locomotives has jumped into popularity so rapidly as the Leach sanding apparatus. The inventor is Mr H L Leach, Jr , Master Mechanic of the Cheshire division of the Fitchburg Railroad, who evidently knew what was wanted to relegate the old crude methods of sanding into the realm of antiquities A very timely demand for this device is reported, one railroad company having ordered 37 sets last month

A remarkable feature of locomotive budding last year, has been the number of compound locomotives constructed. The Baldwin Works have up to the time of writing, built 101 compound locomotives, the Schenectady Works 13, Rhode Island Works 12, Brooks Works 1, the Chicago, Burlington & Quincy 1, the Old Colony 1 and the Lehigh Valley 1 All the other locomotive works of any standing are preparing plans for compound locomotives.

The following is a specimen of the bulletin notices to be seen on the Fall Brook Railroad "A car of wheat was put in a train at Newberry and brought to Corning as an empty. The instructions require the conductors to look into every box car to see for certain that it is empty. This is a matter of record If it happens again the services of the conductor will not be wanted any longer." No names are given in notices of this kind The hint is generally sufficient.

On the 10th of last month Mr J H Agnew, Superintendent of the South Carolina Railroad, left the service of the company. Mr. Agnew went to the road as master mechanic three years ago, and was so successful in operating the mechanical department that he was made general superintendent The company will be the greatest loser by the change While extremely active in preventing waste and in running the road economically, Mr. Agnew was very popular with high and low on the system.

A man walked into the office of Russell Sage one day last month and demanded the modest sum of $1,200,000 When the money was not forthcoming, he exploded a bomb, killing himself and a clerk in the office The man was no doubt mad The first evidence of this is the asking for such a large sum, and the other is that he should ask Russell Sage for anything Russell is one of the millionaries who became rich by not spending anything that could be saved. His closest friends belie him if he ever spent a cent in doing a generous deed.

Blocking frogs and switches costs little and is almost a certain preventive of that horrible kind of accident that results from switchmen getting their feet caught. Yet this provision for safety is frequently neglected, and we are constantly reading of accounts like the following, which was headed Norwalk, Conn., James Dugan, aged 35, an employé of the Housatonic road at Wilson's Point, met a horrible death last night. He had left the switcher to unhook three cars when his foot caught in a frog and held him. Three cars and an engine went over his body.

Mr George E. Todd, Superintendent of the Concord Division of the Boston & Maine, has been granted leave of absence for six months and has gone to Europe in hopes that the change will repair his broken health Mr. Todd was for years General Superintendent of the Concord Railroad, and was considered one of the ablest railroad men in New England. Some of his warm admirers now say that he had few equals in the United States But he settled down to the drudgery of watching the details of a small road and has expended energies capable of much wider scope on a limited field.

Senator Callum has introduced a bill into the Senate, providing for a uniform freight car coupler. All the railroad companies are to be permitted to vote for the coupler, on the basis of the number of cars owned, and the railroad employés will be entitled to one-third as many votes as the railroad companies. If one coupler receives 500,000 votes, it will be declared chosen. In case no choice is made the President will appoint five commissioners to make the selection. An attempt will be made to purchase the patents on the coupler selected. This plan of settling the car coupler question appears to be a good one, but it is certain to meet with great opposition.

The trainmen of the B. C R. & N are mourning the loss of a friend. For years a curious old Scotchman, John B Coathill, has kept a rooming house in Cedar Rapids, Ia , for the accommodation of trainmen None other need apply. Old Jack, as he was familiarly called, acted like a mother toward his boys, washed and mended their clothes, saw that they responded to the caller's summons, and did his best to keep them out of mischief. When a worthy man got into trouble Jack wrestled with manager, superintendent or master mechanic till forgiveness was secured. Jack fell dead in his rooms one day last month and he leaves a vacancy that is not likely to be filled

In the opening address made before the Society of Mechanical Engineers, President Hunt said "The Bessemer process was a failure for all but the higher purposes until Mushet's invention, and while Sir Henry honored himself by settling an annuity upon Mushet, who at that time had made nothing from his invention, still I, for one, would have had my already profound respect increased if Bessemer had even mentioned Mushet's name in his letter, giving the history of his process, which was read at the Pittsburgh meeting of the Iron and Steel Institute" Most of our readers will understand that the Mushet mentioned was Robert Forester Mushet, inventor of the process for making the well known tool steel.

Secure safety by taking no fool chances in the regular working of trains, is the motto held up to his men by Superintendent Brown, of the Fall Brook road The following is a recently posted notice "A South-bound train passed the semaphore at Middlebury and pulled in the side track, after which they came back for orders. This is strictly forbidden. Under no circumstances must locomotives pass a semaphore until they know what the orders are. You will doubtless remember two or three years ago that a train came down Tioga hill too rapidly, and collided with a train pulling out of the switch, causing one man to lose his life. Other similar things are liable to occur unless the rule is complied with."

The Chicago *Herald* lately published a long article on Mr. T. B Blackstone, President of the Chicago & Alton Railroad, accompanied by a very good portrait. Although Mr Blackstone is comparatively little heard of in railroad circles, he is one of the ablest and most progressive railroad managers in the country. He began railroad work as a civil engineer, and is particularly well posted on mechanical matters. His invention for coupling passenger cars makes a train free from the danger of telescoping, no matter what may happen. His policy as a manager is Get the best of everything, men and machinery. The road has always paid good dividends. The sleeping-car and the dining-car both first attained success under the management of Mr. Blackstone.

We have received from Mr. W. P Brady, Superintendent of the Decorah Division of the B. C. R. & N., on account of a curious accident that happened to one of their passenger trains. A large stone, weighing about a ton, slipped from a car of a freight train, and fell between the rails without causing a shock sufficient to let the train men know that anything was wrong. A passenger train came along shortly afterward, running at a high rate of speed and was nearly up to the stone, before it was discovered by Engineer Cary. The pilot struck the stone and threw it 94 feet, but the engine was thrown off the track and went over a small embankment. Engineer Cary remained at his post, and when the passengers went forward, expecting to find his mangled body, they found him drowning out the fire

Colonel Haynes, of the Plant Railroad System, who is president of the Railroad Association, is an excellent speaker and greatly given to story-telling about railroading of the days before the war. In a recent speech he gave a humorous account of the consternation that overcame the officers of a certain railroad when they found it was necessary to change time to make a new connection which required the principal passenger train to be accelerated two hours. A box of pencils was purchased, cigars put in stock and all the officers retired to a room for consultation, and remained there for most of a week. The decision arrived at was to put the time of all the trains on the road ahead two hours. When the change took place all the men engaged in making this sagacious arrangement sat up all night to watch if the trains could run on the new time card

Brother William E. Meade, for a number of years in the service of the Boston and Maine Railroad, representative of Boston Division, No. 61, to the San Francisco Convention, and State Representative to the Massachusetts Legislature for the city of Salem, for the past two years, was elected at the late election State Senator. Honors, thick and fast, of late, have come to the members of our Brotherhood. As the debris of the late election is cleared away, we are informed that in many localities members of the B. of L. E. have been elected to serve in official capacities, not only in municipal but State affairs. In this we are also pleased to mention that at the late election held in the city of Detroit, in a district noted for its close vote and often in daubt, Brother Charles Baker, of Detroit Division, No. 1, was elected alderman by one of the largest majorities ever given a candidate in that city This is but two of the many who will serve not only their constituents with honor, but the B. of L. E.—*Locomotive Engineers' Journal.*

## How to Accelerate Passenger Trains.

BY JOHN PLAYER

The question of making fast time with passenger trains is always one of absorbing interest to all travelers, also to those whose business it is to get the trains over the road with safety and dispatch. The road that can accomplish the greatest distance in the quickest time, is usually the popular route, other things being equal, so far as the comfort of the passengers is concerned. Dining cars have been added stops at eating-houses curtailed; flag stations, where stops are made only on signal, and many other things instituted to gain the end of making the shortest possible time. In view of all this, is it not well to ask where, in the handling of passenger trains, is most time lost? We have reached the point where it is possible to run almost continuously, so far as the motive power and rolling stock is concerned, for hours at a stretch, stopping only for water and maintaining, when running, a speed from forty to sixty miles an hour Still, the desire of high average speed is not accomplished, and 'tis still said we are too slow.

Granted we could run faster than previously indicated, and doubtless we could, it would then become a question of roadbed, so far as safety for higher speed is concerned, especially on curves. Rolling stock and motive power is equal to faster running, and in many places the road bed is good for it; then the question is asked, Why not quicken the time of passenger trains. The answer may be given and correctly · We loiter too much on the way. Almost every train, running any distance, stops and gathers up mail, express and baggage; not only gathers it up, but distributes the same at its destination and wastes no end of time in the operation. Some roads run mail trains, doing mail work exclusively, which is a move in the right direction. Some may run mail and express, some express and baggage exclusively. Would it not pay, and be far more comfortable for the traveling public, if the baggage, mail and express cars were run as perhaps it should be in a baggage, mail and express train exclusively? By so doing, would it not be possible to make quicker time with passengers? Some long distance trains are made up of one or two mail cars, one or two baggage and express cars and one for straight baggage. When they are loaded, as only an expert can load them, these five cars, so far as weight is concerned, make a fair load for an ordinary engine to haul at fifty miles an hour. After taking away this dead weight and delay portion, what may be termed the regular passenger train portion—smoker, ladies' coach, chair car, one, two, three or more sleepers, which would be a good train—could be rushed along with small delay at stations. This part could be handled as it should be if the baggage, mail and express portion was run independently, as it would seem proper to do.

Here is a question that is of great importance for the transportation and passenger departments to consider. First One baggage, mail and express train could do the business for two or three passenger trains, without in any manner, delaying the weary traveler. One baggage, mail and express train could be manned by men familiar with that particular part of the business. Station men could also help, together with all others whose business it is to handle the baggage, mail and express The question of cost of running such a train will be the first question arising, but when the same is considered in connection with the advantages to be derived from the separation of passengers and luggage, so far as speed and convenience is concerned, the question is worth consideration.

If this proposal were carried out, would it not be merely a step in the natural line of train development? The first railroad train was mixed, composed of freight and passenger cars. Then came the second stage, the mixed train composed of passenger, baggage, mail and express cars. Is it not now time for the third period of passenger cars alone? To men wrestling with the problem of getting overloaded trains over the road on express time, it seems that another start in the forward movement is due.

## A Unique Design of Suburban Engine Showing Remarkable Service.

At this day and age, when the average railroad mechanic is thoroughly impressed with the idea that a locomotive, for suburban service, should have as much weight as possible on her drivers and the latter of small diameter, in order to start trains promptly, it is interesting to run across a practice that is successfully carried on, which ignores the set beliefs.

Our engraving was made direct from a photograph and represents a type of engine that was "evoluted" from old, light, 8-wheelers, by Master Mechanic T J. Hatswell, of the Flint & Pere Marquette Road.

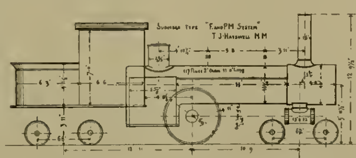
This company has a belt line at Saginaw, Mich., that has developed a large suburban business which is successfully handled by this type of engine.

That we should expect to find single coupled engines in some other service goes without saying, but the remarkable showing by this engine on a "start and stop" job with a fairly heavy train, is, to say the least, something for the opponents of the single express engine to think about. This engine was made from an old 15x22 passenger engine, having a 64-inch wheel, her frame was lengthened to carry the tender and a single truck placed under it

Fig 2 is an outline giving all the principal dimensions.

The great economy of this engine is well illustrated by the following figures taken from the performance sheets

| | Total | Per mile |
|---|---|---|
| Miles run.. . . | 72,870 | |
| Cost of oil, waste and tallow ............ | $190 58 | 0.262 |
| Cost of fuel .. .. . | 3,109 77 | 4.267 |
| Cost of repairs. . .... | 1,116 72 | 1.532 |
| Wages, engineers and firemen . ....... | 3,842 00 | 5.272 |
| Wages of cleaners | 480 00 | 0.659 |
| Total . . .. | $8,739 07 | 11.992 |



No. 2

| | | | |
|---|---|---|---|
| Total weight.. . | 80,000 lbs | Grate area . . | 13 square feet |
| On drivers | 40,000 " | Heating surface of fire-box | 96 " |
| On forward trucks . | 14 000 " | Tubes. . | 684 " " |
| On rear trucks ... .. | 26,000 " | 60 sq feet of heating surface to 1 sq foot of grate surface | |
| Capacity of tank 1,300 gallons of water and 4,000 pounds of coal | | | |

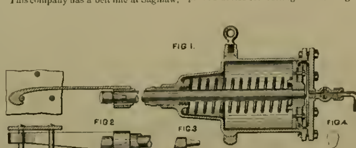
|---|---|
| To one pint of lubrication oil . . | 33 |
| " " valve oil. .. | 93 |
| " " head-light oil .. .. | 46 |
| To one ton of coal .. .. .. ... | 49 |

## Power Stay-Bolt Cutter.

The cut on this page represents an improved device for cutting or breaking out old stay-bolts from fire-boxes by the use of compressed air or steam.



As will be seen, a cylinder similar to an air-brake cylinder is used, a spring employed to keep the piston at one end of the stroke To an extension of the front of the cylinder, which acts as a guide for the rod, there is a sleeve, terminating in a hook. The end of the piston rod carries a cutting-head that is removable. The cylinder is suspended by a ring that passes entirely around the forward flange and has an eye-bolt in it By this arrangement the piston very nearly balanced horizontally and can be turned to any angle

Fluid pressure is supplied through a rubber hose, and controlled by a suitable valve located near the cylinder.

In operation the hook is put over a stay-back of one to be cut, and the tool thrown against the victim with force enough to shear it off next to the sheet, another blow next the opposite sheet cuts the stay out entirely This tool is the invention of Richard W Bayley, of Pittsburgh, Pa

## Uniform Method of Keeping Motive Power Accounts.

BY J B. BARNES

I hope the question of keeping accounts and recording expense in all departments of railroad work, especially the motive power and machinery, will be agitated by the Master Mechanics' Association, until some formula or rule is promulgated and adopted by every road of importance in the States and Territories, so that presidents, general managers and directors can readily ascertain how the money is being expended, and not only that, but it will have a tendency to affect those directly in charge and spur them on to extra effort in securing the desired results at the least possible expense.

For instance, the reports furnished showing the cost per mile run on locomotive repairs, are supposed to contain all labor and material chargeable to that account. A large number of roads carry what is called a betterment account, to which is charged all new parts, such as new tires, new driving-axles, new air-pumps, and in fact, all new attachments bought and placed, whether they replace old devices removed or not. This of course is misleading Other channels are used to divert a percentage of the expense which is chargeable direct to locomotive repairs.

On the Wabash, the system has been in vogue for many years of charging to locomotive repairs, every hour of labor and every dollar's worth of material which is used in rebuilding and repairing locomotives, less the amount received for scrap material removed from the locomotives The labor and material used exclusively in building new engines throughout is charged to the betterment account, and does not enter the expense for cost of operating locomotives, from the fact that the new engines are not operated until completed and in service.

If some such system as this was inaugurated on all lines, the evidence would be plain as to who was the most efficient manager in charge of the respective departments

This subject has been on my mind for a long time, and is more forcibly brought before me in persuing the articles being published by Mr Forney, in relation to the comparisons of English and American locomotives.

In these articles, you will note the Wabash stands well to the front in average mileage and cost of repairs, and I take considerable comfort to myself as I conclude that the other lines represented have not included in the figures they furnish any accounts not included in the Wabash system, to make up the averages as shown. However, if it was known to a certainty that each line carried into these accounts the same expense, the evidence would be still more gratifying

With the compound locomotive, the lever, even at high speeds, is left nearly in the corner This will give some of the present full-stroke fiends a chance to do fairly good work without changing their habits.

The Paulista Railway of Brazil has given an order for four Baldwin compound locomotives, duplicates of some already in use there.

## The Education of Locomotive Engine-men.

[In presenting to our readers the following article from the pen of Eugene V Debs, the editors of Locomotive Engineering cannot refrain from adding a word about the man, not a nauseating, goody-goody fable, but an outline map of his busy life Eugene V Debs enjoys the confidence and esteem of more organized wage-earners than any man in America This he has secured in a decade, and people like to know how a poor boy can step from the shades of obscurity to such an enviable position in ten years.

Mr Debs was born at Terre Haute, Ind., on November 5th, 1855, his father being a grocer in that then little village Like other boys, he passed through the village schools, the city high school and the commercial college. In 1870 he went to work in the paint shop of the Vandalia Road, and in 1871 went on the road as a fireman He took an active part in the organization of the local lodge of the Firemen's Brotherhood, but left the road, after three years' service, to go into a wholesale house in his native city He was elected clerk of the city for two terms In 1880 the affairs of the Grand Lodge of the B of L F. were found to be in bad condition, owing to the acts of the secretary The grand master removed this man and appointed in his stead the subject of this sketch. At that time the association consisted of some sixty lodges and was $6,000 in debt This debt was guaranteed by Debs' personal surety, and he went to work At the end of the year the affairs of the order were so promising that he was re-elected by acclamation by the annual convention, and has been at every convention since The order now comprises 470 lodges and 27,000 members, and has a reserve fund of something like $75,000 Mr Debs was elected to the Legislature of his State in 1884, and was tendered the nomination to the National Congress on a "sure-thing" basis, but refused it The intrigues of politics were distasteful to his open and above-board nature

In the eleven years of his guardianship the order has collected from its members, according to the last report of the board of trustees, the sum of $2,767,717 72 and paid out $2,704,935 99 Over $1,800,000 of this has gone out in death and disability claims. When we think of the good done by such a sum, the suffering it relieves, the burdens it makes lighter, we say at once that to be the custodian of such a fund is honor enough for one man.

In addition to his duties of secretary and treasurer of the order, Mr. Debs is editor of the *Magazine*, the official organ of the order and the best publication of its class.

Eugene V. Debs lives and preaches the doctrine of humanity, his motto is to do all the good he can on earth and leave the hereafter to the hereafter. He is an eloquent speaker, because he speaks from the heart. He never offers advice to his readers or his hearers that he does not believe is for their interests He never says to the men in his order "go," but always "come." Can it be wondered that such a man in such a place would make a name and a reputation, and be known far and near as a friend and a brother?—Eds ]

In discussing the subject suggested by the caption of this article, I am required, at the very outset, to say that the term "education" conveys an idea that some other word in our vocabulary might better express.

The term education involves the idea of thorough training in schools We say a "common-school education," an "academic education," a "college" or a "university education," and a "liberal education."

Necessarily, in discussing the education of locomotive engine-men, I do not propose referring to the so-called "higher education."

I shall have little to say about academic and university curriculums—nevertheless, the more book-education an engine-man may have, if it is familiarity with a certain class of books, the more certain he will be to advance in his calling; to use a phrase, "to get on top."

Primarily, a locomotive engine-man should have a thorough common school education. He should be a passable reader, he should understand orthography, and be exempt from too frequent "bad spells", he should know enough of English grammar to write the language approximately correct He should understand arithmetic, and if he is commendably ambitious, he will master such studies; indeed, if he is aspiring, eager for superiority and distinction, he will do more than I have suggested. He will learn—and "learning," that is "to learn" to get a thorough knowledge of one's business, acquire skill in one's vocation, more accurately expresses my idea than the term "education."

We say "learn a trade," and "study a profession" We say "master mechanic," "master builder", why not use the term "master fireman"? It would involve far more than knowing how to break coal and shovel it in a fire-box It would mean, that the "master fireman" had husbanded his resources and utilized his opportunities in *learning* everything pertaining to his chosen calling It would mean that his leisure hours had been devoted to study, to investigation of reasons why, and it would mean that the master mechanic had set his seal of approval upon his habits of study and sifting research, and had marked him for promotion.

I am not inclined to indulge in impracticable demands upon engine-men, in the matter of education or learning, my own experience teaches me the propriety of modesty in this regard I am not disposed to be speculative, or to offer any fanciful theory of education for engine-men I advocate only the feasible, the attainable, for the men of the present and of the future who are to have charge of locomotive engines

As a general proposition, the men who start in to fire locomotives are not proficient in common school studies, they are lacking in reading, writing and arithmetic. In saying this I do not mean to assume that the young men are entirely responsible for their deficiencies Their opportunities may have been limited, their surroundings unfavorable, the necessities of their situation such that their ambition was not excited, their associations may not have been of a character to awaken anxieties for knowledge, their mental development did not keep pace with their physical growth, and when forced to enter the army of workers, their educational equipment was defective I do not, therefore, hold them entirely responsible for their inadequate attainments. They are lusty fellows, generous hearted, strong of body and will, and thousands of them ambitious to advance in their chosen calling Here the question arises, What will specially contribute to their success?

The great organizations of locomotive engine-men insist upon good moral character as a prerequisite, soundness of body and mind, fidelity to obligation, honorable dealing with associates and with all men. Dead-beatism is not tolerated. In a word, the ethical requirements in such matters are strictly and unbendingly orthodox, and any member of the organizations mentioned who violates the constitutions and the laws designed to keep the orders morally healthy and upright, is summarily "fired." I am, therefore, relieved, even if I were so inclined, of any necessity for forcing upon the readers of Locomotive Engineering any views touching upon moral questions, the engine-men themselves having grasped and solved such problems.

Locomotive engine-men are to be required at an early day to undergo examinations that will put to the test their rudimentol, their elementary, education—they will be required to read, write and cipher; succinctly stated, be fair, common school scholars. The verdict has been rendered that illiteracy on the part of locomotive engine-men will not longer be tolerated, and it will only aggravate the situation to appeal from it, or to "strike" against it. The reason for this is based upon facts that are conclusive

The educational facilities which surround every young engine-man are such that a reasonable excuse for ignorance cannot be urged. If he is deficient in elementary education, it is proof positive that he is supine, inert, unambitious, and therefore totally disqualified for promotion. He who does not see this is blind, he who does not hear the ringing demand for superior educational equipment in the department of locomotive engineering is deaf

The question arises, are the obstacles in the way of reasonable educational equipment insuperable? If such an excuse were presented, the engine-man would at once be required to state the character of the obstruction Such a request would only increase his embarrassment, and his silence would serve to emphasize his confusion. And this would result from the fact that, if he had the will, a thousand avenues are open to him for improvement Text-books are cheap. A week's wages would supply him with a choice library of elementary works I make no reference to "learned blacksmiths" and others who, "self-taught," have achieved fame, claiming only that locomotive engine-men who are willing to be awakened to the reasonable demands which their calling imposes can, if they will, fully equip themselves for the most exacting investigation, and stand up and stand forth, ready for the most responsible positions of their calling, and worthy of confidence and promotion.

In numerous instances, locomotive engine-men have been required, *in writing*, to answer certain questions submitted to them, relating to their vocation. This they decline doing, chiefly, because of a deficient education whereby they were disqualified for the task Orally, they were equal to the requirement, but being deficient in elementary education, they dared not trust themselves when it came to putting their knowledge on paper.

It is not to be denied that in a vast majority of instances, these men were qualified engine-men; they understood the machine, signals, etc., to the end of the chapter, and yet, they were less than their calling required, and for the deficiency, the excuse, had it been honestly stated, would have been anything but agreeable to them and their friends.

In these regards there is to be a new departure. Its initial steps have been taken. The locomotive engine-man has become, by universal admission, one of the important factors in the railroad enterprises of the country, than which not one is more conspicuous The eyes of the nation are fixed upon him with an earnestness that attaches to no other class of wage-workers. If, therefore, he is to respond to reasonable expectations, he must be educationally equipped and since such preparation is within his reach, excuses will not be tolerated

I do not entertain a doubt regarding the future of locomotive engine-men. They have all the brains required, they have courage, will-power, tenacity of purpose; their only deficiency being that mental discipline which qualifies men for patient investigation and takes them far beyond mere routine drill. Manifestly, a new era has dawned—old practices are passing away—new demands are made to which I am confident, locomotive engine-men will respond with alacrity.

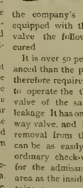
The locomotive firemen of the present are to become the locomotive engineers of the future. Is that goal, when reached, to be regarded as the limit, the *ultima thule* of their ambition? Are there not other positions in the railway service to which they may rightfully aspire? I think there are. Why may not locomotive engine-men become the master mechanics or superintendents of motive power? Indeed, why may they not become superintendents, and finally climb to the top round of the ladder? In replying to such questions my investigations fail to discover any reason why the answers should be discouraging, aside from the fact that the great body of engine-men are not educationally prepared for such positions; and I am persuaded that it is within their power to largely overcome such barrier, and advance, step by step, to the highest positions.

Fortunately, men are so constituted that once the mind begins to expand, the horizon that bounds its vision recedes. The thirst for knowledge increases. Every faculty is brought into play. The intellect triumphs over the animal, and as thoughts multiply, aspirations become more exacting and demand a wider and higher range.

This being universally true, it becomes not a fancy, but a fact in my mind that with a proper appreciation of study, of investigation, of familiarity with books, with the elements of science, the future of the locomotive engine-men of America, is one of far reaching possibilities and gratifying triumphs.

Eugene V. Debs

## Pendry Throttle-Valve for Locomotives.



The annexed illustration shows the Pendry throttle-valve, as used on the Baldwin and Hinkley locomotives, on the Chicago & Grand Trunk Railway system, where these valves have been applied and used for four years and over, under the severest tests, with such results that about 300 of the company's locomotives have been equipped with them By the use of this valve the following advantages are secured

It is over 50 per cent more nearly balanced than the present throttle-valve, and therefore requires less than half the power to operate the throttle than the ordinary valve of the same size. No liability to leakage It has only one seat It is a straight-way valve, and is easily repaired without removal from the dome. The valve-seat can be as easily ground as the seat of an ordinary check-valve The only opening for the admission of steam is of the same area as the inside of the dry-pipe It contains no more parts than the ordinary throttle-valve, and the cost of maintenance is decidedly less. Many of these valves have run years without leaks.

This valve is made by the Detroit Lubricator Co., Detroit, Mich.

The Chicago & West Michigan are receiving six eight-wheeled, 17x24, engines, having 61-inch wheels, weighing 90,000 pounds and carrying 160 pounds of steam, and two ponies, 16x22, all of the Rhode Island build.

## How to Prevent Leaky Flues.

At a recent meeting of the New York Railroad Club, Mr. F. A. Stinnard read a paper on the above subject. The leading causes of leaky flues he held to be, inferior material, poor workmanship in repairing and setting, bad water and want of proper care

The metal for flues, he said, should be

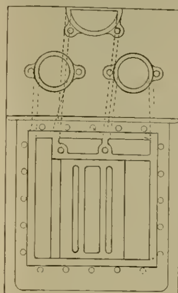


Fig. 2.

homogeneous, devoid of phosphorus or any other substance which would tend to make it brittle. Considered it should be ductile enough to bear expanding without fracture, but still not too ductile.

To prepare the flue for setting, the end should be annealed and reduced in a die, so that it would fit the opening when surrounded with a copper thimble of No. 18, W. G. In setting, he preferred to bead the flue at both ends. Thought that while being beaded, a flue should be held rigidly so that the blow struck will be transmitted horizontally. To meet this requirement, he used plugs or mandrels that are slightly tapered, these are driven into ends of the flue and the ends beaded around them.

He was opposed to the use of the heel-tool. The paper continued: Bad water, that has more or less lime, alkali, salt, or other sediment in it, that may be deposited and incrustate itself upon the surface, is to a great extent the cause of leaky flues. It is a well known fact that the largest amount of incrustotion is developed on the lower flues, while the upper ones will be comparatively clean and free from it, and what is the result? Unequal expansion, the

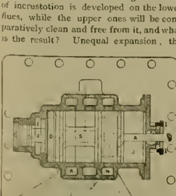

Fig. 3.

flues become what is commonly called mud burnt, the ends will chip or break off, and the flue becomes loose in the sheet. This trouble can to a great extent be obviated by washing the boiler out thoroughly and as often as necessary in order to prevent incrustation with all its attendant evils, for it is an old and true saying that an ounce of prevention is worth a pound of cure. When flues are covered with incrustation and commence to leak, you endeavor to stop them by expanding, rolling, calking, and ten chances to one you will have to repeat the operation before the engine has made two trips over the road. The only remedy for flues in that condition, is to take them out, clean them and reset them.

A reprehensible practice, and one that should be curtailed as much as possible, is running with the furnace door open and allowing cold air to pass through the flues, which, accelerated by the action of the exhaust, will very soon cause them to leak. The furnace door was not made or ever intended to be used as a damper. Engineers should avoid as much as possible pumping water into the boiler when not using steam, in fact, they should guard against anything that would have a tendency to cool off the flues suddenly, thereby causing a sudden contraction of the metal while under pressure, which if repeated a few times will very soon loosen them in the flue-sheet.

The engineer should see that the flues do not get stopped up with ashes and dirt, when 40 or 50 flues get choked up, the process of boring them out is liable to start them leaking. When flues are in this condition, the fireman has to work a great deal harder to keep up steam, and the harder he has to work the more fuel he wastes.

## New Design of Two-Cylinder Compound.

There is now building at the Pittsburgh Locomotive Works a two-cylinder compound locomotive of novel construction, the design of Henry F. Colvin, of Philadelphia.

As will be seen by the detail engravings shown herewith, the cylinders are very plain and simple, there being only one extra core, and that a very short one in the high-pressure saddle. The intercepting-valve and reducing-valve are simple pistons and located in the high-pressure steam-chest cover.

This is certainly the simplest form of compound yet devised and could probably be built cheaper than any of them. It must certainly be some advantage to have the valves away from the heat and separate from the saddles.

This intercepting-valve is not automatic, but is at all times under the control of the engineer, who can start his train and work it as long as he cares to with a plain or single expansion engine. When he gets it into motion he can compound by moving a simple lever instead of hooking his lever up. He can change his engine at will

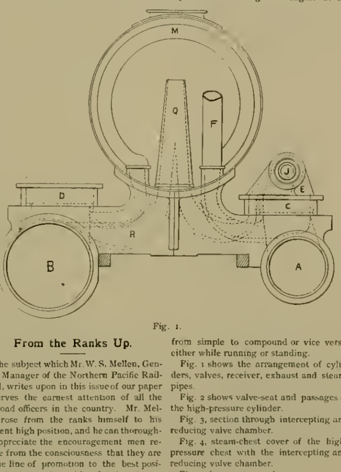

Fig. 1.

from simple to compound or vice versa either while running or standing.

Fig. 1 shows the arrangement of cylinders, valves, receiver, exhaust and steam-pipes.

Fig. 2 shows valve-seat and passages of the high-pressure cylinder.

Fig. 3, section through intercepting and reducing valve chamber.

Fig. 4, steam-chest cover of the high-pressure chest with the intercepting and reducing valve chamber.

Fig. 5, intercepting-valve.

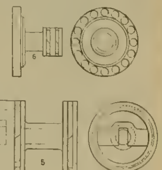
Fig. 6, reducing-valve.

In figure 1. A represents the high-pressure cylinder, B the low-pressure, C the high-pressure steam-chest, D the low-pressure steam-chest, E the intercepting and reducing valve chamber, F steam-pipe from boiler to the high-pressure steam-chest, J intercepting-valve, M receiver, and Q exhaust-pipe.

When the engine is to be run as a single-expansion engine the intercepting-valve is placed in position to allow the exhaust steam from the high-pressure cylinder in the chamber to pass into opening, N, Fig 3, to the exhaust-pipe, Q. While the intercepting-valve is in this position steam from the chest passes up to reducing-valve, raises it from its seat and flows into passage K, through receiver, M, to the low-pressure steam chest, where it is used in the usual manner, and is exhausted through pipe Q. The reducing valve regulates the pressure of steam so that the two cylinders will perform the same amount of work regardless of their different diameters. This valve is controlled from the steam-pipe side and will give the big cylinder the proper pressure to enable it to do the same work the smaller cylinder does with a higher pressure.

When working compound, the intercepting-valve is moved in position shown in Fig. 3. This shuts off the steam from the reducing-valve to passage K, also the exhaust from passage N and opens it to passage K, where it goes through the receiver M to the low-pressure steam-chest, where it is used the same as steam from the reducing-valve when working as a single expansion engine.

In this arrangement there are no valves to keep up, that depend on being ground to seats, when the intercepting-valve is moved to the compound position, it is held by the pressure and it in turn holds the reducing-valve to its bearing.



Figs. 5 and 6.

The valve motion, etc, are not disturbed and the arrangement of the engine is, excepting the cylinders, just the same as at present.

We believe that the principal advantage of this system will be found in the fact, that the man in charge can use his engine simple or compound, just as he wants to

Mr Colvin is a present general manager of the Rue Manufacturing Co, makers of injectors, etc., but he put in half a life-time running locomotives and in the service of the Rhode Island Locomotive Works.

## From the Ranks Up.

The subject which Mr. W. S. Mellen, General Manager of the Northern Pacific Railroad, writes upon in this issue of our paper deserves the earnest attention of all the railroad officers in the country. Mr. Mellen rose from the ranks himself to his present high position, and he can thoroughly appreciate the encouragement men receive from the consciousness that they are in the line of promotion to the best positions in the service, with a fighting chance for getting there. When a railroad company shows by practice that its own men will be advanced to the higher positions, there is always a good loyal feeling among those employed. On the roads where no men are considered worthy of being promoted, there we invariably find discontent, lack of heart and lack of discipline rampant. By all means let us have civil service rule and spirit in the railroad service.

The delays of the law, especially in the deciding of patent cases, are proverbial, but the process is somewhat like the mill of the gods, which grinds slowly but gets there with grim certainty in time. A suit of interest to many power users, has just been decided in the United States Circuit Court at New York, relating to the hot air engine, invented by Captain Ericsson. Robert Deeley & Co., were sued for infringing the patents, and the case dragged very slowly, but it has been finally decided against the infringers.

A practice has been introduced on the Chicago & West Michigan by Mr. W. S. Morris, superintendent of motive power, that is said to be working well in securing desirable men for the position of firemen Every applicant for this position has to file a certificate of eighth grade scholarship, signed by the superintendent of schools. Without this his name cannot be entered on the list. This is not a test of scholarship which any American ought to object to, yet it will insure the hiring of men who have education enough to learn without

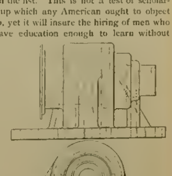


Fig. 4.

difficulty the rules and principles of their business that every engineer and fireman ought to know.

Band saws are now used in some English machine shops for cutting rough forgings to approximate shape They are said to be used very successfully in locomotive building shops. Our machine men have found the milling machine superior to the saw for all classes of iron work, but we do not think that band saws have been tried.

### Alex. Cunningham on His Own Break-Down.

*Editors*

It is again necessary for me to call the brothers to order. I stated in the November ENGINEER the particulars of the only piston I ever had to break. It was when I was pulling out of Rives station, thirty miles from Columbus. Mr. Custis, general superintendent, and Mr. Miller, division superintendent, were on the train, Sam Smith was the conductor. They came out to the engine while I was disconnecting. Mr. Custis asked me what was the matter. I told him that something broke in the left cylinder. He asked me what I was going to do, and I told him I was putting her on one side, which I did in fifteen minutes, went on and made up my lost time. The next morning I took off the cylinder-head, took follower-wrench and piston-head turned in cylinder. I pulled out the piston-head and found the piston broke off close up to the piston-head. There was no machinist working at Columbus then; they did not even have a shop there. They built a small roundhouse soon after and the old man McGinnis, who washed boilers, and two or three wipers were all the men employed there up to 1876. I was running engine No. 71—14x22 cylinder and 5-foot wheel. There was no counter-bore in the cylinder sufficient to fasten the packing. The switch engine pushed me up the hill that night with a train of five cars and I went to Jackson on time. I put her away in the roundhouse and reported on the book a new piston-rod for the left side, and that is all there was about it.

"Engineer" is right about the master mechanic and foreman at Jackson, but they do not know any more about this circumstance than what I have told them. Will "Engineer" at Jackson please sign his name next time he uses mine so very conspicuously, so I cannot see where the puzzle comes in?

If you wish, I will at some future time give you the details of a certain accident which happened to me while I was running the same engine that no one will believe, except two or three that were on the train at the time. I can prove part of it, and the other part I will swear to.

ALEX. CUNNINGHAM.

*Pine Bluff, Ark.*

[Send along your break-down story, Alex., all the boys will be glad to see it.]

### Let the Electric Locomotive Come.

*Editors*

In the *Engineers' Journal* for November there is an article giving an account of an interview with the Wizard of Menlo Park, relative to the substitution of the electric motor for the steam locomotive. The writer intimates that the change would not be popular with the B. L. E. Now if not, why would it not be?

Suppose for instance that every road in the country begin at once and effect the change mentioned. Who is going to manage the motor that has from thirty to fifty heavy loads behind it? Not the street-car motor man, with his experience in stopping and starting electric cars. Not the electrician who thoroughly understands the machine and is familiar with the method of producing and controlling the subtle force that drives it.

Does any one mean to say that a man without railroad experience is to be entrusted with its charge? The train drawn by electricity will have to be handled by a man who "knows how," who is familiar with the grades, crossings, yards, etc. No more trains than are needed will be run, and the man who pilots the electric train of the future, stops it at meeting points, keeps the couplings intact, keeps the head end away from the hind end when it breaks in two, guides it safely over our crowded tracks through rain, fog or snow, must not be color blind—or whisky blind either.

He must be just as good a man as the engineer of to-day—as well informed on train rules, orders, etc., prompt to act. As a writer in the same magazine says of the man who pulls the flyer, he must have "sand." The B. L. E. has nothing to fear from this change, if it ever comes.

If there is to be but one man to "act as pilot and watch the brake," he will of necessity be a good one. The speed will be much greater, and the need for good men as great as it is now. Does anyone imagine the pay will be less? I don't.

They tell us now that it requires a cool head and quick nerve to be a good air-brake man. Won't it then?

So boys don't worry about this and don't oppose progress. Tom Edison can't beat us out of our jobs.

We hear a good deal about progress nowadays, and some people who throw coal seem to think they have a monopoly of it, and that a gray headed old fellow of fifty isn't in it with them at all. We want the electric engine and we want it bad. There will be no headlight to light on windy nights, no injector to freeze up or give out when the mercury goes out of sight, no poor steamers to swear at, no clouds of steam enveloping the engine and cutting off our view of switch and other signals, no coal to make us dirty or delay us in taking it on, no water to take or make close runs for.

We can be comfortably and completely housed in a well lighted pilot house, and the companies will save so much by the change, that no doubt they will raise our pay of their own free will. All that hinders some of them from doing it now, is that they can't afford it.

Now please, Mr. Edison, get a hustle on you, don't be backward on my account in producing this machine.

A MAN FROM PEORIA.

*Green Bay, Wis.*

### What Ailed this Old Roger?

*Editors:*

Seeing the puzzle about Alex. Cunningham's engine, brings to mind an experience of the "fifties," when I was firing a Roger engine, a wood burner on a mountain run, with the grades varying from 75 to 86 feet to the mile, and from 17 to 20 miles long.

One winter afternoon when nearing the top of the mountain, the engine began to get "lame" and in a short distance she was so bad I could only hear two good exhausts, and two others that did not amount to much in the exhaust line.

I said to my old man, "Bill, an eccentric has slipped," and he said to me, "Don't you know what the matter is?"

"Yes, it is the valve out on your side."

With that he laughed at me, which always did make me feel good, and then he said "I thought you was better posted on engines than that."

When the door was opened to put in wood, I would listen and try to solve the mystery, but could not seem to locate the trouble.

The engine began to fail for steam, and after a long struggle we managed to get to a wood-pile and took on a full tank of it, then we waited for the engine to get hot, and while the brakemen were putting on the wood I went under the engine.

I took a lantern and examined the eccentrics and found them all right (they were not keyed on), so that theory was knocked out.

The old man sat on the seat and waited for me to report, and when I did so he had the laugh on me, and he said "Now are you satisfied about that?"

I gave it up and asked him to tell me what the trouble was. He said it was the packing on his side, that had gone down (it was brass ring packing set out with springs). "You ought to have known that, much yourself," he said.

But I did not, and it seemed to me that if it was the packing, there would be a *blow* that I could hear, but he was so well satisfied that he did not take the trouble to get off of his seat and listen at the fire-box door.

He reported "packing on the right side" and was happy.

When I got to the roundhouse the next morning I found the packing had not been looked at, so I took off the cylinder head, and by that time the old man had arrived.

He held the follower wrench while I unscrewed the bolts, and when the follower head came off, he looked at the rings and they were O. K.

Then I felt *good*, and if I had not been overbashful, should have said something to him about knowing all about it, etc.

After he had satisfied himself that the rings were all right, he looked up at me and asked if I was sure the eccentrics were all right. The expression on his face paid me well for all that he had said to me the night before, about not knowing what the trouble was. I said to him, that I *thought* they were right but he had better see for himself, so he did, and found them all right.

When he came out from under the old mill the imprint of agony was still visible on his once genial face. While he was still under the engine, a ray of inspiration glanced my way, so it was very easy then for me to tell him what the trouble was. My bashfulness having departed for the moment, I spoke up real loud, so some of the others could hear, saying, that "the nozzle had come out of the right hand exhaust pipe." "That's so," said he, "we both ought to have thought of that before, ought to have known that much."

We opened the smoke-box door and reached up (this engine had high exhaust pipes that were very near the bottom of the stack), and felt for the lost nozzle and found it in good shape, just as it should be.

You ought to have seen his face at that time, there never has nor probably ever will be another like it.

Now I would like to have some of your readers tell what the trouble was with this old Roger engine. EX.-FIRE BOY.

*Genesee, N. Y.*

### Leaking Off of Brakes—The Tricks of the Emergency Check Valve—A Kink.

*Editors:*

I see in your December number that one of our air-brake friends advocated letting all the air out of the train-pipe in testing brakes. As this paper is read extensively on this road, and as this practice is contrary to my instructions, I take this opportunity to protest against it and give the following reasons.

Three times in the past month I have found triple valves that would not work in service stop after train was fully charged until over 20 pounds had been exhausted, and in consequence the slide valve No. 3 (Plate D, 22, Westinghouse catalogue) was pulled past the graduating ports and the air went straight across over the top of the slide-valve and not through the graduating port No. 7. On taking them down, they were found to be dirty, and when cleaned there was no more trouble with them.

My instructions to all concerned in testing brakes, where time permits, is to make a five-pound reduction and see if all pistons travel past the leakage grooves; then, upon a twenty-pound reduction, they must not travel over eight inches, unless the brake is stiff and wheels are in danger of sliding. I think there is less time lost by charging the train fully before starting.

Another point that seems to be greatly neglected in regard to this matter is the danger of brakes leaking off through check valve No. 15, when more than twenty pounds of air is used, or when train breaks in two. On this road all quick action triple valves have a drain-cock in place of plug No. 26, and by cutting out the valve and opening the cock the brake will fly on, then, if cock is left open a short time, the brake will leak off, unless the check-valve is tight, and to those who have not tried it, it is astonishing to see how many leak. I believe the brass is too light and will spring. We use an old, broken bit drawn to a square point, with edges sharp; put this in a brace, and they can be readily ground in.

I have often noticed, in going down the mountain, that the brakes will hold well until the engineer used about twenty-five pounds of air, when the brakes would seem to ease off and train would increase speed, but it was a long time before I found that it was the air leaking back through the check-valve into the train-pipe, and I think this accounts for trains that break in two, and for their not standing at times or leaking off in dangerous places.

GEO. HOLMES,

Air Brake Inspector, N. & W. Ry.

*Roanoke, Va.*

### Why Quick Action Takes Place with Service Application.

*Editors*,

Speaking of "Black Hills" three-car train on a mountain road, I should locate the trouble with the brake on the sleeper. The slide-valve of the quick acting triple-valve, contains a small conical-valve, called "graduating-valve," which is seated in a cavity in the valve. This conical-valve is connected to the slide-valve stem by a pin; this pin broke off and the air held the conical-valve to its seat, so that in making a service application, this valve did not unseat and let the air go into the cylinder gradually, as it would have done had not the pin been broken. The reduction of 8 pounds from train-pipe left about 60 pounds more pressure on top of piston-valve, than under it—8 pounds to the square inch, so the excess pressure overcame the graduating spring and allowed the valve to travel its full stroke, uncovering the port to quick action-valve, which was brought into action. WM. LANSING.

*Clinton, Iowa.*

### Air in the Foundry.

*Editors*

As the use of compressed air is becoming more general in railroad shops every day, would it not be a good idea to extend an air pipe out to the foundry and connect rubber hose to the same for each floor, thereby doing away with that relic of bygone ages, "the molder's bellows"? Now, do not for a moment think I entertain a particle of animosity, so far as the bellows is concerned. On the contrary, I consider it has earned a well-deserved rest, as well as

one of the molder's hands, in which he can hold his piece of looking-glass, and cast a bright, refulgent ray of light into the innermost depths of his mold, and observe the exact effect of his air, even when the valve is in the emergency position. The idea, so far, is so good that probably the writer should have patented it before sending it broadcast through the country through the columns of your paper. Some practical molder may say that a rubber hose and nozzle would be a fine thing to have laying around under his feet on the floor. Well, let us see what can be done about that. Do you play pool or billiards? No? Well, just get some young man who does to explain that rig for holding the chalk on a string so you can pull it down and walk around the table while chalking your cue, and it may be the means of suggesting a ready method of keeping the hose out of the way when not in use.

F. H. TREACY.

### Continued History of the "Fury."

*Editors:*

I am more than interested in the historical old engines. Your last number contained a sketch of the "Fury," built in Boston. Now, I think I can tell you something about her.

The Lake Shore, or rather the State Line Railroad (for the road was only built to the State line of Pennsylvania at first) then, in '62, I think, the name was changed to Buffalo & Erie. Well, we had on that road a "Fury" exactly like the one you have illustrated. She was inside-connected and independent cut-off, drop hook. She was No. 1 and had "Fury" in brass letters on the side of the cab. She ran there a number of years and was finally put in a stall in the roundhouse, next the sand-dryer.

When the Buffalo & Washington (as it was called then) was built to Emporium she went there and ran passenger for some time. She was No. 2 on that road, and I think Al. Vail ran her. Then, when the Buffalo & Jamestown was built, she ran there, and George Moore ran her on a gravel train. The last time I saw her she was in the B. & J. shop with her fire-box cut out, and Jim Hubbard, who was master mechanic, said she was good for some years yet—anyway, as long as they could get wood for her. That was in the winter of '81.

We had one a good deal like her on the Old Erie, and I believe from the same shop (old 99); maybe some of the old heads down there will remember her. Many a time she has run to Hornellsville in two hours and forty minutes with Jack Sawyer on the right-hand side and Jake Thompson feeding her with Blossburg, and how she used to kick herself away from a station! It used to be music in our ears. She was a broad-guage, so she is in the scrap now, I expect.

OLD WOOD-TOSSER.

*Chicago, Ill.*

### Possible Cause of "Black Hills" Brake Failure.

*Editors:*

The air-brake difficulty presented by "Black Hills" in the December issue would undoubtedly occur under certain circumstances already noted and referred to by correspondents of this paper, but if the case is original there must have been something frozen about the triple-valve under the sleeper. Not that a frozen triple valve is an ordinary occurrence on most roads, but if the pipe from triple body to auxiliary reservoir was nearly choked with ice and the graduating valve or port frozen shut, the brake would act in the way described by the correspondent from Deadwood. It would thus be impossible for the sleeper brake to apply until the triple piston had compressed the graduating spring which would be delayed by the slow accumulation of pressure above the piston owing to the interrupted flow of air from the auxiliary reservoir, the brake holding off until the valve had moved to the emergency point when she would go full on, quick action.

WILL W. WOOD.

*Terre Haute, Ind.*

### More Air-Brake Details.

*Editors:*

Thanking Mr. Paxton for his answer in the last number of your paper, I should like to ask further whether the strainer under discussion stands across the main train-pipe, and if so, at what point? or whether the one to which he has referred is the one where the triple-valve branch pipe is connected with the main pipe, for if the latter be the case I do not see how the conditions he describes are possible, as this perforated metal is of cylindrical shape and forming a continuation of the train-pipe should not offer any more resistance to the passage of waste in one direction than in the other.

The inside lining of the hose being loose and rolling up so as to plug the opening, sounds more like the correct explanation, and I was very glad to see it as I confess it revealed a new possibility to me in a case that I have given considerable thought.

Regarding the problem propounded by Mr Black Hills, I should say that in a number of similar cases which have come under my notice, I have found the small pin that unseats the feed-valve in the triple broken off, the result being that the reservoir pressure held it shut and prevented the escape of air to the cylinder until the slide-valve moved down far enough to bring the quick action into play; this, of course, by a reduction in the train-pipe, affecting the whole train.

PAUL SYNNESTVEDT,

Gen. Air-Brake Ins. C. & N. W. Ry.

*Chicago, Ill.*

### A Plea for Testing Brakes from the Rear of Train.

*Editors.*

I have been hunting for that strainer ever since Mr Paxton related his story or experience; I can't find it. Where is it located? Can somebody tell? The only strainer attached to the car that I can find is the one at the union where the pipe is connected with triple-valve, and a "plug" of waste in behind this strainer can't affect but this one car.

I see there is some kicking about the habit of opening rear cock by the train men to test brakes. Now suppose F. F. D.'s car, as stated on page 232, had been end about, and some careless trainman had neglected to cut the air in a car or two from engine after doing some switching, and some careless engineer had pulled out without testing brakes, and this train had been flagged to stop suddenly. The engineer finding he had no brakes to stop with would certainly call for them. The first thing the conductor or rear brakeman would most likely do, would be to open rear stop-cock of train-pipe. Now, if that car with that hose that stopped the air from passing through the train-pipe for F. F. D. had been the rear car, what would have been the result if the brakes had been tested from rear before starting? It would most likely have been found.

*Clinton, Iowa.* WM. LANSING.

### Two More Puzzles.

*Editors:*

As puzzles seem to attract attention from the readers of the LOCOMOTIVE ENGINEERING, here are two easy ones.

One of our engines broke a right forward eccentric strap-bolt letting the two parts of the strap spring apart and bending the other bolt bad. She was working hard and running fast at the time when the strap opened up, the forward cylinder-head on that side blew out breaking it in small pieces. The piston did not strike it, nor was anything else about the engine except the parts already mentioned, broken. What did it?

One of our engines when standing still with one gauge of water, showed water in bottom gauge, dry steam only at the middle gauge, and steam and some water at the top gauge. These gauges are the usual distance from the crown-sheet, and the top one would show a little water all the time if it was left open for a minute or for two minutes. This condition has puzzled all the different men who had run her for some months. What did it?

I bored the cock out clean and it then had a $\frac{1}{16}$ hole in it. It was almost stopped up with lime scale before, not over a $\frac{1}{32}$ hole at end in boiler.

C. B. CONGER.

Road Foreman of Engines, C. & W. M. Ry.

*Grand Rapids.*

### Three Good Things.

*Editors:*

In your last issue I noticed three things which I particularly desire to speak of; I refer to Mr. Headley's piston-rod fastening, the short article headed "Improvement in Cutting Tools," and the several notices of Leach's improved air sand feeding apparatus. The Gould & Eberhardt cutting tool has been in use here for the last six months, and has proved satisfactory in every respect: it is a very good tool. The piston-rod fastening is one that I have had in mind for a long time, and it appears to be a very desirable arrangement. The Leach sand-feeding apparatus has been in use on several of our engines for some time; it gives good satisfaction. I consider it to be the best and the only good sand-feeding device that we have ever had.

WM. A. FOSTER,

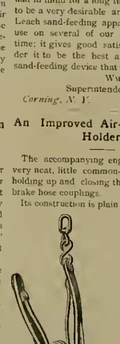
Superintendent, M. P. & M.

*Corning, N. Y.*

### An Improved Air-Brake Hose Holder.

The accompanying engraving shows a very neat, little common-sense device for holding up and closing the opening in air-brake hose couplings.

Its construction is plain from the engraving, the holding is done by the ring on one jaw of the holder that goes over the head of the threaded plug on the back of the coupling. The disk on the other jaw not only closes the opening in the head, but an annular recess covers and protects the rubber gasket. The swivel prevents cramping and putting a permanent kink in the hose.



The best thing about the device is that there is no possible way to hang the hose up wrong, no hook to hang the hinge-pin on. This valve is being introduced by the Beery Valve Co., 605 Phœnix Building, Chicago, Ill.

We have an armful of pencils of all kinds, sizes and colors, with the compliments of the Joseph Dixon Crucible Co., of Jersey City, the makers. We certainly ought to please all kinds of people with all kinds of sticks.

In front of the post-office in Chicago there stands a bronze bust of George Buchanan Armstrong, the founder of the railway mail service. This statue was raised by employés of the railway mail service. Mr Armstrong was born at Armah, Ireland, in 1822, and died at Chicago in 1871. Such men deserve monuments.

### A Locomotive Pioneer Gone.

Another of the pioneer inventors who put a permanent work upon the locomotive has passed away. By a letter from his son, we learn that Thomas R. Yarrow died at Arbroath, Scotland, on November 24, in the 74th year of his age. Mr. Yarrow is known to the engineering world as one of the first to work on the problem of burning bituminous coal without causing sufficient smoke to be a public nuisance.

He was a Scotchman by birth and learned the coppersmith trade. When he was an apprentice, the locomotive engine began to attract attention, and being an ambitious youth he concluded that railroad life would give him better opportunities than any other. He was one of the many workmen whom the democratic railway gave the means of rising above his natural condition. Before the railway era, the chains of custom bound the workman very firmly to the condition of his father. Yarrow worked in different shops after his apprenticeship was finished, and about 1840 went into a well-known locomotive building shop. From there he went to France with some engines. He liked that country and remained at work in Paris, and rose to be a foreman of a railway shop. The scenes of the revolution of 1848 convinced him that life was too cheap in Paris, so he returned to Scotland. He obtained a position as foreman of the Caledonian shops in Glasgow, and rose to be assistant locomotive superintendent. Then he was appointed locomotive superintendent of the Scottish North Eastern Railway, and on the engines of this line all his smoke-consuming inventions were applied.

Coke was the only fuel then burned in British locomotives, on account of the strict laws against smoke nuisance. Mr. Yarrow tried a variety of experiments with fire-boxes to burn coal without causing smoke. In 1857 he settled upon a brick arch with means of admitting air above the fire. This combination proved a success and no more coke was used on Scottish railways. Mr. Yarrow has long been out of railway service, but he kept remarkably well posted on all matters connected with railway machinery. Two years ago the writer, who learned his business under Mr Yarrow, visited the old gentleman and listened to many tales of other years, and of the men and methods that built locomotive engineering into success.

### Quite Home-Like.

We entertain decided views against monopolies of all kinds and it has pained us beyond measure to think that our great country has a monopoly of the practice of train robbing. While we were fretting over this injustice a few lines in the press dispatches brought great comfort. The dispatch went on to say that there has been an unprecedented number of train robberies in Russia in the past few months. The latest instance occurred on the railway line between Warsaw and Cracow, in Russian Poland. A gang of men stopped a goods train near Wlosy station, overpowered the train hands, loaded themselves with booty and made off. A detachment of soldiers were sent in pursuit of the robbers. The fleeing robbers, to escape capture, abandoned a part of their plunder which was carried back to Wlosy by the soldiers. The robbers then made good their escape.

This reads as familiar as if the dispatch had come from Wisconsin, even to the escape of the robbers. The only unfamiliar thing was the robbing of a freight train. Probably the robbery was for the purpose of securing something to eat.

The Brakeman's Brotherhood paid out in death claims $36,000 for the month of October.

The Baldwin Locomotives are putting in a new slotting machine made especially for them, which will slot eight frames at once.

# SHOEN MANUFACTURING COMPANY,

MANUFACTURERS OF

## Articles in Pressed Steel for Railways and Car Construction.

Made to Interchange with any Standard.

**Office & Works, PITTSBURGH, Pa.**

Western Office, 314 Phenix Building, Chicago.

**Pressed Steel Drawbar Attachment.**

Our Pressed Steel Drawbar Attachment commends itself to all for its simplicity and strength.

**Pressed Steel Stake Pockets.**

*For Gondola, Flat and Coal Cars.*

No change whatever is necessary in substituting steel pockets for cast iron, as we make them to interchange in bolt-hole centers and inside dimensions.

**Pressed Steel Corner Bands.**

*For Gondola and Box Cars.*

Our Pressed Steel Corner Bands, as shown in cut, are heavily embossed. The inside corner bands are ribbed the opposite way so that they may lay flat against the timber. Besides being very strong, they add materially to the appearance of the car. At about the same cost as common wrought iron bands.

**Pressed Steel Center Plates.**

Made to interchange with present standard.

By the use of our articles the weight of your car will be decreased from 800 to 1,200 lbs. The cost of repairs reduced to a minimum. All without material increase in cost of construction. We will be pleased to give full information and quote prices upon application.

A set for one fire box will convince you of their merits, safety and economy.

## Civil Service in Railroad Management.

BY WM. S. MELLEN.

To the employer but little need be said to illustrate the fact that the best service he receives is that which comes from willing hearts and hands, and these will not exist except where there is a higher aim than the results of unchanging routine labor There must be something ahead of the present routine work and its compensation—something to be won—to make the employé willing and efficient, and to produce the best results from his efforts.

On the part of the employé in any rank, there is no more discouraging situation than one which does not have for its beacon light the magic words, "Promotion and betterment of condition." The time is rapidly approaching, if the day has not already dawned, when the successfully operated railway will be the one which carries into its system of every day work, the most thorough system of civil service promotion for merit Men who have no incentive to work beyond the stipulated compensation for their grade very soon become inattentive and careless of the property entrusted to their charge, and the result is increased cost of operation and the general inefficiency of the service. On the other hand, the employe, however humble his position, who knows that meritorious work is sure to be rewarded by promotion to a more responsible position, with increased compensation, will give a better and more efficient service in every way.

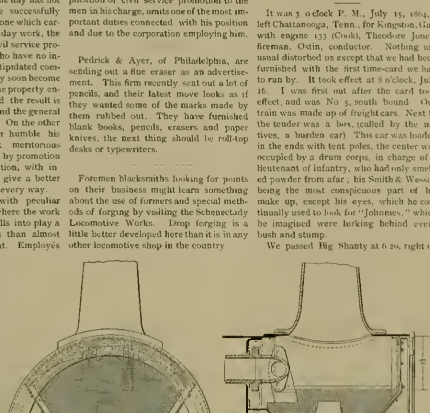
These principles apply with peculiar force to railway operation, where the work is so diversified that it calls into play a greater variety of qualities than almost any other line of employment. Employés should be promoted, whenever vacancies occur, on the basis of character, meritorious service, knowledge of the work in which they are engaged, and fitness for a higher grade of work; and when possessed of these requisities, they should always be recognized and promotion given according to age in the service in preference to the employment of new material. The lower positions should be filled with new material, which in its turn would have the same opportunities for advancement. This policy, carefully systematized and carried out by the great railways of this country, would have a tendency to make employés more permanent, and to largely if not wholly eradicate that undesirable element known as the tramp railroader. There is no large railway in the United States which has not in its various ranks employés who are capable of advancing to the topmost positions, and let it be understood that every position, however high, is available by the man who wins it by meritorious and efficient work, and the railway will receive better results from all ranks of employés. No official should be permitted to fill a vacancy through favoritism; the position when vacant belongs to the next man below in the line, who has capacity and character to fill it, and it should be given him without question. A prolific cause of complaint among railway employés in the past has been the fact that good men were ignored and good places filled without regard to promotion by merit. These conditions are rapidly changing, and I believe that the application of civil service rules, such as are now in effect on a number of railways, will in the future bring out many a light which has been heretofore hidden under a bushel, and result in great improvement. Every subordinate officer having direct charge of men, should consider it one of his first duties to thoroughly acquaint himself with them, and carefully select for promotion, from time to time, such men as are qualified for it by previous good work and length of service, and men who are not in sympathy with this principle are not fitted for official positions on any railway. The growth of our large systems makes it impracticable to a great extent for the higher officials of a railway to become personally acquainted with their employés, but it is their duty to see that in the lines of promotion no man is elevated to an important position, in charge of others, who has not the proper qualifications which will enable him properly to select for promotion the employés of his department. There is no barrier to prevent subordinate officials from becoming thoroughly acquainted with those directly under their supervision. The railway official who neglects the application of civil service promotion to the men in his charge, omits one of the most important duties connected with his position and due to the corporation employing him.

---

Pedrick & Ayer, of Philadelphia, are sending out a fine eraser as an advertisement. This firm recently sent out a lot of pencils, and their latest move looks as if they wanted some of the marks made by them rubbed out. They have furnished blank books, pencils, erasers and paper knives, the next thing should be roll-top desks or typewriters.

---

Foremen blacksmiths looking for points on their business might learn something about the use of formers and special methods of forging by visiting the Schenectady Locomotive Works. Drop forging is a little better developed here than it is in any other locomotive shop in the country



## Front-End Arrangements of N. Y. Elevated Locomotives.

The accompanying illustration shows the plan of arranging the netting in the smokebox of the Manhattan Elevated engines. As will be seen, the fronts are short, with a high, large nozzle. The arrangement of netting puts it into three flat pieces, the back sheet is a deflector.

The two side pieces cut without waste, and the front piece very nearly so. In the front sheet there is a light door to enable a man to reach the nozzle. It is evident that with this form of netting it will be a very easy matter to replace a worn-out sheet. The whole thing is accessible and presents a large area for the passage of the products of combustion.

---

Thirty thousand copies of this edition were printed and circulated. This is the largest edition ever issued by a railroad paper

### A War Time Wreck.

It was 3 o'clock P. M., July 15, 1864, I left Chattanooga, Tenn., for Kingston, Ga., with engine 133 (Cook), Theodore Jones, fireman, Ostin, conductor. Nothing unusual disturbed us except that we had been furnished with the first time-card we had to run by. It took effect at 8 o'clock, July 16. I was first out after the card took effect, and was No 5, south bound Our train was made up of freight cars. Next to the tender was a box, (called by the natives, a burden car) This car was loaded in the ends with tent poles, the center was occupied by a drum corps, in charge of a lieutenant of infantry, who had only smelled powder from afar; his Smith & Wesson being the most conspicuous part of his make up, except his eyes, which he continually used to look for "Johnnies," which he imagined were lurking behind every bush and stump.

We passed Big Shanty at 6 20, right on time. Captain "Wash," Ashmead quartermaster of the Army of the Tennessee—an old Bee Line conductor—was standing on the crossing, and I gave him the time as I passed

Just south of Big Shanty, near the foot of Kenesaw mountain, was a water tank and wood-shed, called by us "Buttermilk tank." Here we took water and wood and then started for Marietta I was a little uneasy for fear some mistake would occur, and we might have some trouble breaking in the new time-card, so I told the fireman to keep a good lookout for engines coming down the hill. After we had gone about a mile, Theodore jumped off his box and told me to lookout, there was an engine backing down the hill. My engine was just leaving a deep cut, around a sharp curve I reversed and called for brakes before I looked out. My reversing and calling for brakes frightened the crew, who hit the "grit" and took the track back to the tank, but the train guard of soldiers set the brakes and stopped the train. At this time I saw a commissary train, engine 37, (Mason) Spence Smith, engineer, backing toward us at about twenty miles per hour, I knew a wreck was inevitable, and remembered the car next to the tender, with the tent poles and drum corps The 133 was pawing away, trying to back up and I was trying to get the soldiers to get out My lieutenant was sitting in the door with his legs hanging out, and paid no attention to my shouting to him, so I run to him and caught him by the leg and told him to jump He did, he got on his feet right quick, and got his "pop" and commenced blazing away at me I ran a few steps up the side of the cut and threw up my hands, to show him I was not armed After two or three shots, the shock of the collision came, and my brave boy was trying to stand on his head between my feet, and I got his gun as quick as possible. By this time every thing was over, the 37, which was backing up, had set her tank on top of the 133, the car of tent poles was on top of 133's tank The boys of the drum corps assisted me to get the poles away from the fire-door and put the fire out I found my fireman down the bank with a sprained knee, and Spence Smith, of engine 37, sprained his ankle.

Now comes the laughable part. The car next the box was an L. & N. stock car, loaded with naptha, in small kegs, to be used for the purpose of quickly igniting bridges or buildings which the policy of war saw fit to destroy. In this car was an army surgeon returning from a leave of absence, and a news boy I must tell you that by order of General Sherman, no soldier was allowed to ride on the engines or in the cabooses. The boy, who had about a half car load of papers, got out and followed the crew, but the surgeon got stuck in the door, and when the crash came, the car bowed up in the middle and completely wedged him in.

Now understand that nearly every persons' first thoughts in these times was of guerrillas. Our surgeon was one of them, and he put up some very pitiful petitions for help, told us all about his sick wife in the North, and what he would give us if we would come and release him before the rebs came and got him. This was all going on while we were saving the engine. It took an ax and several minutes work to release the door's captive without injuring him When Ostin and the crew came up on the wreck train, and were laughed at for deserting us, they said they only went back to flag U S engine 133 is in passenger service on the W & A. at the present time, and is named "U S Grant," and numbered 18

JAS. H. HEVEY

*Rome, Ga.*

---

Locomotive cabs so ingeniously arranged that the reverse lever takes the driver's hand against a steam pipe when it goes into the corner, that have the gauges so far back that he can't see them without trying, the brake-valve behind him; the cylinder cock rig so flimsy that only three cocks open, and a shower bath attachment to the injector overflow, go a good way toward making a class of engines popular (?) with the men.

## Changing Rules About Cars.

The Master Car Builders' Association every year in convention assembled, take up the rules relating to the interchange of cars and amend them. Disputing about these rules gives an excellent opportunity for the display of oratory, and amendments must be made if they confuse all the car inspectors in the country and require railroad companies to hire extra help to do the letter writing called for in settling disputes. It used to be the case that when a car was away from its own road, the company pulling it, put in new brake-shoes or journal bearings if either were needed, and treated the case about the same as they did their own cars. This was too simple and easy a way of doing business for some of the members of the M. C. B. Association. The practice worked very well, for if one road put on brake-shoes and brasses to cars belonging to other roads, the other roads were doing the same thing to its cars. Justice was fairly balanced all around.

At last convention this practice was "amended" by the requiring of every road to be responsible for the brake-shoes and bearings of its own cars when they were away from home. The way the new rule works is that the conductors of all freight trains should make a report of all brasses put into foreign cars, and the car inspectors must do the same thing about brake-shoes and brasses. The change of rule has introduced picturesque variety into practice about brake-shoes and bearings. Some conductors report the number of brasses applied to foreign cars, others forget all about it. Still others charge all the brasses put in during a trip to foreign cars. Car inspectors report the new brasses and brake-shoes as nearly correct as their numerous duties will permit, and by the end of each month a big volume of claims goes into the offices of every railroad company for shoes and brasses. Some of the companies charge only the cost of the articles put in and others put in bills for labor based on a scale that would make the pay of brakemen and of car inspectors equal that of the president. Then the fun begins. But it gives employment to clerks and typewriters and the attention of the railroad world is directed to the important changes made in the rules of interchange of cars by the master car builders at last convention.

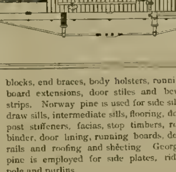
The London & Northwestern Railroad will exhibit a section of track and some of the crack equipment of England, at the World's Fair, at Chicago.

## New York Central Standard Box Car.

The annexed engraving illustrates the latest form of box car used by the New York Central Railroad, having a capacity of 60,000 pounds. The car is very carefully designed, and is well adapted for the severe service to which freight cars are now subjected in the heavy trains becoming so common. The car is 35 feet long, outside of sills, and 34 feet 4½ inches inside of the lining. The width over sills is 8 feet 6 inches and inside the lining 8 feet. The height from bottom of sill to top of plate is 8 feet 1 inch, and the inside height is 7 feet 3¼ inches. The best of material is used in the construction of these cars, secured in the manner best calculated to secure strength and durability.

The following parts are of white oak the carlins, side braces, side posts, end sills, corner posts, draw sticks, stop blocks, needle beams, end plates, door posts, end posts, ladder posts, side cripple studdings, belt rails, roof saddles, door stops, dead blocks, end braces, body holsters, running board extensions, door stiles and bevel strips. Norway pine is used for side sills, draw sills, intermediate sills, flooring, door post stiffeners, facias, stop timbers, roof binder, door lining, running boards, door rails and roofing and sheeting. Georgia pine is employed for side plates, ridge pole and purlins.

The cars are equipped with the Westinghouse air-brake, steel brake-beams and vertical plane couplers.



The most novel feature of the car illustrated, however, is the trucks, which are of the Fox solid pressed steel pattern, fifty of these cars being thus equipped. We give a separate engraving of this truck, that its design may be properly understood by our readers. As the name implies, this truck is made of pressed steel formed under powerful dies. The form of the truck can be readily understood from an inspection of the engraving. It is made to take the Master Car Builders' large journal

## Master Car Builders' Standards.

BY A. M. WAITT.

Of all the beneficial results of the work of the Master Car Builders' Association, probably none has done so much for the operation of railroads as the adoption of the M. C. B standard axle for 40,000-pound cars. Up to the time of the adoption of this standard nearly every road in the country had two or more standards of its own, each one differing in some of its important dimensions from those of neighboring roads. As a result of this great diversity it was oftentimes necessary for large roads to maintain a stock of wheels and axles, whose varieties were legion.

Although at the time of the adoption of this early standard there were many, doubtless, who were incredulous as to the practicability of its adoption, yet it must now be conceded by all as resulting in the saving of many thousands of dollars, even to the roads who were for many years too narrow-minded and short-sighted to adopt it for themselves.

The conditions of railroad service are to-day quite different from what they were twenty years ago. Then the movements of cars were largely local, where now cars may frequently traverse the whole continent. With such a condition of things it becomes a question of vital importance to consider how the cars of various companies shall be maintained when far from the home road. With ordinary service, breakages will constantly occur, and with the tremendous rush of American life (especially railroad life) it becomes an important matter to have necessary repairs made with the greatest dispatch. Dispatch in repairs cannot be obtained if, in making repairs, it becomes always necessary to keep a loaded car waiting until a certain part needed to fit the particular car is manufactured in the foundry, forge shop, machine shop or mill.

Such absence of dispatch must always follow a lack of uniformity in parts liable to frequent renewals or repairs, and so the highest interests of all railroads must be best subserved by having absolute uniformity in details of the principal cars of all roads. This result can only be arrived at by the careful adoption of standards, *and putting them into use after they are adopted*. When will railroads have the general good enough at heart to do away with the "penny-wise-and-pound-foolish" policy of persisting in the use, in new equipment and repairs, of old styles of detail in car construction, when uniform standards have been agreed upon? It is surprising and lamentable that one or two very large and prominent roads continually persist in ignoring the general standards in their own equipment, though these standards have the hearty approval of the best railroad mechanical experts in the country. Alas for the perversity of some few minds who can never see anything good or worthy of copying outside of their own horizon! It is astonishing to find the lack of attention paid to important standards by some of the members of the M. C. B. Association, who come yearly to the conventions. It is surprising to find the amount of ignorance displayed by many members of the M. C. B. Association as to what the standards are which have been adopted.

Within two years the writer knows of one very prominent railroad with over 15,000 cars, and which has been looked to as a leader in car department matters, which had not at that time adopted the U. S. standard screw-threads in its car department, which standard was adopted by the M. C. B. Association in 1872. On this road the nuts tapped at one shop could not be turned upon the bolts cut at another shop. On the same road were two distinct and separate patterns of M. C. B. journal-bearings, which were not interchangeable. I could name at least five companies whose car department heads are among the most prominent in the M. C. B. Association and at the various railroad clubs, who are not using the present standard M. C. B. oil-box or pedestal, and who have, unless recently changed, a journal-bearing key that varies considerably from the standard dimensions. These are serious matters, and are what are doing, and have done, far too much in bringing disrepute upon the standards adopted by the M. C. B. Association.

If I should touch on the subject of draft-rigging, *i. e.*, sizes of spindles or spring-pockets, followers and springs, I am sorry to say that even more diversity exists among roads who can have no good reason in refusing to substitute the recognized standard dimensions for the "good old ways" in which their predecessors traveled.

The M. C. B. Association has adopted, wisely, many standards whose general use in new work would greatly facilitate repairs and gradually bring about that uniformity and reduction of stock to be carried, which is greatly needed, with the crowded condition of so many of our shop-yards.

Three important questions arise in connection with the subject:

1st. How shall we bring about the more universal adoption of the standards that have been adopted?

2d. How shall we get absolute uniformity in the adopted standards, as manufactured by different companies?

3d. What additional standard parts is it essential and advisable to agree upon and adopt.

First. To bring about the further adoption of the standards that have been adopted, I believe the proper committee of the M. C. B. Association, should issue a circular of inquiry to all the roads represented in the association, taking up the standards one by one, and asking if the roads have adopted and are using such standards: First, On all new equipment, if not, to what extent? Second, On all repair work, if not, to what extent? Also, if the standards are not in use, an inquiry should be made to ascertain the reason for their non-adoption. Such a circular would bring about two good results; it would bring freshly before each head of the car departments, the fact that certain standards exist, and just what they are; it would also develop, if they exist, any difficulties which stand in the way of more extended use of any standards.

I believe that much of the seeming apathy in the matter of using some of the present standards arises from the fact that

many of those in authority are not aware that certain of the standards have been adopted. A circular as above outlined would correct this source of inaction.

As to the second question, the method of securing absolute uniformity in the practical use of the present standards, I believe it necessary that patterns for castings should all come from one approved source. It has been demonstrated that, in order to obtain absolute correctness and uniformity in gauges, they must be manufactured by some one reliable firm. I believe that the same holds good as to patterns for castings adopted as standards. Many companies have obtained their M. C. B. standard oil boxes, journal bearings, etc., by obtaining a casting from some other company, and then allowing a patternmaker to copy it as near as possible, without knowing whether the original casting is larger than standard, through too much wrapping or otherwise.

All shops should be furnished with official drawings of the standards, and work only from the dimensions on the drawings, and never from samples. If the above were generally practiced we should have much better results. I hope every reader will immediately examine the M. C. B. standards in use on their roads, and be sure that they are conforming strictly to the official dimensions.

Third. Do we need more standards? I say yes. The adoption of some standards in years past may have been rather hasty, and we can learn a lesson thereby and go slowly *but surely*. We need more standards. I do not at present believe a standard car, of any class, or a standard truck, is feasible, or perhaps necessary, but there are many parts of both which are frequently broken and require renewing and should be made uniform.

1st. Standard dimensions, in section, of sills and floor timbers should be adopted for the leading types of cars. This is of great need.

2d. Standard dimensions, in section, for end-sills and draft timbers should be adopted.

3d. Standard sizes of draft timber bolts should be adopted.

4th. Standard center-plates and size of bolts should be adopted.

5th. Standard uncoupling device for M. C. B. standard drawbar is needed.

6th. Standard brake-beam and hangers would be a great blessing, although a very difficult point to decide upon.

7th. Standard dimensions, in section, for truck bolsters and spring-planks, for both spring-motion and rigid trucks, are much needed.

8th. Standard dimensions, in section, for end posts and corner posts in box cars should be decided on.

I have hastily outlined above a few possible standards which would, I believe, if they could be agreed upon and adopted, add greatly to the value of the invaluable work of the M. C. B. Association.

In conclusion, let me urge the universal use of all standards that have been adopted, the careful examination of the so-called M. C. B. standard patterns and templets in use on our roads, and a united effort to bring about an agreement on some of the more important details of cars, still untouched.

## New Driving-Axle and Crank Pin Lathe.

The engraving represents a new design of heavy axle and crank pin lathe recently turned out by the Bridgeport Machine Tool Works.

The swing is 26 inches and bed 14 feet 6 inches long, taking 8 feet 10 inches between centers.

The head has a three-section cone, largest section being 16 inches diameter and has patent friction clutch-head for instantly changing from belt to gear speed without stopping. Change from back to triple gears made by means of a positive clutch, handle for same being shown on top of front box. Results on speed, as follows. First, spindle driven by belt, three speeds, second, three speeds through first, or double train of gears, at a ratio of 8 to 1, third, three speeds through triple trains of gears at a ratio of 16 to 1. By means of a two-pulley countershaft, six speeds may be obtained without stopping the machine or shifting the belt, making a total of eighteen speeds by shifting the belt from step to step.

The carriages have independent feeds which can be reversed to feed right or left. When used for turning axles the right hand carriage should be run to rear of tail stock.

The tool-posts are arranged so that the centers will come within 22 inches of each other, and the points of the tools 12 inches apart.

The illustration is so complete that a description is unnecessary, all details being clearly shown. The lathe weighs 8,000 pounds.

Every year makes the heating of cars by steam, more successful. The experience of every cold spell overcomes new difficulties relating to details of the apparatus. It is very seldom now that we hear of any one questioning the fact that the deadly stove must go. There is no class of men so enthusiastic in favor of steam heat as the varnish makers and their agents. The steam that leaks from drip-cocks, traps and couplings, help materially in creating the necessity for a new coat of varnish.

A recent description of paper car-wheels says that the disks are so hard that they cannot be scratched with a diamond, and then proceeds to tell how they are glued together under pressure and turned true in a lathe. The mechanic naturally wants to know what the lathe tools are made of.

## RUNNING A RAILROAD.

### The Evolution of the Management of a Jim-Crow Line.

BY JOHN ALEXANDER.

After I got back from my exile in Kansas, following the strike of '77, I struck a job on a road up near my native place, that owned four tea-kettles and some miles of wire fence—by courtesy called a track.

This little road had been built by a hard-headed old merchant and lumberman, to get the products of a certain valley to the river, and he was considered a great man in that section of the country—as he really was. He had a hand in every enterprise in the country, represented the district in the Legislature, and was president of the railroad—we'll call him Higgins.

Well, when the first engine came—a second-hand Hinkley, with lots of new paint—she was named the "Colonel Gideon Higgins," and Dick Pomeroy was imported from New Jersey to run her, and as long as she remainded the only engine on the "cow-path," as the neighbors called it, Dick was king-pin of the concern—and a masher from away back.

There was a rooster by the name of Lester that did odd jobs around the depot at the county-seat, he could telegraph a little, but there wa'n't any to do, he helped with the freight, was express agent, peddled water on the wood train, helped keep books, carried mail, took care of the Colonel's horses, and generally 'lent a hand.'

Business got pretty good, and they had to have another engine, and Dick fell. The new engineer was a prettier man, and had forgot more about steam than Dick ever knew.

When they got four trains each way a day, they had to put up a telegraph line, and Lester done what telegraphing there was to do at headquarters. This was in the day of the old paper-ribbon telegraph machines, when the "operator" could take his time, and long years before I went there.

Lester done *at* a little of everything, and was soon depot agent, nobody liked the critter very well, and yet, nobody had much against him, except some of the boys said he was stingy, because he saved his money.

Colonel Gid had been married twice, in which particular he wa'n't much ahead of his wife, seeing as he was her third choice. The wife had a girl by a former union, that had been left over and to carry, when Colonel Gid was added to the widow.

Now, Lester saw, or thought he saw, where he could do the Colonel a favor, and make himself solid, by subtracting that girl from the Colonel's loss account. That critter was always looking out for a chance to do some one a favor of this kind.

He got the girl, and a little block of the railroad stock, as a sort of premium—stock wa'n't worth anything in the market.

Well, Lester got to be second mate of these eleven miles of road inside of a year or so, not because he knew the road from the turnpike—except when he saw the cars on it—but on account of a whole lot of little causes—mostly because he had married some of it.

Along in the late seventies, there was great excitement in the county seat, it was rumored that the Halifax & St. Louis Road was going right plump through the town, using the "cow-path" and consolidating with it, and at a meeting of freeholders to vote bonds, at which Colonel Gid presided and where Lester got in the crowd, and yelled for Colonel Higgins to speak—an old hayseed got up, and pointing to a map of North America, said:

"Are all you 'uns so plaguery blind that you can't see that we are the pivotal pint, atween Halifax and St. Louis? Don't yer see that we are right kerplunk in the line? Don't yer see that we have the key to the whole siterwation? In course we has. We will be a city bigger nor Bellus Falls inside of two years, and who do yer have to thank for it? Why, our feller citizen, the Honorable Colonel Gideon Higgins, Esquire, sir, and I, for one, vote for three million bonds. What's three million to a city like we'll be? Nothing! just nothing!"

And then every one of them damphools voted a debt upon their children, and their children's children, just for the privilege of seeing the cars go by on the air line from Mud to Ice.

Well, the road *did* finally consolidate with another half-starved road that was struggling through from the East—farmers all along the line doing the grading for fun, and at last but a few miles of rail was wanted to connect the county-seat—the name of which had been changed to Higgindom—with somewhere.

Mrs. A. was homesick to see me, and so wrote that there was great excitement up around Higgindom about a new air line, and that they had a hundred new engines, and maybe, if I would come home, I could get one of them to run. I came home.

I found that Jim Tompkins, the second engineer, was going to be master mechanic, that the road would be connected through in about two weeks, and have ten new engines on hand, and I should have the first one, sure. I got her.

The offices, such as they were, had always been over the depot, and as the road grew, this partition and that partition was taken down to give more room. A 40-foot addition had been added, and the office made that much bigger.

Colonel Gid had his desk there. Lester had one. The train dispatcher had his table of instruments in one corner, with 40 cells

of battery under it, the treasurer was there, the auditor, the road master, the master mechanic, the freight agent, the local passenger department, the bridge builder, the civil engineer, book-keepers, type-writers, a big stove, a colored janitor, an umbrella rack, and a cloud of dust—all in one room. The bigger the business got, the more things were collected in the museum.

Lester was Assistant General Manager to Colonel Gid., and as the Colonel was not there much, he was kind of head of the road.

In earlier years Lester had been familiarly dubbed 'Less, by the boys; when he got married, they changed it to "Helpless," and the first practical railroad man that went into the office and saw him on duty, named him "Useless," and Useless was his name forever after.

I reckon I had been running there two or three years, 'pears to me it was along in '81 or '82, that Jim Tompkins, the master mechanic, commenced to show the worry and work, and looked pretty bad. One day, along in the fall rush, Colonel Gid. came down to my train and told me that Jim had petered clean out, and been home for several days and asked me to come up and take his place till we could see how he came out; but, said the Colonel, as he went away, "I guess it's galloping consumption."

The next morning I was sitting in Jim's chair, up in the general bedlam, and Useless was telling me what to do, and how to handle my department, and I was wondering why he didn't do it himself, by taking a half hour nooning.

Well, for the next week I didn't do much but watch that critter of a Useless and study his methods.

Mr Editor, did you ever, in your boyhood days, watch a company of tumble-bugs build a nest? Don't you remember the big one—I don't know what position he holds, but suppose he is Assistant General Manager—that used to rush from one working bug to another, push him out of the way, take a look at what he was doing, and then rush to the next—but never doing a tap himself? That was Useless all over—I imagined I could see the extra legs on him.

We had a new dispatcher, a good man off the Central, but he didn't know the road nor the engines, and, as I sat next to him he often asked me to help him out. A couple of days after I went there, we were trying to get delayed 6 out of a hole, and not hold all the trains on the road or get any together. He was pounding an order to 21 and 6 and 17, and a special East—confounded compound thing—and I was telling him about what trains could do or ought to do, when Useless dropped down on him like a hawk on a spring chick.

"Excuse me," said he, laying the *Evening Blanket* on top of the poor dispatcher's hands and instruments, "but I want you to help me to formulate a reply to this criticism about the delays to trains on our road."

A pained expression crossed the dispatcher's brow; he held out his left hand imploringly to me, held his key down a minute, and a message commenced to come. The lines around his mouth drew down and his face was white, he opened his key a minute, then called to all operators to put out red flags and hold all trains. He was rigid as the O.Ks. came in from station to station, till at last Lindom O. K.'d and added, "Six is here for orders." Then the dispatcher fainted, and Useless went right on talking to him as he lay across his instruments.

That was a close call for 6 and 17, and the dispatcher resigned—said he wasn't going to help murder people by being an accessory before the act.

Useless was into everything. If a roundhouse foreman asked me for a tool or an extra man, Useless brought the letter to me to ask what reply *he* should make, and like as not remark

"I don't see what we want of a flue expander; the regular boiler makers used to do all that work themselves before you came; might it not be a bad precedent? Wouldn't the boilermakers have a right to infer from this precedent that they wouldn't have to do flue expanding?"

I used to resign every week, but couldn't find anybody with authority to receive it except Colonel Gid., and he refused, cursed Useless, and all would be smooth for an hour or two.

Phelan Haggerty orders a spike maul and three bars. Useless takes the opened letter over to Dan Toole, the roadmaster. Toole is counting up—partly in his mind and partly on his fingers—a very staggery row of figures, supposed to represent the number of rails and ties he has on hand. "Here is another *farmer* railroading," says Useless, "your department is full of 'em. Why don't you get rid of men that don't know what they want. How am *I* to keep track of this. Who is to know whether he wants bars of 60 pounds or 40 pounds railroad iron, or does he want bars of soap?" Toole loses the figures and his temper.

"Ave coorse the mon wants thrack bars! Who the divel but ye would call a *rail* a *bar*, anyhow? Phy in the name of the Howly Smoke don't ye give *me* the letters coming to *me* department, and lave *me* to answer them? No, ye must put *your* fut in the dish. Go 'long ave ye, and send the mon a couple ave bars off some cow yeard."

It subsides and goes back to its desk, but—the door opens and he pops up again.

He climbs into the treasurer's cash account, fingers the books, cusses the colored janitor, kicks the stove, rings his bell for a boy every fifteen minutes—then goes after him before the boy could get half-way there—and generally makes Hades seem like an ice pond in comparison with the office till he goes home

But when it came to arguing a mechanical matter was where he showed up. It was a custom in them days for every road to *design* engines for its particular work. Jim got into that, and had an old Dutchman making drawings of some new engines, and they had been left for me to finish. I knew we had a very ordinary road, and only needed ordinary engines. I looked over the sizes, and sent to Baldwin's for prints of their engines of the same size, had Gottlieb put the names on the cab; and "Great Air Line" on the tank, told him to keep still, and—submitted them.

Col. Gid. was pleased, and gave me credit for lots of things I never saw before, and especially complimented my speed, but Useless was on nettles at the first sight.

"That will never do, my dear sir; you can't have a very good mechanical eye. Just look at the difference in the sizes of them two *dumes*; little one ahead, big one behind—any law for that? Might not the people be deceived? Does it look right to make a radical departure from our practice for years merely for a whim? It don't balance; that will *never* do."

"No," said I, "there is no good excuse for making the sand-box smaller than the *dume*, but you have been looking at that old switch engine with two sand-boxes and no *dume*, and got off your base. If it was not for making a radical departure from our former practice, I should have put the smoke-stack in the center of the boiler and grouped the *dumes*, etc., around it." Then Colonel Gid. stopped us.

Jim had expressed a desire to see the drawings of those engines when complete, and one evening I took them up to him. He was pleased.

"How does the Colonel like them, John?" he asked.

"First-class," says I; "but that man Useless don't like 'em," and then I told him about the *dumes*. Jim laughed. I told him I met Useless on the street when I was coming up, and he made another objection.

"What was it?"

"Well," said I, standing up, "he come up like this"—and I imitated his voice and style—"No, no, Mr. Alexander, we will have to decline those designs; we owe it to our patrons to keep up the *high* standing of our engines. For years we have had large wheels; now you have made half of the wheels under this new engine less than half the usual size (the yard engine had no truck). Our patrons have a right to assume that the next engines will be *all* small wheels. People have a right to assume from this precedent that—"

"Don't!"

I looked at Jim; there was a look of pain on his face, his hand was extended toward me, palm out, as if warding off a blow—I had been too real.

I took his hand; it was rigid. Jim was dead. And do you know, Mr. Editor, that I couldn't get his hand down, and the undertaker couldn't get it down, and none of us could; and we finally had to make a coffin with a sort of mansard roof on it for poor Jim. I reckon he kept that position till he got inside the pearly gates—knowing they'd have no use for Lester there, he *might* take it down.

Lester took on about two pounds of fat every day that he got hold of a requisition for material and supplies.

He would listen to a long discussion on the absolute necessity of building a new bridge where one had burned or been washed out, and then deliberately run his pencil through the requisition for the material, draw a line out to the margin of the paper and write "Half"—this was his idea of economy.

One time he cut out Dan Toole's order for 5,000 pounds of fish-plates but let the bolts for them come on.

I ordered a set of flues for an engine once and he cut it in half—holding the engine in a month till the rest came.

Never a month passed but what we borrowed oil from some one to get through the month.

I got out some rules when we adopted the air-brake and ordered the men to carry twenty pounds "excess" pressure, but Lester made a fuss as quick as he got his eye on it.

"We can't afford to carry around excess air, Mr. Alexander," said he. "Enough is enough, we must do business in a business way and use what we have and no more."

He made an awful kick when the train-master insisted on two red lights on the cabooses and had a fit when he discovered, accidentally, that I allowed for shrinkage in castings. "Castings," he shouted, "castings cost us money, and the foundry must turn out a pound for the price, no shrinkage shall be allowed."

I guess that if the moon had been a department of the road, the officer in charge would have been blamed for allowing her to reduce size after once showing a full disk

But when the consolidation was finally finished, and the stockholders had called in all the stock and bonds, and issued consolidation mortgage bonds, they held an election, returned all the old officials, but voted to have a general superintendent, and inside of a month old Cap. Carr, from the Lake Shore, was added to the general stock in the big pen.

The Cap'en went over the road a couple of times, looked into everything, at everything and everybody, but, like Brer Rabbit, "he lay lo' and say nuffin'."

One afternoon, when he had been there about ten days, he came along to my desk, and says:

"Mr. Alexander, let's walk down to the shops."

I got up to comply—and so did Useless.

"Just wait till I finish this letter, and I will go with you," said he.

"Finish your letter and we will call in for you," said the Cap'en, as he closed the door, and added (on the outside) "when we want you"

"Let's go in here a minute," said Cap., stepping into a restaurant, and, establishing himself in a little room in the rear, he motioned me to a seat

"Waiter (giving him a quarter), two boiled dinners, two bottles of Milwaukee, and no disturbance"

Then he told me he wanted to pump me—and he did.

He wanted to know all about Useless, what? why? when? how? and all—and I told him.

"Think the Colonel would kick if I straightened him out a little?"

"No, often told me to tell him to go to thunder."

"Be in the office at nine to-morrow morning," said he as we parted at the door

"I was there."

Useless was defining the unwritten law of his method of filing letters to a deaf and dumb office boy, when the Cap'en got up from his desk, looking at a letter he held in front of his nose glasses; he stepped to the center of the room and said

"Where did this letter about a scarcity of freight cars at Holdbrook come from, and why hasn't the car accountant had it?"

"I laid it there, thinking you might wish to see it, or, perhaps, could help me out in replying to it," said Useless.

"Ah, yes, yes, by the way, Mr. Lester, is it part of the duty of the Assistant General Manager to open everybody's letters?"

"*We* must keep the run of our business, most certainly."

"Yes, jesso, but who is *our* and *we*? Now, Mr Lester, what are the duties of your office?"

"Well—well—I—'er—"

"You don't know. Well, I do. It is my *specialty* to know what every man's business is on a railroad. One man can't carry so much of a load as—"

"But, sir," interposed Useless, "*some one* must exercise a general guardianship over the whole, *some one* must run the railroad."

"Do you *run* the railroad? No, sir, you don't know the first principles of it. Does Colonel Higgins run it? or Mr. Alexander? or Mr. Murphy? No. *The men who run the engines and fire 'em, and run trains, and sell tickets, and load freight, and tamp ties—they run the railroad.* Not you nor me.

"Mr. Lester, we have passed the one-man stage—the back-yard railroad—this is now the Great Air Line. There must be a grand collection of the many details into one result, we must so work, each in his own line, as to accomplish a certain end, and in order to do this, we must have order, system and time. I can't find any of these things on the place.

"Now, Mr. Lester, just compare the whole road to that clock. There are a hundred pieces in it, each doing its own work, but the whole clock depending on every piece to do its whole duty. If one fails they all fail. A clock has to be wound up, regulated once in a while, watched all the time, cleaned regularly and certain pieces renewed or repaired occasionally—just like a railroad.

"Let us call the main parts of that clock the heads of our departments, the main spring is the motive power department, the pendulum is the treasurer's department, I guess, because it keeps us from going too fast. Now, the wheels and shafts and frames are the petty foremen, superintendents, etc., and the cogs and screws and wires or pins, are the rank and file, the little important parts—the men who run the railroad.

"Each of these little ones does his work and reports to the wheel above him in importance, these to the heads of their departments, and the final result is shown by the hands—the result—the auditing department. These report to me, I am the time-keeper, the head of the operating department, if there is a hitch I hunt for it, repair before the break-down, keep the thing going with the least friction—to earn the most money with the least expense. I don't know how to make, adjust or repair all of these parts, nor any of them, but I know men who do, and I use them to gain an end. Now, sir, some one has been monkeying with the regulator of this clock, got the pendulum out of beat, the spring

loose on the shaft and the alarm wound up—we've got to be cleaned and regulated."

"What part am *I*, sir?" asked Useless, with a half smile.

"Well, you've got the best of me, but you do not belong in my department at all," said the Captain. "Till now you have been a good deal like a toy balloon with a red string to it, bobbing around among the works, not doing much good, but often interfering with the wheels; but you are a part of the case, I guess—the ornament to the works, and its protection. If you don't know, sir, I can tell you that the case is the General Manager's department, and its business is to appear nice to the public, to float the stocks and bonds, look after the surplus, and pay the interest.

"In floating bonds, manager and assistants sometimes retail, but more generally wholesale, but I believe your forte is in the retail line. You have a bent for writing letters, why not write to some of these old farmers, and sell 'em stock? It is worth $100 on its face, and about $8.16 in the market, but bless you, they don't know that? Sell it to 'em at par, $75, $50 or $8.25, and hustle 'em up all along the line. Now, Mr. Lester, over in the new offices—I forgot to tell you that we were going to move in the new brick across the street, not this rubbish, but the men—your office is with Col. Higgins, on the ground floor; we are upstairs; any time you want to come up, step into my office, and my clerk will give you a pass into any department you may wish to visit. But, as to what you shall do, you are not in the operating department at all, but in the manager's department. You should report to Col. Higgins"

"Yes, report to *me*!"

We all looked around, and Col. Gid. sat in his chair, with his feet on his desk—he had heard the lecture.

Then the sun came from behind a cloud and shone in a motherly way on twenty-seven pale-faced men, a smile passed around, a large gob of plaster fell off the ceiling of the great den—and it was light.

## Some Valuable Suggestions.

They have an engineer on the New York end of the Pennsylvania, noted for his good horse sense and dry humor.

He ran one of their new "Class P" engines with the Belpaire boiler and the double-barreled traps to carry steam from the wagon top to the dome, this mill had not been exactly a perfect steamer and the engineer would have been glad to trade her for his old pet.

The engine went into the shop recently, and the foreman asked the engineer if there was anything special that he wanted done. The runner said, that he thought perhaps the engine would do better if they would tack up a blue-print in the boiler, so that the steam would know just where to go.

At another time his superintendent told him that they were arranging to put in another trough to scoop water from, and added, that with this they ought to make the ninety miles in the ninety minutes easy enough.

"The scoops are all right enough," said the engineer, "but you would be sure of success if you had one more, arranged as I could suggest."

"What's your idea?" asked the interested superintendent.

"Put in some device whereby we could scoop a new fire along about Trenton!"

## The Rhode Island Compound Locomotive.

We illustrate on this page a Forney locomotive as compounded by the Rhode Island Locomotive Works for the Brooklyn Elevated Railroad. Very little change has been found necessary in compounding this engine, the intercepting-valve placed in the steam pipe between the high and low-pressure cylinders being the only additional mechanism. This intercepting-valve is the special feature peculiar to the compound locomotives made by the Rhode Island people. It is so designed that the engine can be used simple or compound at any time. In practice this is found to be

an excellent arrangement, since it gives the engine all the power desired for starting a heavy train promptly, or for dragging a train over the crest of a grade where the ordinary power is liable to be slightly deficient.

Figures 1 and 2 give sectional views of the intercepting-valve. In ordinary compound working steam from the high-pressure cylinder is exhausted through the pipe E, Fig. 1, into the receiver and thence to the steam chest on the low-pressure side. In starting, steam is admitted direct from the boiler through the pipe D and reducing-valve B. This pushes back the pistons *a b c* forming the intercepting-valve, closing the pipe E and opening a direct communication with the receiver. When the high-

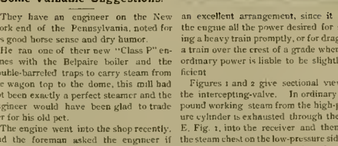


Fig. 1.

pressure cylinder exhausts sufficient steam to raise the necessary pressure in the pipe E, the intercepting-valve is opened, cutting off the supply of direct steam. In case the compound action is not sufficient to supply the power required, a valve connected with the pipe E is opened, which permits the steam to escape into the exhaust pipe and the intercepting-valve is moved to close the connection between pipe E and the receiver. The operation of opening this exhaust-valve admits exhaust steam in front of the intercepting-valve *h* which aids in moving the valve. When this is done, both cylinders take live steam and both exhaust it into the atmosphere.

Fig. 2 shows a front section of the intercepting-valve through ports *d* and *e*.

Two compound engines of the kind illustrated have been running on the Brooklyn & Union Elevated Railroad for over a year with a fuel saving of about 30 per cent. and water saving to correspond. In cities where the water used has to be paid for, the saving is worthy of consideration. Compound locomotives are getting beyond the experimental stage, for they have been in use long enough to show that the cost of repairs is no greater than that of simple engines and the mechanism is quite as reliable.

Let us see what engines of this type would save to the Elevated Railroad Company of New York were all the locomotives compound. During the year ending June 30, 1891, that company used over 190,000 tons of hard coal for their motive power at an average cost of $4 on the tender. The water used cost $65,790. If only 20 per cent. of the fuel and water was saved—and that is putting it very low—the aggregate reduction of operating expenses would be over $165,000 annually.

Compound locomotives are peculiarly well adapted to city and suburban service, owing to the decrease of noise and throwing out of sparks and dirt. Where soft coal is used, the reduced drain on the boiler, will make the prevention of smoke much easier accomplished.

The Pennsylvania recently ran an experimental train from Jersey City to Washington. It was pulled by one of the regular "Class K" engines, having a 78 wheel. The run to Trenton—56 miles—was made in 53 minutes, and the 91 miles to Philadelphia in 88 minutes. At Bristol the automatic water scoop was dropped into the trough, but it was brushed off in an instant. At North Penn Junction the brake was applied to get under control, and it stuck on the rear car and could not be released, and the engineer pulled it on to Gray's Ferry. Query 1. Where was the excess pressure? Query 2. If the excess was there, when was the triple on that car oiled and cleaned?

One of the most expeditious methods of cleaning castings we have ever seen is in use in the works of the Springfield Glue and Emery Wheel Co., at Bridgeport, Conn. They use the swing-frame grinding machine, which most railroad men are familiar with, and run the emery wheel lightly over the surface of the casting. Small wheels are used to reach corners and parts of the casting difficult to reach.

## To Detect Broken Stay-Bolts.

Mr. G. W. Stevens, Superintendent of the Lake Shore & Michigan Southern Railway, writes: It has been our practice for several years to use Fall's hollow stay-bolts, for the staying of locomotive fire-boxes, restricting their use to such portions of the fire-box where the risk of broken stay-bolts is greatest, such as the first row, row from top, around furnace door and the upper corners of the throat-sheet. The iron has given the best of satisfaction, and I have no hesitancy of recommending our practice, believing, that the advantages of the hollow stay-bolts, for the purpose of detecting breakage, is much preferable to the solid bolt, drilled for a short distance, as it is the experience of those making use of the latter practice, that the drilled portion will become coated over with grease and other accumulations and fail to give the desired notice when breakage takes place.

This hollow bolt permits an opening, both inside and outside of fire-box, thereby presenting a double opportunity for detecting breakages, as the annular opening passes through the bolt entirely, and failure of the stay at any point will immediately make itself known.

Railroad men interested in robbing the lime-impregnated feed-water, used in so many districts, of its evil effect on boilers will be sure to read with profit and pleasure the article contributed to this paper by Mr. George Gibbs, Mechanical Engineer of the Chicago, Milwaukee and St. Paul. Mr. Gibbs is eminently fitted to throw light upon this subject, for he has both the scientific knowledge and the practical experience that makes him a safe teacher. Mr. Gibbs graduated from the Stevens Institute, where he had devoted special attention to chemistry, a department of knowledge which is absolutely necessary to the understanding of water purification. In his practical career, he has devoted great attention to the water question, and no man in the country is better qualified to say what can be done to purify feed-water and how to do it.

## To Prevent Overwork in Train Service.

The following is a copy of a bulletin order posted in dispatcher's office in Rome, Ga.:

Sup't's Office, Atlanta, Ga., November, 9, 1891.

*All trainmen*

In order to comply with the State law of Georgia, after a run of (13) thirteen hours trainmen must have (10) ten hours' rest.

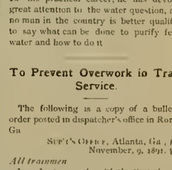

Fig. 2

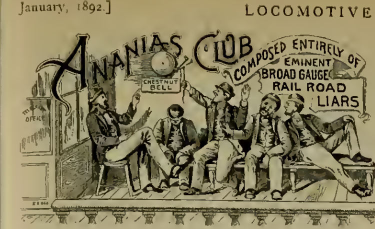
Trainmen must not work over (13) thirteen out of (24) twenty-four hours.

All employés reporting for duty are supposed to comply with this law.

The intention of this law is that the men must not be overworked, and we wish to comply with the law.

Beaupre, Sup't.

The original bill called for but twelve hours' work, but was lobbied up to thirteen, which is far better than no law at all. This law makes the company liable as well as the men.



## A Tribute to Greatness.

"Speakin' of snowplows," said the old timer, as he dropped into the Ananias Corner, "Speakin' of snowplows, reminds me of a cool spell we had whilst I was on the Mexican Central."

"What! cold in Mexico?" asked the gang.

"Yes, cold, c-o-l-d. Why you fellers don't know what cold is. When one of them Chinnooks comes up from Yucatan, it starts the bark on the trees of Mexico, I tell you.

"The time I'm tellin' you about I were deadheadin' south on Tim Fagan's train, when the Chinnook come up. The cars were hett by stoves and the greaser brakesie kept a roarin' fire, but the stove-pipe were a half-inch deep in white frost in spite of him. I had a buffalo overcoat and a pint flask of native brandy, made from red peppers, but I never come so near freezing up in my natural life.

"There was a young married couple sittin' right in front of me and I noticed the groom a shiverin'; finally he ast her to kiss him and she started to do it, when someone opened the door and froze the kiss right on her lips. Yes, gentlemen that poor critter sat there froze as stiff as an order to cut pay, with her dusky face puckered up just like a boy smokin' his first cigarette. That were the saddest sight I ever see," said the old villain, wiping a tear from his eye.

"The engine seemed to go awful slow and jerky like, and I thought perhaps Tim was getting out of wood, so I went ahead. The fireman was leanin' agin the boiler-head froze stiff, and Tim had pulled the engine over to stop and then chilled through.

"I got a drink of pepper whisky into him, and then noticed that the engine was white with ice.

"I couldn't imagin' what kept her a-goin' until I thought a minuit. She was runnin' by vacuum. The condensation was so quick that a vacuum was formed and it was suckin the pistons back and forth

"When we got in we couldn't blow the headlight out—the flame was froze—Tim cut it out with a hatchet and give it to the master mechanic for a paper w——"

"Gentlemen!" said the past president. "Gentlemen, this is our annual election. I do not know the name of the distinguished artist who has addressed us, but I move that all rules be suspended and that he be unanimously elected by acclamation as president of this club. Is it a vote? Carried. Stranger will you please take the chair—and—and treat?"

## The Decline of the Conductor.

"The leveling tendencies of our day," remarked the General Manager with a sigh, "are breaking down all our old idols. In my day the conductor was the great man on the railroad. When I was first raised to be superintendent, every passenger conductor on the road looked down upon me because I had only been a master mechanic before. The way that some of these conductors would walk out of the office, glance at the train and signal the engineer was a sight to behold. All the small boys looked upon the conductor as one having reached the height of human greatness, and the ladies brought him bouquets of the finest flowers, while the engineer had to be satisfied with a bottle of whisky put in his wood-ticket box on the quiet.

"We had a conductor named William Ford who was the most pompous and imposing man I ever saw. He was no good, and the boys called him Windy Bill on the sly, but the hardiest of them dared not say anything less than Mr Ford to his face. He was a big man and dressed in the best broadcloth, and walked about as if the earth belonged to him. One day he walked into the office at a station where my wife and little boy were sitting in the waiting room. As he passed through every one made room for him or tried to show him attention. My little boy watched him quietly till he disappeared, and then he whispered to his mother, 'Ma, was that God?'"

## Where Ignorance was Bliss.

"Large Shipper," "Regular Patron" and "Commuter" are characters specially privileged to criticise and condemn the actions of all railroad officers—just as "Old Subscriber" and "Mr. Constant Reader" are allowed to harass the soul of the editor, not to say the readers.

Some men delight in "making things hot" for the railroad officials who won't run the road for the special benefit of the individual kicker. One of their pet plans is to stir up public feeling against the road or the offending officer by "putting a piece in the paper."

If the official is indiscreet enough to reply in print, he exposes his abdomen to the vicious but irresponsible stabs from the untrained pen of Mr Large Shipper, *et al.*

One of these men became very much offended at General Superintendent H H Vreeland, of the New York City & Northern. Vreeland had the hardihood to run the road the way he thought best, and not the way the kicker thought best. The kicker called upon Vreeland for an explanation, got it, and then unbosomed himself. But Vreeland still ran the trains as he wanted to

After numerous protests, letters, calls and petitions, Mr Kicker sat himself down and wrote a very severe arraignment of the road and its management and published it in the *Tribune*

It remained unanswered and unnoticed while the trains on the "little Northern" ran regularly

Finally the kicker called on Vreeland again

"Say," said he, looking pleased, "the people are taking up this fight, it's going to hurt the road, going to ruin it, in fact, when you get everybody to thinking the same something must *come*. See?"

"Yes, that's so," admitted Vreeland

"Someone's been writing to the *Tribune* about this road and he hits the nail on the head, according to my notion; of course you've seen it?"

"No. Where did you say it was?"

"In the *Tribune*."

"*Tribune, Tribune*," muttered Vreeland, scratching his chin, "that must be a paper; where is it printed?"

"Why the New York *Tribune*, you know——."

"No," broke in Vreeland, "No, I don't remember such a paper. *Tribune*, let's see Charley!" calling one of his clerks, "Say, Charles, do you know of a paper called the *Tribune*?"

"No, sir, there's the *Times* and the *Sun* and the *World*; I think there is some mistake about the *Tribune*."

"James!" another clerk appeared, pen in hand, "James, do you know of a paper called the *Tribune*?"

"No, sir, there aint no paper published by that name around here as I know of."

"Never heard of the *Tribune*?" broke in the discomfited schemer.

"No, never heard of it," said Vreeland calmly. "You see we don't care so much for the howling of these little country weeklies, but we'd hate to have anything come out on us right here in town"

The kicker turned and made for the stairs, and it was so quiet that you could have heard a pin drop.

"That worked pretty good, boys," says Vreeland, "now he can't do anything else except grease the track or wreck a train I guess I'll smoke a cigar—sorry I hav'n't got three"

## A Good Galvanizer, but Not Up in Spelling.

"From memory's store-house, almost buried by years of exciting events of railroad life, I call to mind one incident which may be of interest," said Frank Coolbaugh, an old D L. & W train dispatcher, as he threw his leg over the railing of the Ananias Corner.

"The scene was laid in a country frontier railway town, twenty-five years ago, on a warm June day. No. 1 and No. 2, the only passenger trains the schedule contained, had gone, and the excitement of the day had passed. The townspeople who had gathered, as was their wont, in hordes to witness this 'passing sight,' had departed to their homes, leaving 'Gus' Jones, the station agent and myself alone until next day at the same time, when the same scene would be re-enacted. 'Gus' had just finished billing one coop of chickens and a dead calf, and the writer had just settled back to rest after an exhaustive effort in reporting the arrival and departure of these two trains, when 'Jim' Young, the company's galvanizer, who, to fill the idle moments, bought and shipped to New York butter, eggs, poultry and cheese, and whose tool shanty was a mile down the track, burst in upon us. With pen projecting threateningly from behind his ear, still moist with ink, coat off and sleeves rolled up, and with a face bearing the most troubled expression, we intuitively knew what was coming—we had been subject to these interruptions before. With an expressive movement of the hand, but no change in facial expression, he belched out—and his words were charged with intense disgust for himself

"'Gus, how in the devil do you spell Isaac,' and before answer could be made he said 'Oh, what a stupid damned fool I am—I-s-s-u-c-k,' and turned on his heel and trudged back through the hot sun to his shanty a mile away, and to his arduous duties, leaving us to our own ruminations. The next day at train time we waited anxiously for the arrival of the box, which we knew would explain the perturbed condition of 'Jim's' mind on the previous day, and sure enough, the box came, borne gallantly upon his shoulder, and on it we read in glaring letters

"'ISSUCK JOHSHUN,
"'NEU YORK.'"

## Swearing Back.

"In what is now called the 'good old times' of railroading," said Colonel Haines, of the Charleston & Savannah, in the course of a recent after-dinner talk, "there was a superintendent of a railroad in the South, who was noted for the richness of his swearing vocabulary, and he did not forget the expressions for want of using them. From morning till night he was swearing at some one, and his lash-like oaths were applied on the smallest provocation, or on no provocation. Some of the men got so accustomed to the daily dose of profanity, that they cared no more for it than they did for the bark of a dog, others constantly resented the degraded position they were compelled to hold.

"Among those who strongly objected to be sworn at in a promiscuous fashion was Jim Simpson, an engineer, who had been hired from away up in Missouri or Iowa. Jim had received the vials of the superintendent's wrath poured down his spine several times without cause, and he did not enjoy that kind of medicine. Feeling blue about it, Jim spoke to his conductor one day, and asked what could be done to prevent the superintendent from jumping onto him.

"'The best thing you can do,' said the conductor, 'is to swear back at the old man after he jumps onto you.'

"It was not long before Jim had the opportunity to try this method of repelling his tormentor. The superintendent went for him the next day, and Jim gave cuss word for cuss word, and threatened to pull the old man's nose. Jim instantly got fired.

"Meeting the conductor shortly after, he said, 'that plan of yours didn't work well, for the old man has discharged me for giving him a little of his own medicine. How is it that he does not fire you, when you swear back at him?'

"'Why, you blanked fool,' said the conductor, 'you don't say that you swore to the old man's face! I get even with him by doing my swearing when I get home to Atlanta'"

Some of the supply men are telling a joke at the expense of Jim Brady. The tale goes that on a hot, sweltering day of summer Jim stopped at a junction point to wait for a train, and that in the waiting-room he found some ladies of his acquaintance waiting also. With his usual courtesy and zeal to do a kind act Jim proposed taking them out for a drive, but there was no vehicle at the depot and no person to send for one. Jim remembered that while approaching the place he had noticed through other buildings the letters L I V E on a big, barn-like structure and he concluded that the full lettering read "livery stable." So he started for the place. The sun shone with its keenest rays, and Jim perspired freely as he hurried along, but he was walking in a good cause, and he strode manfully forward, although the distance was much further than he calculated on. At last a full view of the building was obtained, and to his utter disgust he read "Liver Regulator.

We stood in the yards of the Consolidated Road, at New Haven recently, and noticed a switch engineer trying to hang into his cab with his feet in order to see signals, while the firesey was busy at the steam factory door. Looking down the yard we observed that the whole place was on a curve, and that wherever the pony went the engineer was hanging out of the window. Stopping a man, who from his appearance might have been a yard man or a shop hand, we ask him why in the name of the New Haven Road, that engineer didn't turn his engine around so that he would be on the inside of the curve where he could see. The man looked at us suspiciously a moment, and said "I guess you don't live around here, that shifter has been shuntin' cars, headed east, for twenty years. You couldn't turn her around without getting an order from the president over the protest of every official from him down to the train butcher, there ain't no precedent for heading her the other way"

# BALDWIN ✦ LOCOMOTIVE ✦ WORKS.

✶ —ESTABLISHED 1831.— ✶

ANNUAL CAPACITY **1,000 LOCOMOTIVE ENGINES.**

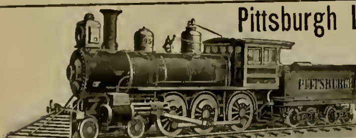
Adapted to every variety of service, and built accurately to standard gauges and templete. Like parts of different engines of same class perfectly interchangeable.

**COMPOUND LOCOMOTIVES.**

Broad and Narrow-Gauge Locomotives; Mine Locomotives by Steam or Compressed Air; Plantation Locomotives; Noiseless Motors for Street Railways, etc.

**BURNHAM, WILLIAMS & CO., Proprietors,**
**Philadelphia, Pa.**

---



## Pittsburgh Locomotive Works.

PITTSBURGH, PA.,
Manufacturers of

**LOCOMOTIVE ENGINES**

For Broad or Narrow Gauge Roads.
From standard designs, or according to specifications, to suit purchasers.
Tanks, Locomotive or Stationary Boilers
FURNISHED AT SHORT NOTICE.
WILSON MILLER, Pr & Trs. D. A. WIGHTMAN, Sup.

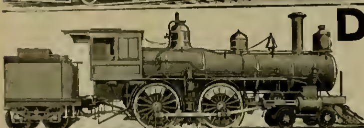
---

## H. K. PORTER & CO., Pittsburgh, Pa.

BUILDERS OF
Light Locomotives & Noiseless Steem Motors

Send for New Illustrated Catalogue, containing information useful to every Locomotive Engineer or Railroad Man *Mention this Paper.*

---



## DICKSON MANUFACTURING CO.

SCRANTON, PENN.

Locomotives of every style and size, Standard and Narrow Gauge, made to Standard Gauges and Templets. Also for Plantations, Mines and Logging.

SPECIFICATIONS ON APPLICATION.

JAS. P. DICKSON, President.
E. W. WESTON, V.-Pres. WM. H. PERKINS, Sec. & Treas.
JOHN DEVINE, Superintendent.

---

Trade Mark

A. CHIPMAN, Treas.

**GOULD'S**
**STEAM and WATER PACKING**
(Patented June 1, 1880.)
Especially adapted for Locomotives.
Never sticks the Throttle.
(The Original Ring Packing.)
In ordering give exact diameter of Stuffing Box and Valve Stem.
None genuine without this trade mark.
THE GOULD PACKING CO.,
East Cambridge, Mass.

---

## ROGERS LOCOMOTIVE AND MACHINE WORKS,

—PATERSON, N. J.—

NEW YORK OFFICE, 44 EXCHANGE PLACE.
MANUFACTURERS OF
LOCOMOTIVE ENGINES AND TENDERS,
And other Railroad Machinery.
J. S. ROGERS, President, } Paterson, N. J.
JOHN HAVRON, Secretary, }
R. S. HUGHES, Treas., 44 Exchange Place, N. Y.
REUBEN WELLS, Superintendent

---

"TWENTY YEARS WITH THE INDICATOR,"
By THOS. PRAY, Jr.
10,100 Sold Price, $2.50.
JOHN WILEY & SONS, 53 East 10th St., New York.

PITTSBURGH, PA.

(1) G H , Burlington, N C , writes

1 Why does the engineer's equalizing discharge valve blow at the exhaust of train-pipe, when the valve is placed on lap and then placed in running position? 2. When you make an emergency application of brakes with the equalizing valve, why is it that the red and black pointer will not vary over four or five pounds? *A.*—1 If there has just been an application of the brake, putting the valve "on lap" does not stop the blow from train-pipe exhaust port, because the piston has not seated the equalizing valve; the blow will continue until train-pipe pressure is reduced below that in the small reservoir. If it blows very long in "running position," it simply shows that the large drum does not contain the necessary pressure, or that the excess pressure valve is stuck. 2. When the lever of the engineer's brake and equalizing discharge valve is thrown to the emergency stop, both gauges are shut off from their supply of air, and a movement of either hand of the gauge represents leaks in the connections to it. This has fooled many engineers, who thought that the reduction, or entire absence, of train-pipe pressure ought to show on the gauge, same as with the old valve. Rest assured, that if there is a rush of air from the emergency port, that your brake is getting in its work

(2) J. T W., Willard, Tex., asks

1 In warming up cylinders do you open throttle a little and shift reverse lever backward and forward, or do you close throttle before you move lever? 2. Does the size of driver have anything to do with the load an engine pulls? A 17x24 engine will pull a heavier train with a four-foot wheel than it would with a six-foot wheel, would it not? *A.*—1. It does not matter, if the lever can be handled easily, it is as well to leave throttle open; anything to get steam through the cylinders. 2. The small-wheeled engine can pull the heaviest load. She uses the power of her cylinders more times in a given time or distance

(3) T J W , Weldon, N. C , writes

In conversation recently with an air-brake man I was informed that the lower a brake-shoe was hung the more power it had. If he is right, please explain why, as he could not to my satisfaction. *A.*—The length of hanger will not affect the power of the brake.

(4) W., Brockton, Mass , asks

Give definition of "Consolidation" engine and tell what constitutes a Wootten fire-box? *A* —A consolidation engine is one having eight coupled wheels and a pony truck (one pair of wheels) A Wootten fire-box is one built above the wheels, much wider than the track and having a bridge wall and a combustion chamber ahead of the grates The engine illustrated on the first page of the paper for December, has a Wootten fire-box, plainly shown.

(5) J N F , Titusville, Pa , writes

Will you please tell me through the "Asked and Answered," how I can get a description of the different snow plows for railroad work? *A.*—The manufacturers of the various rotary plows can furnish you with the details of machine plows The different forms of wedge plows vary but little, we know of no descriptive work on the subject.

(6) J. M , Peake, N. Y , asks

Will you be so kind as to explain the meaning of a degree gravity, in your valuable paper? In Forney's New Catechism, on page 531 it says Air cylinders should be sparingly lubricated with a small quantity of 32 gravity mineral oil. *A* —The gravity or weight of oil is reckoned according to what is called the Baumé scale In this water is put down as 1, and as all oils are lighter than this, their specific gravity is a decimal part of 1. Oil of 32 gravity, has a specific gravity of .8641 compared with water, and one gallon weighs 7.20 pounds. A gallon of water weighs 8.33 pounds.

(7) J. S., So. Brooklyn, asks

1 Why is the outside engine for locomotives preferable to the inside other than it is more convenient? *A.*—The outside engine is cheaper to make, easier to repair and avoids trouble of broken crank axles —a serious matter with insiders. 2. What size are the largest locomotive wheels and where are they? *A.*—The English engine "Cornwall" has drivers nine feet in diameter, the largest we know of.

(8) Sub., Dennison, O., writes

Supposing a train consists of twenty cars, ten cars on the front end are equipped with air-brakes The train breaks in two, eight cars from the engine, how should the engine-man act on finding that the train had parted? Also would like to know whether the answer to this question would also apply to a passenger train breaking in two? *A* —The brakes on forward end of train would prevent its being kept away from the rear, the whole train would stop, and with as much shock as the short distance between cars and the weight of unbraked portion of train would produce. The only thing the engineer can do in a case of this kind is to put his valve "on lap"—this prevents the air from being blown out of the main reservoir and leaves the engineer in condition to at once release his brake This applies to any train with air under same circumstances.

# OUR PREMIUM LIST.

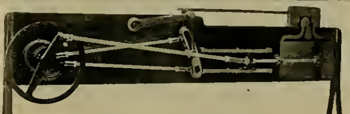
## Useful * Things * that * You * Want!

### AND CAN GET WITHOUT MONEY, FOR A LITTLE OVERTIME......

RECOGNIZING the fact that the railroad men of the land are not made of money, and that those who are most anxious to get tools, instruments and books, are often least able to do so, we have prepared this Premium List. Only the best makes of instruments and tools, and the truly reliable books are offered. These are no job lots that we have got cheap, but every identical thing in the list is new and the latest and best, *and will be shipped direct to you from the maker*—just as though you had sent *them* the cash. None of these goods are for sale by us—we give them for getting up clubs. Below each article named is the maker's price, and the number of subscribers for which we will give the article. Every subscription must be accompanied by $2. When a club is received and the premium mentioned that is wanted, we will order it sent direct to you from the maker—and we will always pay the mail or express, no premium shall cost you an extra cent on any pretext. We want you to work. In sending your club write each name, town, box and street plainly. State when paper should commence; but we can supply back numbers, and prefer that all should commence with January—it is best for those who want to preserve files. Send the money with the list, and give the name and number of the premium you want.

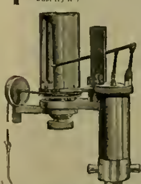
There is no excuse for a Lodge-room without a Valve Motion Model, or Westinghouse Valves; for an engineer to be without standard books, or a machinist without tools or instruments. Every man in the service needs the paper, and will thank you for calling their attention to it.

## DO YOU NEED ANYTHING HERE?



**Premium No. 1. 85 Subscribers.**

This is the new and improved Valve Motion Model. Patents of John A. Hill and F. J. Miller, built by Pedrick & Ayer. *Improved for 1892.* Half the actual size of a 17x24 locomotive. Just as adjustable as a locomotive, no more no less. Tram for setting valves furnished, and complete directions for setting valves, eccentrics, finding exact dead centers, etc., go with each machine. No wood but the main frame—a machine, not a toy! Everything visible from one side—just the thing for lodge-rooms. Crank on back as well as front. Patented audible exhaust, you can watch something else and hear the exhaust. More can be learned from this practical machine than from anything else. *No Lodge room complete without it.* It is worth $60. We will give it for 85 subscribers for 1 year. (A committee from any lodge can scoop 85 subscribers for this purpose in a day. Just try it.)



PREMIUM No. 2

**Premium No. 2. No. of Subscribers 100.**

TABOR INDICATOR.—This is one of the finest instruments made. One of the Ashcroft Manufacturing Co.'s best and improved type for high and low speeds, with detent motion, handsomely finished and plated, with one spring, one scale, two nickel-plated cocks, a treatise on indicating and the indicator, extra cord, 100 cards, oil, screw-driver, and extra drum spring; all put up in a handsome walnut case, with nickel-plated trimmings. Price, $85. Given for 100 subscriptions for one year.

PREMIUM No. 3

**Premium No. 3. For 60 Names.**

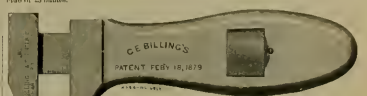
This is the famous full-jeweled Locomotive and Marine Chronometer made by the E. Howard Watch and Clock Co. The porcelain dial is 4½ inches in diameter, the case, nickel plated, 6¼. Nothing finer made. Price, $40. We give one for a club of 60.

**Premium No. 3 A. For 50 Names.**

This is the well known Seth Thomas Jeweled Chronometer. Probably more of these in satisfactory use on locomotives than all others combined. Will keep just as good time as the best watch and last for years. Nickel case, screw on front, 6 inch, are worth $27.50. We send one for a club of 50.

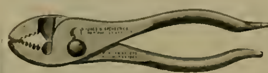
**Premium No. 3 B. For 25 Names.**

This is the Hecker & Lathrop Locomotive Clock, not jeweled. It has as fine a case and looks just as well as the chronometers. The makers guarantee them to keep good time, and we know that there are over 100 of them in use on one road, some of them having run steadily for 11 years. Six inch face, screw on front, dust and damp proof. Works made by Seth Thomas. Cost $10. We give one for a club of 25 names.



**Premium No. 4. For 5 Names.**

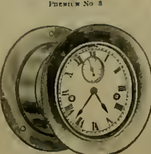
ENGINEER'S POCKET WRENCH. The finest wrench made, drop forged from bar steel and case hardened. Bar graduated in 32ds, opens one inch. Nicest thing out for oil-cups, etc. They are worth $1.00 black, $1.25 nickeled. We will give the black one for 5 yearly subscribers, the nickel one for 6.



**Premium No. 5. For 6 Names.**

COMBINATION PLYERS, WRENCH AND SCREW DRIVER. Drop forged from tool steel, fine finish, the handiest tool ever carried in an engineer's tool box and highly appreciated by a mechanic or in any household. By a quarter turn of the handle, and sliding from one hole to the other, done instantly, changes from 3-16 to 1 inch. Plyer, wrench, wire cutter and screw driver 6 inches long; cut represents plyers one half size. Black are worth $1.25, nickel, $1.50. We will give the black for 6 yearly subscribers and the nickel one for 7.

PREMIUM No. 3A



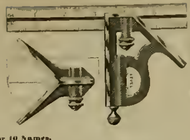
PREMIUM No. 3B

### STARRETT'S FINE TOOLS.

The following list of tools are from the well-known maker, L. S. Starrett, and will be sent direct from his shops. There are no better tools, and a little work will put you into possession of a neat set.

**Premium No. 6. For 25 Names.**

STARRETT SCREW MICROMETER. The finest measuring instrument made, the engraving gives a very good idea of it, being full size. All the latest improvements to compensate for wear, etc. Price, $6.50, in morocco case. We give it for a club of 25.

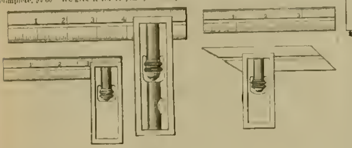


**Premium No. 7. For 8 and 12 Names.**

Combination Square, Level and Center Square.—One of the handiest tools made, a substitute for a whole set of try-squares, a good depth gauge and a splendid tool for transferring measurements. The 6 inch scale, with level and center head, is worth $2, we send it for 8 names. The 12 inch is worth $3, we send it for 12 names.

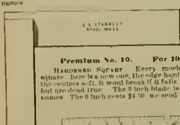
**Premium No. 8. For 10 Names.**

Small Square.—A fine tool for tool makers and others on nice work. Pa tent sliding rule, rule is narrow and can be adjusted to any length, will go where ordinary square is useless. Beveled and narrow blade furnished. Price, complete, $2 00. We give it for 10 yearly subscriptions.



**Premium No. 9. For 10 Names.**

Double Square, Stirred Head. A fine tool, blades cannot get out of square. An extra blade furnished with hexagon and octagon ends. Complete, 6-inch blade, costs $2 50. We will send it for 10 names.

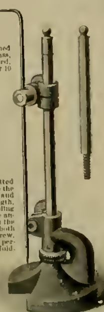


**Premium No. 10. For 10 and 15 Names.**

Hardened Square. Every mechanic wants a hardened square. here is a new one, the edge hardened enough to cut glass, the centers soft, it wont break if it falls. They are not graduated, but are dead true. The 3 inch blade is worth $2 50, given for 10 names. The 6 inch costs $4 50. we send it for 15 names.

**Premium No. 11. For 20 Names.**

Inclinometer. Consists of a cast steel stock and disk, both slotted to receive the blade, which folds in the stock. The blade attached to the graduated rotary disk may be secured at any angle from 0 to 90 degrees, and by loosening the clamp screw it may be shortened or extended full length, or removed for a straight edge. The working face of the stock, extending both sides of the blade, admits of its being reversed, so that the same angle may be laid off in opposite directions without changing the angle in the tool, thus requiring but ¼ of a graduated circle to obtain all angles both ways. At 90 degrees, the blade brings up against a case hardened screw, accurately adjusted, thus forming a try square; by holding the blade perpendicular (the level in the stock being at right angles), a plumb; by folding the tool, a level, length of blade. Open it to any degree and work may be leveled to that incline. The 12 inch blade is worth $5. We give it for 20 names.



Premium No. 12

**Premium No. 12. For 10 Names.**

Surface Gauge. The maker declares this tool perfect, has a new needle clasp, can be used for a depth gauge. The 8-inch size costs $2 00, we send it for 10 names. The 12 inch size has an extension piece, shown, it is worth $4 25, we send it for 15 names.

Premium No. 13

**Premium No. 13. For 15 Names.**

Large Bronze Dividers and Calipers. Every mechanic likes to have a large pair of compasses for use once in a while here is a nice tool, made of bronze, socket legs, caliper points, pencil holder and extension legs. Improved lock and adjusting device. The complete thing, as shown, costs $4 00. We send it for 15 names.

**Premium No. 14. For 7 Names.**

Iron Level and Plumb Plumb. Warranted accurate, six inches long. Worth $1 50, given for 7 subscriptions.

**Premium No. 15. For 8 Names.**

Same as the short level but 18 inches long. Worth $2, and sent for 8 names.

Premium No. 16.

**Premium No. 16. For 5 Names.**

Screw Pitch Gauge. The best on earth, any guage in the set will go inside of a nut or stud hole. This gauge has 20 pitches viz. 9, 10, 11, 12, 13, 14, 15, 16, 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40. Worth $1. Sent for 5 names.

**Premium No. 17. For 4 Names.**

Scales.—These fine scales need no description they are divided as follows: 1st corner, 10, 20, 50, 100; 2d corner, 12, 24, 48; 3d corner, 16, 32, 64; 4th corner, 14, 28. We send the 3 inch for 4 names, the 6-inch for 5 names, the 12-inch for 7 names, and the 24-inch for 12 names.

**Premium No. 18. For 4 and 6 Names.**

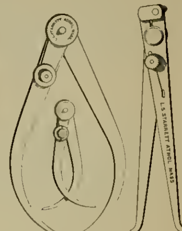
Flexible Rule.—Thin, watch spring steel, graduated on one side only. Worth 65 cents for the 6-inch, and $1.25 for the 12-inch. The small one for 4 names, the long one for 6.

Premium No. 19

**Premium No. 19. For 2 Names.**

Center Gauge, Standard Center and Screw Pitch.—Send you one for 2 subscribers.

Premium No. 20



Premium No. 21.

**Premium No. 20. For 13 Names.**

Trammel Points.—Made of bronze metal, with forged steel points, hardened. Either point can be removed, and the pencil socket, accompanying each pair, put in its place. Adjustable like spring dividers. Light and durable. The 3-inch points adjustable instrument, costs $2 50. Given for 13 names.

**Premium No. 21. For 4 and 13 Names.**

Lock-Joint Calipers.—Simple, light, cheap and good, with a wide scope. The 4-inch size we give for 4 names, the 8 inch for 6, the 12 inch for 8, and the 18-inch for 13 names. You can have either inside or outside.

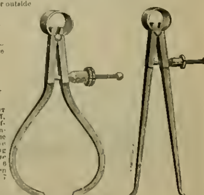
Premium No. 22

**Premium No. 22. For 5 Names.**

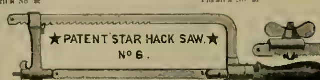
Hermaphrodite Calipers.—Six inch, patent lock nut. We send it for 5 names.

**Premium No. 23. For 6 Names.**

Fay's Patent Spring Nut Calipers.—The bow is stiff, making the caliper reliable. After calipering inside a chambered cavity, by pressing the legs together they may be withdrawn, and as they spring back will show the exact size calipered. Sizes, 4, 5, and 6 inch. The 4 and 5 inch given for 6 names, the 6 inch for 7 names.



Premium No. 23

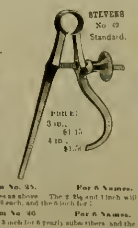


**Premium No. 24. For 8 Names.**

Hack Saw. The teeth are so hard that they cannot be filed, and the prices so low that it would never pay to file them even if they were soft. On account of high temper their cutting and wearing qualities cannot be excelled. The frames are made to hold saws facing in four different directions. They also have connecting pins so shaped that they cannot fall out. No. 6 is a patented Steel Frame, heavy and stiff, is highly polished and heavily nickel-plated. The handle is ebonized. This frame will hold all blades from 6 to 12 inches, and with the extra clamp, as seen in the cut, will hold all broken blades. With one dozen 12-inch blades for 8 names.

## STEVENS ARMS CO.'S CALIPERS.

There is no need to describe these tools, they have been on the market for years and are well known. Always order by No., and state size, and specify "Stevens."



**Premium No. 25. For 6 Names.**

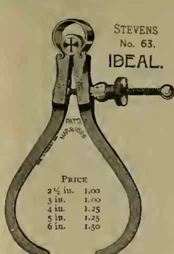
No. 47 is furnished in 6 sizes, prices as above. The 2, 2½ and 3 inch will be given for 5 yearly subscriptions each. The 4 and 5 inch for 6 each, and the 6 inch for 7.

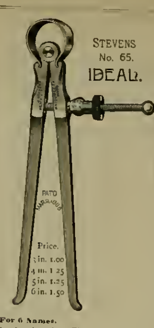
**Premium No. 26. For 6 Names.**

Keyhole Calipers. No. 40. The 3-inch for 6 yearly subscribers, and the 4-inch for 7.

**Premium No. 27. For 6 Names.**

Inside Calipers (No. 50).—Five-inch, given for 6 names for a year.



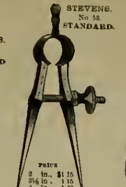


**Premium No. 28.** **For 6 Names.**

IDEAL OUTSIDE CALIPERS (No 63) – Heavy spring, patent nut and washer The 2½ and 3 inch will be sent for 5 names, the 4 and 5 inch sizes for 6 names, and the 6 inch for 7.

**Premium No. 29.** **For 5 Names.**

IDEAL INSIDE CALIPERS (No 65).–Same style as the 63. The 3 inch given for 5 names, the 4 and 5 for 6, and the 6 inch for 7



**Premium No. 30.** **For 6 Names.**

STANDARD SPRING DIVIDERS (No 52) The 2 and 3½ inch for 5 subscriptions, the 4 and 5 inch for 6, and the 6 inch for 7

**Premium No. 31.** **For 6 Names.**

SPRING DIVIDERS WITH THUMB ATTACHMENT AND PATENT WASHER (No 53) –The 2 or 3½ inch for 6 subscriptions, the 4 or 5 for 7, and the 6 for 8

**Premium No. 32.** **For 4 Names.**

HELICAL COIL CALIPERS (No 54) Something extra nice, the two smallest sizes are gold-plated, and are used as watch charms We will send either of them for 4 yearly subscriptions. We will give any size of the larger plain steel for 3 yearly subscriptions

---

**Premium No. 100.** **For 10 Names.**

WESTINGHOUSE ENGINEER'S BRAKE AND EQUALIZING DISCHARGE VALVE Full size with case cut away so as to expose all valves Indispensable in a lodge-room. Not a model an actual valve

**Premium No. 101.** **For 20 Names.**

WESTINGHOUSE QUICK ACTION TRIPLE VALVE –Full size, case cut away so as to show movement of every piece The actual valve Your lodge room ought to have one

**Premium No. 102.** **For 10 Names.**

A FINE GAUGE LAMP –Solid stand, heavy globe, plain or painted Brass cap and base Neatest lamp out Cost $30 a dozen at wholesale We will send you one for a club of 10

## DRAWING INSTRUMENTS.

**We offer Four Sets of Instruments from the well-known makers, Keuffel & Esser, New York. Theee Instruments are Germen Silver, with steel points, highly finished, all put up in Morocco cases with purple velvet lining.**

**Premium No. 40.** **For 12 Names.**

Contains 1 Compass, 3½ inch, with Pen, Pencil and Needle Point, No 702; 1 Drawing Pen with Joint, 4 inch, No 782, 1 Box with Leads, No. 830, Price, $4 50. We will send it for a club of 12

**Premium No. 41.** **For 20 Names.**

Contains 1 Compass, 5 in , with fixed Needle Point, Pen and Pencil Point and Lengthening Bar, No 715, 1 Divider, 5 inch, No 707; 1 Steelspring Bow Pen with Needle Point, No 756; 1 Drawing Pen with Joint, No 782; 1 Drawing Pen with Joint and Pin, No 785, 1 Box with Leads, No 830 Price, $8 50 We send it for a club of 20

**Premium No. 42.** **For 28 Names.**

Contains 1 Compass, 5½ inch, with Pen, Pencil, Needle Point and Lengthening Bar, No 717; 1 Hairspring Divider, 5 inch, No 710. 1 Set Steelspring Divider and Bows, No 755, 750, 757; 1 Drawing Pen, with Joint, No. 782; 1 Drawing Pen, with Joint and Pin, No 785, 1 Box with Leads, No 830 Price, $12 75. We send it for a Club of 28

## BOOKS.

**We offer the following Books, which we consider good and well worth the money. They are grouped according to price.**

**Ten Dollar Books.–For 40 names each.**

MODERN LOCOMOTIVE CONSTRUCTION By J G A Meyer of the *American Machinist* This is the latest exhaustive book on the locomotive, every piece being shown by drawings and rules given for determining strains and designing the machine to meet them About 1,000 engravings This work is now in press and cannot be delivered until March or April, 1892, but we will take orders and fill them as soon as the work is complete.

CONSTRUCTIVE STEAM ENGINEERING By Jay M Whitham 795 illustrations Treats on the construction of all kinds of boilers, engines, pumps, injectors etc Shows the valve gear and all the peculiarities of the different kinds of steam engines. A splendid book to have, as it shows modern practice in steam-engine designs 22 folding plates 908 pages

**Five Dollar Books.–For 20 names.**

TRAUTWINE'S ENGINEERS' POCKET BOOK This is a high class reference book for engineers and mechanics Contains facts and figures on many subjects mostly civil engineering Bound in morocco flap gilt edge. More than 40,000 have been sold

HASWELL'S A standard work much like Trautwine's, same size and style One of the best authorities on strength of materials, etc Contains many useful tables Same price.

BOUND VOLUMES OF "THE LOCOMOTIVE ENGINEER" Four years in one handsome volume–1888 '89, 90 and '91 There is more useful and interesting matter gathered in this volume, that will be prized by locomotive men, than in any book extant Complete index Nearly 2,000 engravings

**Three and a half Dollar Books. For 15 names.**

FORNEY'S CATECHISM OF THE LOCOMOTIVE The new and enlarged edition This work needs no explanation there have been some 30 000 sold. Every engineman and shopman needs it

**Two and a half Dollar Books.–Given for 13 names.**

HEAT–A MODE OF MOTION By John Tyndal This is the best and most interesting work on the mechanics of heat ever written. It reads like a story, is full of illustrations and experiments. No mechanic's library is complete without it A large, handsome work

A TREATISE ON STEAM BOILERS–Their Strength, Construction and Economical Working By Robert Wilson, C E Enlarged and illustrated from the fifth English edition by J J Flather, Ph B , Lehigh University 108 fine illustrations, tables, etc

TWENTY YEARS WITH THE INDICATOR. By Thos. Pray A well known work, no deep formulæ. Many useful rules and tables.

**Two Dollar Books. For 10 names.**

SINCLAIR'S LOCOMOTIVE ENGINE RUNNING AND MANAGEMENT This is a book dear to the hearts of all enginemen–it's about running and firing by a man who has done both. The last edition is improved very much and the number of engravings has been increased You can't afford to be without it.

HEMENWAY'S INDICATOR PRACTICE AND STEAM ENGINE ECONOMY This is the best thing ever written on the indicator and what can be done with it It has been adopted as a text book in the Stevens Institute of Technology Illustrated

WOOD'S COMPOUND LOCOMOTIVES Illustrating and describing the different forms and makes of compound locomotives. 1891

WRINKLES AND RECIPES A collection of practical suggestions, processes and directions, for the mechanic, engineer, farmer and housekeeper With a color tempering scale and numerous wood engravings By Park Benjamin Revised by Profs. Thurston and Van der Weyde, and Engineers Buel and Rose Hundreds of trade secrets and mechanical shop wrinkles

BOUND VOLUMES OF "THE LOCOMOTIVE ENGINEER" for any one year –1888–'89, '90 and '91 Neatly bound and indexed.

**Dollar and a half Books.–For 7 names.**

ALEXANDER'S READY REFERENCE This is one of the deservedly popular little books It contains plain directions for the many distresses of a locomotive–what to do to man and to engine in case of accident Illustrated by plates.

**One Dollar Books. For 5 names.**

PHELAN'S AIR-BRAKE PRACTICE Plain talk on air-brakes from an engineer used to handling it Bound in pocket form, with two large plates showing the air brake in every detail Has rules for figuring leverages and directions for operating under all conditions The Westinghouse Co bought one thousand of these books as instructors The best thing on the subject.

BOILER MAKING FOR BOILER MAKERS A practical treatise on work in the shop, showing the best methods of riveting, bracing and staying punching, drilling smithing, etc and the most economical manner of obtaining the best quality of output at the least expense By W H Ford, M E

**Fifty Cent Books. For 3 names.**

PROGRESSIVE EXAMINATIONS OF LOCOMOTIVE ENGINEERS AND FIREMEN By John A Hill Between five and six hundred questions and answers on practical questions on locomotive firing and running, proposing a new plan of examination of enginemen Adopted by several roads as standard Has 17 colored plates, showing color and position of all signals carried by trains or engines. 1891.

## RADIUS LINK PLANER ATTACHMENT.

—FOR—

Planing Links, Blocks and Circular Work on ordinary Planer.

Quickly Attached.
Easily Operated.
Does Accurate Work.

## Valve-Seat Planer.

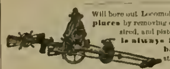
Over 300 in use.

## —LEED'S— LINK MILLER & SLOTTER.

For rapidly and accurately Milling out Links to any desired radius. Can be used on Drill Press or as an attachment to our Heavy Universal Milling Machine.

*A link 20 inches long can be finished in four hours.*

## PATENT PORTABLE Locomotive Cylinder Boring Machine.



Will bore out Locomotive Cylinders **in their places** by removing one or both heads, as desired, and piston. **The end thrust is always in exact line with bar.** It is fed with constant feed of cut gears.

PEDRICK & AYER, MANUFACTURERS

Special Railway Tools

1001 Hamilton St., PHILADELPHIA, PA.

## —LEED'S— Horizontal & Radial Drilling Machine.

Designed to work on or from a Drill Press. Is useful in drilling ends and diagonal parts of frames. Can also be mounted on the work and driven by a sliding shaft and universal joints. Drilling in all directions can be done.

## —DAVIS— Valve Port Milling Machine.

This machine will mill out ports in valve faces of steam cylinders, duplicating work exactly and in the shortest possible time.
It is operated by a rope belt similar to that used for driving drills, etc.
It is much lighter than the cylinder and can be readily placed in position using the stud-holes to attach to for that purpose.

## Greenwood's Universal Planer Chuck.

FOR STRAIGHT, CURVED (CONCAVE OR CONVEX) OR ANGLE WORK.

Used on any planer with cross feeds for links, keys, wedges, etc.

*Indispensable for Locomotive Builders and Master Mechanics.*

## —JOINTER— FOR Facing Locomotive Brasses.

Will hold any size brass same as held by strap when in use.
Some more time required to place brass than screw up an ordinary vise.
Any desired thickness of cut can be taken, jointing the faces perfectly true.
No files required.

## CRANK-PIN MACHINE.

For turning off Crank Pins in position, keeping the original centers of the Pin.

## PORTABLE DRILLING MACHINE.

**For Fitting New or Old Cylinders to Locomotive Boilers.**

It will drill all the holes in smoke boxes and cylinder flanges necessary to hang one pair of cylinders at one setting of the machine.

Quickly set and operated.
Driven by hand or belt power.

# STEEL OPEN HEARTH CASTINGS

STANDARD STEEL CASTING CO.
THURLOW, PA.

## Ross Regulator Valve FOR CAR HEATING.

Low in price and always reliable. No complicated parts. Easily understood. Durable. Has no equal.

ROSS VALVE CO., TROY, N. Y.

## SELDEN'S PATENT PACKING.

With Rubber Core for Steam.
With Canvas Core for Water.

If you are not using it, give it a trial and satisfy yourself of its merits.

Randolph Brandt, SOLE MANUFACTURER, 38 Cortlandt St., New York.

OLD RUNNERS SAY THAT

## Alexander's Ready Reference

IS THE BEST BOOK IN PRINT FOR

Locomotive Engineers and Firemen.

PRICE, $1.50.

Address S. A. ALEXANDER, York, Pa.

## THE GENUINE LORD'S BOILER COMPOUND,

Which is acknowledged by authorities and accorded the confidence of the manufacturers throughout the United States and foreign countries, is manufactured exclusively by G. W. Lord, practical chemist and inventor. Attention is called to other parties, who, through the appropriation of G. W. Lord's antiquated patent, have deluded many manufacturers into presenting them with their order for Lord's Boiler Compound. The use of the above formula, patented in 1869 by Mr. G. W. Lord, has been long discontinued by him, owing to his discovery of many new chemicals which upon critical experiment have demonstrated their superiority. Lord's Boiler Compound manufactured at the present time, is an article greatly superior to the formula patented by Mr. G. W. Lord. For decree of court, etc., address G. W. LORD, 320 Union St., Phila., Pa.

# EUREKA CAST STEEL COMPANY,

Office and Works: CHESTER, PA.

Open Hearth, Crucible and Eureka Steel Castings, Railroad and Machine Castings. Locomotive Cross-Heads and Gearing a Specialty. GUARANTEED KNUCKLES FOR M. C. B. COUPLERS.

ESTABLISHED 1866 ✦ INCORPORATED 1889.

CRESCENT STEEL

# CRESCENT STEEL CO.

480 PEARL ST. NEW YORK — PITTSBURGH, PA. — 64 & 66 S. CLINTON ST. CHICAGO.

FINE STEEL For Track and Machine Shop Tools. Polished Drill Rods For Small Taps, Reamers, Twist Drills, Etc.

Self-Hardened Steel For turning Tires, Axles, Etc. SPRING STEEL of great Strength and Elasticity.

DIE BLOCKS, SHEAR KNIVES,

Milling Cutter Blanks, Coiled Springs, Steel Forgings.

# WATSON & STILLMAN,

204, 206, 208 & 210 East 43d ST., NEW YORK,

MANUFACTURERS OF

HYDRAULIC TOOLS For Railroad Work.

NOW IN USE ON OVER 50 RAILROADS.

Vreeland's Transfer Jack.
Will remove and replace Drivers or Trucks without Jacking up.

Send for Circulars.

WRECKING. BROAD BASE.

## The Original Unvulcanized Packing.

Called the STANDARD—As it is the Packing by which all others are compared.

Accept no packing as JENKINS PACKING, unless stamped with our "Trade Mark."

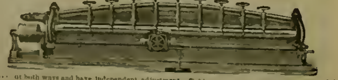
JENKINS BROS. 71 John Street, New York. 105 Milk Street, Boston. 21 North Fifth Street, Phila. 31 & 33 N. Canal St. Chicago.

# TOOLS FOR LOCOMOTIVE BOILER WORK

THIS CUT SHOWS OUR

## Boiler Plate Planer.

WILL PLANE ANY LENGTH OF PLATE.



Tools cut both ways and have independent adjustment. Table acts as a gauge for setting the Plate. Driven by a steel screw, which is supported its entire length so that it cannot be bent or sprung. 7 sizes.

THE HILLES & JONES CO., Mfrs., Wilmington, Del.

# STEEL CASTINGS

True to pattern, sound, solid, free from blow holes and of unequaled strength. Stronger and more durable than iron forgings in any position or for any service whatever.

30,000 KNUCKLES FOR M. C. B. STANDARD CAR COUPLERS, 20,000 CRANK SHAFTS and 10,000 GEAR WHEELS of this steel now running prove this.

Crossheads, Rockers, Piston Heads, etc., for Locomotives. Steel Castings of every description.

Send for Circulars and prices to

CHESTER STEEL CASTINGS CO.,

Works, Chester, Pa. Office, 407 Library St., Philadelphia, Pa.

## Automatic Brakes in Great Britain.

The last Board of Trade report shows that there are on the roads of Great Britain, 9,931 locomotives and 48,777 carriages, fitted with automatic power brakes. Of these, 7,521 engines and 31,519 carriages have the automatic vacuum brake and 2,410 engines and 17,158 carriages have automatic air-brakes.

Every failure of brakes over there must be reported to the Board of Trade, who investigate all serious ones. The board classify brake failures as follows.

(1) "Failure or partial failure to act when required in case of an accident to a train, or a collision between trains being imminent." (2) "Failure or partial failure to act under ordinary circumstances to stop a train when required." (3) "Delay in the working of trains in consequence of defects in, or improper action of, the brakes, distinguishing whether they arose from neglect or inexperience of servants, or failure of machinery or material."

The report of the board for the first half of 1891, shows that neither one of the brakes has a single charge against it for the first class. There were seven failures of the second class reported against the vacuum and twelve against the air, and of the third class, 404 failures against the vacuum and 232 against the air. These are remarkable results and even of the last order, where most failures are reported, there was only one failure of vacuum for each 118,000 miles run, and one failure of air for each 105,000 miles run.

## Speed of Wood-Working Machinery.

It is curious, said a well-known master car builder the other day, as we strolled around his finely arranged planing mill, it is curious how ignorant most of your iron-working friends are about the speed of wood-working tools. Most of them know that this class of machine requires great power to drive it, and that is due to the enormous capacity of these machines for doing work. Wood, of course, is more easily worked than metals, but the material is cut up so rapidly that it represents immense concentration of power. Here are some notes on the subject that may surprise some of the men who are deficient in respect for the wood workers of the country.

A properly driven circular saw has a periphery speed of 7,000 feet per minute—nearly a mile and a half. A band saw is run at about half that speed. Planing machine cutters have a speed at the edge of 6,000 feet per minute, and the cutters of molding machines slice out material at about 4,000 feet per minute. Wood-carving drills are run 5,000 revolutions per minute. Augers one and one-half inches diameter are run 900 revolutions per minute, and those half that size are run at 1,200 revolutions per minute. Mortising machine cutters make about 300 strokes per minute.

No free specimen copies of February will be sent out. The splendid colored plate in this issue cost over $300, and every one is worth a frame. Extra copies can be obtained at the retail price.

## Give the Devil his Due.

That many, many men are killed every year and every day on account of couplers there is not the least doubt.

We never hear of accidents causing death on account of defective draft rigging, yet it is not unlikely that a great many occur that are saddled upon the poor coupler.

A great many of the so-called coupler accidents will show two unbroken couplers, the draft gear has simply broken down or the stops have been forced apart and the draw-head shoved in.

Couplers that do not require the presence of men between cars at all will prevent deaths from defective draft rigging, but give the coupler only its own crimes to answer for—they are enough.

THE LARGEST ROAD LOCOMOTIVE.

## A Modern Samson.

There have just been turned out of the Baldwin Locomotive Works at Philadelphia four decapod locomotives for the Erie Railroad that are so far the largest and most powerful single locomotives ever built.

When you get a 76-inch boiler of ¾-inch steel on ten drivers and a truck, 193,000 pounds on a wheel-base of 27 feet 3 inches, you have considerable locomotive in one lump.

As will be seen, the engine is compounded on the Vauclain plan, having a high and a low-pressure cylinder on each side; the upper or low-pressure cylinders being 27 inches in diameter—the largest pair we ever heard of on a locomotive. There have been 32-inch low-pressure cylinders built for two-cylinder compounds.

The engraving on the next page shows how the cylinders, pistons and valves are arranged. These monsters will be used as freight pushers.

The following are the general dimensions:

Gauge, 4 ft. 8½ in.; actual weight in working order, exclusive of tender, 193,000 pounds; actual weight on driving-wheels, 170,000 pounds, estimated weight of tender, including coal and water, 90,000 pounds, estimated weight of engine and tender, in working order, 283,000 pounds; high-pressure cylinders, 16x28 in., low-pressure cylinders, 27x28 in; driving-wheels, five pairs coupled, diameter, 50 in., total wheel-base, 27 ft. 3 in.; driving-wheel base, 18 ft. 10 in.; total wheel-base of engine and tender, 53 ft 4¾ in., length over all, 63 ft 8½ in., boiler of steel ¾-inch thick, diameter, 76 in., height of center line of boiler above rails, 8 ft., extreme height above rails, 15 ft 6¼ in., fire-box (Wootten style), 10 ft. 11 1/16 in. long by 98¼ in. wide inside; tubes, 354 in number, 2 in. diameter, 12 ft. ¼ in. long, combustion chamber, 36 in. long, heating surface of fire-box, 182.5 square ft., heating surface of combustion chamber, 51.8 square ft., heating surface of tubes, 2,208.8 square ft., total heating surface, 2,443.1 square ft., tank capacity, 4,500 gallons; working pressure, 175 pounds per square in., boiler designed to carry 200 pounds per square in. Each of these engines takes the place of two 18x24 pushers on the Susquehanna grade, and does the work with less coal than formerly used.

## The Record-Breaker of the Empire State Express.

The engraving on this page was taken from a photograph of engine 870, N. Y Central R. R. one of the engines that made the world-famous run on September 14, 1891, and one of those used on the Empire State Express every day The record-breaking run from New York to Buffalo—439½ miles—was made in 425 minutes and 44 seconds, actual running time One day early in January this train (the Empire) made up 31 minutes on the schedule time, which is 52⅓ miles per hour

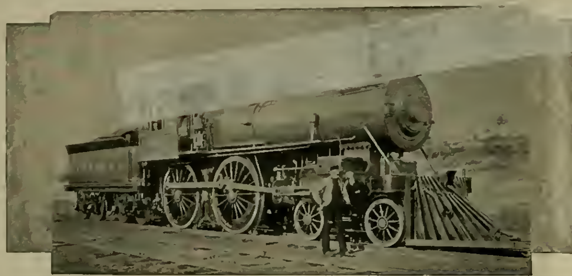
Engine 870 was built by the Schenectady Locomotive Works in 1891 The following are her general dimensions

Gauge, 4 ft 8½ in , cylinders, 19x24 in , diameter of drivers, 6 ft. 6 in , driving-wheel base, 6 ft 8 in., truck wheels, 36 in. diameter , weight on drivers, 80,000 pounds weight on truck, 40,000 pounds, wagon-top boiler, diameter, smallest ring, 58 in , firebox (shallow), 96 in long, 40¾ in wide , 268 2-inch flues 12 ft. long , grate surface, 27.3 square ft., total heating surface, 1,851.50 square ft The boiler has an extension front, 16-inch stack, double nozzles, and a brick arch supported on pipes , working pressure, 180 pounds.

The tender has a capacity of 3,500 gallons of water and 6¼ tons of coal and is fitted with scoop for taking water without stopping Weight of tender, loaded 80,000 lbs., making the complete machine, with tender, weigh 100 tons.

This engine develops a tractive force of 15,720 pounds.

The Empire State Express is now the fastest regular train for long distance run in America.

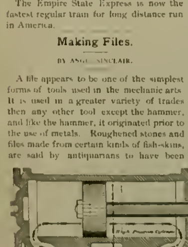


THE RECORD-BREAKER OF THE EMPIRE STATE EXPRESS.

## Making Files.

BY ANGUS SINCLAIR.

A file appears to be one of the simplest forms of tools used in the mechanic arts It is used in a greater variety of trades then any other tool except the hammer, and like the hammer, it originated prior to the use of metals. Roughened stones and files made from certain kinds of fish-skins, are said by antiquarians to have been used as files during the earlier stages of the bronze age These were succeeded by files made from hardened bronze, and later on came the steel, the master material from which files have been made for thousands of years.



ARRANGEMENT OF THE PISTONS AND VALVE OF THE BALDWIN COMPOUND LOCOMOTIVE

VARIED PROCESSES IN FILE-MAKING

A casual examination of a file would lead one to think that the making of this tool must be a very simple operation, but a visit to a file-making factory produces a different conclusion One of my school books had an article illustrating the advantages of subdivision of labor, and showing that it took ten men to make a pin. Those familiar with this phase of manufacture, will not be surprised to learn that a file goes through about twenty hands in passing from the steel bar to the article ready for use.

DIFFICULTIES OF USING MACHINERY.

File making seems a process, highly adapted for being done by machinery, but it is only within the last few years that machinery was successfully applied to the work. An edition of Chambers' Encyclopedia, published in 1885, says, that "many attempts have been made to cut files by machinery with only partial success." Readers of engineering literature will remember that only a few years ago there was a heated discussion about the relative value of hand-made and machine-made files, wherein the latter appeared to be badly worsted , yet nearly all the files now used in this country are made by machinery.

IN THE NICHOLSON FILE WORKS.

File-making, as now conducted, is one of the most interesting operations I have ever followed. Any railroad man visiting the Rhode Island Locomotive Works at Providence, R. I., will find himself well repaid, after satiating himself with the details of locomotive building, to step across the river and go through the Nicholson File Works. If he should stop off a day especially to visit these adjoining works, that are so different in character, yet so full of interest, he would spend the time very profitably

THE STEEL

In the round of the file works I was accompanied by Mr. Pierson, one of the partners, who understands how to lead a visitor so that the various operations of file-making will be seen in their proper order. First, we go to the place where the steel is stored, and here we find bars suited for all the kinds of files that are made. These bars, of course, are made of the best crucible steel.

FORMING THE BLANKS.

The bars are first taken to the shears and cut into the proper length for blanks. From there we follow them to a long room where the first impression received is that the place is as noisy as a boilermaker's shop There are two long rows of small forges with a trip-hammer beside each Here the blank file receives its first manipulation. In some cases it is merely the forging of the tang. That is with plain flat files. Other forms are put into shape. dies cut on the anvil assisting the blacksmith to do the work quickly

ANNEALING.

From the forging room the blank is conveyed to the annealing shop, where it is placed with many more of its kind in a heavy, oblong iron box. This box, when filled, is luted to make it air-tight, then it is put in a furnace and kept at a red heat for the time required for thorough annealing, and slowly cooled. This is one of the critical processes of file-making, it being of the greatest consequence that the blanks shall come out uniform in hardness.

STRAIGHTENING AND GRINDING.

Being handled by men of developed skill and long experience, the future file emerges from the softening process in the proper condition for receiving the impress of tools. It is straightened and then taken to the grinding room Here immense grindstones are revolving and on one of them the file receives the finish that makes its surface ready for cutting. It is highly important that every particle of scale be removed from the surface If the file is plane-faced the grinding is done automatically, a frame holding the blanks to the revolving stone If the face is circular or irregular, the grinding is regulated by hand All the grinding is done on ordinary wet grindstones, that are notable principally for their width and, when new, for their great diameter

FILE-CUTTING BY MACHINERY.

In following the blank to its next place of attention, we enter another large and particularly noisy shop where rows of machines rattle. making up a din like the inside of a power-loom factory The machines are the file cutters, and the noise is made by the constant impact of the numerous hammers A file-cutting machine is something like a small planer, with the cutter operated from the tool post The blank rests on a bed of soft metal, which is moved along on the table at the rate required for the number of teeth to be cut Young women attend most of the machines and appear to be very expert in the manipulation required. The principal skill called for in file-cutting by machinery is in the care of the cutters and in the adjusting of the machines This appears to be attended to by overseers There are numerous points about the operation of file cutting, that will be interesting to a mechanic to watch, which I have not space to describe Round files are cut in a special form of machine and are held vertical and constantly rotated while under the cutter.

FILE-CUTTING BY HAND.

A small proportion of the file-cutting in this establishment is done by hand. Hand-cut files vary, from the coarse rasp, with twelve teeth to the inch, to the file with three hundred teeth per inch. Files have been cut on machines with as many as five hundred teeth to the inch. It takes a good magnifying glass to see the rows of teeth in the finer files made. An exceptionally good workman can cut three hundred teeth to the inch, and under the glass the rows look as regular as if the distance between them was measured. This shows a wonderful development of touch. There is no instrument used to guide the workman. The blank is laid on a block and held secure on a piece of lead. The workman then strikes the first cut at the proper angle, and that is the guide for all the others. A hammer and cutter are all the tools used, the spacing and the horizontal and tooth angles being formed by manipulative skill.

LEARNING THE BUSINESS.

I was interested in how apprentice file-cutters learned their business without spoiling loads of good steel. I supposed that they had to practice on dummies, as young surgeons learning to use the lancet have to practice on the veins of cabbage leaves. But I learned that the apprentice file-cutter practices on the plain rectangular forms of coarse files that can be used for a smaller form if damaged under the hand of the novice.

HARDENING.

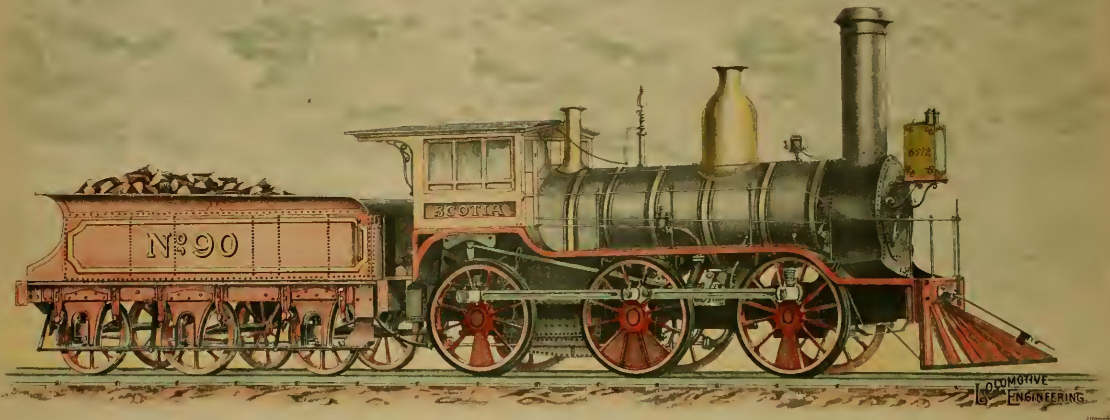
Between the cutting and the hardening rooms the file goes through some minor operations, which need not be described The hardening is done by heating the file in a lead bath to a bright red and then dipping it vertically into a clean-water vat This water is kept in motion and is maintained at an even temperature of about 70 deg. Fahr. There are several methods practiced of strengthening the files after they are hardened. The tang is softened by heating in the lead bath and then dipping in oil.

VARIETIES.

On the various interesting methods of cleaning, inspecting, oiling and packing the files I cannot dwell. An inspection of the curious variety of files that are made here, from wood and leather-cutting rasps up to the needle-like file employed by jewelers, is highly interesting. The finer classes of round files are cut by a process which is not open for the gaze of visitors. A mechanic naturally feels mystified about how the work is performed.

---

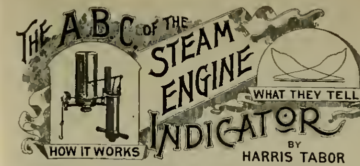
The economy of using labor-saving tools is well illustrated by the introduction some time ago into the shops of the Chicago & Northwestern at Chicago of a power traveling crane which cost about $6,000. The engines and material are handled so much better by this tool that the output of the shop has been increased two engines per month. At the same time the work of several laborers has been dispensed with and overtime on tools has been decreased about two hours per day



THE FIRST LOCOMOTIVE WITH A STEEL BOILER.

DESIGNED BY RICHARD EATON, LOCOMOTIVE SUP'T.

BUILT BY THE GREAT WESTERN RAILWAY OF CANADA
AT HAMILTON, ONT IN 1861



The diagrams shown in first paper were intended to make the reader familiar with the names of the various lines on the indicator-card, and the relation they bear to the movement of the valve and piston in the engine. It is of the utmost importance that this relation between the piston in the engine and the indicator-pencil be thoroughly understood. To make the text as plain as possible, this paper will be devoted to sketches showing the position of the piston and valve in a locomotive cylinder at the points of admission, cut-off, release and exhaust closure through one revolution, with each position of the piston the line that the indicator-pencil would make will be given, until the card is completed.

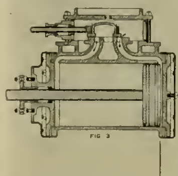


FIG 3

By referring to Fig. 3, which has been reduced from a drawing of a standard locomotive cylinder, it will be seen that the piston is at the beginning of its stroke, and the valve has commenced to open the steam port, allowing the steam to flow into the cylinder through the "lead," and exert a pressure on the piston before it has commenced its movement. The line made by the indicator while piston and valve are at the beginning of the stroke is the admission or lead line. When the valve opens just as the piston is at the end of the stroke, this line is vertical, but when the valve opens before the piston is at the end of its travel, the admission line inclines outwardly, and when the piston has commenced its forward motion before the lead occurs, the admission will incline inwardly; the latter case is often called negative lead. The admission of the steam always occurs when the piston has comparatively no motion.

As the piston advances in its stroke it gives a coincident motion to the paper drum of the indicator, making the horizontal line to the point where the valve closes and the cut-off takes place, as shown in Fig. 4, this is the steam line, and is the second line on the card. Theoretically this line should be parallel to the air line, practically it varies with every engine and condition. Where the steam pipes and ports are large and the piston velocity not too great, this line will run nearly straight to the cut-off, and will approach, within two or three pounds, the boiler pressure. Such conditions are rare, and are to be found only in the best stationary engine practice. In locomotive practice this line is straight only at very slow speed, as will be seen from cards shown later, taken from locomotives running on the road.

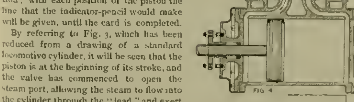

FIG 7.

Fig. 5 gives the next position of the piston and shows that it has moved from cut-off, or where the valve closed, to release, or exhaust opening, it is through this movement that expansion takes place, hence the line made on the indicator-card through this period is called the expansion line. This is the most important line on the card; it represents work done after the supply of steam has been shut off from the cylinder; compared with an engine which takes steam to the end of the stroke, it indicates work done without cost; within certain limits, the earlier cut-off means economy. When the valves and piston are tight, the expansion curve approaches very closely the hyperbole.

Fig. No. 6 shows that the piston has completed the forward stroke, and has moved five-sixths of the return stroke, to exhaust closure, or where compression begins. During this entire movement the exhaust-valve has been open; the indicator has responded to the change in pressure, as shown by the exhaust line from release to compression. While the piston was moving from release to the end of the stroke, the steam pressure in the cylinder dropped nearly to the atmosphere, and before the return stroke had fairly commenced, the exhaust line and air line were practically one. What was said of the steam line is true of the exhaust line, its shape and location depend upon the area of its ports and pipes, and the velocity of the piston. At very slow speeds the exhaust and air lines run together; when at very high speeds there may be a difference of twenty pounds between them. In stationary practice, where the engine is not called upon to blow the boiler fire with exhaust steam, and where expansion runs low, it is not unusual to see the exhaust and air lines run together. In locomotive practice, however, the fire must be blown by the exhaust, and if this be allowed to run too low it reduces the capacity of the boiler to make steam in a much greater ratio than the gain accruing to the engine from reduced back pressure (If the cranks who assume to revolutionize locomotive practice, without knowledge of the conditions, understood these points, there might be fewer failures.) Back pressure cannot be dispensed with in railroad practice, but it should be kept to the minimum with free steaming capacity.

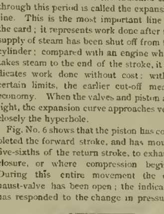

FIG 4

We must now turn to Fig. 3 for a completion of the return stroke. In Fig. 6 the piston has one-sixth of its return stroke to make; with the exhaust-valve closed, the confined steam follows the Mariotte law, rising in pressure as it is compressed into smaller space, and making the compression line, or curve, which is a hyperbole. We now have the completed card, as shown in Fig. 7, which represents the work done on one side of the piston during its forward stroke, and the resistance of the atmosphere and compression against it during the return stroke. If an indicator had been attached to the other end of the cylinder it would have produced a similar card, and the two would represent the work of one complete revolution of the engine. The vertical line at the right of the finished card is the clearance line, and indicates the waste room in the cylinder that the piston does not fill, this waste includes the space between the piston and the cylinder-head when the piston is at the end of its stroke, and all that space in the steam port up to the valve face. The clearance need not be considered in getting the power of an engine, but in analyzing the card it must be taken into consideration. It has the same effect upon the expansion and compression lines as so much additional length of cylinder would have. The steam contained in the clearance space expands after cut-off, and exerts some force on the piston, but up to the point of cut-off it has no effect on the piston. It will be seen at once that large clearance is a source of loss, and should be kept down when possible. In the cylinder under consideration the clearance has been assumed to be 8 per cent. of the piston's displacement.

The link gives peculiar features to its valve motion which can be best understood by comparing the extremes in cut-off commonly used. In the foregoing example the cut-off took place at three-quarters of the stroke. We will now consider a card with a cut-off at one-quarter of the stroke. It will not be necessary, in this case, to use the piston and cylinder for illustration, the movement will be the same except in distance and time. If we keep in mind the fact that the paper drum on the indicator takes its motion from the cross-head of the engine, we can always locate the position of the piston in the cylinder by the points on the card. If the cut-off be at one-fourth stroke on the card, we know that the piston had moved one-fourth its distance when the steam valve closes the port against further admission, and we know if the release show at three-fourths the piston has gone through the same portion of its stroke when the exhaust-valve opened to the atmosphere, and so with all the valve functions. Fig. No. 8 shows the steam distribution we would get with the link "hooked up" to cut-off at one-fourth stroke. A comparison with No. 7 does not show much resemblance, the steam pressure is alike, but in all other cases the cards differ. At three-fourths cut-off the steam is exhausted at 105 lbs. pressure (more than is carried in the average stationary boiler), and all that is not needed to give draft to the fire is wasted. At one-fourth cut-off the expansion line runs down to 40 lbs. when the exhaust opens, showing a fair amount of work done by expansion. The irregularities of the link motion become apparent when we consider the remaining points on the cards. On diagram, Fig. 7, the release occurred at $\frac{11}{12}$ths of the stroke, and on Fig. 8 at $\frac{3}{4}$ths. Following along the exhaust line we find that on Fig. 7 exhaust closure

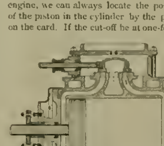

FIG 5

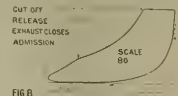

FIG 8

takes place at $\frac{5}{6}$ths of the stroke, and compression runs through the remaining $\frac{1}{6}$th, No 8 has the exhaust closed at $\frac{8}{12}$ths of the stroke, and the piston meets pretty serious resistance in compressing the confined exhaust through the remaining $\frac{4}{12}$ths. In one case the compression rises to 28 lbs. above the atmosphere, and in the other to 80 lbs. above. Coming to admission, or lead, we find that with the $\frac{3}{4}$ths cut-off the valve does not open until the piston has finished its stroke, when, in the case of $\frac{1}{4}$th cut-off, the admission is so much earlier that the lead line has a decided inclination outward. At first thought it might seem that these defects in the locomotive valve gear were a serious fault. This is not so. In a future paper the effect of the variable features of the link upon the economy and running of the locomotive will be considered.

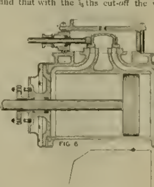

FIG 6

Harris Tabor

---

The annual meeting of the Central Railroad Club was held at Buffalo, January 27. There was a large meeting of practical railroad men who attended ready to take part in the proceedings. Consequently there was a lively, interesting and profitable meeting. They discussed several matters relating to car wheels, brake shoes and car bearings. Mr E. Chamberlin, Master Car Builder of the New York Central, was elected President of the club for the fifth time. This honor is well deserved, for Mr. Chamberlin is one of the best presiding officers we have ever seen. The expeditious way he pushes through business, his faculty for undoing the kinks of conflicting motions and his alluring way of drawing members up to speak have much to do with the success of the club. There was a banquet in the afternoon attended by the lady friends of members and visitors. It was a highly successful affair

The Pittsburgh Locomotive Works have put in a hydraulic flanging plant, and are now able to press out boiler heads, tube sheets, etc., very quickly and accurately, doing any number exactly uniform. They are also pressing out stack bases, cylinder head covers, etc., of light steel in place of using castings or hand-flanged pieces.

The shops of the N. Y. S. & W. at Wortendyke, N. J., were burned down recently, and the site will be abandoned and new shops built at Paterson.

[James H. Hevey was born at Columbus, O., October 11, 1833. He commenced his career as a railroad man on the Columbus & Xenia road as a wood-passer when he was sixteen years old. A short time after this the road was consolidated with the Little Miami, and he was made a fireman. Of this part of his life Mr. Hevey says:

"I fired a six-wheel connected engine named the 'Ohio,' Phillip Wagoner, engineer. About this time Anthony Harkness built some ten-wheelers, and Phil got the 'Hercules,' and I went with him. These engines burned, on an average, seventeen cords of wood per trip of 120 miles. Moses B. Anthony, who came here from Paterson, N. J., to make a success with a Swinbourne engine, built to compete with a Hinckley, received the appointment of Master Mechanic of the Louisville & Frankfort road, and several of the engineers and firemen went with him. He was killed soon after, and I came North again and got a job on the Three Cs between Columbus and Cleveland. I made a little money, bought a saw-mill, busted, and went to firing on the C. P. & I. between Columbus and Piqua for W. H. Romans, M. M. I did not fire long until I was promoted. In 1850 I was put in charge of a regular passenger engine. I remained on this road until 1861, when I went to the Bee Line and ran local freight for about a year, when a Government agent passed through the country hiring engineers for the Government service out of Nashville, Tenn., where I arrived in February, 1863, and remained until late winter of 1864. On my return North I again took service with Mr. Romans and ran a passenger engine between Columbus and Bradford until 1866, when I went into the employ of the city as an engineer in the Fire Department, where I remained three and a half years, leaving the service on account of rheumatism, which disabled me for a year. When able for duty, I went to the U. P. and ran a passenger engine between Grand Island and North Platte and Sidney, having been in this service continuously until the past year."

The picture of Mr. Hevey shown herewith was taken in July, 1864, on Lookout Mountain at Chattanooga, then the seat of activity. The war reminiscences have already called out a great deal of comment and excited interest among engine-men, old and young. Mr. Hevey's mother has just passed away at the advanced age of 92.]

---

"Hello! Have you seen the old man yet? No? Well, he wants to see you—they opened a new box this morning."

A new box meant another consignment of engineers from Nashville to the front (Chattanooga).

At the office I met Engine Dispatcher H——, who asked me if I knew Joe Q—— and Sam C——. I owned to Joe, but did not know Sam. After being questioned as to Joe's skill as an engineer, and my answers being satisfactory, I was informed that I would find him on the wood pile (a favorite resort of the boys when off duty). I repaired to the aforesaid wood pile, and was greeted with numerous questions as to my trip, such as:

"Glad to see you, old man. Heard Wheeler's cavalry had stopped you, and that you were in a fair way to spend some time in Andersonville."

"How did you get away? Heard they made you turn the 126," etc.

I, seeing the new men in the gang, "tumbled" and said:

"Not so bad as that; but I was stopped and the guard driven off, but after the 'Johnnies' had helped themselves to what they wanted, they left us, the guard returned, and we finished our trip."

This kind of chat was put up for the express benefit of the "tenderfeet."

According to instructions, I introduced my friend Joe to Bob K——, Clerk and Time-keeper, who entered him on the payroll as one of Uncle Sam's engineers at $150 per month, less $8 for rations and 50 cents hospital tax.

Joe and myself repaired to the Mess House, near the Crutchfield Hotel, and had our dinner. The bill of fare generally consisted of pork, beans, bread and coffee, with plum duff about twice a week. This was where we got our meals in Chattanooga. On the road we got them in the caboose. After dinner I took Joe to our sleeping quarters, a room occupied by Dusenbury, Freeman, Brown and myself. Our beds were made exclusively of army blankets for both mattress and covering, our coats being used for pillows. Our quarters were a sort of general headquarters for many of the trainmen, to whom I introduced my friend Joe as they dropped in during the afternoon and evening. By the time we went to bed friend Joe had heard of more wrecks and engineers captured and sent to Southern prisons than occurred during the whole war. After listening for a long time, he called me out and asked me if the boys were telling the truth, and being assured he had not heard the half, he drew a long breath and informed me that if the rest of us could stand it, he could—that he had as much sand as any of us. I assured him he would get used to it, as we all had.

The next morning we went to the office, and the engine dispatcher told me to take my friend out with me and learn him the road. This was a new one on me, as heretofore new men were sent out alone; lucky to have a fireman who knew the road. I think the "old man" done it because Joe came from his part of the country.

Well, at 3.30 P. M., with engine 126, we left Chattanooga for Marietta. My friend mounted on the fireman's box, all eyes and ears. I assured him we never had any trouble north of Dalton.

"How far is that?" asked he. When told, he remarked that it would be dark when we passed there. Out about Graysville he mounted the tank box and began helping the fireman by piling wood for him. Below Ringgold the road is very crooked as it winds its way through the mountains; it crosses Chickamauga Creek a great number of times. Along here dark struck us.

My fireman, Jack Carfield, informed me that his Nibs was getting nervous. Now, Joe had been considered game in the North, and I was a bit surprised at it, and thought I would try his nerve a little below Dalton, but how should I do it? All the way to near Tilden I tried to think of some scheme to test Joe's pluck and not hurt him. In my box I had a 38 Smith & Wesson, but how was I to get it out of the box without being seen?

I called Jack over, and said to him, "Tell Joe something to make him look out of the side-window, and keep your wits about you." Jack got in the gangway and laid his hand on Joe's shoulder, which I noticed made him start. I slipped off the box and got the pistol, and up again on the box unnoticed. Holding the pistol on the outside of the cab, I waited for a good level place which happened to be in a dense wood with a thick growth of fine chapparal. Here I fired three shots in rapid succession, dropped off the seat to the deck; Jack squatted in the tank, but friend Joe took a flying leap out of the window. Full of laughter, I shut off, called for brakes, stopped, and the search began. I called, but getting no answer I became frightened, fearing that Joe had seriously injured himself. We searched the ditches, sent men back, but Joe had vanished. The whole crew, train-guard and all, finally joined in the hunt. After about fifteen or twenty minutes, we found the brave lad snugly stowed away between the roots of a large stump, as nearly as possible being covered with pine straw and leaves. After being assured that there was no danger, he came out and we proceeded on our trip. At Resaca, we met a train north bound, which Joe boarded with his grip, and I have never seen him since to explain matters to him.

As soon as possible, he got back north of the Ohio river, where he told marvelous stories of his narrow escape and of the grit possessed by the brave men who ran engines on the Government roads during the war. Old Jerry M., of Galion, had a son in the service, who was ordered home on the strength of Joe's hair-raising narrative.

James H. Hevey

## HISTORICAL LOCOMOTIVES.

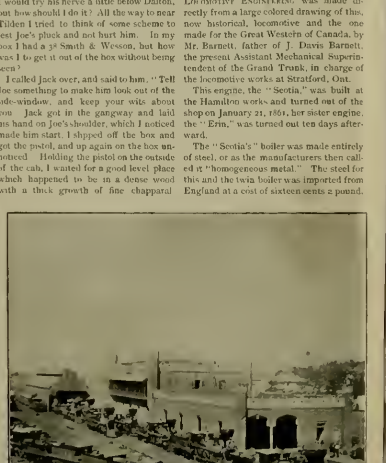
### The First Engine with a Steel Boiler Built in America.

[Colored Inset.]

The colored plate found in this issue of LOCOMOTIVE ENGINEERING was made directly from a large colored drawing of this, now historical, locomotive and the one made for the Great Western of Canada, by Mr. Barnett, father of J. Davis Barnett, the present Assistant Mechanical Superintendent of the Grand Trunk, in charge of the locomotive works at Stratford, Ont.

This engine, the "Scotia," was built at the Hamilton works and turned out of the shop on January 21, 1861, her sister engine, the "Erin," was turned out ten days afterward.

The "Scotia's" boiler was made entirely of steel, or as the manufacturers then called it "homogeneous metal." The steel for this and the twin boiler was imported from England at a cost of sixteen cents a pound.



U. S. MILITARY ENGINES AT NASHVILLE DEPOT, PHOTOGRAPHED IN 1864.

These locomotives are the ones referred to by Alex. L. Holly in his "Railway Practice in the Economical Generation of Steam," 1861, in which he says:

"In this country the practical test of the Albany semi-steel has been quite largely commenced. But both here and in England the use of steel is confined almost exclusively to fire-plates. The author is not aware that any one but Mr. Eaton, locomotive superintendent of the Great Western Railway of Canada, has made an entire locomotive boiler of steel. However the new material may stand the great test of fire, it is quite unnecessary to postpone its known advantages for the outside plates of boilers."

One remarkable thing about these steel boilers was that the thickness of sheets selected was almost exactly what afterward became the standard practice of the country, being as follows: Inside box, tube sheet, $\frac{1}{2}$-in.; door sheet, $\frac{1}{2}$-in., side sheets, $\frac{7}{16}$-in.; crown plate, $\frac{1}{2}$-in., and for boiler the face plate, throat-sheet and dome were $\frac{7}{16}$-in., the barrel sheets $\frac{3}{8}$-in., and front tube plate $\frac{3}{4}$-in., rivets of $\frac{3}{4}$-in. diameter of Low Moor iron were used throughout the construction.

The weight of the boiler, without tubes, was 10,356 pounds, there were 240 brass

tubes used that weighed 4,643 pounds, making the total weight, empty, 14,999.

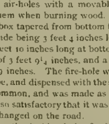
The boiler pressure carried was 130 pounds per square inch. The engine had cylinders 16x24 inches and three pairs of coupled wheels five feet in diameter, no truck.

Mr Robert Archibald, now of Hamilton, and Mr J. G. McIntyre, now of Stratford, were shop foremen at the time of building these boilers, and Mr McIntyre still has a test piece cut from one of the plates and tested by drilling a hole through it and drifting it out of all shape, but without the sign of a crack

Mr Eaton at this time was often heard to say that the price alone was all that stood in the way of the successful use of this metal, both for shell and fire-box plates

The "Scotia" class were designed to burn either coal or wood, and above the foot-plate the fire-box was provided with a line of air-holes with a movable slide to close them when burning wood. The back of fire-box tapered from bottom to top, the size inside being 3 feet 4 inches long at top and 4 feet 10 inches long at bottom, with a width of 3 feet $9\frac{1}{4}$ inches, and a height of 3 feet 9 inches. The fire-hole was elliptic in shape, and dispensed with the solid ring then common, and was made as in sketch, a form so satisfactory that it was not afterward changed on the road.

Across the inside of the fire-box was a water-table, sometimes called a baffle, this water-box was 5 inches thick and $10\frac{1}{2}$



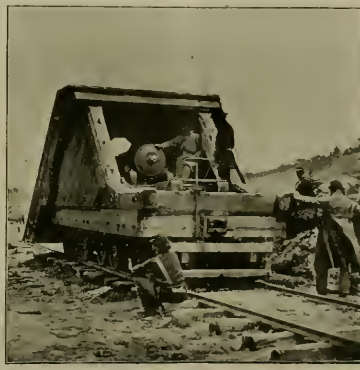
inches wide, it was not set level in the box, but was on an incline, the right hand end being 8 inches the highest, this was done to insure circulation, water flowed in at the lower left side and out at the upper

The crownbars and gusset stays were continuous, and made out of steel plate strengthened on both sides with beot angle irons This was the designer's favorite form of crownbar, and was often used by him, but has proved to be defective because it lacks elasticity. The top corner of of fire-box (side sheets to crown) had a 6-inch radius, and the water spaces tapered from 2 inches at the foundation ring to 3 inches at the top.

The fire-grate was fitted with revolving bars, worked from the foot plate by a screw, so as to either fracture the clinker or dump the fire.

The tubes were $1\frac{1}{2}$ inches external diameter The smoke-box was of thin wrought iron plate, double, with distance washers between

The main engine frames were solid throughout, 8x2 inches in section, and were



forged at the railway shops at Hamilton The hornblocks of cast-iron with V recessed faces, so that the axle-boxes were of a double V section. This design had in view increasing the jaw wearing surface of the box, and getting rid of flanges on the sides of the axle-box. The trailing side of all jaws were fitted with adjusting wedges, the front side was solid.

The "Scotia," or one of her sister engines, had the first set of wrought iron driving wheels forged in Canada. It is possible that Ross Winans & Co may have made some earlier in the States for the B. & O. Ry., but this is open to question

Another point to be noticed in the cylinder design is that the ports in length were equal to the diameter of the cylinder, 16x $1\frac{1}{2}$ in steam, and $16x2\frac{1}{2}$ in. exhaust, with a valve having $\frac{3}{4}$ in. lap and $\frac{1}{16}$ in. lead. This is an early instance of liberal ports

The side-bars were of 2-inch round steel, 3 in diameter, the crosshead was of the "spectacle" pattern, of cast-iron, with brass bushes $13\frac{1}{2}$ in long, and sponge glands or stuffing-boxes at each end of bushes for assisting the lubrication.

Having cylinders inside the frames, the valve motion was direct, but the motion itself was a combination, as it had a curved or Stephenson link in conjunction with a Gooch or movable reach-rod on the valve spindle, both link and reach-rod being connected to short arms on the weigh-bar shaft or tumbling shaft, as now called, as in the Allen straight-link motion, so that, as the curved link was dropped down, the free end of the valve stem reach rod was lifted up. The short arm on the weigh-bar shaft lifting the link was $2\frac{1}{4}$ in. long, the other moving the reach-rod $3\frac{1}{4}$ in. long. The link was suspended from its lower end

The "Scotia" had in each piston three cast-iron rings, $\frac{5}{8}$ in. square, sprung into place This is an early record of this type of piston packing, and the size is correct for a 16-in. cylinder judged by modern practice.

Part of the exhaust steam was used in heating the feed-water.

Weight (presumably loaded) is said to have been 31 gross tons = 69,440 pounds Engine was broad gauge (5 ft. 6 in ), and went out of existence as an engine with the G W Ry "change of gauge"

Mr. Eaton was a locomotive engineer of good and advanced ideas, and he had the courage of his convictions, as these engines show.

The effect of "exercising a proper control of the railroads" by a farmer Legislature, has been illustrated very well by the progress of railroads in the best (?) regulated States the past year In Kansas two miles of new track were laid; Nebraska got forty-four and Iowa twenty-eight

Coolbaugh & Pomeroy, of 29 Broadway, New York, have been appointed general agents for selling the product of the Lukens Iron and Steel Works, Coatesville, Pa The material is steel sheets suitable for locomotive boilers and fireboxes.

## Against the Brake Club.

The common practice followed by brakemen of supplementing their strength by the use of a stick in setting brakes has lately been vigorously opposed by General Superintendent Brown, of the Fall Brook Coal Co. In a bulletin-board notice he says last month "This company put on eighty new brake-beams at Lyons before the Central would receive the cars Most of these beams were broken in the center, caused by the brake being drawn up too tight, and when a brake-beam breaks parts of it are liable to get under the wheels and thereby wreck the train. This led to an investigation, and we found that brakemen were using sticks to set brakes."

The investigation revealed the fact that the caboose not provided with clubs for braking purposes was an exception This led to vigorous action. After giving permanent leave of absence to some men found sliding wheels by means of club leverage, Mr Brown intimated that the rule prohibiting the use of sticks means what it says, and its violation will result in official decapitation of brakemen and conductors

## Cars Designed to Cause Wrecks.

The views on this page are taken direct from photographs made by the Government photographers during the war, the negatives now being owned by the War Exhibition and Photo Co., of Hartford, Conn

The two upper pictures show front and rear views of a battery fixed up by General Grant's men for use on the military railroad before Petersburg This was a very heavy car, made of timbers as shown, in the shape of a snow-plow, the planking was afterward plated with railroad iron

On the car was mounted a heavy rifled cannon as shown, the gunners could push this car back and forth or haul it by horses or locomotives.

It was made very harassing to the enemy, as it would suddenly turn up in a new quarter, do considerable damage and get away before their batteries would be able to get the range to silence it

The lower picture shows another car a flat, mounting a large mortar, which the soldiers named the "Dictator" This mortar did effective work before Petersburg, as it was always to the front The photograph shows the gun crew as they appeared ready for "business"

The *Age of Labor*, a 12-page semi-monthly, has appeared in Chicago, with L. W Rogers, late of the *Trainmen's Journal*, as editor Never mind making fun or kicking at any other paper, Bro Rogers—make your paper bright and interesting—that will help you Let the others win or lose on their merits—if they have any

The Chicago & Alton people are about to order some new ten-wheel locomotives.

## Guides.

Upon this subject probably but little will be said which will materially aid experienced locomotive mechanics. However this may be, I hope to say something which will prove a benefit to apprentices, and those unaccustomed to this class of work. I have seen machinists who claimed to have had vast experience in these matters who could not, or at least who never did, line up a set of guides which would run cool, and not cause excessive wear to the crosshead.

Before starting to line up a set of guides it is, of course, very necessary to have the bearing surfaces of each crosshead lug planed perfectly straight and parallel, also to have each guide planed or ground true its entire length. To true up the crosshead I should proceed as follows.

Place securely in the tapered hole from which the piston-rod was removed a short mandrel; this mandrel should fit the hole perfectly. Place the head on the planer bed with the top side down to enable the bottom bearing surfaces to be planed first. In some shops they use two V-shaped iron blocks bolted to the planer bed, and clamp the mandrel with the crosshead attached in the V part of the blocks. This is a very good plan, and it insures the surfaces being planed in line with the mandrel, which is the thing desired. In case no V blocks are to be had lay the top part of the head flat on the planer bed, and shim under it with narrow strips of roofing tin, or paper, until with the aid of a pair of inside calipers you find that the mandrel is in line with the bed.

Now, it is necessary that the bottom bearing surfaces should be, when finished, equally distant from the center of the piston-rod hole A, Fig. 1.

Now turn the head over, and clamp it to the bed, allowing the surfaces just finished to rest on two parallel strips of iron, B B. This will insure the upper and lower surface of each lug being parallel when finished. It is not necessary that the upper surface of each lug should be equally distant from center A, it is better to leave them an unequal thickness than to plane away the stock to make them equal; plane only enough from each upper surface to true it up.

Now the guides should be planed or ground the entire length of each, that is, when finished the ends A A, Fig. 2, which bear on the guide-blocks should be in line with the wearing surface B. I have known some alleged mechanics who, when they wished to close guides, instead of removing and reducing the guide-blocks reduced the end of the guides as per A B, Fig. 3, to bring the wearing surface C to the crosshead. This is not the way a mechanic would do the job. Better have a liner say ⅛-inch thick on top of each block.

These liners can then be removed, reduced and replaced without disturbing the guides, which thereby remain standard.

After the crosshead is trued up and the guides are ground their entire length all is ready to begin the operation of lining them up. I have taken for example that style of crosshead and guides with which ordinary eight-wheeled engines are usually equipped, for the reason that the task of properly lining up this style of guide is about as intricate as that of any other style.

Before running the line through the cylinder care should be taken to have each guide-block in both the cylinder-head and guide-yoke perfectly level with the engine when each is screwed solidly to place, and to obtain good results each block should be leveled *separately*. I have seen machinists endeavor to level them by placing the level on a straight-edge reaching from block to block across the head. This is poor policy, as it is impossible to level them thus unless the distance from center to lower face of each block is equal; that is, of course, assuming that all other parts are properly constructed. The reason it is impossible to level them in the manner de-

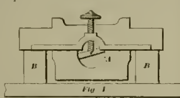


Fig. 1

Fig. 2.

Fig. 3.

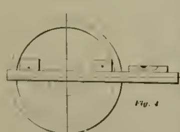

Fig. 4

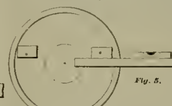

Fig. 5.

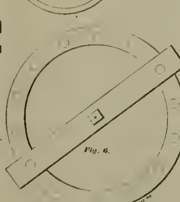

Fig. 6.

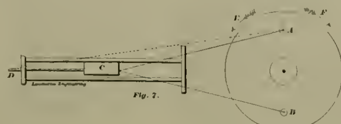

Fig. 7.

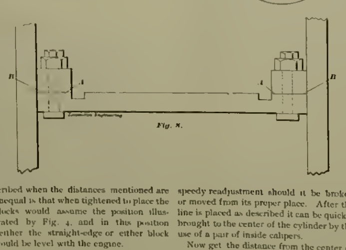

Fig. 8.

scribed when the distances mentioned are unequal is that when tightened to place the blocks would assume the position illustrated by Fig. 4, and in this position neither the straight-edge or either block would be level with the engine.

Therefore, I say the better plan is to level each block separately in the following manner

Adjust the level to a long straight-edge reaching from frame to frame just back of the cylinders, or adjust it to that part of the cylinder upon which the steam-chest rests. Then fasten the level near the end of a shorter straight-edge, then holding the top of the other end firmly to the under surface of each block (see Fig. 5) twist them until the level shows correct, tighten each thus and you are sure that all are level with the engine.

After leveling the blocks, take a narrow piece of board and bore an inch hole through the center; also one through each end, the proper size and distance apart to take two of the front cylinder head studs. Over the center hole tack a small piece of thin sheet-iron, and bolt the board to the cylinder, as shown in Fig. 6. Then mark the center of the counter-bore of the cylinder on the sheet-iron, and with a breast drill bore a hole in the iron through which the line or fine wire will easily pass. After passing the end of this line through this small hole, tie a knot in it, and pass the other end through the stuffing-box in the back cylinder head, and fasten it to a stick driven tightly into the slot in the guide-yoke through which the main rod plays. This method of securing the line in the front end of the cylinder will insure its speedy readjustment should it be broken or moved from its proper place. After the line is placed as described it can be quickly brought to the center of the cylinder by the use of a pair of inside calipers.

Now get the distance from the center of the piston-rod hole in the cross-head to the lower bearing surfaces of the lugs, and compare this with the distance from the under surface of each guide-block (when in place) to the center of the line through the cylinder. Should the latter distance be the greater, then about $\frac{1}{16}$-inch more than would make the distances equal should be taken from the under surface of each block. This allows for a liner $\frac{1}{16}$-inch thick to be placed between each block and bottom guide when placed in their proper positions relative to the center of the cylinder. After scribing on the side of each block the amount necessary to come off, measure from the mark to the top of each, and mark on the same side the amount necessary to make it when finished ⅛-inch less in thickness than is the crosshead lug.

I say ⅛-inch less because, as previously mentioned, I consider it a good plan to have a ⅛-inch solid liner between each block and top guide, so when it becomes necessary to close the guides these liners can be slipped out and reduced the amount required, leaving each block in place. This lowers the top guides and takes up the lost motion between them and the crosshead.

When closing guides the bottom ones should never be disturbed after they are properly lined, for by so doing they are liable to be thrown out of line with the cylinder, and this would surely cause trouble. Then the top of the crosshead and top guides are worn more than are the bottom ones when an engine is working forward, and as locomotives usually run forward more than backward, this difference in wear is marked.

I will try and illustrate why the top guides receive the greater amount of wear when an engine is moving forward. Let A, Fig. 7, represent the crank-pin on the upper quarter; B, the same on the lower quarter; C, the crosshead; D, the piston rod; A to C and B to C, the main rod. Now, when power is applied at D, to move the wheel in the direction indicated by the dart E (forward), the tendency is to bring the main rod, crosshead and piston rod to a straight line indicated by the dots; this pulls the crosshead against the upper guides; then when the pin reaches the point B and power is applied at D, it tends to make the angle D C B greater; this again pushes the crosshead to the top guides. Now, when the thing is reversed, and the wheel made to revolve in the direction indicated by dart F (backward), and power is applied to pin at A, it tends to increase the angle D C A, and this pushes the crosshead to the bottom guides. When the pin arrives at point B, applied power tends to straighten the angle D C B, and this pulls the crosshead to the bottom guides. I hope that this illustration will make it plain why there is usually more wear to the top than from the bottom guides, and also why it is better when closing guides to lower the top than raise the bottom ones.

After having replaced and leveled the blocks, bolt each bottom guide to place with a $\frac{1}{16}$-inch liner between it and each block, leaving the liners large enough to trim off flush with the blocks after they are in place. Put in all of the bolts which are to be left in when the job is finished. Do not use temporary bolts. See that each bolt is a snug driving fit with the soft hammer. Large nuts, or a sufficient number of washers, can be used on top of the blocks in place of the top guides. After all nuts are tightened place a straight-edge lengthwise of each guide to see that tightening the nuts did not spring them. A straight-edge which reaches from oil-slot to oil-slot would be about the right length. Should a guide be high near the center, place a narrow paper liner across under the block at point A, Fig. 8, at the end nearest which the high point is. Should the center of a guide show low, put the liner across at point B. The thickness of these liners, and whether placed at one or both ends, can only be determined by trial. After getting the guides perfectly straight, with all nuts tightened, take the short straight-edge, with level attached, and place it across the face of each guide, and see that it is level, and that the level shows correct with the engine when the straight-edge is placed across both guides. After this is done set the guide gauge so that when the beam is flush with the bottom bearing surfaces of the crosshead lugs the point will be at the center of the piston-rod hole (see Fig. 1). Now place the gauge across the faces of the guides. The point should come exactly in the center of the line or wire its entire length. In case it does not it must be made to do so, by either inserting or removing liners, as the case may require, being very careful not to displace the cross liners of paper put in to straighten the guides. To avoid springing them, it is best to try the straight-edges on them after every change made in the liners.

When the guides are straight, level, and in line with the cylinder, remove the line and lay the crosshead on them. Now we must see that the crosshead lies perfectly level on them at all points, or, to use a common expression, we must "take the rock out of it," and this is about the nicest part of the whole operation of lining up guides, as there is no line to guide one, and unless great care is exercised they will be thrown out of line. Very thin liners and cross liners may be removed or inserted without danger, as the crosshead will show the low points more accurately than did the straight-edges. A good way to ascertain if the guides are level is to draw heavy chalk lines across their faces at different points, for after the crosshead is passed over them they will be erased at the highest points.

When no rock of the crosshead occurs at any point, place a screw-jack under each end of the inside guide so that the bolts will just pass out; remove the bolts and put on the ⅛-inch liners, which, by the way, should be made exactly the size of the blocks, and the holes through them should be made large enough to admit of their sides being flush with those of the blocks when all are in their final positions. Now bolt on the top guide, which should be straightened and leveled by passing the crosshead forward and backward after the jacks are removed, and by the use of the heavy chalk lines previously mentioned.

When finished, the crosshead should pass freely from end to end of the guides, and only admit of the passage of a piece of heavy writing paper between it and the top guide.

Now with a small, very sharp chisel trim the liners flush with the blocks, and finish all with a fine file and emery cloth. After this course of procedure is gone through with on the outer top guide no fears need be entertained in regard to the crosshead running cool, and wearing but little, provided it is made of the proper material.

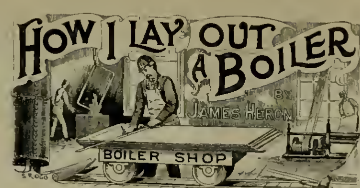
In regard to the proper amount of lateral motion to allow, I will state that I have always found good results follow leaving $\frac{1}{16}$-inch full. That is $\frac{1}{32}$-inch full on each side.

S. C. Hitchcock

---

It is no unusual thing to set up a temporary forge under a bent front frame and straighten it, but to actually weld on a frame broken entirely off is not often done. A six-wheeled Baldwin switcher on the St. Paul & Duluth road, at Gladstone, Minn., recently broke off both the front frames under the buffer timber and they were welded on without removing the frames. A portable forge was mounted on a truck, so as to be moved quickly, air being supplied through a hose, the new ends were "V'd" in the blacksmith shop, the ends of the frames scarfed and good welds made, the job being hammered to a finish.

There is a select club of railroad men in New York, known as the Flat Wheel Club. No man is eligible for membership who does not personally believe himself capable of assuming the duties of any official position on a road, and members can only cast a white ball for an applicant when they believe him a poorer railroad man than themselves. If this was all, the club would overflow with the brains of self-made men, but there are other restrictions—have to bathe in the winter months, etc.



Knowing that I was an occasional correspondent of your paper, many of its readers who have visited shops of which I had charge, have asked me to write something about laying out locomotive boilers, tank sheets and other iron work.

I am well aware that there is no trade that is less understood by the men working at it—the rank and file—than my own. The few who do learn how to lay out and plan work usually keep it to themselves, and the average apprentice rarely gets farther than the riveting hammer and the calking tool. This is especially true of large shops, such as locomotive works, where the best results are obtained by having a specialist for each part.

I know better what my fellow boiler-makers need to learn than how to write it; but I trust an honest effort to help will be appreciated and that my critics will be lenient.

Fig. 1.

Fig. 1 shows the mud ring, or foundation of a locomotive boiler with section of inner and outer sheets at boiler.

To make a boiler of standard dimensions, this ring must be square and of the proper size. To prove this and get the holes in proper place, I use the following method

Take straight-edge and line off from inside of ring as at A A 1, do the same back and front. Now set your trams to center where side lines cross end lines. If one side is longer than the other this will show it. Then tram diagonally, always working from front end, scratch with trams as at A 1. If you strike both back centers, your ring must be square. If you should find ring out of square, say one-eighth of an inch, it will be of no consequence as that can be worked in to flange by putting the holes that much nearer the roof, or nearer the edge, as the case may be, but your starting point, or first hole in front end of mud ring must be square with opposite side, or your stay-bolt holes will not be in line in inner and outer sheets, and your sheet and fire-box would be twisted. This done, with A A as ends find center of ring at ends as at B. This will be your center hole at ends of ring. Now, take your regulator or templote, and lay off holes, working from center at ends, and from starting point at front ends at sides.

The reason I work from front end is this If you have not got side sheets square with each other at that end when you come to build up your boiler, your connection and cylinder will not be straight or in line with sides where engine frames are secured.

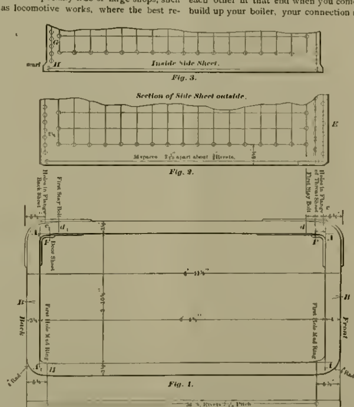


Fig. 3.

Fig. 2.

Fig. 1.

Now we have all rivet holes laid off, we must lay off stud holes for ash-pan and grate-bar rigging, also holes in corners, of which I shall write later, and our mud ring is laid out.

To find position of holes in outside side-sheets, where they connect to back and to hearth sheet, as at c and c 1, and stay-bolt holes as at d d, I have templates for all this work, which I shall illustrate in its proper place, and, as I am not writing for experts, I want you to understand how I made these templates. As you can see by Fig. 1, the corners of the mud ring is 4 in. radius, material ½ in., making radius 4½ inches over all. Corner forms quarter of a circle The sides are flat and must not lap over circle, so we must allow 1¼ in. for lap of side-sheet, added to the 4½ in. radius, making 5¾ inches, which bring us to first hole in side sheet as at E, Fig. 2. The same applies to back and front corners, now you have the length of outside side-sheet from center to center of holes. Note double row in front end.

Now locate first row of stay-bolts, the sketch will explain the rest. Now we have length of side-sheets, and stay-bolt holes laid off one way, we will go to Fig. 3 or inside side-sheets, and you will note at H, that first holes for mud-ring rivets are not on line with holes for flanges My reason for this is that I prefer a short flange at corners, with rivet as close up in corner as I can get it. Then the man with the big hammer and little knowledge of his business cannot wedge off the sheet from mud ring, when a leaking corner is reported. F F gives you the length of this sheet from center to center of hole for flanges, less ½ inch at top, back where door sheet slopes in. This will also be the length of crown sheet, c to c of holes, less ½ inch back end.

Note, 3½ in. water space at bottom and 4 in. at top of door sheet, d d gives position of stay bolts

I think I have made the foundation part clear enough. In my next I will show method of finding rivet and stay-bolt holes vertically.

J. Heron

## An Employes' Paper.

"It appears to me," said the agent of an envious contemporary lately, to a well-known railroad man, "that these fellows running LOCOMOTIVE ENGINEERING are well endowed with cheek when they expect to make a paper that will interest presidents, managers, superintendents, master mechanics, master car builders, foremen, shop-men, engineers and firemen."

"What is the difficulty?" questioned the railroad man. "Don't you think that all these classes of men are likely to be interested in reading news articles and discussions of railroad machinery matters?"

"That is not the objectionable part," said the agent, "it is the attempt to put all railroad men on one plane. Why, that is an employés' paper, and the editors put in things intended for presidents and general managers to read and profit by. The thing is absurd."

"It may seem very absurd to you," replied the railroad man, "but I look at it differently. In my eyes the presidents and general managers are employés just as much as firemen. To put them all on a common plane, and make up a paper that will interest them all alike is a high and useful purpose The difficulty with most railroad papers has been that there was too much class literature in them. The writers wrongly assumed that there could be no common interest between officers and workmen, and the tendency was to open up artificial breaches between classes that naturally come closer together when left alone This thing has been bad for railroad men and bad for railroad papers. It is why most railroad papers are so little read. The effort to carry out a different method has my sympathy."

The agent concluded that he had struck a wrong key, and said "Good day, you will have our paper free, as usual. I hope you will keep on taking it"

---

Nearly all Western railroads have been working long mileage with their freight engines during the last few months, but the locomotives belonging to the Chicago, Burlington & Northern appear to be a little ahead of all others. During the month of December all the engines belonging to the company made over 5,000 miles. For some time there were only two engines out of service.

The Elevated Railroad Company, of Chicago, have contracted for Pintsch gas being used on all the rolling stock

For some heinous crimes the Chinese condemn criminals to be kept awake until they die—usually nine or ten days. Some of our American railroad men are so used to this punishment that they could probably stand eighteen or twenty

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

Subscription Price.

$2.00 postage paid to any part of the world.
Single Copies, 20 cents.

Special Notices.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary—always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

## To Make Repairs Easy.

At some seasons of the year every railroad company in the country is short of power, and at these times a locomotive is from twice to ten times its ordinary value to the company. These are the times when the engine-houses are certain to get filled up with locomotives requiring repairs that will make them miss some trips. One has a cylinder-head broken, another is laid up with a broken eccentric-strap which twisted the rods and called for new adjustment. A broken valve-stem is holding one engine in, and another is bound to be idle for a day or two because the draw-bar of a caboose went through the front casting of the smoke-box. It is needless to enumerate the small disorders or breakages that are keeping other engines in shops when the transportation department is harassed with cars waiting to be moved. The delay of locomotives waiting for small repairs at times when the road is overcrowded with business is a fruitful source of disturbance and of animosity between the operative and the mechanical departments.

Every master mechanic who takes an intelligent interest in his business can readily see the saving of time that would result in the repairing of locomotives if parts were kept in stock ready to put on when an engine came in broken down. Those who do not recognize the importance of this are not a credit to the business. It is over a quarter of a century since the more advanced class of railroad mechanics began advocating the use of interchangeable parts for rolling stock repairs. For twenty years the expatiating on the advantages of an interchangeable system has monopolized the time of railroad men's meetings and the pages of the engineering press. Few men in charge of railroad rolling stock are to be found who do not indorse the interchangeable system, and yet there is not a railroad in the country, except the Manhattan Elevated, that has the system properly in practice. There are roads where duplicate parts are kept ready in stock for certain engines, and great saving of time is effected; but there is no railroad that has in practice the perfected interchangeable system followed in many other lines of machine work. The question naturally arises: Why do profession and practice disagree so thoroughly in this important matter?

The different superintendents of motive power, if asked to answer this question, would reply enumerating difficulties that beset his particular case, and we should receive a mass of conflicting testimony. A careful study of the question leads us to believe that the failure of railroad companies to put into practice a successful system of preparing interchangeable parts for repair work is due principally to the practice of depending upon drawings for dimensions, and on the two-foot rule for measurement. There are other obstacles that hinder the establishing of practical standards, such as the diverse character of the engines and cars purchased, but the real difficulty that has led to nothing all efforts toward interchangeability is the blue print and the boxwood rule. Both of these things are highly useful in their way, but as means for maintaining machine parts of the same size they are a failure.

The thing works in this way: a superintendent of motive power gets out drawings and specifications for a standard locomotive, and a class is established. Engines are built at different times and in different shops, according to the drawings. In laying out the work for the different parts a scribe line is $\frac{1}{64}$-inch to one side, dividers have led to 16-inch error in another place, and the trifling mistakes of those who lay out and of those who execute add up till very few of the parts can be taken from one engine and put upon another without fitting.

A correspondent writing in this issue, who is a well-known master mechanic, and has done important work in advancing the practice of making the parts really standard, proposes a certain remedy. He has struck the right note in calling for more general use of templates. If railroad companies would establish, in connection with their mechanical headquarters, a place where templates would be made by expert workmen for the use of all the shops in the system, it would be the best paying enterprise we can conceive. The templates would be made by men accustomed to accurate working, with good instruments of precision to keep the measurements correct. The development of such a practice would secure uniformity for all parts that were made to the templates.

There is no more certain way to attain diversity than to send out blue prints and order different men to make patterns or templates by the ordinary methods of measurement. There is already said to be half a dozen different standards of the last M. C. B. axle. There is not a standard made for railroad companies by outside concerns that does not have diverse forms that will not interchange with each other. The true remedy for this would be for the mechanical associations to arrange for the making of uniform templates of their standards. Drawings have had their turn and are found badly wanting. The mechanical head of a large railroad system can do for his company all that the associations ought to do for railroads at large. A template-making department could be established at small cost and its usefulness would soon be demonstrated.

## A Voice from the Car Stove.

The cold weather of the month of January has given the first real test of the systems of heating cars by steam from the locomotive, and they have gone through the ordeal very successfully. The systems that use hot water as a heating medium are most popular. Direct steam is much more satisfactory than any of the stoves as a means of heating cars, but with it the temperature fluctuates far more than with hot water. The leading objection to steam is that it keeps the cars too hot. This is bad, but it is not so objectionable as the service of the ancient stove which half roasts those in its vicinity and leaves those in the middle of the car to freeze.

The experience of this winter leaves no excuse for railroad managers to longer delay the providing of their passenger equipment with apparatus for safe heating. It has been the common thing for those who clung to the dangerous stove to say that they were waiting for the perfecting of car-heating appliances. Car-heating appliances that worked satisfactorily last month may be accepted without more perfecting. Those who persist in delay do so merely because they prefer the cheap and dangerous device to that which is safe and efficient, but calls for the expenditure of some money.

After all the fearful losses of life and suffering that have been caused by the heating of cars by stoves, it is amazing the number of cars yet to be found with that means of heating still in use. Several of the roads, doing the heaviest suburban passenger business around New York City, still use stoves. Some of these roads, such as the Delaware, Lackawanna & Western, have crowded suburban trains with red hot cast-iron stoves in the cars, running at very short intervals, and having absolutely no signal system for the protection of trains. It is appalling to think what will be the result when the inevitable collision happens to one of these trains on a winter night.

The last three mild winters have done much to disguise the danger that lurks behind the red hot stove given so prominent a place in so many passenger cars. But every recurrence of severely cold weather gives warning of danger. As we write the daily paper on the desk blazons in bold head lines: "Wreck on the Rock Island, the cars burned up." It was a story as old as our age of railroading. A train heated by stoves, a wreck, and the fractured stoves set fire to the splintered cars. Fortunately in this instance it is not related that a load of passengers was pinned in by the fractured timbers, and held in the wreck till the people were burned to cinders. The managers, who are responsible for the passenger cars of that company still being heated by stoves, deserve no credit for the wreck failing to be a holocaust. Circumstances over which penurious boards and reckless managers have no control, shout with no uncertain sound that the safe methods of heating must be applied to all railroad cars.

## "America's Greatest Railroad"—for Rear Collisions.

One hardly gets over the horror produced by one fatal accident on the New York Central road than another takes place to keep up the interest.

With the exception of the New England the Central wears the medal for accidents, while for killing and maiming human beings it stands at the head.

The Hudson River Division is a double tracked road running hundreds of trains a day, freight and passenger, and using the same methods for their protection that are employed on the meanest single track roads in the lumber regions.

Rear collisions are of almost daily occurrence; trains follow each other "in sight," sixty-car freights, without air-brakes, hurry from station to station to clear locals and dodge sixty-mile-an-hour expresses, without the protection of block signals, while the ornamental president and financiering board of managers "wait for the best signal to be invented."

Absolute block signals have been practically perfect these twenty years, 98 per cent. of the roads in England are using them successfully and yet "America's Greatest Railroad"—God save the mark!—waits for perfection, and dividends.

Absolute blocks will save most, if not all, the rear collisions, but it will not cure the general debility of this magnificent but mis-managed property.

There is dry rot at the core; the men in the train service are demoralized and disheartened; discharges take place without trial; suspensions are free as water; men of spirit are cowed or leave the service, and incompetents multiply. On Christmas Eve a fearful rear end collision took place at Hastings-on-the-Hudson. A passenger train was stopped while a freight got out of the way; the brakeman went back to flag and went into a depot; the express flew by and into the standing train—14 dead, many hurt. Last year this road had a strike of trainmen and put on a lot of inexperienced, cheap men and boys. Was this brakeman one of them?

Block signals would have kept these trains apart—a board from a quarter to half-a-mile from a station, worked by a wire and a man, is not a block signal.

The rule sends the flagman back half a mile; it will take him eight or ten minutes to go so far, yet they run trains sixty miles per hour on five-minute headway, that run this distance in thirty seconds. Penurious management has kept signals off the line; mismanagement has taken the heart out of the men; they are doing a four-track business on two tracks, and gambling in human life to keep it up.

The strength of a chain is its weakest link. Of what use is their stone-ballasted track, their magnificent "870's" that haul the Empire State express, their speech-making president, their Grand Central Station, and their Hudson River scenery, when their hundreds of trains are crowded out upon the line with nothing to keep them apart—absolutely by guess, so far as its directors know.

The engineers save much trouble by good judgment, but if a man has to stop his train on the road, then look out.

Is it not time that some practical railroad men had a place among the directors of this line?

Can the absence of the only known means of protecting trains on a road like this be called stinginess, lack of foresight or carelessness? Is it not crime?

Can the public prosecutor view the remains of these many mangled men and women and write "accidental"? Should he not use stronger language.

## Breakage of Car Couplers.

A great many new freight cars have been ordered within the last month, and it is greatly to the credit of the railroad companies concerned, that air-brakes and the M. C. B. automatic car coupler have been specified for most of them. Automatic couplers are rapidly forcing their way into favor in the face of great difficulties and over tremendous opposition which often has made itself felt in the wanton destruction of railroad property. It is surprising how much damage has been done in yards by those who were anxious to see just how much certain couplers would stand. This species of experiment has nearly stopped and explains to some extent the decreased percentage of breakage. The decrease of breakage, however, is to some extent due to the strengthening of weak parts and to the increasing number of the couplers in service.

The offer becoming common by makers to maintain the automatic couplers for one dollar or less, annually, settles the question of expense of maintenance as compared with link and pin couplers. A car equipped with the old form of drawhead which costs less than one dollar annually for links and pins makes very small mileage in heavy trains.

The weakest part of the M. C. B. coupler, and the part most liable to breakage is the knuckle. The success of the coupler requires the knuckle to be made of very strong metal, the stronger the better. Many railroad men interested in the coupler question, were startled a year ago by a statement made at the New England Railroad Club to the effect that replacing broken knuckles with others made of cast-iron was practiced. Some were indignant, others were incredulous. But cases of replacing broken knuckles with cast-iron substitutes were reported from other parts of the country, and few men now doubt that the practice prevails to a limited extent. We lately heard the statement made by a railroad man that there is a concern in New England which is regularly making knuckles of cast-iron, and that this accommodating foundry goes to the extent of imitating the maker's stamp put on the original knuckle. We examined in the office of the Gould Car Coupler, wretchedly made steel knuckles that had an imitation of the maker's stamp.

There is a good deal heard about the framing by Congress of laws relating to couplers. It would not be a bad plan to make the putting in of cast-iron knuckles a crime. At all events it seems to be time that the makers of couplers obtained legal trade-mark protection for the stamp they put on knuckles. Putting in of worthless material in a car-coupler knuckle besides causing delay, is a source of danger to the train men where the car is running.

## The Oldest Boiler-Plate Rolling Mill.

About forty miles west of Philadelphia, on the main line of the Pennsylvania Railroad, is Coatesville, a neat rural village nestling amidst the groves of a region of low hills and pleasant valleys that attract the city dweller to the haunts of nature undefiled. This Coatesville will excite little more than a passing glance from the traveler, yet it is a place that would be famous among the engineering fraternity if it was the practice here, as in other countries, to acknowledge or magnify the importance of places where valuable industries have originated.

About the finish of the War of Independence, when the infant States were famishing for the want of iron industries, there sprang into being in the valleys and hillsides around Coatesville numerous Catalan forges, where wrought iron was made directly from the ore. The advantage of this district for nursing such an industry was the existence of great forests that provided charcoal, and the fine water-power that operated the crude mechanism employed.

The presence of these Catalan forges and the great wood and water privileges led to the building here, in 1810, of the Lukens Iron Works, which afterwards became the Lukens Iron & Steel Co. The first work done by this concern was the making of iron plate from the charcoal blooms produced in the Catalan forges. Here the first plates for boiler-making purposes were rolled on the American continent, and the product was so good that a demand arose in England for the charcoal plates that could not be procured anywhere else. Standard No. 1 charcoal was the only grade used. The business was carried on in a very crude way at first, for they had no means of shearing the plates, and these had to be sent to the boiler-makers as they came from the rolls. The practice of trimming the sheets was introduced by other mills after a time, and this company had to do so likewise.

Fifty years ago the standard size of plate was 40 inches by 26 inches and ¼-inch thick. When a boiler-maker ordered a sheet this was the size he expected to receive. The Lukens mill has grown in proportion to the business of the country, and the largest plate rolls in America are now to be seen in use here. They roll sheets to the width of 120 inches, and ranging from $\frac{3}{16}$-inch to 1¼-inch thick.

The company have adhered to their specialty of making plate; they have devoted the greatest care and attention to the production of the best article that could be made, and their customers admit that no better plate is to be found on the market. They appear to take particular pride in the uniform quality of their steel.

Until this year this firm has made no effort to obtain customers among railroad companies, but it is now in this field. Lukens steel will soon be as familiar to railroad men as the most popular steels now in general use. The steel plate is made from selected blooms of known quality and rolled by the best machinery, rolling, shearing and inspection receiving particularly close attention.

The quality of the product may be judged from five tests I noted at random in the testing room. The tensile strength was respectively 59,000, 59,300, 57,200, 58,100 and 57,600 pounds. The percentage of elongation was 41, 41.5, 41, 39.5 and 41. The reduction of area was 62.2, 63.3, 61.8, 61.7 and 63.8 per cent. Those familiar with the physical characteristics of steel will note that this article has extraordinary ductility combined with strength.

They are building a fine new rolling mill with open hearth furnaces and gas-making plant attached which will greatly increase the capacity of the works. This is already about 200 tons per day. Coolbaugh & Pomeroy, of New York, have become general agents for the sale of Lukens steel.

---

Some time this coming fall both the engineers and firemen will hold their bi-annual conventions. The entertainment committees of both orders have heretofore thought it expedient to raise a large amount of money and have got some of it by issuing a "souvenir"—usually a rather bulky book with a few pictures of grand officers and a lot of advertisements at high rates.

As a general thing, these "souvenirs" are "farmed out" to professionals who agree to turn over to the committee a lump sum of money for the privilege of doing all the work—and blackmailing the manufacturers of the country.

These disreputable bilks are making the fair names of the orders they use a by-word with decent people, and it will stand the brotherhoods in good stead to shut down on the practice of lending the name of the orders to bunco steerers to use as a club.

There is not one advertiser who pays money for space in one of these books that believes that it does him a cent's worth of good. He does not want to appear mean to men who handle his devices, or else has a vague idea that he is "helping the boys."

The two great brotherhoods are not objects of charity and do not need any Louisiana Lottery annex.

Manufacturers and dealers can rest assured that not above ten per cent. of their money ever gets to "the boys," regardless of what the letter "under seal of the lodge" says to the contrary.

Members of the orders should see that they are not used to further the ends of sharpers, who are experts at promising an edition of 10,000 by affidavit, and 250 by actual count. When this souvenir fake shows up this time, vote DON'T—write it large, and with red ink.

---

LOCOMOTIVE ENGINEERING has an exceptionally large circulation in foreign countries, and a gratifying feature about it is that the foreign readers take a very active interest in the questions discussed in the paper, and display a disposition to express their own views. In this issue we publish letters from correspondents in Belgium, Australia, Mexico, Canada, and several from New Jersey, Missouri and Arkansas. Our office cat reports that these places embrace the ends of the earth.

## NEW BOOKS.

MACHINERY PATTERN MAKING. By P. S. Dingey. John Wiley & Sons, New York. 12mo, cloth. Price $2.00.

This is a book of over 100 pages, containing a large number of engravings. This book is not an elementary one, and does not attempt to teach pattern making; it discusses pattern making methods, offers suggestions, etc. The author is a practical pattern maker, and his book is therefore useful to practical men.

---

The New York Safety Heating & Lighting Co. are equipping the Wagner palace cars with the Gibbs steam hose-coupler.

## Tools and Machinery for Railroad Work.

At the last meeting of the New England Railroad Club, Mr. E. E. Davis, Master Mechanic, Boston & Maine, read a paper on the above subject. He said that a very large percentage of railroad shops are equipped with machinery bought years ago, when the roads first started. This gives the tools such an age, that even if they were not worn in the least, their capacity for work would be such as to make them very far behind the more modern tools, both in amount and quality of the production. But when to these defects is added the wear and tear of years of service, so that the lost motion in every wearing part is such that it is next to impossible to turn out even a fair piece of work, there is assuredly a tremendous waste of money. Not only does the manufactured piece cost extra on account of the longer time required to make it, but when done it isn't as good as the modern tool would have produced, and of course it will not last as long in actual service, and here is another waste of money. Then again it takes two or three times as much power to keep the old traps running as is required for a good set of machines.

CLINGING TO OLD TOOLS.

Officials very often seem to hold rather queer notions regarding those things. They say, "Well, that machine cost a great amount of money and it ought not to be thrown away." They don't seem to realize that this old machinery has done them valuable service all through the years that are passed and that it has long since paid for itself.

Now when these old tools have done all that could reasonably be expected of them, why not let them go and take advantage of the development that has been made in all machine work, by putting in the shops the most modern tools that can be procured? Shops that omit to do this will be left tremendously far behind those that do use the most modern equipment.

TOOL SPEEDS PAST AND PRESENT.

What can we do with a lathe or a planer made twenty years ago when comparing the quantity of work done by it with that done by machines made to-day? A planer running ten or twelve feet per minute, with the feed so fine you can't measure it, won't answer at the present time. We want a planer to run from 16 feet to 30 feet per minute, with table traveling from 1 to 3. There are planers made to run 5 to 1, but I think they are under repairs about one-half the time.

We want a lathe to run from 25 to 45 feet per minute, with feed from 1-32 inch to ⅛ inch, according to the class of work it is on. There are tools made to-day for nearly every kind of work, and these improved tools are what every shop that has the work for them needs. In making the selection of tools for a shop it requires a thoroughly practical man, and after they are selected, it requires an able man to manage them.

There is not much difference between the combination of a modern tool and a poor manager and the combination of an old-fashioned tool with a good manager.

ADVANTAGE OF SPECIAL TOOLS.

Regarding the merits of different tools, the advantage of the screw machine as an addition to the shop equipment may be mentioned. It is without doubt, for what it can do, capable of saving from 25 to 500 per cent. in the cost of work done. When a machine can be had by which you can put a piece of work through a half dozen different operations and finish it complete before it comes out, you have a great advantage over being obliged to produce the same in a lathe, where the lathe must be stopped and the tools changed for each operation, and in the case of the lathe, the uniformity of product is nowhere near equal to that of the screw machine.

In much of the work done by this tool, one machine will produce in a day a quantity equal to what four or five lathes could do with a first-class operator at each lathe.

Take the studs for a boiler for one thing, they can be finished on a screw machine in the same time that they can be drilled and countersunk for a lathe, say nothing of turning.

FAVORS MILLING MACHINES.

Very few shop managers understand to what extent the milling machine for general shop practice could be judiciously used. The idea is, that it is solely for a tool room, to a certain extent it is, and was first used for that purpose, but it is fast taking the place of the lathe and planer on certain kinds of work, and the time has come when no railway machine shop is well equipped for economical work without some milling machines.

Some kinds of work can be done 25 per cent. cheaper on the milling machine than on the planer, and 50 per cent. cheaper than on a lathe.

Take the brass work, say a gauge-cock, with the milling machine, and using an under-cut, with the cutter as wide as the guage-cock is long and with the same form, you can finish the whole casting with one cut, and do more work with this machine in one hour than you can on a lathe in five hours, and do it better, though there are few railway shops that as yet make any account of this machine.

THE VERTICAL BORING MILL.

One of the modern tools for heavy work is the vertical boring and turning mill, most shops do all of the heavy work on the driving-wheel lathe. With the boring mill, you can bore a tire quicker and with half the help. Take for instance a driving-wheel center, the extra labor in shifting the heavy casting around on the driving-wheel lathe will pay the whole expense of fitting the casting ready for the axle with the turning mill.

PNEUMATIC HOISTS.

Now we have another new-fangled idea, as some are pleased to express it, and that is the way of hoisting and conveying the heavy work from one machine to another or one part of the shop to another. That is the overhead railway with the pneumatic hoist, and this hoist is as far ahead of the chain hoist as the chain hoist is ahead of manual labor.

TOOLS IN THE BLACKSMITH SHOP.

Referring to blacksmith-shop tools, there has been the same improvement here as in every other department, and I think the majority of shops, so far as they have room, have quite modern tools, in fact, more so, according to the number of machines, than any other department. But there are some shops where they use the same old beam-trip-hammer, where you have to pull a string connected with the binder to see it go. Now, if there were such a premium on some of the old antiquarian machines, as there is on some old furniture, what a harvest we should reap! I don't know of but one thing they are good for, and that is to remind us of our grandfathers' boyhood days. If you are going to see how cheap a lot of machinery you can keep the smith-shop down to, why not take out the fan-blower and use the old reliable hand-bellows, then you could do away with the exhaust fan and keep the blacksmith-helper busy.

THE OLD AND THE MODERN BOILER SHOP.

Take some of our boiler shops. There are men in charge of railway plants who say they can't do the work so as to compete with outside people. Well, that is right, but where does the trouble lie? Is it the lack of competent workmen in charge of the boiler shop, or is it the men at the head of the concern who fail to realize what a boiler shop needs for tools? Take a well-equipped boiler room with punch and shears, power bending rolls and steam or hydraulic riveter, planing machine, drills, cranes and overhead railways for handling work, and this shop, with a good man at the head, will turn out as good work and do it as economically as any outside people can, and the production will last 25 per cent. longer

MUSHET'S STEEL FOR DIFFICULT CUTS.

So I might go on through each department, but time will not permit We don't find all the improvements in one shop, but we do find things that are quite amusing. One day, while talking with a man engaged in turning off driving tires, I (being quite green and a stranger) asked how long it took to turn a pair of wheels. He said, on an average, about two days; when they were very hard, sometimes four days. He had several kinds of steel for lathe tools, and when they failed he had a piece of Mushet's steel at the bottom of his drawer to fall back on.

Now, I don't intend to enter into a discussion as to the merits of different kinds steel, but there are some shops that are shops that are using for 60 per cent of their lathe and planer work Mushet's steel, and it is cheaper than any other steel, even if it costs $3 00 per pound.

SPEED OF TOOLS

I have seen a man turning off a driving-journal with the lathe running the same speed as when he turned the tire, and the lathe was a modern machine. Another shop claims to turn out twelve to fifteen Master Car Builders' axles per day, all finished ready for the wheel Just think for a moment how fast that lathe must run.

In another shop you can see a planer, 60 x 60, 12-foot bed, with only one head, and running about 14 feet a minute, planing side rod brasses. Now that planer is new, and was all right for engine work 50 years ago, when a locomotive weighed about 12 tons, and where time was of no account, but to-day, with 88-ton engines, it is hardly worth the room it takes up.

THE TOOL-ROOM

Another important factor in the successful operation of a railway machine shop, is the tool-room This is a place where much money can be saved by starting a thorough system of classification and arrangement

It is also highly important that this room should be equipped with all modern tools that will in any way be required, and to have enough of them, so there will be no man waiting on one job while some other man is using the tool he needs, and another point is, not to expect a tool to perform a dozen different services when there should be a separate tool made for each piece of work.

Mr J T Chamberlain held that the remarks made about iron working tools, applied equally well to the condition of wood-working machinery. The location of such tools is of great importance. Knew a shop where the best tools were used but the arrangement was bad A large planer was so placed that the lumber that was brought in had to be carried past this tool to several other machines and then back to the planer There were 24 machines in the shop, and 23 of them required to be moved to make a good arrangement Before the change was made it took 45 minutes to run a stick through the planer, cross-cut saw and tenoning machine After locating the tools properly, the work could be done in 6 minutes

Mr. J N. Lander spoke of the difficulty of getting managers to realize the need for modern tools Thought there was no more wasteful practice than that of repairing rolling stock with worn out machines. Mentioned several cases of machines still in use that would, on account of their age, be valuable curiosities in a museum of antiquities Spoke of the great saving in cost of work, that resulted in his shop from the introduction of screw machines.

Believe that car-shops were as a rule, better supplied with proper appliances for building cars than iron-shops are for repairing locomotives. If you have a four-sided planer for your sills, everything comes out square and the work comes together well, and it costs very little to frame it in comparison with framing work that has never been planed, and the work saved by using such a planer instead of hand work, is enormous in the aggregate. The same principle applies to all the shops of a railroad In many of the blacksmithing shops for railroad work, the crudest kind of machinery is still used If you have a good foreman, and give him power to go ahead and exercise his ingenuity, he would generally produce appliances which will very much lessen the cost of the work.

In boiler shops, as a rule, the work for railroads is done in a very crude way. For repair work, he did not think it paid to use hydraulic riveters. Considered a plate planer a necessity with steel sheets. Its use avoided the danger that results from the grooves made when chipping sheets.

Mr. F D. Adams testified to the economy of using the best kind of tools and shop appliances It is often difficult to convince railroad officers of this. He remembered forty-five years ago, when wood-working machines were first introduced, that mechanics were afraid of them, and feared there would be little for men to do. There is nothing of this sentiment to be found now.

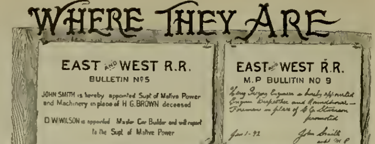
Mr J. W Marden was glad to say that he had never been refused tools which he considered necessary, was a thorough believer in first-class tools. In his shops they have a four-sided planer capable of planing sills at the rate of one a minute. Some people think it is capital tied up because they have not work for this tool half the time Suppose we plane fifty sills in an hour, and the machine remains idle for a week, it is a good investment, for it would take a man nearly a week to do the work on an old-fashioned planer. The same applies to improved mortising, tenoning and other machines.

Mr. Angus Sinclair considered that Mr. Davis was the best shop manager in the country, and his views on the tools necessary for the economical repairing of railroad rolling stock were well worthy of consideration. He knew from his own experience that many railroad companies do their work with tools which no manufacturer could afford to use. This is bad policy and unduly increases the expense for repairs. He thought that more attention was devoted in car-shops to the proper location of tools than in locomotive repair-shops. Was greatly in favor of the milling machine, but found that in many railroad shops its scope was not properly understood. Believed that it would amply repay railroad companies to send their shop foremen out for a couple of weeks every year to observe the labor-saving appliances used in different shops.

President Twombly was a thorough believer in good tools and in all labor-saving devices. He visited Mr. Davis some time ago and was so favorably impressed with the pneumatic hoists in use in the Boston & Maine shops that he went home and built twelve of them Now he cannot see how any shop can be conveniently run without these hoists in connection with overhead tracks. He uses the hoists inside and outside the shop to great advantage. They are carried on overhead traversing rails The practice greatly facilitated production and lessened the expense.

The Chicago, St Paul, Minneapolis & Omaha are getting out specifications for twenty new locomotives.

The demand for the Jerome metallic packing for piston and valve stem glands is reported to be increasing rapidly The railroads generally are coming to recognize that filling stuffing boxes with hemp to prevent the escape of steam is the most expensive plan ever tried, to say nothing of the labor involved. The Jerome packing makes the best kind of a substitute for hemp. It has lately been adopted by the following roads Lake Shore, Chesapeake & Ohio, International & Great Northern, Lehigh Valley, Beech Creek and a number of others Mr. Jerome has lately effected important improvement on his packing



Mr W E Cooper has been appointed Superintendent of the Chattanooga Southern.

Mr. J. H. Setchel was married on January 14 to Miss H J. Davis, Los Angeles, Cal.

Mr. H F. Hallstead, General Manager of the D., L. & W., fought the grip for some days, but finally gave in and lay in bed for ten days.

Among New York men prostrated by la grippe last month, was Mr. Hart, Secretary and Treasurer of the Lappin Brake Shoe Co.

Mr. Moses Hobbs, for many years Round House Foreman of the Chicago, Rock Island & Pacific, at Davenport, Ia., died a month ago, aged 67 years.

Mr. Herbert Wallis, Mechanical Superintendent of the Grand Trunk Railway was elected Treasurer of the Canadian Society of Civil Engineers at the last meeting.

Mr. J. P Hovey has been appointed Master Mechanic of the Oregon Short Line, at Shoshoné, Idaho. He was formerly general foreman of the Baltimore & Ohio shops at South Chicago.

Mr. Albert Langmoid, one of the pioneer New England Master Mechanics, died at Pembroke, N. H., last month. He was long Master Mechanic of the Northern Railroad of New Hampshire.

Mr. George W. Cushing has accepted the position of General Superintendent of the American Steel Wheel Company. He will have charge of the erection of the company's new works at Jersey City.

Mr. Coleman Shanks, Master Mechanic of the Los Angeles Terminal Railroad, is said to be making an enviable record on the Pacific Coast. He went from the Wabash and has enjoyed a highly varied railroad experience. In his efforts to reduce the fuel bills, which run high with coal at $8.50 a ton, he has ordered some Baldwin compound locomotives.

Mr. W. G. Richards has resigned the superintendency of the American Steel Wheel Company's Works. Some of the wheels made by him have been in use over two years, and have proved to possess the strength, soundness and wearing qualities necessary. These solid steel wheels have been produced by processes invented and patented by Mr. Richards

Relative to a rumor that President J. C. Clarke, of the Mobile & Ohio, would resign, that gentleman telegraphed to New York as follows "I see an absurd report from Chicago, printed in the New York papers, in regard to me. The answer is 'Few die, and none resign who can help it.' I belong to the latter class. I shall stay on deck until Gabriel blows his horn."

The facts used in the interesting article on the first steel boiler used on a locomotive were given us by Mr J Davis Barnett, Assistant Mechanical Superintendent of the Grand Trunk Ry at the Stratford Locomotive Works. Mr Barnett is one of the ex-presidents of the American Ry Master Mechanics' Association and one of the best posted mechanics in American railway service.

A circular from the Northern Pacific indicates that General Manager Mellen is practicing the doctrine of civil service rules which he preached in an article in LOCOMOTIVE ENGINEERING last month. Mr. John Dorsey was promoted to be Superintendent of the Yellowstone Division, and Mr J. G. Boyd was promoted to be Assistant Superintendent of the Rocky Mountain Division.

Mr. Jacob Johann expresses great interest in the biography of Mr. Isaac Dripps, published in the January number of LOCOMOTIVE ENGINEERING. Mr. Johann helped to build the locomotive with eight-foot driving-wheels turned out of the Norris Works for Mr. Dripps in 1847. Another incident worth remembering was that Mr. Dripps gave to Mr. Johann the first pass he ever received.

"Yes," remarked Mr. R. Carroll, general manager of the Cincinnati Southern, as he turned over the pages of LOCOMOTIVE ENGINEERING, "I read your paper with much interest. The part I like best is the Letters from Practical Men. I turn to that first because I like to read about the various difficulties encountered by men with engines and air brakes and other parts of train mechanism."

Engineer Palmer, who was for some time traveling engineer on the Chicago & Alton, has gone to the Chicago, St. Paul, Minneapolis & Omaha, as road foreman of engines and air-brake instructor. General Superintendent Scott requires Mr. Palmer to perform various other duties which make him something of a traveling superintendent. Great benefit is said to have already resulted from the duties performed by Mr. Palmer.

The pen lingers lovingly over the sketch of the engineer. For other operatives and railway officials we have at times severe criticisms, even scorn; but for him never. He is the object of our profound admiration. To us he is the embodiment of tireless fidelity, scorching heat of summer, smiting blasts of winter never deter him, flood, tempest and tornado he braves and conquers in ministering to the necessities of his fellows.—*Chicago Times*.

Mr B Malloy, Master Mechanic of the Wisconsin Division of the Chicago & Northwestern, died at Chicago, January 10 His death was caused by a blow from a broken link, received when he was superintending the putting a derailed engine on the track. Mr Malloy was all his working life on the Chicago & Northwestern, having begun work in the Fond du Lac shops when a boy He rose to be roundhouse foreman at Fond du Lac A year ago he was made Master Mechanic of the Wisconsin Division.

Mr W E Hall, who has been for some years Assistant Master Mechanic of the Pennsylvania Railroad at Altoona, has gone to be assistant to the superintendent of the Niles Tool Works. We think that the Niles Tool Works people have made a good selection, but we are sorry to see a bright young man like Mr. Hall leaving the railroad field It takes a long time to convince railroad companies that they can afford to pay salaries that will retain the services of good men.

Mr. William Smith, Superintendent of Motive Power of the Boston & Maine Railroad, died at his home in Lawrence, Mass., last month. Mr Smith began work on the Boston & Maine as a machinist forty-three years ago. After working in the shop for a year he went firing, and in three months was given an engine to run. He was an engineer for twenty-three years and then was made roundhouse foreman. From this he rose by different stages to the position he held at the time of his death.

Mr. J. D. McIlwain, who has been for the last eight, ten or twelve years Superintendent of the Car Department of the Grand Trunk Railway at London, Ont., has accepted the position of Superintendent of the Harvey Street Car Works at Chicago. Mr. McIlwain was on several American railroads before going to Canada, and was noted for his advanced ideas in car construction. The company he is now with will build wood as well as iron cars, so that the new superintendent will have wide scope for his ability as a car builder and designer.

Mr. J. R. Petrie has been appointed joint inspector of cars for the New York Central and the Lake Shore & Michigan Southern Railways at Buffalo. An interesting feature of the appointment is that Mr. Petrie receives the highest salary of any joint car inspector in the country. The recipient is well worthy of the large salary for he is one of the ablest men in his line in the country. He has been employed at Black Rock, N. Y., with the New York Central for several years. Mr. Petrie has been regarded by the Central Railroad Club as the best authority on interchange of car matters.

We find that the radial devices for tapping stay-bolt holes for locomotive boilers invented and handled by Mr. J. T. Connelly, Milton, Pa., are growing greatly in favor among railroad men. A few hours saved in repairing a locomotive fire-box is frequently of great value to railroad companies. Mr. Connelly's method of tapping holes without calling for the removal of frames is one of the most important time-saving inventions ever introduced into a railroad shop. Those who have not tried this invention are not doing themselves and their companies justice.

George W Syfan, an engineer on the Columbia & Greenville branch of the Richmond & Danville, has recently been placed on the pension list at $30 per month. He has run a locomotive fifty years—forty of them on the Abbeville branch. Mr. Syfan has been an extra faithful man, never having injured a passenger or seriously damaged rolling stock He ran from 4 A. M. to 10 P. M. most of last winter, doing the hardest kind of service, but broke down in August and has been confined to the house ever since. Mr Syfan hauled one of the first Confederate soldier trains and brought home the body of the first Confederate soldier killed in the war. He is 71 years of age.

There is a curious inkstand on the desk in the office of Mr. James W See (Chordal), Hamilton, O. The mechanism that operates the covers of the different bottles is interlocking and the opening of one closes the others. See got it from some one who found the stand in England. He thought it might be put on the market and examined the mechanism to judge of the cost of production. The device is exceedingly complex, over twenty parts being employed. See then put on his inventing cap and schemed an arrangement that would do the interlocking by means of a single piece. That invention ought to be on the market. See used to write about making a market for things. Now is his opportunity

Mr. James Sedgeley, well known among railroad men as having long been General Master Mechanic of the Lake Shore and Michigan Southern Railway, died at Washington, D. C., January 12 Mr Sedgeley was born in Maine in 1824. He began his railroad career on the Northern Railroad of New Hampshire, and rose to be master mechanic of that road. He left there in 1865 to take the position of General Master Mechanic of the Lake Shore, and was succeeded by Mr. J. N. Larder, then a young man. Mr. Sedgeley retired from the Lake Shore in 1884, his health having failed. He was very fortunate in outside business investments, and was well off He was for a year vice-president of the Master Mechanics' Association, and was an honorary member at the time of his death. Mr Sedgeley leaves a wife and two daughters

Mr. E. Lord, Assistant Superintendent of Motive Power of the Fort Wayne Division of the Pennsylvania Railroad, has been made Superintendent of Motive Power of the Cleveland, Cincinnati, Chicago & St. Louis. Mr. Lord is a young man, who went through a very thorough training at Renova, Altoona, and other parts of the Pennsylvania system. He has taken his part in all kinds of work connected with locomotives. He has worked as a machinist, as a draughtsman, as a fireman, as an engineer, and as an engineer of tests. These lines of work represent Mr. Lord's experience. Socially, he is one of the pleasantest men we have ever swapped stories with The numerous graduates of Renova, who are holding important positions all over the country, look upon the elevation of Mr. Lord as another proof that Renova men lead the railroad mechanical world.

The men who have charge of boilers or are in any way connected with steam plants owe more than they know to an old, venerable gentleman living at Coatesville, Pa This is Mr. Charles Huston, President of the Lukens Iron & Steel Co. Mr Huston has been engaged in making boiler plate for the greater part of his life, and through his patient and intelligent investigation and experiment many facts were learned about boiler plates that have done much to promote the safety of boilers. For years after he went into plate making no attention was bestowed upon strength for a unit of thickness. Ductility had not been heard of. Mr. Huston labored hard to educate the people on the requirements of boiler material necessary to secure safety He was several times sent from Pennsylvania to give evidence to Congressional committees on boilers. His views had great weight in the framing of existing laws relating to steam boilers.

Among the well-known men who passed away last month, was Mr. Edward Nichols, President of the Brooks Locomotive Works Although he has been president of these important works for nearly five years, Mr Nichols was not known personally to a large circle of railroad men, which appears to have been due to the retiring nature of the man. Mr. Nichols was born at Middlebury, Vt., in 1850, but was raised in New York State. He was educated in the Rensselaer Institute, Troy, N Y., as a metallurgical and mining engineer. He devoted great attention to chemistry and was for some time assistant professor of chemistry in the Institute. Then he went traveling for a time, investigating metallurgical matters. During the Centennial Exposition in Philadelphia, Mr. Nichols held a position on the Reception Committee Next year he associated himself with the Baldwin Locomotive Works and other capitalists in Philadelphia, and as their agent started a blast furnace in Georgia An attack of sickness compelled him to leave the South, and in 1883 he located at Columbus, O., where he had an expert iron practice At this time he married Miss Jessie Brooks, daughter of Mr. H. G. Brooks, originator of the Brooks Locomotive Works. Four years afterward, on the death of Mr. Brooks, Mr. Nichols was elected President of the Brooks Locomotive Works. Here his interests principally centered until the time of his death. He was highly popular in Dunkirk, and his departure leaves a blank in a large social circle. He was a member of the Railway Master Mechanics' Association and attended several of the meetings but took no active part in the proceedings.

N. W. Sample, who, as Superintendent of M P., made himself famous by the work done by his narrow-gauge locomotives on the D & R. G. Ry., has been made general superintendent of that system. It is safe to say that no other road of its size in America has power so uniform as the "Little Giant of the Rockies." All the standard-gauge engines are of one make, and there is one kind and size for freight, one for passenger, and a switcher made up of the parts of the other two. There are no odd kinds or sizes The old narrow-gauge stock is nearly as uniform, being, with the exception of twenty-eight engines, all of one make, though there are several sizes. Though a mountain road, the running repairs have been remarkably low per engine mile. Mr. Sample is one of the few railroad officials who does his whole duty by the directors and the stockholders and yet is in full sympathy with his men, he was always as approachable as the roundhouse foreman, and it was positively refreshing to a man hunting a job to go up and have a talk with Mr. Sample even if he had no work to give. As general superintendent his sphere of usefulness will be widened, but if the motive power goes out of his control, it will be a loss to the road—it is in the hands of a master.

## Standard Sizes in Locomotives.

BY M. A CHINIST.

Much stress is laid, in these days, on the importance of standard locomotives and the interchangeability of their parts.

We constantly hear that engines, built at this or that establishment, are, as a class, interchangeable in like parts.

Railways claim that they have a system of the same kind, but when the time comes to make the exchange, it is, as a rule, found that parts do not do so, they may be duplicate in dimensions approximately—that is, as close as the several workmen may each approximate, by a rule, the exact dimensions given on a drawing This not only applies to work that may be done by rule measurements, in the same shop, taken from drawings, but also applies to a road of several divisions that work from templates, but which were made in the several shops, when the deviations made in laying out the templates are as disastrous to an interchangeability of parts as when the work is laid out from drawings, unless it was possible to put a distinctive mark upon the engine to correspond to a similar one in the templates by which the engine of a template class, as it were, could be recognized. Templates are not only to produce duplicate work, but also to cheapen its productions. The use of a good template system not only will reduce the time an engine may be in for general repairs, but will also facilitate running repairs and by that prevent loss by the engine being out of service, but to get the advantage the system must be perfect, and the question is, what that is. Before taking it up, let us consider, for a moment, what part of an engine it is that requires a close system and how far interchangeability is carried.

Take an average road, and we find an engine with the same diameters of cylinders, that smokestacks, front cylinder-head, and piston followers, steam-chests and piston-rod glands, steam-chests and covers, will interchange because all attaching-holes are one-sixteenth larger than connecting-bolts or studs. Truck wheels, tender and driving springs and truck box, also brass, may be a standard for one or more classes of engines or designs of engines of the same weight and exchange because close fits, connections or adjustments are not required, yet with the margin allowed in fitting parts, it is often the case that these parts are not in common use in several divisions of a road.

Another class of parts that is more affected by the difference in measurements in laying out work from drawings in templates is the rods, valves, yokes, back cylinder-heads, crossheads and pistons, and all motion work Attempting to exchange these parts means refitting; holes do not come in line, piston-rods are too large or too small for the crossheads, and some detail of any of the parts mentioned will generally be found to be out It may be but a trifle, but if it is in connecting holes that a trifle means delay and an unnecessarily enlarged hole. If the piston-rod, then the shoulder has to be trimmed off to enable the piston to fill the crosshead, the distance between the shoulder is altered and may cause doubt in the future when a new piston is to be put in.

Rod keys is another detail that often requires renewal, yet the new keys may fit properly, they are kept in stock with a margin in size over the proper one to allow for fitting due to variation in key-ways

Another class of parts, many of which can be made common to all classes of engines, and the balance to more than one, is the steam-gauge and steam-cocks, pipe-nuts, boiler-plugs and oil cups, not only in their connecting parts, but in their own details, and here again comes in the approximate size of the special tools required to make the work, or a gauge-cock or wash-out plugs, maybe, twelve-thread in one class of engines on divisions of the road, and fourteen on the other, even if of the same dimensions.

This is about the condition on most of the so-called engines of duplicate parts. The original intention was to duplicate them, but the necessity of providing a system for doing so was overlooked, and about all the duplicacy in the engine is in the design

Master mechanics say it is the best that can be done, and that gauges and templates made in the several shops of a road will not agree. If that is the case, then why not have all templates and gauges made in one shop for distribution, and by selected workmen, using improved tools for measurement, and who, becoming specialists in this work, could not only produce duplicate templates, but a system of templates to apply to all the details of a part, and also the many special tools required to duplicate as well as lessen the cost of making standard valves, cocks and cups.

A department of this kind should be closely allied to the drawing room, and, to a certain extent, under its control or advice when a standard has been adopted The templates and tools required to produce and maintain it would be distributed with the drawings

This would simply be adopting the principle that is now universal of procuring standard taps and reamers from makers who have facility for producing duplicates. Those who fail to produce taps in this manner have difficulty in the exchange of nuts or standard bolts, while the product of the work done by specialists never fail to be correct. Were the conditions such that templates and the tools mentioned could be procured in the same way it would be well to do it, but they are not, and the nearer the methods employed by the specialists are used, the nearer we will approach interchangeability.

In place of a system that applies to the exchange of sheets in a tank and forgets the rod keys, intelligent directions must be given as to what parts should duplicate and what need not, but not only is a proper gauge and template system required, but a careful consideration in the drawing room to what or how many details can, without detriment to the efficiency of the engine, be made common to all classes.

## Hawkin's Hand-book of Calculations.

A WORK OF INSTRUCTION AND REFERENCE FOR ENGINEERS, FIREMEN AND STEAM USERS.

Carefully edited, large octavo, 6x9 in., on heavy paper, freely illustrated. Contains every calculation, rule and table necessary to be known by the engineer, fireman and steam user. Published in 10 parts, 25c. each. Send 25c. for Part I and subscription blank for the whole issue. Also in one volume, cloth bound, for $2.50. Send for Catalogue, with Testimonials.

THEO. AUDEL & CO., Pubs. 91 Liberty St. (Office 3), N. Y.

## AMERICAN SAW CO.

TRENTON, N. J.,

Manufacturers of the Celebrated

# ALLIGATOR WRENCH.

These Wrenches are forged solid in one piece, from best refined iron, with tempered steel jaws. They have ratchet teeth, cut diagonally across one jaw, thus enabling them to bite with three teeth at once.

INVALUABLE TO ENGINEERS, GAS FITTERS AND JOBBERS OF ALL KINDS.

## DIXON'S

GRAPHITE

# PIPE JOINT

GREASE,

**FOR STEAM OR GAS PIPES, BOLTS, SCREWS, ETC.**

**Far Better and Cheaper than Red Lead.**

Makes a tighter joint than red lead, that can be opened with perfect ease many years after.

NO LONGER ANY NECESSITY FOR—

BROKEN PIPES, STRAINED TONGS, or LEAKY JOINTS.

Put up in 1 lb. 5 lb., 10 lb., 25 lb. & 50 lb. packages

☞ Send for Illustrated Catalogue containing more information concerning Graphite and its uses than is in print elsewhere in any language. ☜

## PROGRESSIVE EXAMINATIONS OF LOCOMOTIVE ENGINEERS AND FIREMEN.

By JOHN A. HILL, editor of *Locomotive Engineering*, for ten years a fireman and engineer. Plan is the one proposed by Mr. H. to the American Railway Master Mechanics Association and so strongly recommended by their committee. Tells what should be required of a man when he goes firing. Examines him the first year on signals and the rudiments of firing, the second, on combustion, etc., and the third, on mishaps, breakdowns and the engine. Practical; nearly 200 questions and answers to 'em. Seventeen colored plates showing position and color of every signal carried on engine or train. Standard code. Adopted as official examination on several roads. Invaluable to engineers and firemen, and tells every young man with an ambition to run a locomotive, just what he ought to know to start with and what he must learn before promotion. Send 50 cents (U. S. stamps are good) for this neat book, pocket form, round covers, red and gold, to

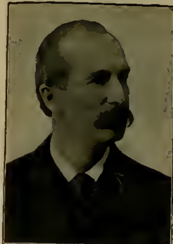
## How Much of a Machinist Should a Locomotive Engineer be?



[Clinton B. Conger is of old New England stock and was born in Plymouth, Ohio, in 1847. He spent his youth on a farm; lost his father in the Civil War, and at 17 found himself virtually the head of a family. Got an academic education and taught school some, but was anxious to handle machinery, and in 1870, at 22, went firing on the P. H. & L. M. R. R., then 18 miles long and being built westward from Port Huron, Mich., and stayed on it through all its vicissitudes till it was a trunk line to Chicago, being now the C. & G. T. Railway. The road at that time was very hard up financially and he had to get along with as little fuel, oil, machinery and wages as possible, because the company was too poor to furnish *all* that was necessary. It is a hard way to learn railroading, but if a man lives through it he knows how. After the C. & G. T. Ry. Co. bought the road, he was sent to Valparaiso, Ind., as locomotive foreman, remaining there two years, till September, 1882, when he came back on the main line as passenger engineer. In November, 1887, the Commissioners of Railroads of Michigan appointed him mechanical engineer in that office, and he held the position with credit to himself and advantage to the railroad men till March, '91. A very strong effort was made by the employés to have him reappointed by the new administration, but his politics were the wrong brand. He was appointed to his present position, that of road foreman of engines, of the Chicago & West Michigan and leased lines, last year. Clinton B. Conger is another example of a locomotive engineer, who goes up because he makes himself "conspicuously useful" in any capacity that he finds himself. He is a man who believes in "getting to the front" as far as he can in the matter of knowledge of his business, and that railroading is a profession even more than law or medicine.]

This question you heard more of ten years ago then at present, and for a very good reason. Then the engineer had to do a good deal of machinist work on his engine himself, now he reports the work to be done on the book, and goes home secure in the idea that his duties for the trip are finished.

Running a locomotive nowadays is most all pulling a train and getting there on time without getting in anybody's way. To do this requires an intimate knowledge of every grade and sag in the road, every curve and switch on the line, and some considerable knowledge of the habits of the other engineers, how fast they run into and through stations, where they stop for water and coal when you are following them close, and on what grades they are likely to stall.

The man who learns this on the left side of the cab *first* and learns the shop work afterward, is more likely to be successful than one who puts in a long apprenticeship in the back shop first, going on the road afterward; because it becomes a habit to think of the safety of the train first, the running rules and regulations are uppermost in his thoughts, as they were learned first in his railroad life.

If a fireman, when about to be promoted, is put in the roundhouse as a helper to the machinist, who does the running repairs or what is better, with one of the pit gangs in the back shops setting up repaired engines, it is a great help to him when he becomes an engineer, but the trouble is, he is wanted there steady every day; as he is liable to be out part of the time as "spare man" on the road; that spoils the shop arrangements.

One disadvantage some machinist engineers labor under is that of being past the age to learn the bottom principles of handling a train and running an engine when they leave the shop. He is then more apt to think of the way his engine is built, her weak parts and how to help them than getting his train in on time when late, or getting over the hills with the extra car all yardmasters think he can pull.

Engines are built to earn money for the company drawing coaches or tons of freight, and they can do it and still be well taken care of by the man running them if he does not know just how every joint is put together. The ones he has to take apart when he breaks down are what he keeps his eye on.

Let him learn the shop work at an early age, and be ready for promotion from firemen to engineer before thirty years old.

To be sure there are plenty of engineers who can do all the light running repairs around an engine, such as reducing and lining up rod brasses, making joints, changing journal brasses, grinding in globe valve seats, keeping their air-brake in good order, etc., but a fair share confine their work to keeping bolts and nuts tight when on the road, oil cups feeding, sure; main rod brasses keyed up so they suit them, and last but not least, setting the wedges just right. But there is a lot of machinist work attempted by engineers which can be done by the shop men easier and better; for instance, lining or closing guides, changing the eccentrics, setting the valves, changing liners under driving-box shoes to make the drivers track square, taking down cylinder packing, etc.

On roads where the engines are "chain ganged" or even double crewed, so much of the work needed each time the engine makes a trip is attended to by the engine inspectors and roundhouse force, that engine men get out of the hang of doing anything except packing and cleaning up. When a man brought up that way leaves the old road with its hundreds of engines, which he may have run one after the other, and goes on a little road, or some branch where he is obliged to take care of his machine and keep it in order as well as draw the train, it is pretty hard work at first. That is the place where a machinist runner comes handy.

There is a good deal said about a man having only one trade, and having a thorough knowledge of that trade. That is quite true; but on the other hand the more an engineer knows about the branches of his business, *if he knows it all well*, the more valuable man he is anywhere. Being well posted makes a man more self-reliant in times of trouble and the regular routine of business. The trouble with the machinist engineer has been that some of them only half understand either trade and did bragging enough for both. When you run across an engineer who is a good machinist, you hear him say very little about it, he is an engineer first and all the time, going in the shop only when he has to or finds a better paying job.

It is a fact that running an engine and repairing one, are getting to be widely diverging branches of the business. Repairing and building them is the same trade it was years ago, except new improved machines, standard sizes and shapes of the different parts of an engine make it cheaper and quicker to repair and rebuild them.

On the other hand, running one is getting to be more of a profession every day. A locomotive now is a combination of so many independent devices that it takes more skill than manual labor to handle one. Because some of the most successful engineers we have now did not fully understand the business when they took the right hand side of the cab years ago, and learned it afterward, it is no reason that an engineer can be as successful with the same amount of knowledge to-day. A man going out on an engine for his first trip with a main-line train, must know nearly as much as a regular engineer if he gets along, as just as much is required of him. He has to do as well or he is rated "no good."

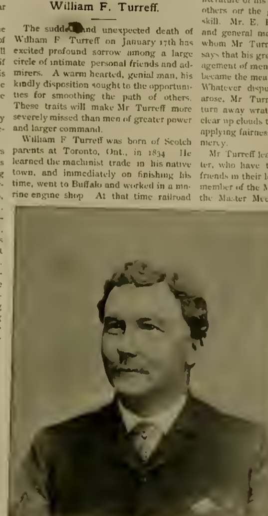
Let us hear the machinist end of this question.

C. B. Conger.

## William F. Turreff.

The sudden and unexpected death of William F. Turreff on January 17th has excited profound sorrow among a large circle of intimate personal friends and admirers. A warm hearted, genial man, his kindly disposition sought to the opportunities for smoothing the path of others. These traits will make Mr. Turreff more severely missed than men of greater power and larger command.

William F. Turreff was born of Scotch parents at Toronto, Ont., in 1834. He learned the machinist trade in his native town, and immediately on finishing his time, went to Buffalo and worked in a marine engine shop. At that time railroad



machinery was considered of secondary importance compared with the appliances connected with water transportation, but it was every year advancing in consequence, and ambitious mechanics began to turn their eyes to railroads as the coming Mecca. In 1853, when he was 19 years old, Mr. Turreff, who had gone still farther West, did his first railroad work in the shops of the Cleveland & Columbus Railroad. This road had been chartered only eight years before and track was laid as far as Columbus. It was the first link of what was afterward worked up into the chain of roads forming the Bee Line, and eventually the Big Four's system.

When Mr. Turreff went to work for the road as a machinist the company had fifteen locomotives and 138 miles of track laid on the soil of the virgin forest through which part of the line passed. He remained eleven years with the company as a machinist, and then started out to learn the ways of other shops and of other railroads. Seventeen years afterward, rich in experience, he returned to the company as a division superintendent and remained on the road till he became superintendent of motive power of a system having 1,478 miles of main line, 340 locomotives and 13,800 cars.

Rather more than a year ago, Mr. Turreff left the Cleveland, Columbus, Cincinnati & St. Louis, and was appointed assistant superintendent of the Western divisions of the Erie system. Owing to the illness of Mr. Ross Kells, Mr. Turreff was in New York with charge of the mechanical department of the whole system. About a week before his death he contracted a severe cold which developed into pneumonia and proved fatal after an illness of four days.

Mr. Turreff attained the highest position a railroad mechanic may expect to reach and with the means within the grasp of every ambitious workman. He had merely a common school education, but he improved himself by reading and study of the literature of his business, and he rose over others on the grade of intelligence and skill. Mr. E. B. Thomas, vice-president and general manager of the Erie, under whom Mr. Turreff had served for years, says that his great strength lay in his management of men. Here a kind disposition became the means of advancement in life. Whatever disputes or misunderstandings arose, Mr. Turreff was always ready to turn away wrath by a soft word, and to clear up clouds that threatened conflict by applying fairness and justice tempered by mercy.

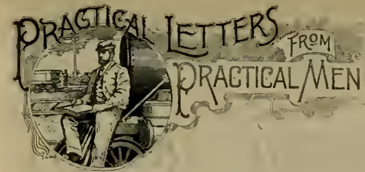
Mr. Turreff leaves a wife and one daughter, who have the sympathy of hosts of friends in their loss. He was a prominent member of the Master Car Builders' and of the Master Mechanics' Associations and took a warm interest in the work done by these organizations. For the excellent portrait of Mr. Turreff we are indebted to Mr. J. C. Davis, of the Congdon Brake Shoe Co., Chicago.

---

Those who are interested in drills will find the works of the Universal Radial Drill Co., Cincinnati, a good place to visit at present. Business is particularly active in the shop and there are some curious drills in course of construction. There is one for the Grant Locomotive Works with three heads for drilling locomotive frames, unusual ingenuity being displayed in the design. There are six special drills for the Union Switch & Signal Co., one of them having 30 spindles, 20 acting vertically and 10 horizontally. Besides the numerous drills these works are turning out other machine tools, among which we noted a large double-ended engine lathe and two combined turret and checking lathes.

Mr. Henry H. Horton has been appointed Master Mechanic of the Florida Midland Railroad. Mr. Horton was formerly a foreman in the machine shops of the East Tennessee, Virginia & Georgia, at Knoxville, Tenn. His ability as a foreman gives the promise that he will make an excellent master mechanic.

Mr. C. J. Clifford has been appointed Master Mechanic of the Calumet & Blue Island Co., in charge of locomotive and car departments, with office and shops at South Chicago, Ill. Mr. Clifford's jurisdiction has been extended over the locomotive and car departments of the Chicago & South Eastern, Chicago & Kenosha and Joliet & Blue Island roads.



## The "Bull Pups" of Mexico.

*Editors:*

In the article captioned "Long vs Short Eccentric Blades," mention is made of the D. & R. G. narrow gauge consolidation engine. Here on the F. C. N. M. a good many of the same type of engine are used; in fact, I believe some of the engines here were built for the D. & R. G.; 36 inches is a small diameter for a driving wheel, particularly on a division as long as ours—213 kilometers, or about 132 miles. They have the short blade, with considerable lead, making them quick to start but hard to hold down on the short curves, where it takes five rails to keep one of our "bull pups," as some of the boys call them, on the track. The short boiler and wheel base make them look puggy, hence the name.

The intermediate rocker arm is the cause of much lost motion, and a large percentage of break-downs consist of pulling out or breaking the studs that hold the blade on the strap. They are not, as usually, bolted to the straps, but butt on to them. They do splendid work, and while the services of a machinist is a constant necessity they hold up well. The flanges fail first from the extreme shortness of the curves, seldom lasting a year, while the tread of the wheel shows no wear. We burn wood entirely on the southern division, and when our Mexican firemen get a tank of dry pine the "bull pup," as she sails up the side of the mountain, more than rivals the 4th of July fireworks in a good sized Western town.

When they come out of the back shop first you can drop them four or five notches shut off, but as the lost motion runs up gradually to ⅛, ½ or ⅜ of an inch, you have to narrow down to 3, 2 and even 1 notch, and some of them even make less noise if left in the first notch. This is, of course, hard on valves and cylinders, but a long stroke savors so much of dissolution that no one attempts it. They are, as Bro. Hill says, capable of surprising speed; a kilometer a minute, or about 40 miles an hour, is easily made, or was, before our traveling engineer was born.

EUGENE MCAULIFFE.

*Acambaro, Estado de Guanajuato, Mex.*

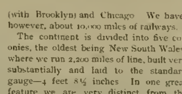
[The engines mentioned on the D. & R. G. were consolidation engines having no intermediate rockers or reach rods, and giving no trouble about laying the lever down among the od cans. Some 10-wheelers, with extra reach rods and hangers did object to running shut off in any position far from the center.]

## Engine-men's Barracks on the New South Wales Railways.

*Editors:*

Ever since I have taken your valuable paper I have been considering the advisability of sending you an article for publication in connection with our New South Wales railways, and I do so now. I understand but little is known of Australia in the States, but some interest may be awakened amongst my brother engine-men when I say that Australia is nearly as large as the United States, although it holds but little more people than are contained in two of the largest American cities—New York (with Brooklyn) and Chicago. We have, however, about 10,000 miles of railways.

The continent is divided into five colonies, the oldest being New South Wales, where we run 2,200 miles of line, built very substantially and laid to the standard gauge—4 feet 8½ inches. In one great feature we are very distinct from the American roads, as instead of the lines being controlled by companies with a care only for big dividends, the lines here are owned by the State and worked for the good of the State. The management is in the hands of a board of three commissioners who to a large extent are non-political, and as they have no incentive to



earn big dividends, they are enabled to give the men, while acting with due regard to the public interest, considerable benefits and privileges, and to-day I believe the engine-men of New South Wales stand in a better position than any men engaged in similar work in any part of the world. If of interest, I could give you more particulars as to their duties and pay later.

I intend only to speak of one feature of the administration of our lines now, and that is the efforts taken to secure the comfort of the men. The commissioners, headed by Mr. E. M. G. Eddy, the chairman of the board, said to be one of the ablest railway managers in England, who came here three years ago to take the chief commissionership, Mr. Fehon and Mr. Oliver have taken a very lively interest in all matters that tend to promote the social and moral welfare of the men, and the outcome of one of their improvements is the introduction of engine-men's cottage homes at the locomotive centers. I send herewith photograph of the one just completed at Picton.

All engine-men have necessarily to spend some little time away from home, and the commissioners, feeling this, have provided the men with homes and expenses while away. The barracks are a credit to the commissioners and the men that inhabit them. These barracks are built of brick, with a veranda three parts around, with slated roof. Three parts of the building is divided into bedrooms, the other part into a dining-room, lavatory, kitchen, pantry and bath-room. The bedrooms are furnished with two single beds, spring mattresses, clean sheets, pillow-cases and blankets, two chairs, dressing-table and mirror, and a large kerosene lamp. The dining-room with large white pine table and forms, with half-a-dozen armchairs, side table, hat and coat racks, and a large fire grate. The lavatory has a slate slab, with porcelain basins set in with plug at the bottom; the water is let into the basins with suitable spring tap. Roller and Turkish towels, soap, brushes and combs and large mirrors are furnished. The bath-room is provided with plunge and shower baths, grated wood floor over a cemented floor; the cemented floor is so made that the water is carried away by a drain at the side of the room to the outside of the building. The water is laid in from the engine supply-tank.

The kitchen is fitted up with a large stove, two large 10-gallon kettles always ready for the men as they come in, pans and saucepans. The pantry or store-room is used to keep blankets, sheets, etc. On the large veranda large lockers and gauze wire netting safes are kept to keep the men's provisions in while staying at the barracks. The care of the rooms is generally entrusted to the widow of a deceased railway man or by the wife of a man who is past active work, so that the double purpose is served of a necessary appointment being made and a helping hand held out at the same time to a woman who, by reason of a husband's past services, deserves well of the railway department. The sleeping compartments are numbered, and the men, when they retire to rest, put the number of their room on a blackboard to guide the caller, so that he will not have to wake up every person in the house before he gets the right one.

QUICK ACTION.

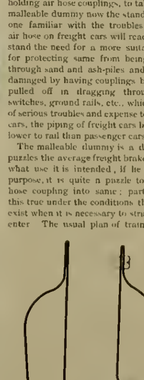
*Sydney, N. S. W.*

## A Dummy Hose Coupler.

*Editors:*

I inclose you blue print of a device for holding air hose couplings, to take place of malleable dummy now the standard. Any one familiar with the troubles had with air hose on freight cars will readily understand the need for a more suitable device for protecting same from being dragged through sand and ash-piles and otherwise damaged by having couplings beaten and pulled off in dragging through frogs, switches, ground rails, etc., which is cause of serious troubles and expense to air-brake cars, the piping of freight cars being much lower to rail than passenger cars.

The malleable dummy is a device that puzzles the average freight brakemen as to what use it is intended; if he knows its purpose, it is quite a puzzle to introduce hose coupling into same; particularly is this true under the conditions that usually exist when it is necessary to strain hose to enter. The usual plan of trainmen is to



hang coupling on the hook of dummy; this allows point of hook to come in contact with the rubber joint of coupling, and but a short journey of the cars is necessary to ruin the joint.

To overcome these difficulties on our own equipment (the South Carolina Ry.) and reduce our repairs to trifles by foreign materials being blown into them, and the excessive renewals of hose and couplings, the device shown was devised, and I think it meets all the requirements. It is not a puzzle to trainmen; its appearance makes its purpose plain; hose couplings are easily introduced and as easily detached, no straining necessary. The gasket is protected and securely sealed to prevent dirt entering pipes.

Being made of tempered steel, they are light, durable and cheap. Arrangements have been made with the A. French Steel Spring Company to manufacture the device.

E. M. ROBERTS,
M. of M.

## Compressed Air in Workshops.

*Editors:*

Please to kindly give us in your paper, some details about the use of compressed air in machine-tool shops, what are the best machines used for that purpose, and at what pressure of air they are working.

CARELS BROS.,
Locomotives and Steam Engines.

*Gand, le Belgium.*

[Compressed air is used very extensively in American shops, especially railroad shops. In most cases the air plant started in a small way using a Westinghouse air-brake pump as compressor. In some shops there are several of these at work; we know of one using sixteen of them. Other shops have larger compressors, generally belt-driven machines. Lines of road using the electro-pneumatic operated block signal have large compressors directly connected to a steam cylinder. The use of compressed air is legion; it is used to test brakes undergoing repairs, to test steam fittings, to handle cranes, to run small engines for special drills, etc., coaches are cleaned by jets of it, for pneumatic riveting and seam-calking, to blow fires, to lift and carry oils, to blow up fires in dead locomotives. Boilers are filled with it when engines are rebuilt, and they are run out of the shops before firing up, and workmen use it to blow chips out of planer slots and away from other work. As a usual thing the pressure is 60 pounds per square inch; this pressure is about right for testing brakes, can be maintained without heating compressor, and is safe to handle. Requiring no drain for waste, as in hydraulics or exhaust pipes as in steam, being cool, and an aid to ventilation, it has many advantages and is destined to be as necessary in a railroad plant as the motive-power itself.]

## A Case of Forgetting.

*Editors:*

It is surprising how much one forgets.

While reading the several accounts of the now celebrated "Cunningham Puzzle" in your paper, it reminds me how easy it is to forget, and some are more prone to do so than others, and judging by how much Mr. Cunningham forgot in the two short months between his two letters, that he is one of the "more," and if it is fair to use these two months as a basis to know how much he would forget in twenty years, it is a wonder that he now remembers of ever running on the M. & O. R. R. at all, and when he says there was no engine house or shop at Columbus, Kentucky, until 1876 he proves his forgetfulness. In September, 1867, there was a shop and also engine house. B. F. Partridge was foreman, and then a man by name of Perkins took his place as foreman. There were lathes and drill press, etc., also a carpenter shop which had several men working in it; there was a young colored man running the shop engine. Now, when he tells you that the M. M. and foreman do not know any more about his breakdown than he has told you, it leaves a very wide margin for doubt, owing to how much one will forget sometimes.

## Testing Brakes from Rear End.

*Editors:*

Considerable attention has been paid on some roads to testing brakes from rear of train, and our attention has been called through your columns to difficulties that arise from local causes.

We have seen that obstruction in train-pipe may interfere in *either* direction with free passage of air, or, in other words, that brakes will not always operate alike from both ends of train. Now, this is no reason for testing from rear end, because service applications are only made from head end in controlling train, and what else are they for? Passage of air forward is most to be desired. Obstructions in train-pipe should be located at terminals and are of rare occurrence anyway if any sort of attention is paid to testing cars in yards by men whose business it is to do so.

There is another view to be taken of the practice in its effect in general on the delicate and numerous parts of a system of quick-acting automatic brakes in train.

At the head end, our engineer has at his hand an air-valve in its most approved form for the purpose of controlling automatically the release of air from the train-pipe, also, before him are gauges that show what he and the valve are doing or can do.

At the rear end, what have we?

1st. An average brakeman.

(Thos. Carlyle says the average man is a "damn fool"—which being a general remark and applied to all of us, we can have no grievance.)

2d. There are no gauges whereby this average brakeman can tell how much air he is going to release.

3d. There is an ordinary train-pipe stop-cock that opens a slot $1\frac{1}{4}$ inches long, or nothing.

Now, from actual measurement, as compared with the maximum area of service opening in train pipe resulting from use of engineer's air-valve, the train-pipe cock should not be opened more than $\frac{1}{16}$ of an inch.

As a result of the above we have in nine cases out of ten an *emergency* application to determine whether the brakes are in condition for a *service* application, which is not the same thing.

I fail to find that the W. A. B. Co., or anyone else for that matter, recommend the use of the emergency as a regular thing. While not so disastrous on draw-heads and wheels when applied on a train at rest, yet the tendency to disarrangement of parts causes lots of trouble from undue strain. Bang! bang! we hear the brakes go on all around us from brakemen (and other conductors) monkeying with them because they are required to. In vain are they "jacked up" about it. Our average brakeman cannot strain his nerves to adjusting stop-cocks within $\frac{1}{16}$ of an inch. Not only does the practice make trouble, but wastes an enormous amount of air needlessly.

Our overworked air-pumps labor away to make up this waste.

They make no demand for overtime, however, wherefore let us rejoice and be exceeding glad. Thus appears one redeeming feature of testing brakes from rear end.

H. STILLMAN, M. M.

*Dunsmuir, Cal.*

## The Waste in the Train Pipe.

*Editors*

I see some of the readers of the LOCOMOTIVE ENGINEERING are skeptical about the waste in train pipe described by Mr. Paxton in September issue, so it will be necessary for me to do as Alex. Cunningham is going to do ("prove it and swear to it") Mr. Paxton fully described the action of the brakes. I found on disconnecting train pipe at T, where triple valve branch pipe connects with train pipe, a bunch of waste wedged tightly in train pipe at end of T or drain cup farthest from engine. The fact that I had released the brakes just before disconnecting train pipe led me to believe that the motion of the waste was from one end of the strainer to the other as the pressure was increased or reduced from engine, and I still think that such was the case. Whether the entire plug moved or not, the fact remains that air would pass through to rear end of train but would not from rear end to head end. This, I think, is conclusive evidence that there must have been some movement of the waste, either wholly or in part.

Replying to Mr. Synnestvedt, would say that strainer is in drain cup or T when triple valve branch pipe connects to train pipe. If he will measure he will find considerable difference in diameter of strainer and train pipe, and still more between strainer and union swivel on train pipe. If this were not the case, the waste would have passed through train pipe into hose. Mr. Lansing, I should judge, handles nothing but cars equipped with "quick action brake," or he certainly would have found "that strainer." In conclusion, I believe the only way to test brakes is through medium by which they are to be handled on the road.

## Are Railroad Managers Unmindful of Stockholders' Interests?

*Editors:*

Having taken some interest in the manner in which improvements were accepted on railroads generally, and finding so much indifference shown to a really good thing many times, it leads me to make the above inquiry.

While reading the *Railroad Gazette* of January 8th, 1892, I saw that the Baltimore & Ohio Railroad had closed a contract with the Baldwin Locomotive Works for forty locomotives of different classes, and that none of them were to be of the most improved type, *i. e.*, compound. I do not see how this is, for the B & O R R were the first to use a compound locomotive, and have had one running for nearly three years, also have been testing another that is to go to a committee (appointed by the Convention of Master Mechanics) which is to give it a trial.

This shows that the B. & O. management are not ignorant about these compound locomotives which are showing from 15 per cent. to 40 per cent. saving of fuel in every-day service. I think I am safe in saying that these figures of saving have not been questioned by any one as yet, and cannot see how they can be, as the report of the experts of the Franklin Institute, on this B. & O. compound, demonstrates the above fact, and shows this type of engine to be simple, durable and economical, meeting with universal favor wherever used. So much for facts.

Now let one take a few figures and see how much might be saved on an order of forty locomotives by the company using them, if they had been of the most "improved" type, *i. e.* a compound engine. It will not overrate the matter to assume that these forty engines will each burn four tons of coal per day, and run at least 300 days a year, which makes something worth looking after, if 25 per cent of it could be saved. The forty engines, at four tons each per day, would burn 160 tons, and in 300 days would burn 48,000 tons, which it is fair to assume represents \$2.50 per ton. This would amount to \$120,000, and a saving of 25 per cent. would show a net gain of \$30,000 per year.

These figures may not be exactly correct, but I am sure they are nearly so.

If these things are at all correct, do the railroad managers look to the interests of the stockholders?

I do not think any one can show up a man who would manage his own private business in that manner.

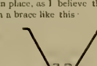
Why should corporations be managed differently from private business?

*Baltimore, Md.* STOCKHOLDER.

## Ex-Fire Boy's Puzzle.

*Editors*

What ailed the Roger? Well, I would say it was the block that held the tumbling shaft in place, as I believe the block was held in a brace like this:



and the bolt through the bottom of the brace and into the block was lost or broken, allowing the tumbling shaft to lift up, and, of course, she would work very little if any steam on that side. W. G. W.

*Boraboo, Wis.*

*Editors:*

The question is asked, "What ailed this old Roger?" "Old" Roger engines had their cylinders bolted to the "smoke-box;" they had exhaust pipes bolted to the cylinders; their pipes were quarter turns, their top ends joined, and exhaust tips or a long pipe, whichever suited the rigging, were bolted on top of them. The joint in one of these pipes gave out, or there was a hole in one of the pipes. L. W. MARTIN.

*Elmira, N. Y.*

*Editors:*

I had the same experience one year ago with a Danforth mogul. Eccentrics were not keyed on, set screws of left back-up eccentric were bad, which would leave the left back-up eccentric to move backward and forward. When I did look at them, they would appear all right, when I could get a speed of twenty miles an hour or more, would exhaust as square as possible, when less than twenty miles an hour, sometimes there would be two, three or four exhausts. I put it down to be partly due to the eccentric moving a little, and so much lost motion in the eccentrics, link block, etc. I dropped her down a notch, and then engine was O. K. C. P. R.

*Winnipeg, Man.*

THE ANSWER

*Editors:*

In answer to the "Old Roger" puzzle, will continue my story.

After getting so badly left in our surmises, we sat down to think, then the engineer got up and asked me to hold the door on the front end open (it was one of the kind that was hinged at the top and swung up), and he felt up inside to see if the nozzles were loose, but they were all right.

These old engines had copper exhaust pipes extending up above the door on the front end, and when we got light inside the front end we found the exhaust pipe on the right side had burst down near the bottom, in the bend where it was turned up, and that was what made the engine act as before described.

*Genesee, N. Y.* EX-FIRE BOY.

## Those Puzzles.

*Editors.*

In answer to Ex-fire Boy puzzle would say that the bridges were broken, partly closing the steam passages.

In answer to C B Conger puzzle would say that the eccentric strap spread just as the valve closed the forward port, preventing the escape of the exhaust, and causing undue compression which caused the head to break.

S. WOOLMINGTON.

*Cleveland, Ohio.*

## Make Time or Quit.

*Editors*

A fatal accident happened to the Union Pacific fast mail train bound for Portland, Ore., December 29th. The train left La Grande, Ore., early in the evening, pulled by a "hog" and the usual ten-wheeler. The road west here lies through a narrow, winding cañon in the Blue Mountains, beside the Grande Ronde River. It's all curves—short and sharp—picturesque and dangerous. About three miles out of La Grande the "hog," by her enormous weight, is supposed to have spread the rails, and the second engine plunged down the bank, carrying to swift and instant death the engineer, R. E. Law, formerly of New Brunswick, and fireman George Miller, of Iowa. Both were "extra" men. The accident is of a kind too common on our mountain roads in winter.

In the present case the coroner's jury found the railroad company to blame, both for the condition of the roadbed and the use of "hogs" on fast trains.

In the telegraphic news to-day I see that the State Board of Railroad Commissioners have also been investigating the cause of the accident, and blame the company for using "hogs" on such fast trains as the fast mail. This is truly wonderful! The California Railroad Commission is popularly supposed to be a part of the railroad companies' clerical force. I doubt even if their authority extends beyond adjustment of rates and fares. At any rate, they never bother about roadbeds, or engines, or railway accidents. Likewise, a California coroner's jury rarely blames anybody but the engineer or trainmen, and the railway companies' attorneys have a patent process for proving beyond doubt that the engineer committed suicide.

Passenger trains on the U. P. have orders not to exceed twenty miles an hour. As a matter of every-day fact, they usually run from thirty-five to fifty miles an hour on up grades, and there are a few places on level track where they spin along at the rate of sixty miles an hour. Of course, the officials know it. They know it has to be done often in order to make time. So long as everything goes right it's all right. In case of accident there is abundant proof of contributory negligence on the part of the man killed. Isn't that so all over the country?

But this meddlesome Board of Railroad Commissioners seems to have overlooked all precedents by recognizing these facts as facts. A few more such men in the right place could do a world of good for the men who have to "make time" or quit.

HONORARY MEMBER.

*Oakland, Cal.*

## Where is it?

*Editors*

In Mr. Tabor's able articles on the indicator, where he shows the expansion line, there is a slight mistake in the figures. I am not calling attention to this for the purpose of correcting Mr. T., but to start the boys to watching the figures. There is a mistake of one pound. Where is it, boys? P. J. FIEKINGER.

*Beaver Falls, Pa.*

Mr. A. G. Darwin, who was well known to railroad men owing to his connection with various supply interests, died at Glen Ridge, N. J., last month. Mr. Darwin was born in New York State, and early in life followed Greeley's advice and went West. He entered railroad life on a part of what is now the Chicago, Milwaukee & St. Paul system, and arose to be superintendent of one of the roads. About 1868 he became President of the Allen Paper Car Wheel Co., and through this connection acquired an exceptionally wide acquaintance. Since he left that company he has been President of the Strong Locomotive Company, and a holder of an important share in other railroad enterprises.

## Testing Brakes from Rear End.

*Editors:*

Considerable attention has been paid on some roads to testing brakes from rear of train, and our attention has been called through your columns to difficulties that arise from local causes.

We have seen that obstruction in train-pipe may interfere in *either* direction with free passage of air, or, in other words, that brakes will not always operate alike from both ends of train. Now, this is no reason for testing from rear end, because service applications are only made from head end in controlling train, and what else are they for? Passage of air forward is most to be desired. Obstructions in train-pipe should be located at terminals and are of rare occurrence anyway if any sort of attention is paid to testing cars in yards by men whose business it is to do so.

There is another view to be taken of the practice in its effect in general on the delicate and numerous parts of a system of quick-acting automatic brakes in train.

At the head end, our engineer has at his hand an air-valve in its most approved form for the purpose of controlling automatically the release of air from the train-pipe, also, before him are gauges that show what he and the valve are doing or can do.

At the rear end, what have we?

1st. An average brakeman.

(Thos. Carlyle says the average man is a "damn fool"—which being a general remark and applied to all of us, we can have no grievance.)

2d. There are no gauges whereby this average brakeman can tell how much air he is going to release.

3d. There is an ordinary train-pipe stop-cock that opens a slot 1¼ inches long, or nothing.

Now, from actual measurement, as compared with the maximum area of service opening in train pipe resulting from use of engineer's air-valve, the train-pipe cock should not be opened more than $\frac{1}{16}$ of an inch.

As a result of the above we have in nine cases out of ten an *emergency* application to determine whether the brakes are in condition for a *service* application, which is not the same thing.

I fail to find that the W. A. B. Co., or anyone else for that matter, recommend the use of the emergency as a regular thing. While not so disastrous on draw-heads and wheels when applied on a train at rest, yet the tendency to disarrangement of parts causes lots of trouble from undue strain. Bang! bang! we hear the brakes go on all around us from brakemen (and other conductors) monkeying with them because they are required to. In vain are they "jacked up" about it. Our average brakeman cannot strain his nerves to adjusting stop-cocks within $\frac{1}{16}$ of an inch. Not only does the practice make trouble, but wastes an enormous amount of air needlessly.

Our overworked air-pumps labor away to make up this waste.

They make no demand for overtime, however, wherefore let us rejoice and be exceeding glad. Thus appears one redeeming feature of testing brakes from rear end.

H. STILLMAN, M. M.

*Dunsmuir, Cal.*

## The Waste in the Train Pipe.

*Editors.*

I see some of the readers of the LOCOMOTIVE ENGINEERING are skeptical about the waste in train pipe described by Mr Paxton in September issue, so it will be necessary for me to do as Alex. Cunningham is going to do ("prove it and swear to it"). Mr. Paxton fully described the action of the brakes. I found on disconnecting train pipe at T, where triple valve branch pipe connects with train pipe, a bunch of waste wedged tightly in train pipe at end of T or drain cup farthest from engine. The fact that I had released the brakes just before disconnecting train pipe led me to believe that the motion of the waste was from one end of the strainer to the other as the pressure was increased or reduced from engine, and I still think that such was the case. Whether the entire plug moved or not, the fact remains that air would pass through to rear end of train but would not from rear end to head end. This, I think, is conclusive evidence that there must have been some movement of the waste, either wholly or in part.

Replying to Mr. Synnestvedt, would say that strainer is in drain cup or T when triple valve branch pipe connects to train pipe. If he will measure he will find considerable difference in diameter of strainer and train pipe, and still more between strainer and union swivel on train pipe. If this were not the case, the waste would have passed through train pipe into hose. Mr. Lansing, I should judge, handles nothing but cars equipped with "quick action brake," or he certainly would have found "that strainer." In conclusion, I believe the only way to test brakes is through medium by which they are to be handled on the road.

## Are Railroad Managers Unmindful of Stockholders' Interests?

*Editors:*

Having taken some interest in the manner in which improvements were accepted on railroads generally, and finding so much indifference shown to a really good thing many times, it leads me to make the above inquiry.

While reading the *Railroad Gazette* of January 8th, 1892, I saw that the Baltimore & Ohio Railroad had closed a contract with the Baldwin Locomotive Works for forty locomotives of different classes, and that none of them were to be of the most improved type, *i. e.*, compound. I do not see how this is, for the B & O. R R were the first to use a compound locomotive, and have had one running for nearly three years; also have been testing another that is to go to a committee (appointed by the Convention of Master Mechanics) which is to give it a trial.

This shows that the B & O. management are not ignorant about these compound locomotives, which are showing from 15 per cent. to 40 per cent. saving of fuel in every-day service. I think I am safe in saying that these figures of saving have not been questioned by any one as yet, and cannot see how they can be, as the report of the experts of the Franklin Institute, on this B. & O. compound, demonstrates the above fact, and shows this type of engine to be simple, durable and economical, meeting with universal favor wherever used. So much for facts.

Now let one take a few figures and see how much might be saved on an order of forty locomotives by the company using them, if they had been of the most "improved" type, *i. e.*, a compound engine. It will not overrate the matter to assume that these forty engines will each burn four tons of coal per day, and run at least 300 days a year, which makes something worth looking after, if 25 per cent. of it could be saved. The forty engines, at four tons each per day, would burn 160 tons, and in 300 days would burn 48,000 tons, which it is fair to assume represents $2.50 per ton. This would amount to $120,000, and a saving of 25 per cent. would show a net gain of $30,000 per year.

These figures may not be exactly correct, but I am sure they are nearly so.

If these things are at all correct, do the railroad managers look to the interests of the stockholders?

I do not think any one can show up a man who would manage his own private business in that manner.

Why should corporations be managed differently from private business?

*Baltimore, Md.* STOCKHOLDER.

## Ex-Fire Boy's Puzzle.

*Editors*

What ailed the Roger? Well, I would say it was the block that held the tumbling shaft in place, as I believe the block was held in a brace like this:

and the bolt through the bottom of the brace and into the block was lost or broken, allowing the tumbling shaft to lift up, and, of course, she would work very little if any steam on that side. W. G. W.

*Boraboo, Wis.*

*Editors.*

The question is asked, "What ailed this old Roger?" "Old" Roger engines had their cylinders bolted to the "smoke-box;" they had exhaust pipes bolted to the cylinders; their pipes were quarter turns, their top ends joined, and exhaust tips or a long pipe, whichever suited the rigging, were bolted on top of them. The joint in one of these pipes gave out, or there was a hole in one of the pipes.

L. W. MARTIN.

*Elmira, N. Y.*

*Editors:*

I had the same experience one year ago with a Danforth mogul. Eccentrics were not keyed on, set screws of left back-up eccentric were bad, which would leave the left back-up eccentric to move backward and forward. When I did look at them, they would appear all right, when I could get a speed of twenty miles an hour or more, would exhaust as square as possible, when less than twenty miles an hour, sometimes there would be two, three or four exhausts. I put it down to be partly due to the eccentric moving a little, and so much lost motion in the eccentrics, link block, etc. I dropped her down a notch, and then engine was O. K. C. P. R.

*Winnipeg, Man.*

THE ANSWER.

*Editors.*

In answer to the "Old Roger" puzzle, will continue my story.

After getting so badly left in our surmises, we sat down to think; then the engineer got up and asked me to hold the door on the front end open (it was one of the kind that was hinged at the top and swung up), and he felt up inside to see if the nozzles were loose, but they were all right.

These old engines had copper exhaust pipes extending up above the door on the front end, and when we got light inside the front end we found the exhaust pipe on the right side had burst down near the bottom, in the bend where it was turned up, and that was what made the engine act as before described.

*Genesee, N. Y.* EX-FIRE BOY.

## Those Puzzles.

*Editors*

In answer to Ex-fire Boy puzzle would say that the bridges were broken, partly closing the steam passages.

In answer to C. H. Conger puzzle would say that the eccentric strap spread just as the valve closed the forward port, preventing the escape of the exhaust, and causing undue compression which caused the head to break.

## Make Time or Quit.

*Editors.*

A fatal accident happened to the Union Pacific fast mail train bound for Portland, Ore., December 29th. The train left La Grande, Ore., early in the evening, pulled by a "hog" and the usual ten-wheeler. The road west here lies through a narrow, winding cañon in the Blue Mountains, beside the Grande Ronde River. It's all curves—short and sharp—picturesque and dangerous. About three miles out of La Grande the "hog," by her enormous weight, is supposed to have spread the rails, and the second engine plunged down the bank, carrying to swift and instant death the engineer, R. E. Law, formerly of New Brunswick, and fireman George Miller, of Iowa. Both were "extra" men. The accident is of a kind too common on our mountain roads in winter.

In the present case the coroner's jury found the railroad company to blame, both for the condition of the roadbed and the use of "hogs" on fast trains.

In the telegraphic news to-day I see that the State Board of Railroad Commissioners have also been investigating the cause of the accident, and blame the company for using "hogs" on such fast trains as the fast mail. This is truly wonderful! The California Railroad Commission is popularly supposed to be a part of the railroad companies' clerical force. I doubt even if their authority extends beyond adjustment of rates and fares. At any rate, they never bother about roadbeds, or engines, or railway accidents. Likewise, a California coroner's jury rarely blames anybody but the engineer or trainmen, and the railway companies' attorneys have a patent process for proving beyond doubt that the engineer committed suicide.

Passenger trains on the U P. have orders not to exceed twenty miles an hour. As a matter of every-day fact, they usually run from thirty-five to fifty miles an hour on up grades, and there are a few places on level track where they spin along at the rate of sixty miles an hour. Of course, the officials know it. They know it has to be done often in order to make time. So long as everything goes right it's all right. In case of accident there is abundant proof of contributory negligence on the part of the man killed. Isn't that so all over the country?

But this meddlesome Board of Railroad Commissioners seems to have overlooked all precedents by recognizing these facts as facts. A few more such men in the right place could do a world of good for the men who have to "make time" or quit.

## Where is it?

*Editors:*

In Mr Tabor's able articles on the indicator, where he shows the expansion line, there is a slight mistake in the figures. I am not calling attention to this for the purpose of correcting Mr. T, but to start the boys to watching the figures. There is a mistake of one pound. Where is it, boys? P. J. FIRKINGER.

*Beaver Falls, Pa.*

Mr. A. G. Darwin, who was well known to railroad men owing to his connection with various supply interests, died at Glen Ridge, N. J., last month. Mr. Darwin was born in New York State, and early in life followed Greeley's advice and went West. He entered railroad life on a part of what is now the Chicago, Milwaukee & St. Paul system, and arose to be superintendent of one of the roads. About 1868 he became President of the Allen Paper Car Wheel Co., and through this connection acquired an exceptionally wide acquaintance. Since he left that company he has been President of the Strong Locomotive Company, and a holder of an important share in other railroad enterprises.

## Baltimore & Ohio Coal Car.

The one hopper gondola car illustrated in the annexed engraving is the standard coal car for 60,000 pounds now used by the Baltimore & Ohio Railroad. The car is designed with a view to carrying, without distress, the heavy load specified, and experience with the cars in the severe train service of the mountain roads of Pennsylvania and Maryland indicates that the car is going to prove highly satisfactory. It was originally designed by Mr. E. W. Grieves, Master Car Builder of the Baltimore & Ohio for a coal company, and gave so much satisfaction that, with a few improvements, it was adopted as the standard of the railroad company.

The leading dimensions of the car are: Length over end sills, 27 feet 3 inches; length outside of end planks, 25 feet 3 inches; length of car inside of end planks, 24 feet 9 inches; width over side sills, 7 feet 10 inches; height of side and end planks, 5 feet 1 inch; depth of hopper, 2 feet 6 inches; hopper opening, 6 feet 4 inches by 7 feet 6½ inches; distance between track centers, 17 feet 9 inches.

Yellow pine is used for side sills, center sills, intermediate sills, center springer, bridging, end planks, side planks, furrying pieces and running boards. The specifications require all yellow pine used to be untapped, and to show one face clear of sap; the other side to show not less than two-thirds heart. It has to be free from large or defective knots, wind or heart shakes and injurious sap.

White oak is employed for construction of end sills, draw-bar pieces, draw-timbers, foot-boards, stakes, body-bolsters, side bearing-blocks, slope-timbers, cross-rails, liners, filling-in pieces, brake-step, center sill roof-pieces, side-pieces and door-pieces. This oak must be all free from large or defective knots, bark-edges and heart-shakes. It will not be accepted with heart over three inches in diameter, which must be solid and in center of timber.

All bolt-heads, nuts and threads conform to the Master Car Builders' standard, which is the United States standard for these parts.

The side sills are 6x12 inches between body-bolster and tapered to 5x8 inches at the ends, and framed to end sills with 1½-inch tenons, with 2 inches space between tenons. Each sill is provided with pressed steel stake-pockets, which are fastened with double ¾-inch round iron yokes. Bolsters are secured to side sills by ¾-inch bolts which are put in place before furring is laid.

The intermediate sills are 4x10 inches, tapered to 4x10 on end, and are framed to end sills and bridging in the same way as the ends ills. Body-bolsters are fastened to intermediate sills with ¾-inch bolts. The intermediate sills have 2x4-inch liners fastened underneath between body-bolster and bridging The end planks are strongly secured to sills by strap bolts which lip over top of planks and pass down inside of car and through intermediate sills.

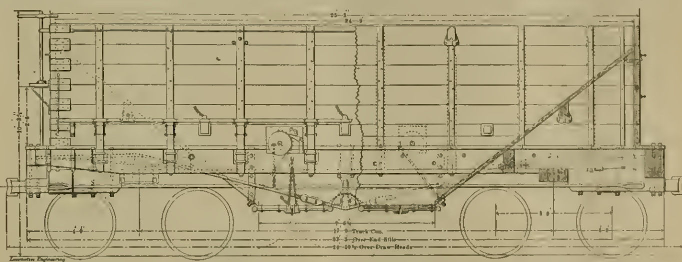
Center sills are 4x10 inches. A very substantial method of construction is followed for securing the draw timbers to these sills

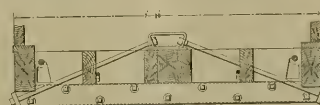
The body-bolsters are compound and made of three pieces of white oak 4½x6½ inches and two pieces of iron ¾x6 inches, bolted together with ¾ bolts. When finished it is 6¼x15 inches and cut off flush with the outside of side sills, and on an angle to receive truss rod washer and gained 2 inches deep to receive the side sills. Bolsters are placed 4 feet 9 inches from outside of end sill. Bolsters are trussed with strap ⅝x3½ inches, forming a pocket to receive 1¼-inch round truss rods, passing outside of bolster and through intermediate sills.

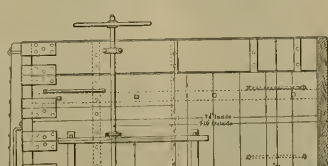
The side planks are 3 inches thick, 10 inches wide and 25 feet 3 inches long, laid on top of furring and fastened to frame of car with heavy strap bolts, and by pressed steel stake pockets. Each stake is riveted to side planks by ⅝-inch rivets with heads on outside of stake. The side and end planks are secured at the corners by seven pressed steel plates placed on the outside of car body. These are fastened by ½ inch rivets passing through the planks.

The car is provided with the American continuous drawbar.

All details of construction have been worked out with masterly ability. The material and proportions are designed to provide a car that will give the best possible service. The staying, bracing and trussing in a way to overcome the natural weakness of every point Mr. Grieves has good reason to be proud of the car.







## Leaving Well Enough Alone.

The advantage of leaving well enough alone was very well illustrated in a case mentioned by one of the Westinghouse Air Brake Co.'s inspectors. The company had equipped a small road in Canada with an entire outfit of brakes, and nine years afterward the superintendent of the road sent word to the brake company that the brakes were not working well. An inspector went to inquire into the cause of the trouble, and naturally asked what attention the triple valves and brake cylinders had received.

"Attention," said the superintendent, "they were never touched. I gave orders when the brakes were put on that no one should ever touch the brakes, and my orders are obeyed on this road."

"You never cleaned them or oiled them?" asked the inspector.

"Never a clean or an oil," was the reply. "I was afraid that if any of my men took the thing apart, they would never get it together again. You put all those things in good working order again and let us see if they can go nine years more without attention."

---

People going into Philadelphia, on the Pennsylvania Railroad, will notice on the left near the river, a fine new five story brick building. This is the new factory lately erected by the Berry & Orton Co., for their business of making wood-working machinery. The building has been erected in the most substantial style and is equipped with the best machinery for machinist work. The main building is 123 x 80 feet and there is an L 68x45 feet. Power for driving the machinery is obtained from an engine of 150 horse power. Elevators are used for moving material and workmen to the different floors; heating is done by what Mr. Orton considers the best steam system; electric lights are provided in sufficient number to make working at night nearly as clear as working in daytime. Tracks that come into the yards of the works connect with all the railroads coming into Philadelphia The finish of the offices is particularly fine and artistic, the work having been done by Harlan & Hollingsworth. The new shops give the company about four times the capacity they had before. Mr L. O. Orton superintended all details in the construction of the works.

JOHN WILEY & SONS, NEW YORK.

## Concerning Car Building.

The Baltimore & Ohio have ordered 1,500 cars.

The Boston & Albany have contracted with the Erie Car Works for 200 box cars.

The New York, Susquehanna & Western are in the market for 300 coal and 50 box cars.

The New England Railroad Club will discuss the subject of freight car trucks at next meeting.

The New York Central are reported to be in the market for 1,000 box and 1,000 coal gondolas.

This is magnificent weather for the testing of steam heater apparatus, and we will be surprised if the frost does not bring out some surprising "vindications"—on paper, anyway.

The Missouri Car and Foundry Co. are busy on cars for the Chicago, Burlington & Quincy, the East Tennessee, Virginia & Georgia, and the Savannah, Florida & Western.

The St. Charles Car Co. have received an order from the Missouri Pacific for 200 cars. It is reported that the order will be stretched out to 2,000 before the cars are delivered.

The Norfolk & Western are building 500 cars in the Roanoke Machine Works and they are said to be in the market for 2,000 more cars. Business on that road is very heavy.

The Chicago & Northwestern have ordered 120 new passenger cars from Pullman. This is the beginning of the preparation of this company to have plenty of passenger cars to handle the World's Fair business.

There have been a variety of disputes aired in the courts by steel car patentees of late, but railroad companies do not display the interest in this kind of car that would make patents of much value or worth fighting about.

The Duluth & Iron Range have placed an order for 200 ore cars. The ore-carrying business was very dull last season, but it is expected that it will be very active directly. Several other roads are contemplating the ordering of new ore cars.

The Louisville & Nashville are reported to be in the market for 1,000 freight cars. Cotton moving is slow in the South owing to low prices, but there is a good crop, and the cars must be had to haul it. Other Southern business grows apace.

The Chicago South Side Elevated Railway have ordered 75 passenger cars. They are substantially the same car as those used on the New York Elevated Railroads. The cars will be lighted by the Pintsch light system, which will be duly appreciated by the patrons of the road.

The Dayton Malleable Iron Company intimate to railroad men that they remodel for malleable iron, any pattern used for gray iron. By this means malleable iron castings can be used in car construction or repair without any change in the drawings or measurements.

The Committee of the Master Car Builders' Association, investigating the subject of steel-tired wheels, have sent out a circular calling for information on the subject. Mr. R. E. Marshall, Superintendent Motive Power, P. W. & B. Railroad, Philadelphia, is chairman, and replies should be sent to him.

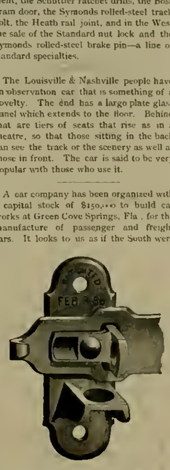
An odd form of flat car has been ordered by a car company in St. Louis. It is 60 feet long and is intended for the carrying of street cars from the makers. The Litchfield Car Works are building twenty of these cars. This company is also building 1,000 freight cars for a Kansas City transportation company.

A number of the unfortunates who have claims against the United States Rolling Stock Company are trying to have Receiver Hegewisch removed. If Mr. Hegewisch manages the property as receiver in the same fashion as he managed it before, the creditors will have some reason to demand a new deal.

Frank Bakeman & Co. report business in a highly gratifying condition. This firm handles the Cushing draw-bar attachment, the Schuttler ratchet drills, the Boss grain door, the Symonds rolled-steel track bolt, the Heath rail joint, and in the West the sale of the Standard nut lock and the Symonds rolled-steel brake pin—a line of standard specialties.

The Louisville & Nashville people have an observation car that is something of a novelty. The end has a large plate glass panel which extends to the floor. Behind that are tiers of seats that rise as in a theatre, so that those sitting in the back can see the track or the scenery as well as those in front. The car is said to be very popular with those who use it.

A car company has been organized with a capital stock of $150,000 to build car works at Green Cove Springs, Fla., for the manufacture of passenger and freight cars. It looks to us as if the South were



overdoing this business of building new car shops. Those in existence are not waxing fat. There is plenty of lumber to be had cheap but very small demand for the cars.

It is reported that an order has been issued by the Chicago, Burlington & Quincy to postpone the delivery of the freight cars under construction for the company at the Madison Car Works. The cars have been equipped with the New York air-brake, which is not working satisfactorily, and the purpose is to have the apparatus made right, or another brake substituted before the cars are put on the road.

Some time ago the Louisville & Nashville people adopted iron bolsters for their passenger cars. There were several good reasons apparent for this change but experience has demonstrated that they were more apparent than real. A fatal objection to iron bolsters is that they make the car ride harder than a wooden bolster. On account of this the company are returning to the use of wooden bolsters.

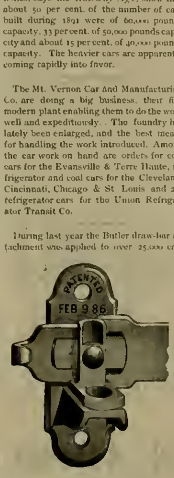
Those who are interested in transporting perishable commodities in good order, would do well to investigate the merits of the Hanrahan automatic refrigerator car, whose headquarters are in the Phenix building, Chicago. This car is designed to act in harmony with nature's laws, with the result that it maintains a low temperature with the smallest possible expenditure of ice. This car is certain to become popular.

The Elmore Car Axle Box Lid Company, Chicago, report that their lid has received a good share of patronage among the large number of freight cars lately ordered. The Elmore lid is standard on several railroads and is a great favorite wherever used. The lid is now made of pressed steel and is self-closing, making a dust-proof cover to the box. Those who have not tried the steel lid are requested to send for a sample.

The orders given out lately for cars have almost invariably specified a capacity of 60,000 pounds. The movement in this direction has been very rapid. Recent statistics, says the *Railway Age*, show that about 50 per cent. of the number of cars built during 1891 were of 60,000 pounds capacity, 33 per cent. of 50,000 pounds capacity and about 15 per cent. of 40,000 pounds capacity. The heavier cars are apparently coming rapidly into favor.

The Mt. Vernon Car and Manufacturing Co. are doing a big business, their fine modern plant enabling them to do the work well and expeditiously. The foundry has lately been enlarged, and the best means for handling the work introduced. Among the car work on hand are orders for coal cars for the Evansville & Terre Haute, refrigerator and coal cars for the Cleveland, Cincinnati, Chicago & St. Louis and 200 refrigerator cars for the Union Refrigerator Transit Co.

During last year the Butler draw-bar attachment was applied to over 25,000 cars



and used on railroads representing more than 50,000 miles of track. All who use the attachment admit that it puts an end to the pulling out of draw heads and couplers. Considering the small cost of the attachment, its simplicity and durability the surprise is that so many railroads delay putting it upon their cars. The saving of draft timbers is calculated to be sufficient in one year to pay for the device.

The 1,500 new freight cars lately ordered by the East Tennessee, Virginia & Georgia are going to be equipped with air-brakes and master car builders' type of coupler. The officers of this system say that there has been a great deal of breakage among the vertical plane couplers in use, but valuable experience has been gained which is likely to reduce the breakage. With all the drawbacks due to the period of mixed draw-bars the E. T., V. & Ga. people say the expense of using the Janney style coupler compares favorably with the link and pin.

The Consolidated Car Heating Co. informs us that it has been favored with a most prosperous business for the four months ending January 1, 1892. They have furnished to railroads 13,459 steam couplers, 459 complete car equipments and 162 locomotive equipments. The Old Colony R. R. has had 99 equipments, the Boston & Maine 175, the Canadian Pacific 45, the Concord and Montreal 64. The Canada Atlantic, the "Soo Line," and all the Vanderbilt lines were also large buyers. On the first of January they had orders yet to be filled for 130 complete car equipments.

There is nothing in the way of improvement of the American railroad car so badly needed as platform gates. Scores of people are killed every year by getting off the wrong side of a train and getting in the way of other trains, falling off platforms when sick or intoxicated, or getting thrown off by lurching of the train, or because there is ice or snow on platforms. Vestibuled trains are all right in this respect, but the platform of the ordinary coach is what needs protection. The Old Colony and one or two other New England roads are well equipped in this way and their example should be followed. It is only a few days ago that a man fell off the platform of an express train in the tunnel approaching the Grand Central station in this city and narrowly escaped death, gates are cheap and efficient—let's have them.

## Dayton Malleable Iron Company's Door Fastener.

The annexed engravings illustrate a very efficient form of door fastener made by the Dayton Malleable Iron Co., for freight cars. The points of superiority claimed for the fastener are:

It has no pins, hooks or chains to be broken or lost—the gravity button taking their place.

It is very strong and perfectly simple; anyone can see at a glance how it works.

It can be put on the door, or the door-post, working either right or left.

It can be sealed with wire or tin seal, or locked with padlock.

It is the cheapest, strongest, and best fastener in the market.

It has double-slotted hasp, so that, if desired, the door can be locked open for ventilation. Single-slotted hasps furnished if preferred; also hasps with offset, for stock cars.

## An Unwelcome Intruder.

In the yards of the New York, Providence & Boston Railroad, at Providence, there is to be seen a modest-looking frame house bearing the inscription "Freight Office." The sign appears to be put there to deceive, for the building is filled with the offices of Master Mechanic Butler. It is an exciting place to locate an office, for at all times of the day and night there are flying cars to the right of you, flying cars to the left of you and switch engines bumping their victims in all directions. It is a good place not to sleep in, and Mr. Butler says that is right, for it is not intended as a sleeping place. The location has its drawbacks, however, even to a man not fond of repose. The other day as Mr. Butler, soothed by the tumult outside, was cogitating on how many engines he would have overhauled during the winter and calculating the expense, the exterior racket became a little more impressive than usual, and suddenly the end of a freight car probed its way through the side of his office, and tried to run the building across the tracks. It only succeeded in moving the master mechanic's office a few feet, but Mr. Butler declares that it spoiled one of the best calculations he had ever made.

Captain John Kerr has been appointed assistant mechanical superintendent of the Grand Trunk Railway with charge of the car department at London, Ont.

The mechanical department of the Northern Pacific Road lost a valuable man in the sudden death, on December 20th, of G. W. Goodman, M. M., at Mandon, N. D. Mr. Goodman succeeded J. E. Phelan as general road foreman of engines and was only recently made master mechanic.

Those who are in the confidence of President Manvel, of the Atchison, Topeka & Santa Fé, say that he is about to infuse gladness to many by ordering twenty-five new locomotives.

## Two Kinds of Locomotive Runners.

Any road engineer who visits the Carnegie works in Pittsburgh and sees the young boys in charge of the little locomotives about the mills is apt to think there is not much ability or experience needed there, but the concerns have some standard gauge switches with grown-up men on them.

Not so very long ago the company bought two 16x22 saddle-tank engines, one Baldwin, the other a Pittsburgh; they were to all intents and purposes alike.

After some months of service it came to be common talk and belief that the Baldwin could pull more than her mate, although the Pittsburgh had a great reputation as a steamer.

Inability to handle certain loads in certain places became a trouble at last, and word was sent to Superintendent Wightman of the Pittsburgh Locomotive Works that his engine could not pull near as much as the Baldwin.

Wightman is not very superstitious, and refuses to believe that 140 pounds of steam will do more work in one 16-inch cylinder than in another because it was made by any certain firm or in any certain place; he was sure his engine would do as much as the other, and just as sure that it could not do more; anyway he would go over and investigate.

The work done by the little mills is hard only in spots, and the "runs" are only a few car lengths—not much trouble about teaming. After listening to his engine for a moment, the builder ordered the smoke-box door opened, and investigation showed the nozzles choked to about an inch and a half in diameter, these were cleaned down to two, the engineer worrying all the time about killing her for steam.

The thing was started now, so they opened the front of the Baldwin and found that the engineer had removed the exhaust tips altogether, said the engine would steam all right, and it gave her more chance to do heavy work for a short time, then they took the tips out of the other engine and now both exhaust direct from the base, and one can "put as many cars up" as the other.

You don't have to sit up nights to figure on which one of those two men was of the most use to his employers, had the best judgment or was the best engineer.

## A Headlight Signal Device.

Darkening the headlight is now a regular signal on all roads using the Standard Code of Signals, and the device here illustrated is intended to facilitate the use of and, perhaps, add to that mode of signaling.

There has been a good many curtain devices gotten up to darken the headlight from the cab, most, if not all, of them being trappy and liable to derangement, and often in the way of cleaning the glass. The device shown here is the invention of Foreman Hyde, a fireman on the P. R. R. at New Brunswick, N. J., and has some good points.

The plan is to raise a tube up around the burner of the headlight. Mr. Hyde made his model to carry two sizes of tube, one inside the other, so that one could be used as a red or green globe to give a separate signal.

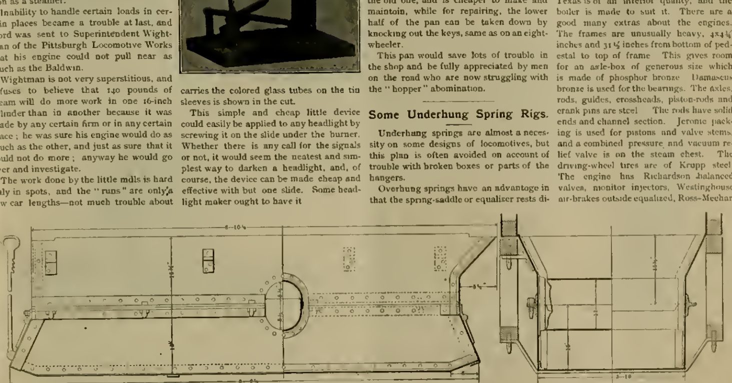
The picture shows the inside slide raised up, the larger one down, the movement being effected by the simple levers shown, connected by wire or cord to the cab through the hand-rail. Only the base that

carries the colored glass tubes on the tin sleeves is shown in the cut.

This simple and cheap little device could easily be applied to any headlight by screwing it on the slide under the burner. Whether there is any call for the signals or not, it would seem the neatest and simplest way to darken a headlight, and, of course, the device can be made cheap and effective with but one slide. Some headlight maker ought to have it

## Improved Ash-pan for Shallow Fire-box Engines.

The engraving shown herewith illustrates a new form of ash-pan designed by W. H. Thomas, Superintendent of Machinery of the E. T., V. & G. Ry., for engines with shallow fire-boxes, the one shown being the size used on his 20x24 consolidation engines.



All who are familiar with the usual "hopper" ash-pans, universally used in this country on engines having an axle under the fire-box, know how difficult it is to keep them reasonably tight, how their shape causes a wedging action of the ashes and cinders, especially if wet, that makes them hard to clear; how hard it is to get ashes out of them on account of there being no opening except at the bottom, how miserably they warp if a little live fire is shaken into them—because it is concentrated at two points, and last, but not least, what an infernal nuisance they are to get down and up again for repairs to the boiler.

The pan shown herewith is a long pan, such as used on eight-wheelers, except that it is unusually deep. It is made in halves, as shown, and a sleeve surrounds the axle, half of it being above, the other half below it.

The upper pan is held to the upper rail of frame by lugs and keys, as shown, while the lower one is held to the lower rail and to the upper half of the pan, as shown.

The angle irons around the center of the pan serve to stiffen it and prevent warping. This arrangement leaves a long free pan that can be cleaned from sides or the ends. It will carry safely a third more ashes than the old one, and is cheaper to make and maintain, while for repairing, the lower half of the pan can be taken down by knocking out the keys, same as on an eight-wheeler.

This pan would save lots of trouble in the shop and be fully appreciated by men on the road who are now struggling with the "hopper" abomination.

## Some Underhung Spring Rigs.

Underhung springs are almost a necessity on some designs of locomotives, but this plan is often avoided on account of trouble with broken boxes or parts of the hangers.

Overhung springs have an advantage in that the spring-saddle or equalizer rests directly upon the top of the box and needs no bolt or other fastening to keep it there.

Master Mechanic Thompson, of the Long Island road, has long used underhung springs with all the advantages of the overhung, for while the spring itself is located below the box, the hangers reach to the top and rest in pockets.

Fig. 1 shows a plan long in use with Mr. Thompson, the four hangers coming down beside the box and being joined below to a steel block, as shown; this plan worked well, but was not easy to get apart when necessary.

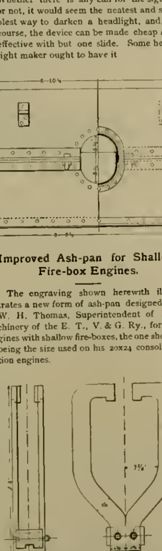


Fig. 1.

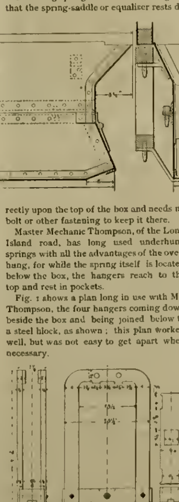

Fig. 2.

Fig. 2 shows another plan for the same thing, but handier and easier to get springs in and out of. The hangers proper are straight, and by this plan the spring can be got up closer to the frame. They are cheap and very strong.

## Cooke Locomotive Works.

Since this company got into their new works they have found their capacity for building locomotives a little ahead of orders, but they are doing a very good business. The shops are very convenient for the handling of material and the tools in use are nearly all good.

In the erecting shop I found some fine ten-wheel engines for the International & Great Northern. The engines have cylinders 18x24 inches and wagon-top boiler 58 inches at smallest ring, made of 9-16-inch steel, and good for a working pressure of 165 pounds. The fire-box is above the frames and is 96x42 inches. There are six hollow stay-bolts at each side of the fire-box, each having an opening one inch in diameter. Four of these are also put in the front and four in the back of the fire-box. A brick arch is used in the fire-box and there are 240 tubes 13½ feet long. This would appear to be a big boiler for the cylinders, but the coal obtained in Texas is of an inferior quality, and the boiler is made to suit it. There are a good many extras about the engines. The frames are unusually heavy, 4x4¼ inches and 31½ inches from bottom of pedestal to top of frame. This gives room for an axle-box of generous size which is made of phosphor bronze. Damascus bronze is used for the bearings. The axles, rods, guides, crossheads, piston-rods and crank pins are steel. The rods have solid ends and channel section. Jerome packing is used for pistons and valve stems, and a combined pressure and vacuum relief valve is on the steam chest. The driving-wheel tires are of Krupp steel. The engine has Richardson balanced valves, monitor injectors, Westinghouse air-brakes outside equalized, Ross-Meehan brake-shoes and the National hollow brake beams on tender. The boiler is covered with asbestos.

Some moguls for the Chicago, St. Paul & Kansas City road that are in the erecting shops are also well worthy of examination. The cylinders are 18x24 inches and the boiler is 54 inches diameter of ½-inch steel. The fire-box has the bottom corners dropped down to admit of a double-riveted mud-ring at these points. The engines bear the traces of careful designing, and apparently no expense has been spared to make them efficient and convenient. The Cooke people are building twenty-five of these engines.

The officers of the Schenectady Locomotive Works are mourning the loss of one of their most valuable assistants, and the workmen generally are regretting the loss of a friend in R. Mitchell Gifford, who died very suddenly a month ago. Mr. Gifford was a comparatively young man, but he possessed the elements from which successful men are made, and in a few years worked himself up to a position of honor and responsibility. He was a technical school graduate. After finishing his educational course he donned overalls and went to work in a machine shop. Then he went to Brasil and ran a locomotive there for three years. Returning to this country about 1880 with a load of valuable experience, he went to work in the drawing office of the Rhode Island Locomotive Works. From that he went at the invitation of Mr. Pitkin to Schenectady, where he was engaged mostly in inspecting, testing and scientific work for the firm. He was water commissioner of the city of Schenectady and was a highly popular and valuable citizen.

## "TESTS."

### What Do They Show?—Of what Value Are They?—Does It Pay to Make Them?

BY I. R. CATECHISM.

The above questions often enter my mind when reading of some wonderful showing that has been made after the most thorough and critical tests which ought to prevent the possibility of any doubt. And then to know that it is only one of the many thousands that have preceded it with the same display of facts, all of which, after a short period, ended in smoke or something of less value.

Any attempt to call your attention to all of them would be ridiculous, for their names are "legion," but I will try to name you a few only in your line that you may see why I would like to have you answer the above questions.

Some years ago there was quite a "revival" in saving of fuel on locomotives, which was the father of many inventions which had that object in view, such as grate bars, ash-pans, smokestacks, spark burners, feed-water heaters, etc., too numerous to mention.

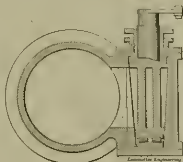
To go a little more into detail, we will look at the spark burner which was championed by the late Chas. F. Pike, of this city. It was put on several roads and several engines on each road, which, according to the *many tests*, showed wonderful saving in fuel—enough, if it could have been kept up, to make any railroad company rich. Then came the Hawkes and Paine sparker with still better results. I think it was put on all of the locomotives of the Fitchburg Railroad Company, and the "Union Locomotive Improvement Co." was chartered to manufacture and improve the locomotives according to these patents, said company paying large dividends (according to circulars issued by them).

Patent boilers had their share of attention, such as the "Phleger," "Dimpfel," "Boardman," the "Amory" and "Weston;" each would show from 25 to 45 per cent. saving of fuel. After a series of tests of the most exhaustive kind the Weston boiler was adopted by the Lake Shore & Michigan Southern R. R., also the C. C. C. & I. R. R. Of later date we have the "Wootten" and the "Strong" boiler, the former, according to the committee of experts of the Franklin Institute of Philadelphia, Pa., shows a saving over the ordinary boiler so great that no railroad could afford to do without it. (See Journal of the Franklin Institute for September, 1891.)

The feed-water heaters have had their share of attention also. Ever since the time of "Ebbert," of Chicago, who, some time in the fifties, put his in the smokestack, it has been followed up by "Clark," of Hazleton, Pa., down through the succeeding generations, each one with a triding change, down to the "Magoon" of Vermont, then the "Taylor" of the Old Colony R. R., finally the "Rushforth" (which is quite likely will be the last for a short time only). Each one of these have saved their 25 to 35 per cent. of fuel in their day, besides helping the engine to do much more work.

The valve motions that have been produced that saved the like amount over the poor and friendless link motion are legion, it would require quite a large book to hold all of their merits. Some of them were the "Independent" cut-off, the "Ross Winan" cam, the "E. N. Dickerson" valve gear, the "Joy," "Walscharet," the "Wilson" (of the Chicago & Alton R. R.), the "Wolfe" (of St. Paul), down to the "Strong," which probably is the worst, and quite likely the last for some time. All have made same saving, from *actual tests*.

The different types of engines have been through this same thing, giving us such as the "Fontaine," "Coventry," the "Hippy-to-hop" engine with its "facets" on the tire of driving-wheels, which was indorsed (after a thorough test) by the former superintendent of motive power of the Chicago & Northwestern R. R.



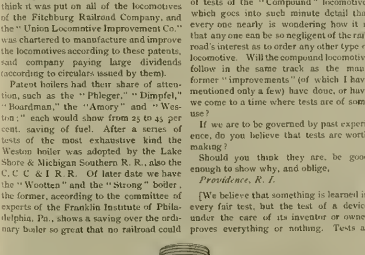
Just now we are having a regular feast of tests of the "Compound" locomotive, which goes into such minute detail that every one nearly is wondering how it is that any one can be so negligent of the railroad's interest as to order any other type of locomotive. Will the compound locomotive follow in the same track as the many former "improvements" (of which I have mentioned only a few) have done, or have we come to a time where tests are of some use?

If we are to be governed by past experience, do you believe that tests are worth making?

Should you think they are, be good enough to show why, and oblige,

*Providence, R. I.*

[We believe that something is learned in every fair test, but the test of a device under the care of its inventor or owner proves everything or nothing. Tests as usually conducted are of no practical value. The final test of the compound will be made in road service by the rank and file of engine-men extending over a large territory and some years of time. If the compound comes out of this test with a record of better service or economy, it will be adopted—just as steel tires, lubricators, pop-valves, air-brakes, injectors and other improvements have been adopted. If it does not show an economy or an improvement in some other way, it will follow the Dimpfel, the Swinerton, the Strong and the Fontaine down the wreck-strewn branch that ends at Oblivion.]

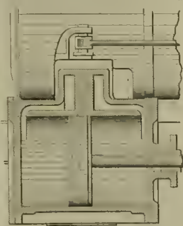


## Brousseau & Patterson's Steam Valve.

The illustrations on this page show the plan and application of an improvement in valves for steam cylinders, the invention of H. Brousseau and G. Patterson, two railroad men of Newberry, Mich.

The valve is of the vertical plug form, two being used on stationary engines and one on locomotives.

The general features are not unlike other valves of the class, but there are some refinements of detail not found in other valves, the principal one being the bearing of coned rollers that carries the valve and prevents its sticking in the shell, or on its seat.



The engravings show the arrangement and plan of the device and a detailed naming of parts is useless, in operation it is like a slide valve, the plug covering and uncovering straight ports.

The principal advantage claimed by the inventors is that the valve is perfectly balanced, is cheap to make and keep in repair, and does away with steam-chest and cover.

For locomotives the valve is made short and large in diameter.

We understand that the device is being tried on one engine.

## A Cylinder Cock Without "Rigging."

The engravings on this page make plain the details of a new cylinder drip-cock recently perfected by Mr. Harry Howell, of Wilmington, Del.

As will be seen, the valve is located in the center of the cylinder's length, and is connected to the ends by pipes and elbows. The pressure of steam in the cylinders tends to close the valves and keep them closed. These two valves are each connected to a diaphragm in the center of the case in such a way that when pressure is applied between them they will force open the drip valves. Pressure used for this purpose can be steam or air, preferably the latter. When steam is used the long valve stem running across the case is brought into use to get rid of the water of condensation, as long as there is pressure between the diaphragms this valve remains closed, when the pressure is relieved this valve is opened by the coiled spring shown, allowing any moisture to escape.

Fig. 2.

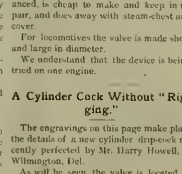


Fig. 3

Fig. 4

Through this case there also runs an eccentric rod, one end of which terminates in a handle outside the case, shown in the engraving, this is used to keep the valves open when the engine is dead.

As will be seen, there are no rods, levers, bell-cranks, etc., required to handle this valve. A small pipe leads from the cab to the valve cases, at the cab end it is connected to the pressure through a small three-way cock, conveniently placed. This is always easily handled, requires no holes in the deck, nor is it subject to derangement as much as the light, trappy rigging generally used for operating cylinder cocks.

This valve has been in use for some months on the Maryland Division of the Pennsylvania road, and giving satisfaction.

Byram & Co., Detroit, makers of the well-known Collian cupolas, are about ready to put upon the market a cylindrical core oven which will be the means of preventing the chilling of core ovens when the doors have to be opened for the putting in or taking out of cores. The cylinder stands on end and can be revolved so that only the section to be reached is exposed to the outside air. It is divided into sections which fit the door. By revolving the cylinder every section can be reached in turn, and the oven can be kept free from the admission of air while all the shelves in the cylinder are being loaded or emptied.

It is reported that President Hill, of the Great Northern, is working himself up to the sticking-point of ordering 100 new locomotives. The operative department say that they could find work for the whole lot were they delivered to-morrow.

It is rumored that Mr. E. P. Lord, Assistant Superintendent of Motive Power of the Fort Wayne Division of the Pennsylvania Railroad, has been made Superintendent of Motive Power of the Cleveland, Cincinnati, Chicago & St. Louis. Mr. Lord is a young man, who went through a very thorough training at Altoona and other parts of the Pennsylvania system. He has taken his part in all kinds of work connected with locomotives. He has worked as a machinist, as a draughtsman, as a fireman, as an engineer, and as an engineer of tests. These lines of work represent Mr. Lord's experience. Socially, he is one of the pleasantest men we have ever swapped stories with.

## Schenectady Locomotive Works.

A NEW ERECTING SHOP.

The Schenectady Locomotive Works have lately finished the building and equipping of a fine new erecting shop which adds very materially to the capacity of this rapidly growing establishment. It is a two-story building open throughout in the middle, the second floor forming galleries where light machine work is done. A fine Sellers crane traverses the building, and an arrangement of a platform projecting from the gallery enables the crane to be used for moving material to and from that part of the building. The shop is heated by the Sturtevant system, exhaust steam being used to supply the radiators with heat. The shop is of brick, with substantial stone foundations. The leading dimensions are 315x69 feet, and lean-to 28 feet wide. The building has a monitor roof and is finely lighted throughout. Steam is supplied by Babcock & Wilcox boilers, on which a pressure of 200 pounds of steam is carried, the high pressure being utilized for testing locomotive boilers. There is an Edison electric light plant run in connection with this shop.

A DURABLE FLOOR.

When this building was planned the question of the best kind of floor for an erecting shop received a great deal of attention. The officers in charge examined all the species of floors that were reputed to be most durable, and they decided on concrete, with a coating of cement on the top upon which a plank covering is embedded.

A POINTER ON EMERY WHEELS.

A great deal of work is done here on emery wheels, and they have a way of making the wheels that is worthy of notice. They cast a plain center of good iron, roll the periphery in glue and then in emery, dry properly, and the wheel is ready for use. When the emery wears off, the glue is removed by a simple process, a fresh coating applied followed by the emery, and the wheel is as good as new. None of these wheels have ever broken, and they run much cooler than the common emery wheel. For the grinding of guides, they could not find any other emery wheel that would give satisfaction.

UTILITY OF MILLING MACHINES.

An experience was gone through in these shops with milling machines that is edifying. Channel side rods are becoming universal, and it was the practice in finishing these rods to start the channel with a milling cutter and then plane out the greater part of the stock to be removed. Several years ago they tried to do the entire work by milling, but found it slower than planing. Some months ago a new unusually powerful milling machine was purchased, and the intention was to use it for beginning the cutting out of the rod channels. As an experiment the whole of the channel was cut out by this machine, and it was then found that milling was cheaper than planing.

I have repeatedly heard this question of the relative cost of milling and planing discussed by men in charge of machine shops, and I know that there is great diversity of opinion about it. One man insists that it is cheaper to mill certain work than to plane it, and another is of the opposite opinion, and tells that he can prove the correctness of his conclusions by figures that George Washington never rivaled in truth. May the diversity of opinion not be due to the different kinds of milling machines used?

While on the subject of milling machines I might remark that it would abundantly pay many railroad companies that have milling machines in their shops to send the foreman to visit locomotive builders and other manufacturers of machinery to see the many uses a milling machine may be applied to advantageously. There is too much depending on a machine-shop foreman to learn by intuition all the capabilities of a strange tool.

VENTILATED CABS.

An improvement that will greatly promote the comfort of engine-men is used on the greater part of the large locomotives that were under construction in these works. This consists of a hatch placed on the top of a cab, which can be partly opened during hot weather.

MAKING ASH-PANS TIGHT.

Another improvement effected on all engines having the fire-box above the frames, is a sheet iron liner, that extends from the mud ring to the inside of the ash-pan, effectually filling the openings that permit so much dirt to be blown out from most engines of this kind. There will be fewer hot boxes when this small improvement is put on all locomotives that need it.

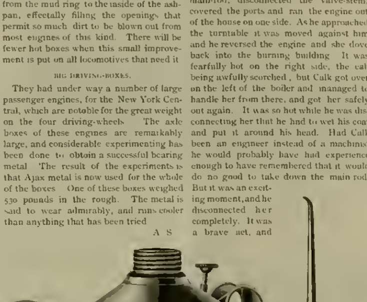
BIG DRIVING-BOXES.

They had under way a number of large passenger engines, for the New York Central, which are notable for the great weight on the four driving-wheels. The axle boxes of these engines are remarkably large, and considerable experimenting has been done to obtain a successful bearing metal. The result of the experiments is that Ajax metal is now used for the whole of the boxes. One of these boxes weighed 530 pounds in the rough. The metal is said to wear admirably, and runs cooler than anything that has been tried.

A. S.

## A Life Saver.

Not long since the shops of the N. Y. S. & W., at Wortendyke, N. J., burned, there were also four locomotives in the shop that were ruined. C. Calk, a machinist on duty that night, showed what he was made of in saving an engine. The 14 was in the roundhouse, with steam up, but she was jacked up in front and her truck was pulled out ahead of her, one cylinder-head was off and the piston-packing out. Calk had no help, but he went into the building, ran the truck to place, lowered the engine upon it, took down the main-rod, disconnected the valve-stem, covered the ports and ran the engine out of the house on one side. As he approached the turntable it was moved against him and he reversed the engine and she dove back into the burning building. It was fearfully hot on the right side, the cab being awfully scorched, but Calk got over on the left of the boiler and managed to handle her from there, and got her safely out again. It was so hot while he was disconnecting her that he had to wet his coat and put it around his head. Had Calk been an engineer instead of a machinist he would probably have had experience enough to have remembered that it would do no good to take down the main rod. But it was an exciting moment, and he disconnected her completely. It was a brave act, and showed his fidelity to and value as the servant of the road, and we are glad to note so far the responsible officers have not discharged him, made him serve time or pulled him off "pending investigation." The "14" ought to hold Calk in grateful rememberance, too, he saved her life.



## Some Improved Engine Oil Cans.

Men who have slopped oil all over a boiler head trying to oil the valves on a fast-running locomotive, or those who spoil the polish of a nice lubricator by spilling oil in trying to fill it, will probably be interested in the simple devices shown here.

The large "filler" can is a neat thing for valve oil or as a handy device for engine oil to fill small cans from.

It has a screw top, and a spout-closing and venting valve similar to that shown in the long oiler.

The tallow pot form of valve oil can is a dirty, slobbery thing at best, and its usefulness went out with tallow and the advent of the sight feed lubricator.

These cans are made by the Rau Manufacturing Co., Chicago, Ill.

Mr. J. B. Renniff has been appointed Master Car Builder of the Toledo Division of the Lake Shore & Michigan Southern.

Mr. O. O. Winter has been appointed Superintendent of the Minneapolis Terminals. He was formerly on the Fort Worth & Denver.

Mr. J. F. White, who recently resigned the position of Master Mechanic of the Fort Worth & Denver City Railway, was presented with a gold-headed cane and a diamond stud by the employés of the mechanical department.

Some time ago the New York, New Haven & Hartford obtained possession of several small roads that are now operated by the controlling company. The enginemen on these roads had smaller pay than the main line, and efforts were made for adjustment on a uniform basis. These efforts resulted last month in Grand Chief Arthur, of the Locomotive Engineers, and Grand Chief Sargent, of the Firemen's Brotherhood, holding a conference with the officers of the road. A satisfactory adjustment of the pay was effected without difficulty.

Mr. Ross Kells, Superintendent of Motive Power of the New York & Lake Erie, is again in bad health and is in the Danville Sanitarium under treatment. He has been given six months' leave of absence.

During the month of December all the locomotives belonging to the Chicago & Northwestern made an average of 4,700 miles in train service.

Mr. M. R. Clapp a well-known railroad supply man has made an engagement to travel for the Baker Heater Company, of which Mr. W. C. Baker is President.

In Europe and in some parts of Canada the boiler-head of a locomotive is called the "face-plate."

The Canadian Locomotive Works at Kingston, Ont., are building some engines for the Canadian Pacific.

The Schenectady people are very busy, and orders are in that will keep them in work for half the year. They have lately received an order for twenty engines for the Chicago, St. Paul, Minneapolis & Omaha.

The people of the Canada Southern Division of the Michigan Central are boasting of a mogul engine with cylinders 19x24 inches and driving-wheels 68 inches diameter, recently built in the company's shops at St. Thomas. They say that this is the largest mogul ever built in Canada, but the Grand Trunk and the Canadian Pacific are yet to be heard from.

A new class of ten-wheel locomotive is being designed by the Pennsylvania mechanical department. It will be called Class X, and will be specially adapted for the fast freight trains of Western lines. This company has been in the habit of contracting for from 75 to 100 locomotives annually, but they now expect to build in the new shops at Altoona all the locomotives required by the roads for years to come.

The Baldwin people are building a compound rack-rail locomotive for the Pike's Peak Railroad. They are also building the locomotive equipment for the Chicago South Side Rapid Transit Co., consisting of twenty locomotives, compounded. Each engine weighs about twenty-eight tons. Among other work in Baldwins are two switching engines for the Minneapolis & St. Louis, five compound moguls for the Calumet & Blue Island, and 40 engines of different classes for the Baltimore & Ohio.

When the Secretary of the Railway Master Mechanics' Association submitted his annual report at last convention, there were only two deaths reported during the preceding year. This was a remarkably low death rate among over four hundred men, most of them past the meridian of life. The appearances now are that the year of a singularly low death rate will be succeeded by one abnormally high. Nearly every month since the convention one or more deaths of members have been recorded and last month there were four deaths. Several of those who are gone will be missed at next convention for they have gone regularly to the meetings.

## Notice to Club Raisers and Club Members.

The club business has grown to such proportions that it is impossible to keep the list in clubs. Hereafter all names received from club raisers will be put in the general list, which is alphabeticalized both as to names, towns and States. So, if John Jones writes a card to change his address from Norwich, Conn., to Horton, Kan., we can find him. As it has been, he might have been a member of any of forty clubs gotten up in some of the New England States. Another advantage of the new system will be that every subscriber will get a notice of the time of his expiration. It has often happened that in the event of the death or removal of a club raiser a whole club was cut off without notice.

Club raisers will have to keep a list of their subscribers, as these cannot be furnished next year. New subscriptions and renewals count the same to them, and we are just as glad to receive subscriptions through them as from individuals, but where they fail to notify a subscriber of his expiration, we will do so, as this is but fair to the readers.

LOCOMOTIVE ENGINEERING.

## An Improved Safety-Plug and Low-water Alarm.

"Wonst," said the old-timer, slowly taking a chew of seed-leaf, as he leaned back in the Ananias corner, "Wonst, when we were building across the desert, I had a green Dutchman put on with me as fireman.

"He had the engine fever bad enough and was awful anxious to please me and keep the engine howling.

"He had been wipin' in the house and had heard the firemen tellin' hair-raisin' stories about havin' to put out their fires to keep from thawing the crown-sheet out, etc.—the water there was dreadfully ornery stuff—and Jacob was exercised over the water level any how—kinder suspicious like.

"One night we stopped at a lonesome section-house to eat, but Jacob carried his lunch and did not go in.

"As I got down to go, the pop went up with a roar, and I hollered to Jakey to watch the glass and if it went down much to 'put a little water in her to cool her off.'

"When I come back, Jakey was settin' on the end of a tie eatin' his lunch, and you just ot to seen him. He was as black as a nigger, all his moustache was gone, and his yellow hair singed off clean up to his cap.

"'You bade your schweed life she dond got the pest from me, already,' he said, proudly. 'Phen dot water-klass id commends to yump, I youst put in dot water like you toldt me—you don't got no purnt krown-sheed mit dis engine phen Yacob Kritsman vas der firemand—undt ton't you furged it.'

"When the water in the glass dropped after the pop shut, Jakey thought some conspiracy was on foot to burn that old cold water Hinckley, and he just nipped it in the bud. He had fired pad after pad of water into the fire-box regardless of the 'kick,' and the fire was black out.

"'That's right,' Jakey,' said I, 'don't you take any chances,' and then I fell down in a fit—of laffin'."

## The Secret of his Prosperity.

The men who enter railroad service from the top are not generally popular, and they are seldom noted for knowing much about the business they follow, but there are exceptions. One of the brightest exceptions to this rule is Mr. M. E. Ingalls, President of the Big Fours and the Chesapeake & Ohio Railroads. Mr. Ingalls began his railroad career as president twenty years ago of a poverty-stricken road, which good management made prosperous. Various other lines were drawn into the orbit of its prosperity, and an aggregation of impecunious small roads were bound up into the lucrative Big Four's system. Much of the success was due to Mr Ingalls far-sighted management. With the success of his efforts, the author attained fame and prosperity. His treatment of people connected with the roads is of a character to make everybody rejoice in Mr Ingall's good fortune.

Before coming to Ohio Mr Ingalls was a lawyer in a small town in Maine, where he was raised. Before leaving home he had not risen above his companions far enough to dazzle their eyes. He now tells a story against himself to illustrate the truth of the saying that, "a prophet has no glory in his own country."

After being nearly twenty years away from home, he paid a visit to his native village. Many of the old worthies were still there, and Mr. Ingalls went the rounds shaking hands with the acquaintances of his youth. All were glad to see him, and many were the congratulations expressed in homely phrase. No discordant note was heard in the tune of welcome till one of the hardest politicians among the natives was called on.

"Why," exclaimed the politician, "they tell me, Ingalls, that you have become a railroad president. Is that so?"

"Yes," replied Mr. Ingalls, "I am now president of a railroad."

"Does it pay well? How much of a road is it?" were the next questions.

"It pays well, and there are about two thousand miles of track."

"Well, well," groaned the politician, biting off a generous chew, "it is wonderful what a little money and a great deal of cheek will do for a man."

## Fast Traveling.

Our Fifth Vice-President has a friend in London, the Rev Rohab Romenaught, who is the sympathetic manager of the Royal Eleemosynary Institute for Literary Idiots. They were school-boys together at Harrow-on-the-Frog, and being of congenial temperament, they still correspond at rare intervals, although seas between them roll, as the reverend manager always says.

Our Fifth Vice-President went out yesterday and left his desk unlocked, and we straightened it up a little. The following is an extract from a letter written by Rohab which we found therein:

"My soul is harrowed by the pernicious influence which the natives of your adopted country are exercising upon our people. I am afraid that the falsehood and exaggeration that characterizes the conversation of Americans are undermining the truth and modesty that have always been the glory of Englishmen.

"I was painfully impressed with this dismal influence during a visit I made to your friend, Mr. Hartfat, at the Hotel Metropole. I sent up my card and your friend came down stairs. He is evidently a man of education, but the freedom of his manners appalled me. He seized my arm and led me, partly by physical effort and partly by force of his will, to his room where, without asking my consent, he introduced me to several other Americans and two or three of my own countrymen. They were all smoking cigars in the most barbarous fashion, and drinking a strange beverage which I weakly consented to indulge in, and it exerted a mortifying effect upon me.

"I confess, with sorrow and contrition, that I remained in the company of that ribald band for hours, and I weep to think of the violations of truth and veracity that characterized the anecdotes and stories related by some of those young men. I shall repeat part of a conversation, which I hope and pray is not the kind of talk to be heard in the home sanctity of your people.

"The subject of fast railway traveling was mentioned, and, of course, all the world knows that in England alone can fast, comfortable and safe railway trains be found. The controversy was brought about by one of the Americans mentioning that a train was run from New York to a town called Chicago in twenty-four hours.

"This coused one of my countrymen, who had evidently been contaminated by contact with his trans-Atlantic associates, for he exclaimed

"'If you want to see speed, travel on our Flying Dutchman; the telegraph poles, as you pass them, remind you of the teeth of a dressing-comb.'

"'That is a rapid gait,' said an American, 'but it does not begin to touch the fast trains we are now running in the States. Out West our railroad trains are run by electricity generated by the Falls of Niagara, and the ordinary way-train speed is a thousand miles an hour. They tried the full speed of the electric current, but heavy trains running thousands of miles per second were dangerous. But I tell you a thousand miles a minute is getting there.'

"'In what way was the full current velocity dangerous?' queried one of the company.

"'The trouble was that the high velocity induced such a strong current that it would take everything along. Trees, stocks, farm-houses, cattle and men would be all picked up by the current and carried along. Why, the first time the full current was tried the train left an entire new town when it stopped, in which there were three churches and twenty-one saloons.'

"'Could you not control that force in some way and make it useful?'

"'We expect to, and half-a-dozen of dry goods clerks have formed a company with ten millions capital to work it out. It is a great scheme. Everything to be transported will be put on the side of the track. The current generator will flash past, and corn, stock, lumber, iron and everything to be transported will pass along quicker than the twinkling of an eye.'

"'But how will you keep the track, ballast and things not wanted from——'

"'As I was saying, I am satisfied with a thousand miles an hour gait. But it is going. Why, a month ago when I was leaving home in Kansas City my wife came to see me off. Just as the train was starting I leaned down to kiss my wife, and the train got going so sudden that instead of my wife's lips, I kissed a cow's tail fifty miles out. That is our pace in the States!'

"I would ask," concluded the Rev Rohah, "if there is any truth in these stories, or if they are pure fabrications? The scientific press tells so many wonderful things about electricity that these tales may be true. If they are based on fact, please send me notes with more particulars and I shall prepare a lecture on the subject for the institute of which I am the unworthy manager."

---

He stood and looked at the steam roller that was working on the asphalt. "Great thing, ain't it?" said a bystander. "Great nothing!" was the reply. "You must be powerful slow in these parts. Why, out to Slam Center they'd shoot an engineer that couldn't go no faster'n that."

---

A Michigan paper under the heading "interesting and pleasing railroad items," mentions that more railroad employés have been killed and injured on a certain division of the Lake Shore in the last six months than have occurred before in that number of years.

---

One of the night trains out of Chicago carries so many inebriates to the Keeley Bi-chloride of Gold Cure at Dwight that the boys have named it "the jag train."

---

There was some very sensible person in the Vanderbilt party that passed over the Michigan Central in a special train last month. A present of $35 was given to the train men on each division.

## In the Niles Tool Works.

One of the busiest shops I have lately visited is the Niles Tool Works at Hamilton, O. They have within the last year made several important additions to the shops, which greatly increase their capacity and improve the convenience of the shops as a manufacturing establishment. The ground addition comprises a new side 100x 400 feet, part of the addition being two story, the whole giving 2,000 square feet of additional floor-room. The main part of the works now comprise five parallel shops 216 feet wide and 400 feet long. Two of these shops are served by traveling cranes that traverse the whole length. In the erecting shop there are two 25-ton cranes, and two 20-ton cranes handle work for the shop having the large tools. The foundry, pattern shop, pattern storage house and other buildings detached from the main part of the works, make up an extent of buildings that appear as great as the main shops. In all of the buildings, the visitor is struck with the good facilities provided for handling work and materials.

It is necessary to have powerful appliances for handling the work, for some of the tools made are enormously heavy. The works have been engaged upon some ponderous tools for the Government, and there was on the floor a planer that weighs 150 tons—as heavy as two large locomotives. This splendid tool is for the Lake Engine Works of Buffalo. It planes a piece 12 feet square and the table travels 26 feet. It has double heads on the rail, and there is a side head with a vertical and horizontal feed, and an extra side attachment for planing very large work that will not go under the cross rail.

The parts that attract a railroad man, however, in these works, are the tools that are destined to labor for years on material used in the building and repair of railroad rolling stock. Watching the growth of these tools from the rough castings and forgings to the finished machine is interesting and attractive. Here we see the numerous painstaking operations that are contributed by recurring skillful hands, the aggregate securing accuracy and durability in the product. The finished tools stand up like old friends dressed in holiday garb, for their numerous twin brothers have made the writer's acquaintance in various shops from Maine to California.

The different forms of lathes, planers, boring mills, drills and slotters were as familiar as a Rogers locomotive, but I was introduced to one tool which was a comparative stranger. This was the screw-cutting turret lathe, which is becoming very popular with railroad men and is one of the most useful tools that can be put in a shop.

Hamilton, where these shops are, is little more than an hour's ride from Cincinnati. We do not know how a railroad man visiting the latter city could do himself more good than by going out and having a ramble through the Niles Tool Works. A. S.

---

A notice has been issued by the Westinghouse Air-Brake Company, intimating that the prices have been reduced for engine, tender and freight car equipment. The engine equipment now costs $250, tender or freight car $40. The price now asked for the engine equipment is a very good illustration of the reduction of cost that results from perfected methods of manufacture. When a mechanic looks over the apparatus supplied for $250, he is certain to be surprised that all the parts could be made for the sum named.

---

The East Tennessee, Virginia & Georgia have ordered a compound locomotive from the Baldwin Works and one from the Schenectady Works, both of the same general dimensions. The engines will be run against each other as a test of the relative value of the two classes of engines.

---

Mr John Richards, editor of *Industry*, has been elected President of the Technical Society of the Pacific Coast.

(9) R. G. Y., Chicago, says

If I have a gold lid taken out of my watch and an iron one put in, and then pay $5 for the change, how much am I charged for having my watch protected from magnetic influence? *A* We give it up. We suspect, however, that the protection is not worth the price paid.

(10) S. Woolmington, Cleveland, O., asks:

There was patented some time in 1851 a locomotive boiler with flues extending back into the fire-box. I would like to know what became of it, and if there is any used now *A*—This was the Dimpfel boiler, water tubes extending from the crown sheet over the grates and ahead, through an opening to near the front of the boiler—practically the crown sheet was the length of the boiler. It was tried on several engines but was an utter failure. None have been built for over thirty years.

(11) A. E. H., San Marcial, N. Mex., asks

Where is the "center of motion" of a locomotive?—*A*. Our correspondent probably refers to the center line of motion, often referred to. The center line of motion is a line drawn through the main axle and the link block, and often inclines from the axle *down* in front, this is to admit of getting the links up for back motion, or other reasons.

(12) D. A. P., Weldon, N. C., writes

1. I heard two engineers speaking about Alex Cunningham's break-down recently. One said that she would have had but two exhausts, and the other said she would have had three, and the exhaust from lame side would be heavier than the two from good side when engine was linked up, which was right? 2. Would an engine running reversed, pump as much pressure in her steam-chest with cylinder cocks open as she would with them shut, in a given distance? *A*—1. The engine would have had three exhausts, one heavier than the rest. 2. No, if the cocks were big enough she would expel all the air there.

(13) W. H., Humboldt Bay, Cal., asks

After working one kind of water in a locomotive boiler for three or four years and then change to another kind of water, will it have any foaming effects or not? *A*—This depends entirely upon the kind of water used, or rather upon what the water contains, generally a change from comparatively bad to good water will cause forming or loosen up scale and cause leaks. 2. Are surface blow-off cocks generally used, and of what use are they?—*A*. No. They are excellent things when there are impurities in the water that float, such as oil, as this can be pretty well cleaned out, they are of little use where impurities are held in solution.

(14) Pan Handle, Columbus, O., asks

1. Was there ever engines built without lap and lead? 2. When was lap invented? 3. What is the object of using lap? 4. What do you mean when you say a valve is line and line? 5. How do you give an engine lead? *A*—1. The earliest stationary engines had neither laps nor lead, but we know of no locomotives without laps. 2. Probably by Watt, late in the last century. 3. To get work out of the steam while expanding. 4. No single-valve engines are now built without lap, line-and-line inside means that the inside edges of the exhaust cavity are line and line with the inside edges of the two steam ports, or the outside edges of the bridges, which is the same thing. 5. By adjusting the valve motion so as to cause the valve to open the port before the piston has quite completed its travel. On a locomotive with link motion this is generally done by advancing the eccentric on the shaft.

(15) J. S. C., Albany, Ga., asks

1. Suppose you were running an engine with pony truck and broke cross equalizer back of long equalizer, and had no chain, what would you do?—*A*. If I had no way to fasten forward ends of front springs down, would block on top of forward driving-boxes. 2. If you were running an engine and broke a water-gauge cock, and had no round file, would you trust to reducing steam pressure and plugging with wood by keeping steam pressure low?—*A*. A small hole plugged with soft wood that fits the whole entirely through split-up on the end will usually swell enough to stand full boiler pressure.

(16) J. Ludlow, Ky., asks

1. If you were running an engine and were to lose a driver, pedestal, brace and wedge, what would you do?—*A*. If it was a main driver, would disconnect that side. If it was other than main driver, would take down side rods and run in light. 2. Suppose you are running an engine with spring or metallic packing in valve-stem and piston stuffing-boxes and they began blowing and popping and blowed *very*, *very* bad, how can it be helped if you had no new rings and could not get any?—*A*. If you have nothing to put in and can't get anything, we know of nothing except to run without anything or disconnect.

(17) Brakeman, Ravena, O., writes

Last night we broke a brake beam on the rear car of a passenger train and had to "cut-out" the air-brake. There was no handle on triple valve cock and I cut the hose between rear car and one next to it, shut the cocks, hung up the hose and bled off the brake. When the engineer was told he refused to go until we cut the brake out at the triple and connected up the hose again, we had a dispute about it and agreed to leave it to you, who was right, and why? *A*—The engineer was right, by having the air in train pipe of the rear car the train would be stopped before damage could be done if the rear car broke off, and again the conductor's valve would be operative from the rear car in case of emergency. You had cocked and primed a deadly boomerang which only needed touching off by the rear car breaking loose on some grade.

(18) P. J. C. S., Kaukauna, Wis., writes

There is considerable discussion here about the position an engine should stand when keying the main rod. The old rule of keying on the dead center is claimed by some as bad practice, they claiming that as the pin receives the greatest pressure at this point, it will wear the most there, and it should be keyed on its largest diameter. Where should she stand to present this condition? *A*.—The back lower eighth or upper forward eighth presents the widest part of a worn pin between the forward and back halves of the main rod-brasses, and is therefore the safest place to key the back end of the main rod, but always key side-rods on the dead center, or rigid points. Keying back end of main rod on center can be done safely on new engines and has been done with care on old ones, but it is easy to pinch a brass too hard during part of the revolution on a worn pin and cause heating.

(19) E. B. M., Philadelphia, Pa., writes

One of our trains (Penna. R. R.) running between here and Washington, has an air-brake puzzle attached. The train is a four-car one. Going south the engine is attached to the baggage car, at Washington the engine turns and takes the same train back to Philadelphia, but pulling from the other end, baggage car then being in the rear of train. Going south the brakes work all right, but coming north they "creep on" and cause trouble, yet all the conditions are apparently the same. What causes it? *A*.—The train-pipe cock on the baggage car leaks, when this is next to the engine it does not affect the train because the leak is not to the atmosphere. When this end of the car is at the rear the hose is not in use, and the leak escapes through it and sets the brake. A similar case has been reported where the conditions were opposite, and it was found that one hose was spongy and porous, causing quite a leak, pretty well muffled. This train gave trouble when this bad hose was next to the engine, and none when it was the rear of train—because then it was out of use.

(20) Mr. M. C. Glenn, Burlington, N. C., writes

Suppose we have a train of 30 cars equipped with the automatic brake, train line pressure is 70 pounds, reservoir 90 pounds per square inch. This train parts, and brakes go on. How much pressure will it take to relieve brakes on the 30 cars? And please explain how to make calculations for this. We have a man on this division who says it will take 130 pounds of air to release these brakes. *A*.—This depends a great deal upon the travel of the brake-cylinder pistons. Suppose they traveled 10 inches, the 70 pounds of air in each auxiliary reservoir would be expanded into the cylinders and reduced in pressure correspondingly, while if the travel was but 2 inches, the *volume* of air would be but slightly increased, and the pressure decreased. The pressure increases or decreases inversely as the volume—in other words, if you expand your auxiliary capacity to double, the pressure will decrease just half. If the travel of the pistons under the train you mention averages 8 inches, the pressure would expand, in an emergency application, to about 50 pounds, and it would require, perhaps, 5 or 6 pounds more than this to release them, just enough more to overcome the friction in the triples, no pump gets up 130 pounds in service, you ought to know that.

(21) B. M. G., Pittsburgh, asks

What do you calculate is the depreciation of a passenger car on its original value in ten years, provided it has been kept all the time in first-class repair. *A*—Five per cent. a year is the ordinary rate of figuring depreciation. In the first five years the real depreciation is likely to be greater. After that the annual rate becomes smaller.

The Vanderbilt system of roads has adopted the Gould coupler and platform for all their passenger equipment—cars and locomotives. The Gould platform is what was formerly the Cowell.

A prominent professor of optics has been forced to the conclusion that a train man may pass an examination for color blindness by the use of real signals that will be perfectly safe and reliable even though the same man may fail in matching colored threads.

The numerous friends of Mr. N. E. Chapman, of the Latrobe Steel Works, who has been at a health resort in Indiana for some months under treatment for rheumatics, will be pleased to learn that he is now quite recovered and is back to duty.

The Flint & Pere Marquette Railroad system occupies a strategical position in relation to the transportation facilities of the State of Michigan. Centered in the heart of the lumber and salt section of the State, the system reaches, on the east, Toledo, Detroit and Port Huron. At all of these places close connection is made with all the Eastern trunk lines. On the west, by the company's superior line of steamers, direct communication is had with Chicago, Milwaukee and Manitowoc. These steamers are in commission all the year round, and in the winter, when the regular transportation boats between Chicago and Buffalo or Canadian points, are laid up, this company, in connection with the Green Bay, Winona & St. Paul Road, forms an important link in a short and direct route for grain and flour from the Northwest and the Atlantic seaboard. The numerous branch feeders and logging spurs, in connection with the demands of main line traffic, call for great care and ability to make an economical showing with the necessarily diversified power. Under the able management of General Manager, W. H. Baldwin, Jr., the physical condition of the property has been greatly improved, and that, too, in the face of greatly reduced operating expenses.

Mr. Robert McKenna, the veteran Master Car Builder of the Delaware, Lackawanna & Western, at Scranton, has been confined to the house with illness during the greater part of last month.

Mr. M. D. Watson has been elected President, and Mr. C. W. Higgins Treasurer, of the Schuttler Mfg. Co., Chicago.

# THE ASHCROFT MANUFACTURING COMPANY.

Our double Bourdon Spring Gauge is the only one with actuating mechanism independent of the case. Case, dust and steam tight. Large figures.

## RADIUS LINK PLANER ATTACHMENT.

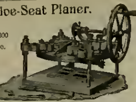
—FOR—

Planing Links, Blocks and Circular Work on ordinary Planer.

**Quickly Attached.**
**Easily Operated.**
**Does Accurate Work.**

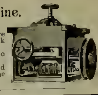
## Valve-Seat Planer.

Over 300 in use.



## — DAVIS —
## Valve Port Milling Machine.

This machine will mill out ports in valve faces of steam cylinders, duplicating work exactly and in the shortest possible time.
It is operated by a rope belt similar to that used for driving drills, etc.
It is much lighter than the cylinder and can be readily placed in position using the stud-holes to attach to for that purpose.



**PATENT PORTABLE**

## Locomotive Cylinder Boring Machine.

Will bore out Locomotive Cylinders **in their places** by removing one or both heads, as desired, and piston. **The end thrust is always in exact line with bar.** It is fed with constant feed of cut gears.

## PEDRICK & AYER, MANUFACTURERS

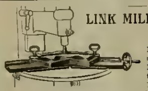
## Special Railway Tools

1001 Hamilton St.,
PHILADELPHIA, PA.

## —LEED'S—
## Horizontal & Radial Drilling Machine.

Designed to work on or from a Drill Press. Is useful in drilling ends and diagonal parts of frames. Can also be mounted on the work and driven by a sliding shaft and universal joints. Drilling in all directions can be done.

## —LEED'S—
## LINK MILLER & SLOTTER.



For rapidly and accurately Milling out Links to any desired radius. Can be used on Drill Press or as an attachment to our Heavy Universal Milling Machine.

*A link 20 inches long can be finished in four hours.*

## Greenwood's Universal Planer Chuck.

FOR STRAIGHT, CURVED (CONCAVE OR CONVEX) OR ANGLE WORK.

Used on any planer with cross-feeds for links, keys, wedges, etc.

*Indispensable for Locomotive Builders and Master Mechanics.*

## —JOINTER—

FOR

## Facing Locomotive Brasses.

Will hold any size brass same as held by strap when in use.
No more time required to place brass than screw up an ordinary vise.
Any desired thickness of cut can be taken, jointing the faces perfectly true.
No files required.

## CRANK-PIN MACHINE.

For turning off Crank-Pins IN POSITION, keeping the original centers of the Pin.

## PORTABLE DRILLING MACHINE.

**For Fitting New or Old Cylinders to Locomotive Boilers.**

It will drill all the holes in smoke boxes and cylinder flanges necessary to bang one pair of cylinders at one setting of the machine.

Quickly set and operated.
Driven by hand or belt power.

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

VOL. V. No. 3. NEW YORK, MARCH, 1892. PRICE, { 20 Cts. Monthly. $2 00 per Year.

## Lehigh Valley Compound Locomotive.

The Lehigh Valley Railroad Company have long been noted for their fine locomotives, and for keeping in the front with all improvements introduced in locomotives. In pursuing this policy they have lately turned out of their shops at Wilkesbarre, Pa., a compound consolidation locomotive built after the designs of Mr. F. W. Dean, the well-known mechanical engineer. The engine is shown in the annexed engraving. The engine is of the two-cylinder type of compounds, the high-pressure cylinder being 20 inches, and the low-pressure cylinder 30 inches diameter, with a stroke of 24 inches.

In ordinary working the steam passes into the high-pressure cylinder, and after doing its work there exhausts into a receiver, part of which is formed of a horse-shoe pipe in the smoke-box. From the receiver the steam is supplied in the ordinary way to the low-pressure cylinder. The arrangement of the receiver and intercepting-valve will be seen in the small cut on next page. It will be seen that Mr. Dean puts a series of rings round the outside of the receiver-pipe to increase the capacity of the same for intercepting heat of the smoke-box. The intercepting-valve moves vertically, and will therefore wear indefinitely. This is the second engine that has this form of intercepting-valve, and both of them are noted for starting promptly. The receiver is unusually large, having 2¾ times the volume of the H. P cylinder.

The boiler of the engine is of the Belpaire form, of steel, with butt joints. The diameter at the smallest ring is 58 in. The fire-box is of steel 6 ft wide and 11½ ft. long. There are 252 tubes, 2 in. diameter and 11 ft. 2½ inches long. The grate area is 69 sq ft, and the total heating surface is 1,658 sq. ft The steam carried is 175 lbs The driving-wheels are 50 in. diameter. The wheel base of drivers, 14 ft. 9 inches, total wheel base, 22 feet 10 inches. Weight on drivers, 109,088 lbs; on truck, 16,464 lbs

The engine was built by Mr. Alexander Mitchell, under the immediate charge of Mr Frederick Roth, master mechanic in charge of the shops. The machine is in every way highly creditable to Mr Roth and to the other men employed under him.

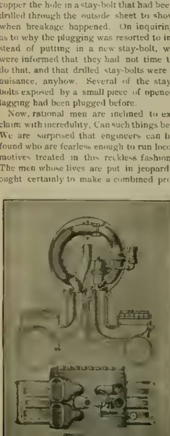
Dean Compound on Lehigh Valley Road

## Tempting Boiler Explosions.

Explosions of locomotive boilers have been so common of late that there is general nervousness among the men in charge where high pressures prevail. We have heard the question put very often within the last two months, what are we going to do to prevent accidents to our boilers? To us the answer is very simple. Inspect the boilers regularly and systematically and remedy in time the defects that lead to explosions. Objections are raised to this course, on the ground that the men held responsible do not have time or facilities to inspect boilers with the regularity considered necessary. In that case we say that it is time State inspectors were put in charge of the locomotive boilers belonging to roads that do not consider themselves in the position to adopt the precautions necessary for preventing their property from becoming dangerous to the community.

Nearly all boiler explosions are caused by broken stay-bolts. There is gross carelessness on many roads about the inspection that ought to detect broken stay-bolts, and we are sorry to find that the proper remedy is not properly applied when fractured stay-bolts have been discovered. While strolling about an engine-house belonging to a big railroad lately we happened to see the jacket and lagging removed from the outside of a fire-box. Being of an inquisitive disposition, as becometh a newspaper man, we climbed upon the running board to see what was going on. A workman was engaged on the delicate operation of plugging with a piece of copper the hole in a stay-bolt that had been drilled through the outside sheet to show when breakage happened. On inquiring as to why the plugging was resorted to instead of putting in a new stay-bolt, we were informed that they had not time to do that, and that drilled stay-bolts were a nuisance, anyhow. Several of the stay-bolts exposed by a small piece of opened lagging had been plugged before.

Now, rational men are inclined to exclaim with incredulity, Can such things be? We are surprised that engineers can be found who are fearless enough to run locomotives treated in this reckless fashion. The men whose lives are put in jeopardy ought certainly to make a combined pro-



Arrangement of Dean Compound.

test against the practice. Where things of this kind are done, the matter for surprise is not that boilers explode, but that they explode so seldom.

## Defective Air-Brakes.

There has been considerable excitement concerning brakes in the West during the last month. The Chicago, Burlington & Quincy, which specified the New York Air-Brake for a lot of freight cars, tried the brake on a fifty-car train and it took over fifteen seconds for the application to reach the last car. This, of course, is not a quick acting brake, and would not handle a long train safely. In consequence, the railroad company have refused to accept the brake, and the brake company is said to be getting out a new triple valve.

Tests were made at different times and places by the Chicago & Northwestern and the Chicago, Milwaukee & St. Paul Companies of the Lansberg brake, and it was found far behind the M. C. B. requirements for an automatic air-brake.

Owing to this information about the effects of the brakes mentioned, the New York Central and several other Eastern roads have established a rule not to use on their trains any air-brakes except the Westinghouse. When cars having other air-brakes on are offered for transportation the cars will be accepted but the brakes cut out.

## How to Become a Successful Fireman.

By W. H. WHALEN.

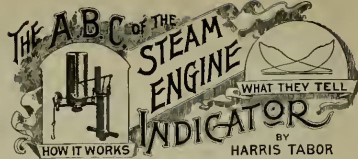
He should be a temperate, honest man, of at least medium size, and should have a good education. He should go to his engine an hour before leaving-time, and should examine the fire, grates, ash-pan and front end, if the engine is of that make, and should see that there are tools and supplies for the trip, and in fact *know* that everything is in readiness. He should have his fire laid, that is, have the grates covered with incandescent coal, the thickness to be governed by the amount of work the engine is about to be called upon to perform.

After they have started and the lever has been cut back, he should give her a light fire, and if the engine is working hard repeat this often, having the coal cracked about the size of an egg. Open and shut the door in the shortest possible time, avoid heavy firing, as it is wasteful in all ways, and a great source of annoyance to the engineer, especially in bad weather. Nearing each station he should allow the fire to burn down, so to avoid smoke and popping, while steam is shut off. When the engine is again started, be governed by the same rules as at the beginning of the trip. After being out fifteen or twenty miles he should see that the grates are loose by "*just moving them*," then after twenty-five or thirty miles shake them *slightly*, repeat this a few times during the trip. He might vary from these rules slightly according to circumstances, knowing that as he cannot shape them to him he must shape himself to them. And while taking coal or water, cleaning ash-pans or front-ends, or any other work he may be called upon to perform, do it with dispatch.

These rules may be followed to the end of the trip, and they will be *all right* where there is good boiler feeding being done. But when the "feed" is shut off with the engine, and started with it, or just before, or is wide open or shut off at all times regardless of conditions, they will not. The way to do in this case is to give the engine enough of coal, that is "try and keep her hot," regardless of smoke, waste, or anything. He should not bother the engineer with talk that does not concern his work or the engine, he should teach himself to think about his work as he does it, he should learn the "peculiarities of the engine" and the cause for the same, he should recognize nothing as a mystery, but the effect of some cause, his duty is to learn the cause. After the engine has been housed, he should get it ready for the next trip whether he goes out on it or not. But he should be given a regular engine to fire, as he can give better satisfaction to the company, the engineer and himself, and in this case he can afford to keep it clean, and I would advise him to do this, as it will make his work on the road more pleasant. Let cleanliness of person and engine be his motto.

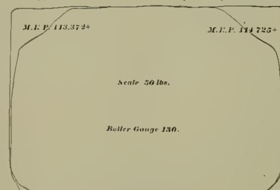
After his work is done he should go at once to his home, if he has one, if not, he should waste no time in getting one, and if he is in need of rest get it at once, after this has been done, and he has not been called for duty, he should spend his time in studying or reading something treating on his work. In this way he will command the respect of his associates, as well as the officers of the road, and it will enable him to attend to his own affairs, a great requisite in a railroad man.

[The above article was written at the request of a railroad officer by one of the successful enginemen of his road.]



In the second paper attention was called to the irregular action of the link and its effect on the diagram. It was shown that all the valve functions were influenced by a change in the position of the link the travel of the valve is also controlled by the link, when the reverse lever is "down among the oil cans," and in position to give the latest cut-off, the valve will be at its maximum travel, and will give the greatest port opening; when linked up to the middle notch, the valve's travel will be valve when cutting off early in the stroke that makes the steam line on the card fall away so rapidly.

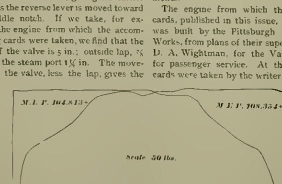
It is a source of regret with many engineers that the link motion cannot produce fine, symmetrical diagrams such as are obtained from Corliss and other stationary engines of the better class. They shut their eyes to the good points in the link and see only its defects. If they would study the conditions to be met by the motive power department of our railroads—



9.22 Miles per hour.
Reverse lever in 7th. notch.
Throttle ⅓ open.
Grade 47½ ft. per Mile.

reduced to its lap and lead, at any point between these extremes of the reverse lever the movement of the valve will be proportioned to the position of the link, and the port opening will correspond to the reduced movement, giving an earlier cut-off as the reverse lever is moved toward the middle notch. If we take, for example, the engine from which the accompanying cards were taken, we find that the travel of the valve is 5 in.; outside lap, ⅞ in., and the steam port 1½ in. The movement of the valve, less the lap, gives the conditions that vary with each mile of road-bed, calling for a large engine here and a small one just beyond—they would see the wonderful adaptability of the locomotive of the present day to meet the requirements.

The engine from which the series of cards, published in this issue, were taken was built by the Pittsburgh Locomotive Works, from plans of their superintendent, D. A. Wightman, for the Vandalia road for passenger service. At the time the cards were taken by the writer she was in

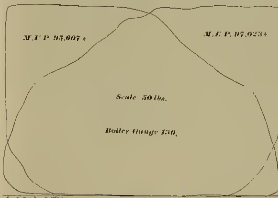


7.19 Miles per hour.
Reverse lever in 5th. notch.
Throttle open.
Grade 30 ft. per Mile.

port opening, the sum of the laps ⅞ in. plus ⅞ in; equals 1¾ in., and this amount taken from the travel of 5 in. leaves 3¼ in., which is ¼ in. more than the sum of the port openings, an excess of ⅛ in travel beyond the required 1½ in. at both ends. This extra travel insures freer admission of the steam for induction, and makes the exhaust opening that much larger. If we assume the lead in mid gear to be ¼ in., the valve will travel the sum of the laps and leads ⅞ in. plus ⅞ in. plus ¼ in. plus ¼ in. equals 2¼ in. Here we find a variation in the travel of the valve of 3¼ in., more than three-fifths of the total movement. It is this reduced travel of the service on a freight train between Terre Haute and Indianapolis. The general dimensions were as follows

| | |
|---|---|
| Cylinders | 18 x 24 in. |
| Steam ports | 18 x 1½ in. |
| Travel of valve | 5 in. |
| Outside lap | ⅞ in. |
| Inside " | ⅛ in. |
| Lead, full stroke | 1/16 in. |

The first card of the series was taken with the reverse lever in the last notch. The throttle was only one-third open, but at this slow speed it is doubtful if the steam line would have been any higher with full throttle. It will be noticed that the steam lines are straight up to the point of cut-off, which is about seven-eighths of the stroke. The terminal pressure is about 90 pounds, and the mean effective, or average pressure throughout the entire stroke, is 113 and 114 pounds. This card represents about the maximum power of an 18-inch cylinder, with 130 pounds boiler pressure, for train starting and grades. This large mean effective pressure is very often called upon. The second card was taken with the reverse lever in the fifth notch. We see at once a marked difference in the formation of the cards. The terminal pressure is 75 pounds instead of 90, and the mean effective has fallen to 104 and 108 pounds. Running along the steam line we find that the cut-off took place earlier in



11.06 Miles per hour.

the stroke, and more work was done by expansion, which accounts for the reduction of 15 pounds in the terminal. Release is somewhat earlier, and the exhaust-valve closed enough earlier to make a decided difference in the appearance of the compression line. This is the first stage in cylinder reduction. The third of series, taken when the reverse lever was in fourth notch, shows clearly that all the functions of the valve commenced earlier in the stroke, and, as in the previous case, less work has been done during the revolution. This progress toward less work and earlier valve action continues as the reverse lever approaches the center notch.

If we take the whole series of cards, from seventh to first notch, it makes an interesting study. We have found that as the engine "is hooked up" the apparent defects of the link motion are brought into prominence. We say apparent defects for the reason that investigation lessens the evils the link has been charged with. The conditions of running must be considered with the cards, if they are to be discussed intelligently; we must not assume that a seventh notch card represents the running on a level track, nor that the first is generally used in starting; we must take the conditions as they occur in running, and if we do this, we shall lose none of our respect for the valve-gear of the standard American locomotive.

The maximum, or seventh notch card, is the most extravagant in the use of fuel. We have only to consider the pressure at which the steam is released and blown into the atmosphere to understand how great this waste is; the terminal pressure on this card is greater than the initial pressure in the average stationary engine. The conditions under which this card is made may be classed as train-starting and grade-pulling, and occasionally low boiler pressure. It is fortunate for the coal heap that the piston speed is generally very slow when the lever is in this notch, and in consequence the horse-power developed small, notwithstanding the enormous foot-pound energy developed with each revolution. On ordinary roads the loss from working the valve in this notch cannot be great, as it is in use so little of the time. The fifth notch card is more economical, but this is too wasteful for ordinary work; it divides time, or should, with seventh notch. The fourth notch card is more pleasing to the eye, and is decidedly more in harmony with smaller coal bills; it is a beautiful diagram, showing very fine engine performance. The third notch card could not well be better. The slow speed at which it was taken has brought out all the features of the diagram very distinctly, but the engine gave good cards at all reasonable speeds. This third notch card ought to cover a large range of work, it shows a fair amount of expansion, and its terminal pressure is high enough to blow the furnace fire under average conditions. It is, by odds, the most economical card thus far considered. The first glance at the next card, with lever in second notch, tells the story of small port opening from reduced valve travel. The steam lines are not as well maintained up to the point of cut-off as in the preceding cards. The speed is much greater, which will, in part, account for the reduction in these lines, but at the same speed the reduced valve travel would show on the card. This card shows economy in steam to a greater extent than any of the others. It is doubtful, though, if it could be as generally produced as the third notch card, on account of the lower terminal pressure. The chances are that the draft might be deficient, even with the smaller amount of steam required to do the same work. There is a larger per cent. of work done in this case, by expansion, than in any of the preceding cards, and expansion is not carried so far that serious loss would come from condensation. This card is well adapted to high speeds on account of the liberal compression and lead which serve to cushion the reciprocating parts of the engine. When the valve is unbalanced engineers, as a rule, dislike to run "hooked up" to this notch, and with reason; the higher pressure of the boiler on top of the valve and the lower pressure in the cylinder, on the opposite side, tend to make the valve hard to handle, especially with a full throttle. Under these conditions of unbalanced pressure the wear of the valve is excessive. The last of the series brings us to the first notch, with more expansion and compression shown than in any of the others. In this case the release was so early that all the steam above atmosphere was out of the cylinder before the piston reached the end of the stroke. The fireman would have a sorry time on a long run under such conditions, but his coal consumption would be small.

We have seen that the position of the reverse lever from seventh to first notch has gradually reduced the engine capacity from a mean effective pressure of 114 pounds to 33 pounds, nearly three and one-half times. This reduction has been at both ends of the cylinder, expanding at one end and compressing at the other. There is no loss in compression, and there is a decided gain in expansion. The compression is a help to smooth running, and in that way gives an unquestioned gain. It is doubtful if any valve-gear can take the place of the present link and give as good all-round results. These cards show a remarkable case of valve setting. If the reader will compare mean effective pressures marked on the opposite cards he will find a uniformity rarely seen. The valves were set by the indicator.

## Repeating Old Good Things.

"I like your paper very well" said an old friendly critic as he turned over the pages of LOCOMOTIVE ENGINEERING, "but there is a good deal of matter in it that is not new. There are many ideas paraded in a new dress of words."

This might have lacerated our feelings had it not been that we considered there was profound wisdom in some paragraphs in one of Chordal's letters contributed to the *American Machinist* some ten years ago. We commend the words to our critic. Chordal says:

"The apprentice boy in a machine shop with a weakness for reading trade literature finds in the simplest every-day matter a subject of novelty to himself, and in the course of time his mind becomes stocked with material gathered there item by item, each one as old as the hills to the world, but as fresh as the daisies to him.

"An apprentice boy sits on a block at noon reading a mechanical paper, and is thoroughly interested in an illustrated article on lining up engine guides. Some old gray-haired fellow looks over his shoulder, gets a general idea of the illustrations, and sneeringly remarks to the boy, 'Pshaw, that thing's a thousand years old. Is that what you fellows read about in those papers?' If the boy is smart he will reply 'I am 14 years old, and this is the first I ever knew of this guide business. How old were you when you found it out?'

"When this same boy gets to be, say, fifty years old, he may possibly get disgusted with this kind of shop literature, and begin to think that the editor ought to be kicked for putting old things in the paper, thinking that they can be passed off for novelties. He may forget his own experience.

"Professional literature forms the annals of professional progress. The artisans' literature is not, and need not be consecutive in any of its arrangements. It presents a series of items which each individual arranges in his own mind for his own individual annals of progress.

"The real fact is that the literature of the artisan to be of any real value must contain repetitions on literary subjects, and there is a fine problem involved in finding out how often a repetition should occur."

We have among our readers the apprentice boy and the old workman, also the fireman and the old engineer. Behind them are the mass of other readers who will not suffer from having old stories told in new words. Men forget things so quickly that old memories will stand feeding with the knowledge that is new to the younger generations.

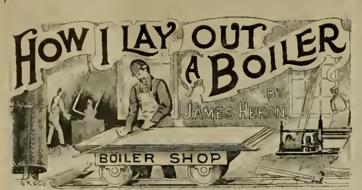
---

There was a curious case heard in a Boston court. A railroad company was trying to obtain some privilege and it was vigorously opposed by Mr. Brown, a business man. The lawyer for the company was trying to make out that Mr. Brown was opposing the privilege on account of personal antipathy to the company and its employees. He had been making it hot for some of the witnesses, and general nervousness was manifested by those who had to go through the ordeal of giving testimony. The superintendent of the railway company was called, and the lawyer was prepared to show that Mr. Brown disliked this man. "Do you know Mr. Brown?" asked the lawyer. "Yes," was the reply. "Have you met him lately?" "Yes, I met him at the United States Hotel yesterday." "Did you have any conversation?" "Yes" "What did Mr. Brown say to you?" "He said 'let us go and have a cocktail.'" The superintendent was excused from further testimony.

---

An engineer in Chicago writes as follows

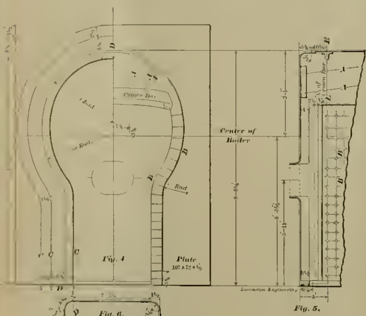
Why is it that we cannot get good valve oil for locomotives? I am running a locomotive on a road that was buying good valve oil, and we were able to make the run over the division comfortably on a pint. A big corporation bought up our road, and, when the change of management took place, they began giving us the oil used by the big road. The stuff is said to cost more than the good oil we formerly had, but it will not go half the distance, and there is no end of trouble with dry valves and groaning pistons. This does not appear to be good business. Why is it that so few railroad companies use vacuum oil and valvoline? It is not because these lubricants would not be best and cheapest. There are some things about railroading that no fellow can understand.



## Laying Out the Back Head.

The large engraving shows the boiler we will lay out in the course of these articles, one piece at a time, and is used here the outer door-sheets. This means a saving of labor, as there are no holes to be drilled by hand when the boiler leaves the boiler-shop.

There is no necessity to locate stay-bolt lines are not the same distance apart in inner and outer sheets. Now I get two pieces of iron, 1x⅜-in., and 1x½-in., one of each, this represents thickness of plate to be used for side sheets. I bend one to shape of back flue-sheet, the other to shape of back head. I lay these on stay-bolt lines, Fig. 4, and mark lines on pieces, putting a center punch mark at each bolt; then I straighten them out and mark straight plate from them, this gives me stay-bolts in side-sheets vertically. Before finishing side-sheets, as regards rivet holes, I will have to first lay out back heads. The flanger has to be kept going. One-half of Fig. 4 shows lines laid off to guide flanger as to size of sheet when finished, also showing how to get proper length of material, so that when sheet is flanged there will be no trimming of same.



Height of boiler, 8 ft. 6½ in., ½-in. off for thickness of plate of wagon top. Height of back head, 8 ft. 6 in., 4½-in off for radius of corner outside, leaving 8 ft. 1½ in.; to this add 6¾-in. required to form quarter circle at corner, as at *D*, Fig 6, and and 2¼-in. for loss, and you have length of sheet required. Now punch all holes, and before cutting out door-hole punch one hole in center of same, then get inside sheet, find center of same, square off bottom; mark center mud-ring hole and center of door hole; punch these two holes and bolt inner and outer sheets together, and mark off stay-bolt and door holes. These must come opposite when boiler is fitted up. *E E*, Fig. 5, gives starting point for crow-feet and first crown-bar, of which I shall write later. Hearth-sheet, mentioned in last paper, should read throat-sheet.

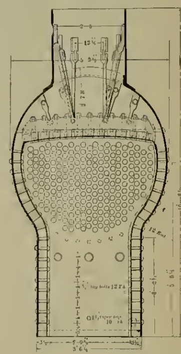
J. Heron

## Pennsylvania Railroad Enterprise.

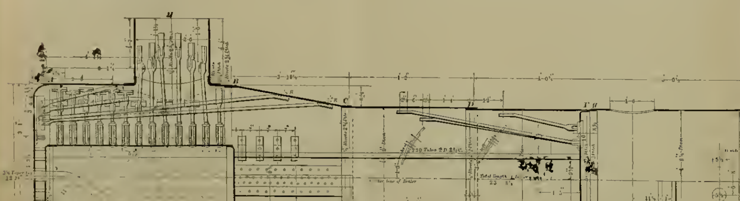
The mechanical officers of the Pennsylvania Railroad at Altoona are working on the designs of a compound locomotive for the use of the company. The engine will prise, are sparing no expense in finding out all that needs be known about compound locomotives. They have just ordered a ten-wheel compound from the Schenectady Works, that the merits of this engine may be thoroughly tested.

---

Accompanying an order for LOCOMOTIVE ENGINEERING we have received from Mr. M. R. Jefferds, London, a long letter giving



an interesting account of the opposition encountered by those who are trying to introduce the American style of tubular iron car into England. The tubular iron car represents the American type of freight car, and English railway companies are naturally prejudiced against the thing to begin with. Mr. Jefferds is mak-



BOILER. MODEL SOFT COAL BOILER.

better to show the student what is aimed at

Fig. 4 shows plate 107x72x½-in. This sheet is to form door-sheet, or what is more commonly called the back head. On this plate I lay down full view of boiler looking from back By this means I can locate all holes in proper place and see that all parts clear each other, such as vertical and longitudinal braces, as at *A A*, Figs. 4 and 5, also washout, gauge-cock, in fact all holes that have to be put in inner and holes on sketch, as in any well-regulated shop your blue print will show them. If not, you have to use your own judgment. What I want to point out to you is how to get your starting points. In the last paper I showed you how to find stay-bolt and rivet holes in side sheets longitudinally, now we want to get them vertically.

I lay lines down representing center of stay-bolt, always following surface of sheet as at *B B*, Fig. 4, so as to have bolt square with surface of plate. Note that

be of the two-cylinder type, and will have the Lindner starting-valve arrangement.

There are five Vauclain compound locomotives at work in service mixed with other simple engines of the same capacity. There is no difficulty whatever experienced by the men in handling the compounds The engines are chain-ganged, and give entire satisfaction. The saving of fuel effected by the compounds is about 20 per cent.

This company, with their usual enter-

ing a gallant fight to convince railway companies and shippers of freight that the car of large capacity is the proper way to move freight cheaply, but his prospects of success are exceedingly dubious.

The English are intensely set in their ways, and the small cars have been in use so long that the people would think some institution was going to the dogs if a change were made. Then their freight-houses, sidings, turn-tables and means of handling are suited for small cars.

## A Lesson on Heating Surface.

By JOHN ALEXANDER.

My boy Fred seems to have inherited the cursed taint of the Alexanders—not scrofula, or consumption, or gout—but a burning desire to "invent something."

It is not a year ago that he sent me a wooden model of a new valve motion—Fred is running now, you know. But he seemed to have done a good deal of hard thinking, and not very much good reading, for he re-invented the very identical motion that I did twenty years ago, and that was patented, still further back, by a better man than I, who knew about as little about what was wanted on a locomotive.

A contraption that will let a locomotive cylinder make a Corliss card won't let it pull a train successfully. I explained this to Fred till he "tumbled," but bless you, my dear sir, here he is again with a combined brick arch, water-table, and feed-water heater that just makes my old heart ache.

Feed-water heating on a locomotive is a dead failure. I don't know as I know just why, only that it won't work, never did, and never will. I don't mean that they won't heat the water—any on 'em will do that—but I mean that they don't and they can't do it for nothing, with waste heat or anything like that.

The Lord knows that I tried my level best to get things into that curly head of his right, but where in Sam Hill he ever come to think that a petrified iceberg in the shape of a brick arch would do any good and not do harm, I don't know.

Time and time again have I explained to him that the heat absorbed by the fire brick, and given off in cool times to ignite the gases and aid combustion was where the advantage was—not in making the products of combustion go around another corner?

Haven't I sat up nights to explain to him how a heater placed in the shape of a table in the fire-box would act as a cold blanket to keep ambitious gases that wanted to burn from doing it, and condemn them to die of chills and fever?

Haven't I showed him the drawings of these traps, tried long before he was born, and all pictured out in Daniel Clark's railroad Bible? and now he goes and makes an ass of himself to his proud old father.

Why, my dear sir, it ain't three years ago that he dug up a pile of blackened pipes from the woodshed loft, and I sat down and told him the history of a blamed old fool—by himself—just to get a few facts about heat and combustion, and heating surface, and *effective* heating surface, straight in his skull, just to keep him from *not* profiting by the experience of his ancestors, just to anchor a red buoy on a shoal discovered by a shipwreck, just to be sure he would be a better mechanic than his illustrious father—it's a poor boy that can't be better than his father—and here he comes to me with his blasted ice-cream freezer attachment, and expects my approval and blessing, and, maybe, thinks I'll be proud of his inventive genius. But I won't.

Perhaps it may do a bit of good to the inventive young roosters who read Locomotive Engineering if I should set down again, and take and tell that story of the pipes and the fool that made 'em. So here goes.

It was away back when this same Fred was a baby. Mrs. A. and I were fixed up cozy in a little three-roomed nest, taking comfort by the square mile, and only worrying about the pay-car and this precious Fred that is now trying to make fool of himself.

Noting with what peculiar care the madame prepared the bath for this young rooster—it was before the days of water-backs and heaters, for us—I conceived the idea of supplying her with hot water, in wholesale lots, for nothing.

An Incident of the Blizzard—Old-Fashioned Snow Bucking.

Our road were just putting on the air then, and the shops were full of three-quarter inch pipe, and I borrowed a couple of lengths. These I cut up, and with the aid of elbows I made a little square pen of pipes that just fitted into the fire-box of our little cook stove—that dear, little, old, No. 7, that was such a comfort when Mrs. A. deigned to make sweet rusks and fig cake.

The pipe was arranged in a spiral from bottom to top, and the two ends were brought out of a hole drilled in the end of the fire-box opposite the door. These ends connected to pipes that were carried along the wall and entered a 30-gallon whisky cask set on a corner shelf on a level with the stove.

I carried water from the well for that heater reservoir and the coil of pipes kept 30 gallons, more or less, boiling like a glass of ginger pop.

Mrs. A. was very much pleased over the heater. It was so nice to draw all the hot water you wanted, when you wanted it, instead of waiting for the deliberate act of a cast-iron tea-kettle that thought twice and then counted one hundred before it spoke. She was proud of her inventive husband, and inside of three days had promised that I should make one for each of four or five of the neighbors.

Before this dire contagion had got beyond our own doors, the cold, naked truth was kicked into me, and I learned something about *effective* heating surface.

I was going to be home for Sunday, and Mrs. A. condemned and beheaded a loud-talking and polygamous young rooster of her own raising, and prepared his carcass as a burnt-offering to the patron saint of a dinner-pail victim named John. She made him (the rooster) false vitals of bread crumbs, oysters and sage, and shut him in the oven of that famous little baker with the idiot attachment.

I took care of the baby while Mrs. A. prepared the feast. Often did I notice her go to that oven and probe in an inquiring way to see how the baking progressed, but that rooster did not get above blood heat.

At last in disgust and anger she called me. Something was wrong. The fire was good, the water in the barrel boiling, but the rooster wouldn't cook. I preached to her that there was some little thing the matter, there was a cause for the trouble. I lay on my stomach and scraped the space under the oven. I examined the dampers and both of us got hungry. In sheer desperation the cold-blooded rooster was taken out, drawn, quartered and fried, while I swore a bloody oath that I would never pay the rent till the measly landlord cleaned out the chimney.

In the middle of the week I came home from a 36-hour wrestle with the "renakaboo" run, and Mrs. A. danced a little as she told me the joyful news that the stove was all right again and baked "just lovely."

I was a little suspicious of women monkeying with the science of things and asked her what she had done. She replied that the landlord had cleaned out the chimney, but added that she thought she had ruined the heater, for it had run dry and the pipes got red hot, but that it was all right, because she filled the barrel next morning and it was working now the same as ever.

The next Sunday I did the baby act, as usual, while the dinner was being concocted. After a while I heard a 20x24 sigh, and pushing open the kitchen door beheld the flushed face of the madame. She was glaring at a long broom straw covered with a pasty mess that she had drawn from something in a pan that looked like the crater of an extinct volcano.

"It's fell," she said dolefully, as I approached her, and recognized the stuff in the pan as the mummy of an angel cake.

I sat down and thought I went over the chimney, the drafts, the fuel and the heater.

"It never acted so until after you put in that heater," said Mrs. A.

"What's the heater got to do with it? Ain't the grate just as big? Don't it burn as much wood, and more, too?" I said warmly.

But I thought I would try an experiment, not so much for myself as to allay any doubts in the mind of my partner.

I drew the water out of the barrel and dumped the fire, and asked Mrs. A. to mix another cake.

By the time the cake was ready I had disconnected the pipes, and had the pen of pipes out in the back yard, and a raging fire of kindling. That time the cake baked.

Just as I balanced the third quarter section of that delicious dough upon the tips of my fingers Mrs. A. asked me what I thought about the heater, and why it prevented the oven from getting hot.

I looked at her wisely and asked her if she didn't know. That's the way engineers do with firemen when they ask questions too deep for 'em.

She didn't know, but I had at last seen the light, and so I lectured her something in this wise.

The reason the oven wouldn't bake was because the heater had absorbed the heat and conveyed it, through the medium of the water, to the barrel and there stored it up, the same reason that I cannot eat this cake to-day and keep it till to-morrow, the heat can't be in two places at the same time.

Manifestly the pipes of water were more effective heating surface than the walls of the oven, and carried away the heat, when they were removed the oven got the benefit. Perhaps if I had used less heating surface that would have heated the water well enough, and not have so seriously crippled the oven.

This law holds good on a locomotive as well as on a stove, you can't use the same heat twice; the *effective* heating surface does the business, the rest is useless, perhaps a detriment.

We know that the heating surface should be in proportion to the grate surface, we know that when you get ten square feet above or below sixty square feet of heating surface to one of grate you burn more fuel to evaporate a pound of water, but I never knew any one who could tell just why.

We know that boilers with enormous grates, and about forty feet of heating surface to one of grate, have given poor results in actual service, and we know that boilers filled with water-tubes, etc., until there was shown eighty or ninety square feet of heating surface to one of grate, did no better, and showed no loss in evaporative effect when 25 per cent of their heating surface was cut out.

I believe that we could get along with far less heating surface than the average in use if it could be arranged to be more effective, put where the fire could get at it on one side and the water on the other.

But trying to make a cold arch feed-water heater, and figure on increasing your heating surface at the same time, in this age and day, is going backward, and if Fred don't know it by this time I will take him through a few experiments that will bring him back to earth, for, after all, his case is mild; he is not claiming per cents of saving yet.

When an alleged inventor figures out just what per cent. his device is going to save, before one has been made or tried, I always see in my mind's eye the Incurable Ward at the State Insane Asylum. This percentage business is killing people.

## In the Rhode Island Locomotive Works.

The Rhode Island Locomotive Works are better situated than any of the others that we have visited lately, for the shops are working to their full capacity on full time. Although orders for locomotives have been scarce generally these works have enough orders on hand to last several months. They are building some of the standard six-wheel switchers for the Chicago, Milwaukee & St Paul, and they are likely to build a compound and a simple engine of the same capacity for this company, to be used in tests by the Master Mechanics' Committee on Compound Locomotives. Several Forney suburban engines have lately been built here for the two Brooklyn elevated railroads, and one of this class was under construction for the Franklin & Megantic, a small railroad in Maine. The principal work in the shops during our visit was a group of eight-wheel passenger engines for the Boston & Albany, with cylinders 20x26 inches, driving wheels 58 inches, boiler 52 inches diameter at smallest ring, and deep fire-box 72 inches long inside, the total heating surface being 1,270 square feet. The engine finished weighs 91,000 pounds, 61,500 being on the drivers. These engines are built from drawings furnished by the company. The engines are finished with all the latest conveniences and they look very handsome, the only weak point being that the cylinders approach so close to the boiler in size.

H. L. Leach, P. O. Box 2225, Boston, Mass., has recently perfected a working model, designed for instruction and advertising purposes, showing the operation of the different styles of Leach's sand-feeding apparatus for locomotives, and the manufacturers solicit correspondence from railroad men who wish to make themselves familiar with the device. A compressed air plant, while desirable for its proper operation, is not a necessity, for a healthy man can blow all the wind necessary for its successful operation.

## J. Davis Barnett.

J. Davis Barnett started railway work young, getting most of his book knowledge after working hours. Spending three years in the pattern shop, foundry and drawing office on the Great Western Railway of England, at Wolverhampton, London and Swindon He came to Canada in the fall of 1866, entering the erecting shop of the Grand Trunk Railway, at Montreal, as an "improver," thence working his way through the drawing office from junior to senior After doing occasional out-door relief duty on divisions, he was promoted, thirteen or fourteen years ago, to assistant mechanical superintendent, which position, at various locations, he has since occupied, except that previous to the absorbtion of the Midland Railway of Canada by the G. T Ry, he, at the request of the latter, filled the position of mechanical superintendent of the Midland. This is practically more than a quarter of a century's service with one company. He has taken an active interest in the American Railway Master Mechanics' Association, of which he is a past president, the Canadian Society of Civil Engineers, the I. C. E & I. M E. of England, and the British and American Association for the Advancement of Science.

Mr Barnett is a single man, very much devoted to his mother, both of his parents being still alive. He is something of a bookworm, and one of the best read men in the country. His library is the most extensive private one in British America

Mr. Barnett has immediate charge of the locomotive works of the Grand Trunk at Stratford, Ont.

## The Rogers Locomotive Works.

In the erecting shop of the Rogers Locomotive Works there are some very large consolidation locomotives for the Nashville, Chattanooga & St Louis They have cylinders 22x24 inches, driving-wheels 50 inches diameter, and 60-inch boiler with Belpaire fire-box 11 feet long The boiler will be safe for 175 pounds of steam, and would evidently be safe under 200 pounds. There are a great many good points about the engine that are well worthy of imitation. They represent the ideas of Superintendent of Motive Power Cullen as necessary for a good freight engine

A six-wheel switching engine for the government is in the shop nearly ready for shipment. It has a straight boiler and saddle tank

A number of small switching engines for Cuba are nearly ready They are entirely covered in with a large cab.

These works have several orders for locomotives to go to South America. Like other locomotive builders, they are figuring on the building of compound locomotives, but the designs are not finished.

## New and Old Tools.

By T B. PURVIS, Jr.

No one in this progressive period will maintain for an instant that an old tool is as good as a new one No one will say that the work done with an old tool is better than that done with one of the latest improved machines of its particular kind, and those of us in the railroad business who are surrounded by old lathes, planers, etc., are led to exclaim "What are we going to do about it?" Are we going to throw up the sponge and call ourselves beaten because we can't have as good as our neighbor? I think not. We are going to make the best of the situation and wrestle with the old things as long as they are here. A little ingenuity displayed in the right direction will sometimes transform these old scraps into quite useful machines.

No doubt some shops feel greatly the need of a boring mill for boring tires and finishing driving-wheel centers A very nice tool to have—if you can get it—but if you can't get it, and you have an old single-head wheel-lathe—one about thirty-five or forty years old will do—you can rig up a boring-bar with spliner attachments, and by rearranging your tool-post, you can finish a driving-wheel center ready for the shaft in about ten hours. To be sure, when you get your boring tool feeding pretty lively, and an eighth-inch feed traveling across the face or down the rim, I must admit that the old thing shakes and trembles, and makes an unearthly noise, but it gets there all the same, and we don't mind the noise, but on the contrary, rather enjoy it, because it reminds us of bygone days when this old friend was obliged to toil day and night in order to keep the tires up in shape I know it used to consume two or three days turning one pair of wheels, and when we put in the new double-header we didn't like the thought of routing out the old one, and so it stood and rested about ten years, and now we use it for finishing driving-wheel centers

I am reminded right here of the case that came under the observation of Mr. Davis, and cited in his paper before the New England Club, where the man was, on an average, two days and when very hard, four days in turning off one pair of tires.

Now, if this was on an old time single-head lathe, the man did fairly well, but if it was a modern tire-lathe, there must have been something wrong somewhere, and I am not inclined to lay the blame on the man either. Perhaps he thought that he was doing all that could be done.

At this point the foreman should have shown his hand. See if he was using tools best adapted for the work, that the lathe was speeded just right and that he had the *proper amount of feed on*, and when these points were made, he would find that instead of turning one pair in two days, he would turn two pairs in one day, and by a little extra crowding could get out three pairs, providing they were not extremely hard. To do this your lathe must make one revolution in two and one-half minutes, must feed one-eighth of an inch across tire at each revolution, and no time be lost in working out the flanges.

This time has been made on Krupp tires with the indispensable Mushet for tools In fact, first-class time must be made when you take a consolidation engine in shop, turn off tires and get it out in two and one-half days.

This refers to tires that it is only necessary to take one cut from, as ours are never allowed to wear below three-sixteenths of an inch

All are aware that the ordinary every-day railroad shop machinist is not a rusher, that the finer the feed, and the slower the speed, the more contented he seems to be, and I don't remember of having seen one who enjoyed being told to "put on five or six more teeth," or "throw your belt up on the next speed," but it pays to look after these matters a little

To return again to old tools.

We have an old planer at our place that came to us second-handed many years ago, and it stood unused and unnoticed for a long time. We never were fortunate enough to get a radius attachment for planing links, so we rigged one of our own design and make on this old planer, and the work it turned out would surprise you.

We also use it for another purpose, with counter-shaft and wood-drum overhead, and an emery-wheel and pulley attached to cross-head; we surface guides, etc., with it and won't growl if we can't get a better one. I realize that it would be a nice thing to have a double-head axle-lathe, but as long as we can turn six a day in our old machine, we are not going to find fault with anyone because our neighbor can can turn out twelve in ten hours with his new one.

If you have an old slotter that will accommodate only one driving-box at a time don't use it for this purpose at all, but rig up a radial-head and put it on the cross-head of your best planer, and do as many boxes with one operation as your table will hold.

If you haven't a special planer for rod brasses, speed up one of your smaller planers to twenty-eight or thirty feet per minute, put in as many pairs as your chuck will hold, and use a double-tool that will cut down the inside of both flanges with one operation. The time gained on one dozen pairs will surprise you.

If you have no improved tool for sharpening your reamers—here is something that will do it first-rate

Refit the carriage on the V's of your oldest lathe, place wood-drum and counter-shaft overhead, and with a small pulley and emery-wheel held in a fork at the tool-post, your reamer on the lathe centers, one movement of the carriage the length of each cutting edge of reamer, will make it as good as new.

I do not desire to be classed in opposition to new tools; on the contrary, I am an advocate of them, and any new method that will produce the manufactured from the raw material cheaper; but because you haven't as good or as improved machinery as the A. or B shops have, I don't think that it is just the thing to lapse into a state of "innocuous desuetude" or go about groaning all the day long, and allow some smaller shop to distance you, but take the bull by the horns and with a small bit of ingenuity and a big bit of push and energy, you will be surprised how the old traps can be fixed up.

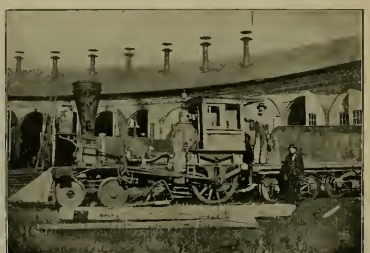
## The Diamond Stack an Efficient Spark-Arrester.

A very tedious and remarkably important law-suit has just been decided at Fort Wayne, Ind. The case turned upon the efficiency of the diamond stack as a spark-arrester as compared with the extension smoke-box The White Wheel Works were burned down, and being at the side of the Nickel Plate track, it was, of course, claimed that the fire originated by a spark from some of the railroad company's locomotives. To the claimants this would be much more likely to happen than the setting fire of the place by a spark from the owner's cupolas The insurance companies paid $50,000 for fire damages, and then joined with the owners of the wheel works in suing the railroad company to recover payment for the loss.

The excuse for the suit was that the railroad company used the diamond stack on their locomotives, and that it was not so efficient a spark-arrester as the open stack and extension smoke-box. A host of experts in the shape of engineers, master mechanics, superintendents of motive power and scientists were examined as to the good and bad character of the two forms of spark-arrester in question. After all the evidence was in and properly digested the decision was made that the diamond stack is as good a spark-arrester as the extension smoke-box. It was decided that the advantage of the extension smoke-box was that it promoted cleanliness and saving of fuel. This decision makes the diamond stack legally as good a spark-arrester as anything in use. The question has been before the courts several times.

## The Old "Pioneer."

Mr. William Smith, Superintendent of Motive Power of the Chicago and North-western, sends us the following points about the historical locomotive "Pioneer" shown in the annexed engraving:



This engine was built by M. W. Baldwin, in Philadelphia, in June, 1836, for the Utica and Schenectady road, and was afterwards bought by the Galena & Chicago R. R. It was the first locomotive bought by that company, and was purchased by them in 1852.

The engine was in service for thirty-five years, and is now laid up at Turner shops, in good working order. The engine stands as represented in the photograph, but her flues are in good working order, and any day that we want to put on a little "style," all we have to do is to fire her up and start.

When the "Pioneer" was bought there was only about two miles of track laid, and that was the strap-rail. Afterwards the company began pushing the road to Turner, and then to Elgin, and then the "Pioneer" ran between Chicago and Elgin.

The first engineer that run her here was P Ebbert, a brother of the first master mechanic of the road, and he afterwards became assistant to his brother, Mr. John Ebbert. Patrick Degan succeeded Mr Ebbert as engineer of the "Pioneer" Both of these gentlemen are now dead. Mr. R W. Bushnell, Master Mechanic of the B. C. R & N., at Cedar Rapids, ran the engine for a short time.

At the time the "Pioneer" was running three or four freight cars was considered a good train for her. She has been known to take five freight cars from Chicago to Turner, a distance of thirty miles, and that was considered an exceptionally heavy train, as it is up grade in some places. She used to take in seven cars from Turner to Chicago, and she was considered a great mogul then to be able to handle so many cars. These cars would be loaded with iron, ties, or anything in the line of railroad business. The cars, to be sure, in those days were nothing near the size they are now, but I have been told by parties that saw her do the work that the cars were 26 or 28 feet long.

The engine has a hook motion, and is worked with two small horizontal bars about the size of damper rods. They pass through the cab and work backward and forward into a notch. The engineer, in order to work these bars, has to stoop down, and it would appear to me that he would have to be an expert to stop the engine at any particular point he wished to.

The engine is what you might term a half crank inside-connected engine. Her main rods are not any heavier than the eccentric blades of our large engines. The guide-bar is hollow and forms the pump; the plunger working through the center of the guide-bar. There are four studs in the steam-chest, one at each corner.

The engine was brought by lake to Chicago, and after her arrival here visitors flocked from far and near to see her. I am informed by those who were on the ground at the time, that wherever the engine happened to be, it was like a country fair, so many people came to see her.

This engine would show a wonderful contrast providing she was placed alongside of one of our modern locomotives in the World's Fair. I think it would attract as many visitors as a good many other articles on exhibition.

## Reminiscences of the "Pioneer" Locomotive.

Mr. R. W. Bushnell, Master Mechanic of the Burlington, Cedar Rapids & Northern, who was previously on the Chicago & Northwestern, sends us the following notes:

My first remembrance of the "Pioneer" which at all interested me was when she was taken into the roundhouse for general repairs. This was at Chicago, on the Galena & Chicago Ry., in the year 1855, if I recollect right. I was then working in the back shop, but, as I was desirous of going on the road, Mr. John Ebbert, M.M., offered me the "Pioneer."

The engine was of Baldwin make, and built in the year 1836, and of the following dimensions: Cylinder, 11 x 18; 2 drivers, 54 in. diameter; boiler, 37 in., with 108 1¾ flues 7 ft. 6 in. long; weight, 24,000 pounds.

The engine originally had but one eccentric on each side for the forward and backward motion, and these were placed under the foot-board with the usual levers and starting-bars peculiar to that motion. At this time the engine was given two eccentrics for each side, and these were placed outside and attached to a pin in the hub of the drivers. The reach-rod, or reverse-rod, was made like a sand-box lever, with notches and a catch in front of cab to hold it in position.

The engine was also fitted with an Ebbert's patent heater, a product of the inventive genius of Mr. Peter Ebbert, the foreman of the roundhouse.

The heater consisted of vertical pipes, placed around the inner side of the inside pipe of the smokestack, and connected at top and bottom with return bends, the pump forcing the water through these pipes to the boiler.

The stack was of the ordinary pattern for wood-burners of those days; but in order to get ample surface for the water heater, the inside pipe was made very large to get as many pipes in as possible. To cap this, and retain heat in the stack (I suppose), the cone was made unusually large. You can imagine the possibility of an engine making steam, handicapped with such an apparatus as this in the stack.

Well, after a seemingly long time to me, the engine was at last ready for service. Mr. Ebbert, the inventor of the heater, was to take her out on the first trip, and I was installed as fireman, after which I was to take the engine and run her. I cannot relate all the incidents of that trip, but were they written in a book, verily they would fill a volume; and should a person relate them as they occurred, he would be placed at the head of the procession in your special column for liars. You can bet there would be no lounging on the seats while the talk was going on, for all would be on their taps to gather material for future occasions, and there would still be fun enough left to entertain a large audience.

We started for Sterling (110 miles from Chicago), the terminus of the new line then building to Clinton. How long we were making the trip I cannot say, but there were several lodgings in my bill for the round trip. We would run along for a few miles until out of steam, then stop and wait until steam came up again from natural draft, then we would proceed and repeat the operation. When making a meeting point, to save steam the water was allowed to run down, and in some instances it went so far beyond our vision that we had to restore it to sight by manipulating the plunger of the pump by hand with the bell cord.

At last we reached Sterling, and Mr. Ebbert, whether from disgust or business demands, as he alleged, took the first train back to Chicago and left me with the engine in charge of Mr. Burgess, who was foreman there, to take back to Chicago; telling him at the same time what a nice run we had out and what a pleasant trip he would have in going back with her. Burgess tumbled to the situation at once, and after Ebbert was out of sight removed the bonnet from the stack, took out the cone and reduced it to the size of a small wash basin. Our trip homeward was not so eventful, still there was enough of it to make fun for the boys and enliven their usual Sunday morning gatherings for some time. Some were so thoughtless as to tell that Burgess went into the field and hired a farmer to leave his plow and take his four horses and help take the engine over the hill. I never confessed; still it was current among the boys and many of them believe it unto this day.

The engine was intended for hauling the pay-car, superintendent's car and other light work. Before going out again, Ebbert discovered that the cone had been reduced, ordered it out again and had it enlarged, and herein lay the agony of my soul. The heater in the stack and the large cone almost precluded the possibility of the engine making steam. As this was my first trial as an engineer, these things weighed heavily upon me and cast a shadow over my prospects.

At this time the telegraph had not come into use with us for handling trains, and the boys when away from terminal stations would often make their own arrangements as to meeting points to suit themselves, regardless of card time or rules. This would often result in trouble to themselves, collisions of their engines, and a disagreeable contact with the "Old Man." The greatest divergence from card time was when coming to stations where they got their meals, and at other stations where trains met and where the men would meet around the table for a social conference and take dissolving views of the sweetening at the bottom of the glass. Half an hour or so of such gatherings was not an unusual occurrence. These arrangements were all very well when the same men were on the runs to meet each other, but when a strange man came out who knew nothing of their special agreements, chance only saved them from disastrous results.

I well recollect how one such an arrangement was abruptly ended. At one of the terminal stations the way freight left so early in the morning that the boys could not get breakfast. It was, however, arranged between the crews of the opposing trains that this train would stop at an intermediate station for breakfast, and the other train would hold back for them at the next station, which was their regular meeting point. But to facilitate their work and get breakfast the train which had the right to the road was held. One morning the superintendent unexpectedly appeared at the latter station and wanted to know why the train which had the right to the road did not proceed. The boys, ever ready with an answer, said they saw the smoke of an engine just beyond the station, and were waiting for them to come in, thinking they had broken down. The superintendent was somewhat incredulous, but the train soon coming in, the trainmen having their excuse at their tongue's end. A broken spring-hanger served as a pretense for the delay; the superintendent was satisfied, but this ended the special agreement of the boys on that division, and the telegraph soon coming into service prevented these little divergencies.

To get back to the "Pioneer": A new superintendent came on the road and was to go over the line. I was delegated to haul him with the "Pioneer." When coming to those uncertain points where the boys were liable to come in ahead of time, I would lay back, and the superintendent would come forward with his time-card and watch and urge me to go ahead. The appearance of smoke in the distance soon convinced him that I was acting according to time-card rules, taking the safe side in case of doubt. Our first trip was over the line to Sterling, then back to Dixon and then over the Illinois Central to Freeport. We reached Dixon in the evening, and when within a few miles of Freeport, the fire turned black, the steam went down and the engine stalled. Here we were on a strange road in a dark night, and not knowing just how far we were from the station. Fortunately we were only a few miles from the end of the journey. After standing awhile steam came up and we started, but soon came to a stand again for want of steam. After another trial or two, with the help of an easy grade, we finally reached the station. I reported the condition of affairs to the foreman and went to my lodgings. In the morning the engine was steamed up, and the foreman reported her all right. We coupled up to the car and started, but had barely passed the city limits when the fire and steam went back on us, as on the evening before. We however managed to get back to town, and I put the engine in the house and the superintendent put his car on the regular train and went to Chicago. After examining the front end, pipes, netting, etc., the foreman pronounced "nothing the matter with her;" but upon further examination I found the back half of the petticoat had collapsed and closed up the petticoat so that the exhausts were turned back into the flues. This remedied, we were soon on our way to Chicago, which we reached without mishap, except one little affair, which, but for the interference of our good fate, might have ended the future of the "Pioneer" and, perhaps, the days of the man and myself.

When reaching Elgin the freight was not due to leave the junction for some minutes. This was twelve miles away. I said to the fireman, "I think we can venture to the Fox River switch," which was about a mile away. We had scarcely got the switch open when a headlight appeared from around a curve and shone full in my face, and our engine only reached the limit post when the freight shot by us at twenty-five miles an hour. An examination of my watch showed that the freight was barely due to leave the second station east of us. This was another of the convenient divergencies the boys had from card time. Such were the chances a fellow took when running a wild train before the days of the telegraph.

Another incident occurred near this place, which also came near terminating the history of the "Pioneer." I was with the pay-car at Elgin (H. H. Porter was paymaster) coming east. A tail-end collision between the freight and a gravel train bunched several trains at this point, and necessitated my taking with the pay-car twenty empty flats to the next station. As we were about to back the cars on to the side track I looked back and saw Mr. Porter with his money-box rushing down the bank as fast as his feet could carry him. I stepped to the other side of the engine and saw the freight coming around the curve behind me. I immediately gave the engine steam ahead, and had scarcely got a move on her when the freight engine came crushing into our rear end, piling up flat cars, engine and box cars promiscuously. A misunderstanding among the trainmen was the cause of the accident. The number of flat cars behind the "Pioneer" relieved her from shock, and she came out of the battle unscathed.

The fates were again with us. Had we been a few car lengths further back on the side track, the "Pioneer" would have been doomed for the scrap heap.

A demand for the engine on a small branch out from the junction relieved me from running her, and also, perhaps, from an untimely end.

## The Progressive Plan.

Superintendent L. F. Loree and S. O. Noragon, foreman of engineers on the C. & P. division of the Pennsylvania road, have just instituted an innovation that the patrons of the road will surely appreciate. The firemen on the road, and there are 110 of them, are given an examination every year as to their fitness for promotion to the position of engineer. The examinations are very thorough. It is the purpose of the investigations to have two competent men on the engine at all times.

The examinations have resulted in some curious findings. One fireman who had been on the road eleven years only ranked 30 per cent. in the examination. Another who had been on the road but five months stood 75 per cent. The list of questions to be answered cover fifteen sheets of type-written copy.—*Cleveland World.*

## Collateral Security.

Mr. David McCargo, General Superintendent of the Allegheny Valley, tells of a very smart retort made by a young lady who was enjoying the novelty of a ride on one of his locomotives.

The lady and a gentleman, well known as a Pittsburgh capitalist, got up on the fireman's seat and the train started out. The road is noted for curves, and the gentleman put his arm around the lady's waist, remarking that this precaution was necessary to prevent her from being thrown off the seat by the lateral swing of the engine.

"Oh, I understand," remarked the girl, "there is lateral danger and you give me collateral security."

"Hardening cracks are more often the result of uneven heating than of any defect in the steel. Do not determine the quality of any steel by the appearance of the fracture of a piece. The grain, whether fine or coarse, depends principally on the heat at which it was finished by the hammer or rolls. Do not try to harden any bar of steel without first removing the scale from it." The above pointer is from a little catalogue of sizes of steel recently issued by the Crescent Steel Co., of Pittsburgh, Pa.

A dreadful boiler explosion happened to a locomotive belonging to the Chicago & Alton last month. The engine was pulling a freight train near Joliet when, without any warning, the boiler exploded, killing the fireman and head brakeman instantly and severely injuring the engineer. We have been unable to find out the cause of the accident, but it was no doubt due to broken stay-bolts or similar defects.

LOCOMOTIVE ENGINEERING.

## Smoke.

Smoke, like the poor, is always with us. The outward appearance of American cities every year make it more apparent that the smoke nuisance has come to stay. There may be some amelioration of the malady effected, but a thorough cure is hopeless. The increasing number of manufactories and metallurgical industries that must use bituminous coal serve to make the atmosphere of our cities more murky every year, and the increasing number of hard-worked locomotives pour upon rural scenes clouds of smoke that cannot be hid, and the eyesores of railroad origin move the rustic statesman to impose penalties. There are many nuisances far more injurious than smoke to the public health that are seldom heard of because they are not conspicuous. Smoke appeals to various senses, so that the objectionable features of the article are not likely to be overlooked.

For this reason there have always been periodic outbreaks against smoke ever since "sea coal" began to be used as fuel. There is an epidemic of acrimony against smoke in American cities at present, and it seems to be an opportune time to make some reflections upon the smoke question.

All bituminous coal contains resinous, tar-like ingredients that are known to chemists as hydro-carbons. These burn at a comparatively low temperature and make the flame and smoke of a fire. When the coal that has been put in a furnace or fire-box becomes heated to a certain temperature, the hydro-carbons are released and escape in the form of smoke and gas, the visible black part, which forms the smoke, being composed of very fine particles of pure carbon. The temperature required to release the hydro-carbons is not sufficiently high to convert them into flame. Under conditions favorable to smoke forming, these gases pass off as they are released from the coal. They contain very valuable heating qualities, and it is important in the interests of fuel economy that the hydro-carbon gases should be burned. The conditions necessary to convert these gases into flame are a hot fire and a supply of air at some point between the surface of the fuel and the entrance of the flues. The oxygen taken from the air is essential to the burning of the gases. Without that element the gas will pass off uselessly without generating heat, no matter how hot the temperature may be. When the volatile gases leave the coal the greater part of them are in an invisible condition, but on reaching the cooler portion above they go through a sort of condensing process and become smoke.

The means of preventing smoke, then, are the maintaining of a high furnace temperature and the providing of a liberal supply of air. In a furnace made for experiment, it is no difficult matter to regulate the supply of air just to suit the requirements of the gases passing from the fuel. When this is done smokeless combustion of soft coal is successfully carried out, and the fuel gives its highest heat-making duty. Those who have carried out experiments of this kind are ready to say that smoke prevention is merely a question of care and intelligence on the part of firemen.

Any one interested in smoke preventing can make interesting experiments with a common kerosene lamp. Cutting off the supply of air or cooling the chimney will show points about combustion that are far more impressive than a written article upon the subject.

The fire-box of a locomotive doing hard work, or the furnace of a factory boiler that has to be forced all the time presents difficulties in burning fuel economically that do not seem to be realized by those who experiment in laboratories. A high furnace temperature and a generous supply of air are antagonists not likely to exist together in the harmony that produces a smokeless fire. If there is a light fire and a strong blast, so much air will pass through that the fire-box temperature is likely to be reduced below the igniting point of the gases, and smoke will result. If the fire is thick, sufficient air will not be supplied to all the gases passing off, and they will go into the tubes in the form of smoke. The medium between these extremes is the center of economy; but it is next to impossible for a fireman to maintain the favorable conditions. If the fire has to be forced it is utterly impracticable. When a fire-box or furnace is large enough, so that steam can always be maintained with a mild draft, smoke can be prevented and the fuel burned economically. There are few fire-boxes or furnaces worked in this way.

When a fireman does his work in such fashion that the smokestack is constantly pouring out a stream of black smoke, the chances are that he is an inferior hand and an expensive man for his employers. Fuel can generally be burned to best advantage about half way between the black smoke and the smokeless conditions, that is, with a moderate amount of smoke. A brick arch or other means of mixing the gases as they pass through the furnace brings the point of economy toward the smokeless conditions. The firemen who work on roads where premium is paid for fuel-saving may be left to find out what kind of firing makes steam with the least consumption of coal. They have discovered that strict smoke-preventing and fuel-saving do not go together.

At present the representatives of railroad companies and owners of furnaces in cities are searching for the means of satisfying the demands of health authorities for the abatement of the smoke nuisance. With railroad men the trouble generally is, that the firemen have received no training whatever about how to keep down smoke, and the well-known provisions for regulating the admission of air to the fire-box have not been provided. When a spectator can stand on a height overlooking yards, where the switching engines belonging to a variety of railroads are at work, and see those belonging to certain companies painting the atmosphere black, while the engines belonging to other roads cause little smoke, the impression received is that there is bad management somewhere. The degree of smoke-prevention practicable would satisfy most sensible people if it were only carried out. If real and absolute prevention of smoke is called for, larger boilers or less duty for those in use is the remedy.

## Loss Due to Coupling Driving-Wheels.

Our versatile correspondent Mr. Wm. Barnett Le Van comes to the front in another column with an interesting article in support of his favorite theory, that locomotives with a single pair of drivers are the proper kind of motive power for high-speed trains. There are a great many good features about locomotives without coupling-rods, but there also are many shortcomings. The French engineer quoted by Mr. Le Van as finding that the frictional losses due to coupling the driving-wheels amounted to 25 per cent. of the total indicated horse-power is certainly making out an extreme case. If we remember rightly, Mr. Regray experimented with engines having one pair of drivers against others with two pairs coupled. If he had happened to try a decapod locomotive, the friction of the rods and extra driving-wheels would have used up more power than the cylinders developed, and the engine would have been useless. This may be carrying the line of reasoning to an absurd length, but it is no more absurd than the claim that 25 per cent. is wasted by the increased friction due to the side-rods of four-wheel connected locomotives.

The imputation is made by Mr. Le Van that the great fuel economy of British locomotives, as compared with those used in this country, is due principally to the absence of side-rods. We are not, by any means, prepared to admit that British-made locomotives are more economical of fuel than our own when doing the same work. It has not been found so in foreign countries, where British and American locomotives were worked together. The economy of the Webb locomotive, as compared to others on the Pennsylvania Railroad, is alluded to as if it afforded a striking contrast. The Webb engine is a compound, without coupling rods. The engine uses about 20 per cent. less fuel than class K engines when pulling the same train. This is just about the saving effected by other compound locomotives when working against simple engines on the same class of trains on other railroads. The Webb locomotive either saves no fuel through the compound working or she shows no marked economy of fuel over American engines when worked under similar conditions.

We believe that there is loss of useful effort due to the coupling of driving wheels together, and we are inclined to think that American locomotives are harder on fuel than those operated in Europe, but we feel certain that the magnitude of both sources of loss is greatly exaggerated.

## Taking Care of Air-Hose.

There are very few roads nowadays that do not pay considerable attention to the repairs of the brake apparatus, and most of the good lines have air-brake inspectors, whose duties are utilized to prevent rather than cure defects.

Great care is taken to see that the proper leverage is applied to cars; that the pistons travel between 6 and 8 inches; that the triples are oiled, etc., etc.; but who ever heard of an inspector, or anyone else, doing anything about a hose until it failed?

Surely nothing receives harder usage than the average brake-hose. Grease, the sworn enemy of rubber, is poured through them, heated by a pump whose air passages are choked by dust and grease, water collects in them; they are subject to varying pressures; are often located where they chafe against brake-beams or other apparatus, and they are expected to last for ever.

It would seem an easy matter to establish a limit for keeping hose in service; a time limit would seem to cover the necessities of the case. Certainly a hose should not be allowed to run until it fails. A limit should be established for the hose used between engine and tender, as these especially are subject to more ills than their neighbors on the cars that are uncoupled and drained regularly.

The writer was on an express train recently where the quick action went on with a bang when the train was within less than half a mile of the terminal—a hose between engine and tender had ruptured, there was no extra hose on the engine, and the train lost twenty minutes while they took the hose of the rear car and put it in place of the one that failed.

The old hose was porous and pulpy, showing the effects of grease, water and heat, having been in use since the engine came out of the shop.

The engineer of this train reported delay "on account of failure of brakes." Was it not a failure to inspect? A failure to prevent a delay that could be plainly foreseen? A failure to have some means to determine the safe life of a vital part of the air-brake mechanism—the very part that in the nature of things should be expected to fail first?

## The Reading Deal.

The greatest railroad deal ever effected was made last month by the Philadelphia & Reading Railroad Company securing control of the Lehigh Valley and the Jersey Central Railroads. The deal is extraordinary in more ways than on account of its magnitude. As an idea of the work done by these roads can be better obtained through the number of locomotives and cars used than by the mileage, our readers who are not familiar with the properties in question will understand the following statement: The Philadelphia & Reading Railroad consists of about 850 miles of track, which is operated by 650 locomotives and about 30,000 cars. This company has obtained control of the Lehigh Valley Railroad, which has about 1,855 miles of track, 610 locomotives, and, according to the *Railway Equipment Guide*, over 40,000 cars, and the Central Railroad of New Jersey, which has 630 miles of track, 420 locomotives and over 34,000 cars. In addition to that, the Reading or its friends have secured control of the lines leading from Pennsylvania to New England by the Poughkeepsie bridge and the New York & New England Railroad.

For years past the Philadelphia & Reading Railroad Company has been noted principally as being in a chronic semi-bankrupt condition. The present President and General Manager, Mr. McLeod, has done wonders to straighten out the company's financial embarrassments, but still the present deal very closely resembles the Scripture prophecy where lean kine came out of a river and swallowed up the fat ones. The deal puts almost the whole of the railroads handling anthracite coal under one management. Not a few consumers of this necessity of life are nervous about the effect of the combination on the price of coal. It will be well for all concerned if the enormous power thrown into the hands of one set of men is used wisely.

## Insure Reliable Air-Brakes.

In our January issue, after reviewing what has been done towards providing reliable air-brakes for freight trains, we urged that no new form of air-brake should be accepted by railroad companies without first undergoing tests to demonstrate its efficiency. Events have shown the soundness of the position we took on this question. A variety of air-brakes were coming into service, the owners claiming that they were as efficient as the Westinghouse automatic quick-acting air-brake, and that they were interchangeable with it. The Chicago, Burlington and Quincy had ordered a large number of New York air-brakes on new cars under construction. When the first lot of cars with that brake on were delivered the railroad company's mechanical officers made tests of the brake on a fifty-car train, and it was found that the quick action did not reach the last car in less than seventeen seconds. A brake of this kind is, of course, not safe to make an emergency stop with on a long train.

The New York Air Brake Company then got out a new triple valve, and tests were made with it last month on the C. B. & Q. and on the Lehigh Valley Railroad on fifty-car trains. The application was satisfactory on both roads; but all the brakes could not not be released by the engineer. From 10 to 50 per cent. of the brakes had to be released by bleeding.

Cars belonging to several fast freight lines, and some belonging to railroad companies have been equipped with the Lansberg brake. Within the last two months this brake has been subjected to tests by the mechanical officers of the Chicago, Milwaukee & St Paul, the Chicago and Northwestern, the Cleveland, Cincinnati, Chicago & St. Louis and of the Atchison, Topeka & Santa Fé, with the result in every case that the brake was declared away behind the M. C. B. requirements. In fact, this brake is not quick-acting under any circumstances.

The result of these discoveries has been that several railroad companies have given notice to their car inspectors and trainmen that none but Westinghouse brakes must be used in the controlling of trains.

A committee of the M. C. B Association on air-brakes has taken up the question, and it is likely soon to be forced to a practical settlement. Mr. G. W. Rhodes, who is chairman of the committee, speaking at a meeting held lately, insisted that all brakes offered to railroad companies should have to pass a practical test before being adopted. His idea was that, either through the agency of the Master Car Builders' Association or of the American Railway Association, there should be located at some central point a test rack, the equivalent of a fifty-car train, where tests of all brakes seeking patronage should be made. In his opinion, this was essential. For instance, some car-building company in filling an order might desire to place a cheap brake upon the cars turned out by them, but if it were requisite that any given brake should pass a satisfactory test at such a central station as that to be provided for, inferior devices would be barred necessarily from introduction. If cars were offered with a break of unknown efficiency, the question could be asked, Have you passed successfully the test at our standard test department? If the answer was in the negative, the railroads would be warranted in refusing the cars equipped with a brake not possessing the required certificate of efficiency.

This is putting the demand we made two months ago into practicable shape. We see no reason why a brake company, prepared to do a legitimate business and willing to provide a reliable brake, should object to the terms proposed.

## Standard Nuts and Bolts.

The Railway Master Mechanics Association have a committee investigating the subject of bolts and nuts, and they have directions to report at the next convention on the best size for nuts and bolt-heads, rough and finished. Some people might think that inquiring into this subject was like investigating the best form and size of screw threads, but the cases are not parallel. There is no disposition now to agitate in favor of screw threads different from the U. S. standard, but there is not nearly so much unanimity in regard to the sizes of nuts and bolt-heads. The standards for these were established at the same time as the standards for screw-threads, but some manufacturers of bolts were a long time in adopting the standard sizes, and this has led to confusion that is by no means ended to-day. A report on standard nuts and bolt-heads, with discussions on the subject by conventions and railroad clubs, would have a very good educational effect upon railroad men.

The more enlightened and progressive class of railway mechanics have been as ready to recognize the advantages of uniformity in screw-threads as the leaders in any line of engineering. Yet there are men in charge of important railroads who have not exhibited any of this spirit. Manufacturing concerns, that make anything for sale with bolts and nuts as parts, have been forced by the prevailing practice of the country to use standard sizes, consequently U. S. standards are universally adhered to in the trade outside of what might be called close corporations. Railroad companies we sometimes find to be very close corporations in their adherence to vicious practices. It may be highly flattering to insular egotism to specify the standard threads or nuts of the X. Y. & W. Railroad, but to men of enlightenment and good sense it is highly ridiculous.

While investigating this subject we have been very much surprised that there are still very large railroads in the United States, claiming to be first-class in every respect, that do not have a standard screw-tap in their shops, or at least a tap that would be considered good by a manufacturer. There is still in use for locomotive repair work all sorts of bastard sizes, and the men doing repairs waste more time annually searching for, or making nuts to suit threads different from the standard, than would pay for the scrapping of all odd sizes. On roads of this kind, the fact that there are standard sizes of nuts and bolt-heads is unknown. This condition of things comes from the reluctance of narrow minds to scrap a thing as long as it can be used. There is no more expensive policy possible, yet it is followed on the plea of economy.

Before looking into the condition of affairs we thought it would be insulting the intelligence of the men in charge of railroad rolling stock to ask them, at this late day, to discuss the propriety of adopting standard screw-threads and standard nuts and bolts. We have changed our minds, and consider that no subject could more profitably receive attention. If the investigation extended to the relative cost of purchasing bolts and screw-cutting tools from manufacturers, and the making of them in railroad shops, very interesting facts would be elicited.

## Rules of Locomotive Inspection.

The only way to use locomotives satisfactorily when chain-ganging is practiced is to introduce a system of thorough inspection at division points. The New York Central have lately established a system of inspection of running engines, and the following orders have been issued to the inspectors by Mr. Wm. Buchanan, Superintendent of Motive Power

1st—Examine grates in fire-boxes; see that they are properly connected, and that all bolts and keys are in place and grates not broken. Examine ash-pan; see that dampers are in good condition, and that the ashes do no not escape in the axle-box or wedges

2d—Examine all parts of engine and tender, all bolts and nuts, see that they are in proper position, and nuts screwed up; also that all pins and keys are in good order, provided when necessary, and none left out from any part of machinery Give particular attention to all bolts and nuts in eccentric straps and blades, and closely examine side-rods and crank-pins.

3d—Examine air-brake equipment throughout, and see that pump works properly, that pipes and connections are in good order, and no leaks in same; also that triple valve and reservoirs are properly drained. Examine steam-heating pipes, valves, etc.; see that they are in good order.

4th—Examine all spring and spring-hangers under engine and tender, see that they are not broken, and that bolts and keys in same are in good order. See that tender and engine pilot are correct height from rail.

5th—Examine bumpers on engine and tender; see that springs on hook-bumpers are in good order; also that all bolts, nuts and keys of same are in good shape; also see that link and pin for coupling are provided where necessary.

6th—Examine engine truck and tender journal and boxes, also brasses in same. See that they are all in good condition and each box properly packed; also that cellar bolts are in place and adjusted so that they will not lose out.

7th—Examine particularly driving-box cellars; see that they are properly packed and oiled. Examine top of driving-boxes, see that they are not filled with dirt and are provided with proper amount of waste, and if tallow or any other hard lubricating material is found on top of driving-box remove same and clean out holes.

8th—Examine all wheels and axles under engine and tender, see that tread of wheels is perfect and that there are no flat spots; also that flanges are not worn sharp and wheels not loose on axle.

9th—Examine driver and tender brakes and test same; see that brakes are properly adjusted so as to be effective, also that bolts in tender-brake are not badly worn, and that they are provided with proper keys.

10th—Examine and report all leaks in boiler and fire-box, leaking wash-out plugs, boiler connections and mountings.

11th—Examine weekly pipes in smoke-box and netting in same and in stack

NOTE—Inspectors on finding defects must immediately report the same to the person in charge, and will keep a record of all or any defects found by them, entering the same in the Inspection Book provided for this purpose, and under date of discovery, and in the same manner, under date, of when defects are remedied.

## Train Robber's Flight with a Locomotive.

A train robber running away with a freight locomotive on one track pursued by trainmen with an express engine on another track, was an actual occurrence on the New York Central Railroad last month. The imagination of dramatists or novelists never conceived anything more exciting or more dramatic.

A man, who was evidently an old trainman, boarded the American Express Company's special express matter train on the New York Central at Syracuse, concealed himself on the top of the cars, climbed over the express car, and by means of a rope ladder got down beside the window at the side of the car. This he smashed, and called upon the messenger to surrender. Instead of doing this, the messenger pulled the bell-cord and grasped his own revolver. A duel began, and the messenger was shot in the head and leg. The conductor of the train heard the whistle signal and stopped the train. The robber, who had got inside the express car, opened the side door and fired shots at the trainmen when they attempted to go near him. The conductor sent one of his brakemen back to the nearest station to telegraph an alarm, and gave the engineer a signal to go ahead, thinking they could capture the robber at a stopping-place where assistance would be got. At the next station reached the train was stopped and the express messenger was found to be badly wounded. The robber had disappeared. The train proceeded. When a stop was made at the next station an excited crowd collected, the news of the robbery having reached ahead. Among the crowd was noticed a man who had been seen on the platform at Syracuse. A sharp trainman reasoned that the stranger must have come on this train, and as there were no passengers, he must be the robber. On an attempt being made to arrest the man, he pulled out two revolvers and backed towards a freight engine that was at the station, pulled the pin, ordered the men off, and taking possession of the engine started out.

The express trainmen also acted promptly. They secured a shot-gun, uncoupled the engine from the passenger train and pursued the robber. There are four tracks on the New York Central, and the fugitive was on the freight track and the pursuing engine on the passenger track. The long-legged passenger engine soon overtook the freight mogul. When the robber saw his pursuers approaching he suddenly applied the brakes and reversed the engine. As the passenger engine flew past he fired a volley of shots into the cab. The passenger engine was quickly stopped and reversed, the robber following the same tactics. As the engines passed the second time the shot-gun was fired at the robber, and he returned the compliment with his revolver. No one was hit on either side.

The trainmen did not feel like continuing this novel sort of duel, so they returned to the station and got a sheriff and a reinforcement of guns. Then the pursuit was renewed. The robber deserted his engine at a road crossing and made for the woods. After an exciting chase he was captured and safely landed in jail.

The Vanderbilt roads centering in Buffalo have an arrangement of joint inspection of cars that is calculated to materially facilitate the movement of cars. The new plan is to keep cars moving forward as much as possible. When it is found that a car must be repaired before proceeding farther, instead of sending it back to the yard of the delivering road, it is repaired by the receiving road. Several modifications of the M. C. B. rules of interchange have been agreed upon. It is understood that the plan was worked out by Mr. A. M Waitt of the Lake Shore

A party signing himself "A Machinist" has gone to the trouble of writing to the *Railway Age* about hot pins on locomotives The funny statement is made that hot pins are nearly always caused by the lack of judgment in keying brasses. When men write to papers, pretending to throw light on subjects they are profoundly ignorant of, they deserve to be criticised. The correspondent referred to uses a wrong signature. If he wants people to know exactly his professional standing, he ought to subscribe himself "Ass."

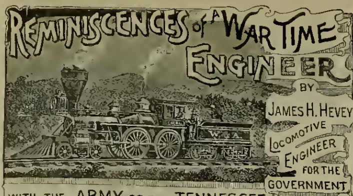
Railroad companies continue to display scandalous apathy toward supporting the recommendations of the M C B. Association Executive Committee in favor of gauges for the standard car coupler. Those that want to show themselves alive in the smallest way to the interests of interchangeable parts ought to order these templates from the Pratt & Whitney Co., without delay. The interchangeability in this case means finally the ability of one make of car coupler to couple with that of another make.

There is a point connected with the adjustment of the piston travel of air-brakes that ought to be more generally understood. If the travel is adjusted when a car is loaded and the brake is hung from a part of the car above the springs, the travel is different when the car is empty. The same is the case with a loaded car whose brake has been adjusted when the car was empty. If the piston is set at 6 inches on a loaded car it may stand at 4 inches when the same car is empty. If the piston is set at 6 inches when the car is empty it will probably stand at 8 inches when the car is loaded. It is good to make a note of these things.

### Luminous Paint.

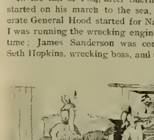
A foreman car painter writes us "I have been experimenting with luminous paint but have not hit it very well. There was some talk that luminous paint would be a good thing for switch targets and a great variety of other railroad things, and I have been trying to mix up color that would be luminous, but it does not shine at night worth a cent. I have use phosphorus as the base of my operations. Can you give me some pointers?"

The only pointers we can give are extracts from our scrap-book, which say. "For orange luminous paint, 46 parts varnish are mixed with 17.5 parts prepared barium sulphate, 1 part prepared Indian yellow, 1.5 parts prepared madder lake, and 38 parts luminous calcium sulphide. For yellow luminous paint, 48 parts varnish are mixed with 10 parts prepared barium sulphate, 8 parts barium chromate, and 34 parts luminous calcium sulphide For green luminous paint, 48 parts varnish are mixed with 10 parts prepared barium sulphate, 8 parts chromium oxide green, and 34 parts luminous calcium sulphide. A blue luminous paint is prepared from 42 parts varnish, 10.2 parts prepared barium sulphate, 6.4 parts ultramarine blue, 5.4 parts cobalt blue, and 46 parts luminous calcium sulphide. A violet luminous paint is made from 42 parts varnish, 10.2 parts prepared barium sulphate, 2.8 parts ultramarine violet, 9 parts cobaltous arsenate, and 36 parts luminous calcium sulphide. For gray luminous paint, 45 parts of the varnish are mixed with 6 parts prepared barium sulphate, 6 parts prepared calcium carbonate, 0.5 parts ultramarine blue, 6.5 parts gray zinc sulphide. For oil-color paints, use equal quantities of pure linseed in place of the varnish; the linseed oil must be cold pressed and thickened by heat. All the above luminous paints can be used in the manufacture of colored papers, etc, if the varnish is altogether omitted, and the dry mixtures are ground to a paste with water The luminous paints can also be used as wax colors for painting on glass and similar objects, by adding, instead of the varnish, 10 per cent. more of Japanese wax and one-fourth the quantity of the latter of olive oil. The wax colors prepared in this way may also be used for painting upon porcelain, and are then carefully burned without access of air. Paintings of this kind can also be treated with water glass."



### Two "Scares" at the Front.

In the fall of 1864, after Sherman had started on his march to the sea, Confederate General Hood started for Nashville I was running the wrecking engine at the time; James Sanderson was conductor, Seth Hopkins, wrecking boss, and Charley



Burnett, fireman. We had a train-guard of forty men in command of Lieut. Theodore Wilson, of the Fortieth Indiana Infantry, and were lying at Dalton, Ga., awaiting orders.

Chestnuts were beginning to ripen, and early one bright morning, several of the men and myself took axes and started for the woods, intending to cut down some of the trees for the purpose of securing the nuts. The men had partly cut some of the trees, when we were hailed from the road by a member of the First Georgia Cavalry, (there were two regiments recruited at Dalton in 1864), who warned us to get away from there, as Hood's whole army was coming up the Resaca road. We did not at first pay much attention to the warning, thinking perhaps he had an interest in saving the timber, he noticed that we made no move to "get out o' thar" and returned to us and called me to the road to see for myself. On going out to the road one look satisfied me, for as far as I could see the road was full of Confederate cavalry.

As quick as possible we made our way to Dalton. Our scout had spread the alarm, so that when we arrived all was hurry and bustle. It was every one for himself. As the fires were never drawn in the engines, it did not take long to get steam enough to get away. We had a code of whistle signals for calling the different members of the crew, also for calling the whole crew, this signal I sounded and all the crew responded except Hopkins. I called him several times, but he did not show up. Several trains had already left. The operators had gathered up their instruments and left on the first train for Chattanooga. A report came that the tunnel, at Tunnel Hill, had been blown up and we would have to go by the way of Cleveland. Citizens were leaving with their traps. The Eighth Missouri Battery had mounted and manned the guns on the breastwork overlooking the town. Infantry and cavalry were hurrrying in every direction.

By this time we had concluded that Old Seth had skipped on some other train. Everything had left except an officers' train of five coaches and ourselves. It was now a question of who should get out first, the special or us, as usual the officers got there first, leaving us to bring up the rear.

Leaving Dalton we heard the boom of one of the guns from the battery. We passed a large number of "refugees," some mounted, more afoot; all loaded down with plunder of some kind. When we reached Varnel's water-tank, we found trains strung out a long distance waiting for water which was being pumped by two very diminutive mules. As we had a good force of men and plenty of buckets, we started a bucket-gang from a convenient pond. In this manner we got two tanks of water, one for ourselves and one for the officers' special, and the men all got a drink of officers' whisky. All this time we had been worrying about 'Old Seth."

Having an errand to the caboose of the derrick car about this time, I made a discovery. On this caboose we kept coiled a 4-inch hawser, possibly a hundred feet long; it made quite a pyramid, and was so coiled that there was a large circular opening in the center. The whole coil was covered by a canvas tarpaulin. Thinking I heard something move, I raised the canvas and there, coiled up nicely, I found "Old Seth," who put up his hand, cautioning me not to make a noise, at the same time chuckling to himself about what a safe place he had secured.

I got on my dignity and demanded his reasons for not showing up when I called

him. He informed me that he had that rope coiled in that cab expressly for the purpose he was now using it." Because, you know, George (he always called me George), that no bullet could get through this coil of rope." I told him it was not using me right to cause me so much uneasiness on his account; that we came near getting captured by waiting for him. "Well," said he, "didn't that pesky critter on the hoss tell you to 'git!'"

"But, say, George, where are we? Are we safe now, and can I come out?"

I told him we would not be safe until we got to Chattanooga, and he did not leave his safe retreat until we were sidetracked there.

We arrived at Cleveland, where all was hurry scurry to get away; every train was loaded with refugees. The fort at Cleveland was dismantled, and the guns sent to Chattanooga. We arrived there about 10 o'clock that night, and every man was pressed into the service of throwing up breastworks.

The whole thing was a scare, except for a small skirmish at Dalton, where the depot was burned and a few negro soldiers killed.

---

I want to relate a comical incident that took place at Stephenson, Ala., in the fall of 1864. It had been raining almost continuously for several days; the mud was hub-deep to the army wagons and about the consistency of corn meal batter; I was sitting on my engine reading when I was accosted by a native, a genuine mountaineer, with. "Say, mister!"

I looked out and saw in the middle of the wagon road a very lank specimen of a mule, on which was a woman and two packed baskets.

"Is there a steam horn on your kar, mister?"

"Yes," I answered, for I knew he referred to the whistle.

"Mister, will you please toot your kar horn, my wife likes to hear it"

Now, I had that whistle so it was a terror on the screech; I asked the man if it would not frighten the mule. "No; nothing ever 'scart' that mule."

With this assurance, I let her screech. In less than a minute that mule was over a hundred yards from the woman and the baskets, which were landed in the mud. The man made no effort to assist his fallen spouse; he looked very much surprised, and I said to him.

"You made a mistake, my friend, your mule fooled you."

"No, stranger, he fooled the old woman; but I say, stranger, that is the first 'pesky' thing that I ever 'seed' that would scare that mule."

The last I saw of the pair they were following after the mule.

James H. Hevey

### The Way the Yankees Tied Up a Rebel Locomotive.

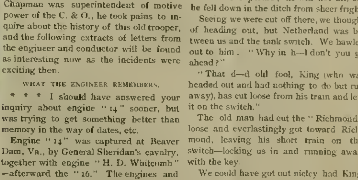
The Chesapeake & Ohio road recently cut up engine "14," one of the old timers, and a wounded veteran of the war. The "14" was wounded and left on the field for dead at Beaver Dam, Va., during the progress of the Battle of the Wilderness. Her engineer and conductor are still alive, and from them the story of her mishap is gleaned.

Some four years ago, while Mr. T. L. Chapman was superintendent of motive power of the C. & O., he took pains to inquire about the history of this old trooper, and the following extracts of letters from the engineer and conductor will be found as interesting now as the incidents were exciting then.

WHAT THE ENGINEER REMEMBERS.

* * * I should have answered your inquiry about engine "14" sooner, but was trying to get something better than memory in the way of dates, etc.

Engine "14" was captured at Beaver Dam, Va., by General Sheridan's cavalry, together with engine "H. D. Whitcomb"—afterward the "16." The engines and cars were burned and a cannon ball was



shot through the boiler of the "14" just back of her checks and under her dome. This happened while both armies were at or around Spottsylvania Court House, and just before or during the Battle of the Wilderness. I was running the "14" at the time she surrendered, but my conductor, Capt. C. S. Anderson, remembers the circumstances better than I do, and will enjoy telling you about our narrow escape and the foot race we ran through the fields and woods with the bullets of Sheridan's cavalry whizzing around our ears.

R. J. GOODWIN.

*Charlottesville, Va.*

THE CONDUCTOR'S STORY.

* * * It is with mingled feelings of pleasure and sorrow that I recall the incident of our war experience at Beaver Dam, in May, 1864.

Grant and Lee had fought along down the line from Culpepper to opposite Beaver Dam, in Spottsylvania County, when General Superintendent Whitcomb got orders to move supplies from Gordonsville to Beaver Dam.

We had everything in the shape of power that we could rake and scrape, even to the little old "Richmond," with old man King on her. Well, we got four or five trains to Beaver Dam one afternoon, and all was bustle. Some of the trains were waiting orders, some unloading, and some waiting to get up to the pile of bacon—the largest some of us had seen.

I remember that Rob Goodwin and I were on the depot track nearest to the west switch. "Lex" Netherland was just ahead unloading, and the empties were ahead of him on a long siding that has since been taken up, it ran cast, but had a "cross-over," or "run-out," near the depot.

Some one said "Three hundred Federal prisoners are coming, and in sight" At once there was a dispute as to who should take them to Richmond. We had wasted ten or fifteen minutes in this discussion, when all at once, over the country road opposite the depot and the other side of the trains, we heard firing, which increased rapidly—it was Sheridan's cavalry firing on our guard

It was some minutes before we could realize what had happened, it was all so sudden, but it lasted only a few moments, and then we commenced to figure on escape.

Rob and I wanted to back right out of the west switch, and I ordered the negro brakeman to throw the switch; he ran past the rear of the train, but a bullet reminded him of his exposure; he was not hit, but he fell down in the ditch from sheer fright.

Seeing we were cut off there, we thought of heading out, but Netherland was between us and the tank switch. We bawled out to him. "Why in h—l don't you go ahead?"

"That d—d old fool, King (who was headed out and had nothing to do but run away), has cut loose from his train and left it on the switch."

The old man had cut the "Richmond" loose and everlastingly got toward Richmond, leaving his short train on the switch—locking us in and running away with the key.

We could have got out nicley had King taken his train, as the firing was done by Sheridan's advance guard only—the main body had not yet come up.

When we saw there was no hope of getting the engines away, we all started in a general southern direction, on foot, scattering through the woods and fields.

Night soon came on, and the cavalry burned everything, the bacon lighting the country around for miles.

Bob and I stuck together, and, after dodging about for a time, concluded to go into Philips graveyard, near the cut west of Beaver Dam, and watch until the Yankees left. We were soon driven out by skirmishers, and came near being killed, the whole line firing at us as we ran down the hill. I fell into a ditch, and Bob fell down on top of me, but I laid low; it was dark, and I thought it was a Yankee, sure. Bob seemed to think I was a "Yank," for he got up and ran like a whitehead.

I ran, too, but in a somewhat different direction; we came together after a while, and went to the house of the father of one of the railroad men named Hall, and spent the rest of the night.

We trudged back to Beaver Dam the next day, getting in there in the afternoon. We found that about thirty-five cars and all the engines had been burned; all the car irons lay on top of the trucks, spaced off the proper distance, like skeletons, just where the fire had left them.

I remember the "14's" cannon shot; it was an ugly looking hole right through the boiler; I never expected to see her run again.

Mr. King and the little old "Richmond" received great praise and glory from the public for their nerve and daring in making their escape, but they got many a curse from us for running away and leaving their train in front of us.

CARTER S. ANDERSON.

*Richmond, Va.*

The "14" was an 8-wheeler; cylinders, 15x22 in., 60-inch drivers, and weighed 55,400 lbs. She was built in June, 1855, by the New Jersey Locomotive & Machine Co. at Jersey City, N. J. The engraving shows form of boiler and the patch over her "wound."

## New Shops for Cedar Rapids.

The Burlington, Cedar Rapids & Northern Railway Company are about to expend $100,000 in making shop and yard improvements at Cedar Rapids, Ia. Among the things to be done are the building of a new car-erecting shop and a new twenty-five-stall roundhouse. Both buildings will be put up in first-class style, and equipped with the most approved tools. Beside the shop there is a large stagnant slough, which is a source of disease to the shop men and to the citizens generally. A great portion of this will be filled up and turned into yards and sites for buildings.

The new car shop will be 221 x 86 feet, and 32 feet in height. It will be of brick, with an iron truss roof. The shop will have a capacity of 22 box cars per month, if the company should decide to build their cars. For some time to come it can be kept busy with repairs.

The Supreme Court of Texas has rendered a decision that ought to rouse every railroad man in Texas to demand an amendment of the law. The case was know as that of Turner *v.* Cross & Eddy, Receivers of the Missouri, Kansas & Texas Railroad. John Turner's mother was suing for damages for the death of her son, who was killed on the railroad named. The case went to the Supreme Court on appeal, and the judges decided that the receivers were not liable to pay the damages because the law mentions specifically as liable owners, proprietors, etc., but says nothing about receivers. The decision is an iniquitous straining of a technicality to defeat justice. The first thing that Texas railroad men should do is to have the wording of the law amended to take in receivers. Their next duty is, to have judges appointed to the Supreme Court who are not likely to strain the law to favor corporations and against popular rights.

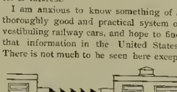
Col. Hain, of the New York Elevated roads, has issued an order prohibiting the practice of chewing tobacco by the trainmen, and it is stated that among other questions asked an applicant for work the one, "Do you chew tobacco?" is an important one.

## From Holland.

*Editors:*

I have long been an interested reader of your valuable paper, and note that in your new heading you include "rolling stock," so I expect to have your opinion on a matter of interest.

I am anxious to know something of a thoroughly good and practical system of vestibuling railway cars, and hope to find that information in the United States. There is not much to be seen here except



in some spare cases, such as the state trains of monarchs, where leather bags of accordion shape are being used.

I would be much obliged if you could give me any information, either print or drawings, of these weather-proof inter communications between railway cars as used in America.

TH. A. BERTRAND,

Managing Engineer Dutch State Ry. Shops, Loco. and Rolling Stock Dept.

*Utrecht, Holland.*

[Our illustration shows the modern American vestibule, the photograph being taken from the Pennsylvania's limited train. The end platform and entrance to American cars makes the vestibule particularly adapted to them, the hood or roof extension over the platform is strongly framed and able to carry the top of the vestibule extension. The combined door frame and friction plate in this style of vestibule, the Pullman pattern, is made of wrought iron about ¼-inch thick and 6-inch wide on the face; this frame is supported and pushed out from the end of the car by four rods running back into spring pockets in the car frame. When the cars are coupled together these door frames of iron are pressed closely against each other, making a very tight joint, but permitting of free movement of each car. The platform proper has folding doors on each side into the vestibule; over the ends of the platform and to the front of the vestibule, as well as on top, a rubber sheet, folded like an accordion, is used. The Wagner vestibule is like the Pullman in appearance, but has no buffer springs to secure contact; the door frames are free to move, within certain limits, and are clamped together, the movement due to running being all accounted for in the rubber connections. These vestibules are lighted, and have a rubber mat from one platform to the other; it is perfectly safe and easy to pass from end to end of a vestibuled train; keeps the cars clean from cinders and prevents fully one-half the noise being heard. Vestibule trains, however, are more difficult to ventilate properly.]

## Boiler Explosions—The Cause and the Remedy.

*Editors:*

When a boiler explodes it is always from *one cause*, and that is, *the strength of the boiler was not equal to the strain that was brought to bear upon it.* There are very few cases on record where there was any undue pressure on boiler at the time of explosion, and that proves the fact that nearly all explosions result from depreciation of strength of boiler during its time of service.

The question is often asked, "Who built the boiler?" which often leads to an unjust criticism upon the maker. The question that should be asked is, "Who has had charge of the boiler since in service?"

The deterioration of boilers occur from many causes. Some that may be termed *natural*, and many that should be classed *unnatural*. The former come under the head of unavoidable and the latter negligence.

When boilers are constructed in a form best suited for durability, they require much less attention than other boilers, which are constructed so that it is possible to use them under special conditions, regardless of form. This type of boiler is often used on locomotives, and are limited to a certain space and width of fire-box, regardless of size of the cylinder part of boiler. The 40-inch boiler has the same width of fire-box as the 72-inch, and this prevents the possibility of having a good design of boiler.

When the shape of any boiler is such that an undue strain is put upon it with every change of heat or pressure, it then commences to tear itself to pieces as soon as it goes into service, and the difference between the life of such a boiler and one of the best form possible is as great as the difference between old age and quick consumption.

It is out of the question to have all boilers made in the best form for durability, and meet the many requirements that are demanded of them, and when this fact is plain it then becomes the duty of those having charge of boilers to govern their work accordingly.

The worst form of boiler can be kept in safe condition by proper inspection and repairs, the cost of which will be in proportion to the form and amount of pressure carried. One of the greatest troubles that exists in having boilers cared for, is that those having charge of the work will base their opinion and actions on who made the boiler, and how long some other one has run without repairs, not taking into consideration that they are of very different form and in different service.

When you come to the locomotive boiler, it will be seen that nearly all explosions are caused by the failure of stay-bolts, and when this is not the cause the next most prolific cause is the hot crown sheet, which becomes weak by over-heat, and the result is it goes down, leaving the stay-bolts. The only remedy for this is to keep water on the crown sheet when there is a fire under it, and that is much less trouble than it is to always keep good stay-bolts in a boiler, which is one of the most important points, and requiring more judgment than any other thing in the care of boilers. It can only be done by constant inspection by careful and competent inspectors, the best of which will make some mistakes, but when doing so they will generally be on the side of safety, as in case of thinking that a bolt is broken when it is not, this always results in getting a new one in place of an old one, which if not broken, is much more likely to break than one just put in.

There are many locomotives now running with boilers from twenty to twenty-five years old, and are apparently good, and in fact prove themselves so by not giving any trouble. Such boilers have been cared for properly, as the design of them warranted.

When those having charge of boilers become aware that different forms of them require different care, then and then only will the number of explosions become less.

In the majority of cases the builder does not have anything to say about the form of the boiler he makes, and when anything happens to one through negligence in its use and care, then the builder is often unjustly censured.

This idea of economy in using high steam, as is done by many, is one of the most fruitful sources of the deterioration of boilers; for in many cases where it was intended to carry only 125, when engine was new, they have been loaded down to 150 after many years' service, without making any extra provision for strength, except giving the engine a repair and painting. Every cause will produce an effect. How long must this state of things continue?

FAIR PLAY.

*Philadelphia, Pa.*

## Metallic Packing Diseases.

*Editors:*

Your answer to Question 16 in February number is just a little misleading. You say run without anything or disconnect. What's the matter with replacing the worn-out rings with hemp? This can be done by taking off the gland and spring, and filling the stuffing-box with whatever may be handy in the shape of packing; this will answer to get engine and full train over a 200-mile division. It will be necessary to disconnect the valve-rod from valve-stem, in order to get spring out of box, and the same will have to be done with the piston. You will, no doubt, say this kind of work would not be practica-

ble, but under ordinary circumstances, valve-stem or piston can be changed from metallic or spring packing to the old style of hemp, or "hay consumers," in twenty minutes. "NEMO."

*Marquette, Mich.*

[We should say decidedly that taking piston-rod out of cross-head on the road was impracticable; the valve-stem might do. If Jerome packing is used new rings can be put in at any time without disconnecting stem or rod. With small chance to compress fibrous packing into a hole recently occupied by metallic, we have little faith in its staying there long. We tried it.]

## How Much of a Machinist Should a Locomotive Engineer be?

THE MACHINIST END OF THE QUESTION.

*Editors:*

Clinton B. Conger, Esq., has an article on this ques ion in your February number, and throws down his gage to the machinists by saying "Let us hear from the machinist end of this question." I humbly accept the challenge, though I fear I will prove but a poor champion.

In the first place, I am a machinist who believes that it is not absolutely necessary for an engineer to be a machinist also, but I see no good or valid reason why a machinist should not make as good a man with an engine as a man from off the farm, or out of the wiping gang, sand-sifters, or coal-heavers, from whose ranks the engineers, as at present constituted, are largely recruited. It seems to need no argument to prove this; it is patent of itself; yet we hear it constantly asserted that machinist runners "are no good;" on the other hand, most machinists insist that no man but one who thoroughly understands the machine should be allowed to run it. I differ from this view, because it matters not how expert as a machinist you are, if you are so fortunate as to be running, you are not expected to work as a machinist in these days, but experience as a machinist ought not, and I think cannot, justly be considered a drawback to such a man, while I can't see that a man's experience as a farmer, or a sand-sifter would be of *any* advantage to him as an engineer; therefore it follows that the machinist is, or should be, the better man.

The machinists are not the only men that fail as engineers; the only thing that gives color to the accepted belief that machinist runners "are no good" is the small proportion of them that ever get a chance, hence the failures are made more conspicuous. I would like to prick that fallacy expressed by Mr. Conger: "He is then more apt to think of the way his engine is built, her weak parts, and how to help them, than getting his train in on time when late." This is a delicious morsel that the anti-machinist men lay close under their tongues. I have heard it time and again, and I am sure there is no more misleading slander against the machinist than this. The engine is not expected to break down, no man can tell when she will give way, unless it be some disintegration that would be plain to any one, no one understands this better than a machinist, consequently I am firmly of the opinion that our machinist-engineer doesn't trouble his brains about what, when, or where she is going to give out.

I have seen an engineer set a jack under the back driving-axle to jack the engine up in replacing her on the track. I have seen an engineer in taking down side-rods work himself hard for a half-hour or more trying to get the keys out so the straps would pull off, when in this case the keys were no obstacle to taking off the straps, as it was the back ends he was taking down, and the key was back of the pin, the keys fitted snug, and were burred a little by set-screw. I have seen an engineer report that his injector-throttle could not be opened, when it was already wide open. An engineer once wanted me to tighten down the expansion-plates so they couldn't work. Another one asked me to tighten down bottom end of right-heel brace, "it kept working." I explained to him that it was built that way, and was doing just what it ought to do; "Then, for God's sake," he said, "fix the left one, so it will work, for it is tight." I knew an engineer who was unlucky enough to slip an eccentric, and he absolutely knew nothing of how to proceed to set it; he threw away every wrench on the engine and was towed in; because he had "no wrenches to fit the set-screws," he was discovered in this ruse, and discharged for it. Now, I submit that men who aspire to run locomotives should at least be machinist enough to avoid such shallow pitfalls as these.

Now, there is no denying the fact that the large majority of engineers are fully the equal in lack of mechanical ability of the several individuals mentioned above, hence the strenuous efforts put forth by some of the more progressive ones, such as Mr. Conger, John A. Hill and others (who certainly, by their faith and works, prove the necessity of it) to bring them up to a higher standard, which is a point we should all strive for, both machinist and engineer; and while it is not necessary for an engineer to be a first-class machinist, I am decidedly of the opinion that the engineers' standard of excellence could be improved in no better way than by admitting machinists to the degree of the "eagle-eyed."

And, now, a word of apology. I hope I have given no man umbrage in this article; I had to draw the contrast sharply between engineer and machinist to make points clear. I think the man who has risen from an humble station to a higher one is more entitled to honor than the one who had a better start in life. I have more respect for the "Prince on the dung-heap than the beggar on the throne;" if you will allow me to reverse the proverb, or, perhaps, the old and often-used lines

"Honor and fame from no condition rise,
Act well your part, there all the honor lies"

suit better.

W. H. WESLEY.

*Nashville, Tenn.*

## Tool for Grinding Inside Check-Valves.

*Editors:*

I got up some time ago a very useful and convenient tool for grinding inside check-valves on the boiler, and, thinking it might be interesting, I inclose drawing and description, from which it will be understood:

A is a round, steel rod, one end bent to form a hook, and a crank fastened to the other end, as shown; D is a round handle, turning freely on A, between collars B and C, fastened tight to A by pins, as shown.

In order to grind a valve, the tool is held in the left hand by D; the hook is hooked in the valve, and the valve is turned by the crank E with the right hand.

Any desired pressure can be brought to bear on the valve with the left hand, while with the right a steady rotation to the right or left can be kept up. By the use of this tool a valve can be ground much more quickly and thoroughly than by the use of the old-style hook, worked backward and forward with one hand.

DAVID M. PERINE.

*Baltimore, Md.*

## Keying the Main Rod.

*Editors:*

In your answers to correspondents, No. 18, you say the "lower back or forward upper eighth is the proper place to key the back end of main rod brasses." I beg to differ with you, and will give my reasons. There is comparatively no strain or pressure on main pin on the *center*, hence that is the largest part of the pin and the *proper* place to key the brasses. The reverse is the case with the wrist-pin or front end of main rod. Owing to the up and down motion of back end of main rod the wear on wrist-pin and brasses is in a line with center of cylinder and axle (in a horizontal engine), and pin is smallest there, and would be a bad place to key up on; hence the proper places to key main rod is on center for back end, and quarter for front end. Prove this wrong and I'll apologize. E. J. RAUCH.

*Manhattan Shops, N. Y.*

[It goes without saying that the greatest wear on the main pin will be at the point where it bears the greatest pressure. That this point is the dead center it is not hard to prove. When the piston is at or near the dead center there is some pressure on it due to compression, and this is supplemented by the lead, and steam is admitted at this point nearer to boiler pressure than at any other. All indicator cards show the highest pressure when the piston is leaving the end of the cylinder. From the center to nearly the end of the stroke the pressure diminishes. This is as true of the front end of the rod as of the back end. We believe that all will agree that the brass should not be keyed across the narrowest part of the pin, and this is certainly at or a little past the dead center.]

## A Presentiment.

*Editors:*

It is an old maxim that coming events cast their shadows before. I will relate a circumstance which happened to me, my life being undoubtedly saved by being forewarned of danger. During the spring of 1871, I was running engine 71 on the M. & O. R. R. I was pulling the express train between Jackson, Tenn., and Columbus, Ky. I would go north in the morning and south at night. We left Columbus one evening about 6.30; black clouds appeared in the southwest and the thunder and lightning was terrific. I had only gone two or three stations when the rain came down in torrents; sometimes the wind seemed as though it would blow the engine and train off the track, at other times there would not be much wind but the lightning was terrible. But I ran along on time until I got about two miles south of Dyer station, when I saw the top of a large tree on the track. I called for brakes and reversed, but could not stop until I went through it; but it did no damage except battering up the steam-chest and cylinder casing. We lost a little time in clearing out the limbs from under the cars, and as I came into Trenton a perfect hurricane of wind and storm struck us. I could hardly find the station; I could not see the smokestack, but it was over in a few minutes.

As I was leaving Trenton, about the time I passed over the south switch I pulled out my watch to see the time, and I said to myself "Eight minutes behind time." About that time it seemed as though I was shocked with electricity, and something said to me: "Yes, and a big tree across the track ahead of you."

I was sitting on my seat, and this shock seemed to weaken me so I don't think I could have lifted five pounds, but in a few minutes was all right again. I was fully satisfied in my own mind that I would find a tree across the track before I got to Humbolt. By the flashes of lightning I could see the track as far as though it was daylight. I kept on running at a good rate until the storm got far behind me, and the flashes were very dim in front. By that time I was within two miles of Humbolt. Then I had a field to go through of about three-quarters of a mile; then it was heavy timber to the north switch at Humboldt. Just before I got to the timber, I shut off steam and let her roll along slow. After I got in the timber about a quarter of a mile, I was running not more than seven or eight miles an hour, it was sprinkling rain, just enough to keep my headlight glass wet, so I could not see more than about fifty feet ahead. I was standing up with my head out at the side window and my hand at the reverse lever, when I saw a tree about one foot in diameter lying across the track.

I then immediately reversed and gave her steam. She struck the tree and shoved it about four feet; then she stopped. It mashed the pilot back under the trucks, and turned the trucks crosswise of the track. This tree lay within fifteen or twenty feet of a deep ravine, with a culvert in it, and had I been running at my usual speed along there, the engine would have certainly turned end over end; then my fireman and myself would have had a poor chance of saving ourselves from a sudden death.

Conductor James Bright and Superintendent M. M. Miller, who was on the train, came out to the engine, and Mr. Miller asked me what was the trouble. I told him I ran into a tree and was off the track. He said, "Did anyone flag you?" I told him no. He said, "I don't understand how you happened to be running so slow." I told him I understood it. We went to work and got the engine on the track, and went in a couple of hours late. I did not tell anyone that night about being warned of danger, but the next trip I told Mr. Bright all about it, and he said he could not help but believe me. James Bright is now keeping the Robinson House in Jackson, Tenn.

If anyone has any doubt about this story being true, I will swear to it if they wish me to. ALEX. CUNNINGHAM.

*Pine Bluff, Ark.*

## Releasing of Brake When Valve is "On Lap."

*Editors.*

I ask the question: I reduce ten pounds, place the valve on lap, and the air in drum and train-pipe equates and brakes release. What is the matter with engineer's valve? WM. LANSING.

*Clinton, Iowa.*

[Probably air leaks under the main valve.]

## Storage Electric Car Lighting.

*Editors:*

As a matter of information, I wish to advise that we have been testing for the past two weeks a storage electric light system on two of our cars running between Cincinnati and Washington; one combination passenger and baggage, and the other a coach, the coach having eight 16-candle power lamps, and the combination car five. The coach is equipped with 24 cells of W. L. Silvey's storage battery, the combination 12, which are placed in crates of 6 cells each. These crates are placed in boxes, bolted to the bottom of the car at right angles to the length of the car. The batteries are charged at Cincinnati and will make the round trip between Cincinnati and Washington, giving us between thirty-five and forty hours lighting, full candle power of the lamps. The batteries can be changed in a train of five or six cars, by two men, in less than an hour's time. Enough batteries for fifty cars can be charged in the same length of time as it would take to charge for one car. It will take from eight to ten hours to charge the batteries to their fullest capacity after having been exhausted, all of which can be handled by one dynamo engineer and electrician. The lights are simple and are very easily manipulated. The ordinary trainman can operate them without any difficulty or any liability of damage to the system.

I am of the opinion that this light can be produced at a much less cost than the present system of electric lighting, where electricity is generated by a dynamo in the train. The Silvey storage battery is a

new device and has until recently been unknown. I consider it nearest to perfection of any I have seen. There is no danger with this battery of plates bending or buckling, which has been a great source of annoyance with all other batteries that have been used for this purpose.

I give you this as a matter of information, thinking perhaps you would like to look into the subject more fully. Mr. Silvey or our Mr. Haller, at Covington, Ky., would explain the details of the system.

W. GARSTANG,
Chesapeake & O. R. R.

*Richmond, Va., Feb. 3, 1892.*

## How to Thaw Out an Engine.

*Editors:*

An experience I had some winters since may be of benefit at some time to some reader of LOCOMOTIVE ENGINEERING in the cold, frozen North, and while the topic mentioned above is a seasonable one, a relation of the circumstance will go to show that an engineer can sometimes learn of a division superintendent, provided they get near enough together and are both in a frame of mind to give and receive information.

At the time of which I write I was going West on freight with a little old 16x24-inch "Tweed"—the 69, I believe. There was a heavy fall of snow on the ground, with the "cuts" full and flanges "bad."

This particular engine was a great student of the Signal Service reports, and no sooner was a snow-storm bulletined than she would begin to skip and dance in anticipation of the first "beautiful" she should find on the rail, and when she struck a drift or a frosty rail she did not seem to weigh a pound.

The weather had been favorable all day, but as evening approached the air showed indications of a change, and an hour later we were in a veritable blizzard, slightly broken by a small body of timber. We had arrived within about ten miles of the end of our run and the remainder of the trip lay over an open prairie, where many a better engine and more experienced engineer had "laid quietly down" and waited to be "shoveled out." We had two cars of live stock in the train which it was very desirable to have brought through to the division station, and on our arrival at "The Springs" the train dispatcher asked us if we thought we could get through with the stock and caboose. We were in a valley surrounded with timber, and it was a difficult matter to judge of the force of the storm on the open prairie; besides, there was a good supply of water there, and we had coal enough for several hours of standing on the side track, and there were good boarding accommodations at hand. So, after taking in the whole situation, we "wired the office" that we considered it extremely doubtful. However, we got orders to take the stock and come ahead.

The first mile and a half was up a 50-feet grade, and by the time we were at the top of the hill it was apparent to "Charlie" and I that we had undertaken a big job. The old 69 had been nobody's pet for a good while, and no friendly hand had chinked up the holes and cracks about the cab as is usually done by men on regular engines in that latitude in the winter season. The result was that myself and fireman did not see each other from the time we struck the first drift until we stopped on an open piece of track about four miles from the start. The fuel was about equal parts of snow and coal, and with the engine slipping it was not surprising that the steam pressure was low, as well as the water line in the boiler. We had a short piece of clear track on a down-grade for a start, and, after filling her up with water and getting her "hot," we started to make the final run that was to land us at home or —— elsewhere, and "elsewhere" caught us. We were now less than three miles from home, at about ten o'clock at night, with the wind blowing from the northwest over an unbroken plain, and colder than "Jehu." We had plenty of water and some coal, and there was nothing to do but make ourselves as comfortable as we could and keep the old kettle alive as long as the fuel held out or until a "rescuing" party arrived. Next morning a section gang arrived "overland" and assisted in getting hay and corn for the stock, and from a farm-house near by we got a substantial breakfast. It was still cold and blowing, but not snowing. About noon the supply of coal gave out, and we proceeded to lay the "old girl" out in the regulation style. We took everything down on the left (south) side preparatory to being "towed in," but put off our attack on right side until the weather had modified as much as possible. The engine was almost a solid mass of ice and frozen snow, especially on the north side, and, when late in the afternoon a "snow-bucking" outfit showed up and the disagreeable job of disconnecting that side could no longer be delayed, I applied the regulation invigorator—burning waste saturated with kerosene—to the mass of ice and iron; it made about as much impression as a parlor match would on a cupola charged with scrap-iron. It is needless, perhaps, to say that when the rescuing party arrived the noble 69 was not ready to "tow," and your humble young engineer was not a little embarrassed, the more so as Division Superintendent Fred. Underwood was with the party. Upon his inquiry as to what was the matter, I explained that owing to the "froze up" condition of things I could not get her disconnected on the right side. The superintendent took a brief survey of the situation, and soon noticed a pile of hay that had been left after feeding the stock, and he at once directed the men to bring it and distribute it about the engine. We tucked it in around her links and eccentrics and machinery in a way that reminded me a good deal of the way I used to fix the schoolma'am for a trip to spelling-school not so many years before. The torch was applied to that hay, and the way the ice slid off of that old "scrap pile" was a sight to restore the circulation in the veins of a benumbed engineer. It is surprising how little hay or straw is required to do the work, and the secret of its success is that it burns up quickly, warming all parts at once, and goes out before any of the parts become overheated. We had to use a few shovelfuls of snow to protect the running-boards, and did not put any hay far enough back to affect the cab.

This remedy is not applicable where depots or other inflammable structures are in close proximity, as the afore-mentioned superintendent informed me he used the same means to liberate some engines frozen in alongside of a coal-shed on the S. M. once, and it brought the engines out all right, but they had to "hustle" to save the coal-sheds. This same superintendent was, the last I knew of him, burning Ha—vanas in a better position on the "Soo Line," and I have emigrated to a clime where the snow-balls do not cluster in such luxuriant profusion.

AB. TUCKER.

*Chillicothe, Mo.*

## Road Tests of Air-Brakes.

*Editors:*

Correspondents of the two preceding numbers of this paper have very different ideas about the testing of air-brakes, each stating a certain reduction of train-pipe pressure as necessary to a satisfactory test.

Cars arriving at terminal or lay-over points, shop tracks, etc., should be given a "repair test" by applying the brake from the different indicated points of the brake-valve, and should receive a thorough inspection, and, when necessary, oiling and adjustment.

A "service test" should follow a change of engines or any change in the make-up of a train, as adding cars, cutting train, etc., and is intended to make sure that the pipe line is open continuously throughout the train, and that all brakes will apply and release; it is neither a fitting time nor place for taking down a triple valve, and if sufficient cause exists, cut out the car; but if a triple fails to graduate and goes full on at service application, the type of triple should determine the proper course; if a plain style of valve, non-graduation is better than no brake on that car, but if a quick-acting triple it had best be cut out and reported.

Passenger train stops are short as possible, and when engines only are changed a light application of the brake will show their condition and insure a quick release and quick departure.

When the inspector calls for the brake about ten seconds before leaving time, there are engineers who discharge all of their train-pipe pressure with an emergency application, and if some brakes fail to release, declare that "those new quick-acting triples are no good—always sticking on you."

But another case, where a through train changes engines and is inspected after backing in on two additional cars. After the train has been inspected, the fresh engine is coupled on and the inspector calls for the brake; the auxiliaries of the two rear cars contain no pressure except the small amount drawn from train pipe of the other cars, and there is no time for changing, so the train-pipe pressure must be completely discharged in order to apply the two rear brakes.

Any orders or instructions regarding service tests of brakes must be ignored oftener than obeyed on roads where time and avoidance of delays are of any consequence. Instructions to men handling and inspecting air brakes should be information as to the construction and operation of the brake, allowing them to use their own judgment, and bearing in mind that cases are governed by varying circumstances, some of which are not apparent to one not thoroughly acquainted with the running of trains.

In the January number Mr. Synnestvedt states that cases have come to his notice similar to the one by "Black Hills," and gives as the cause a broken guide-pin of graduator, but it would be interesting to hear an explanation from Mr. S. how such a defect in the graduating valve would delay action of the brake on that car for a half minute after each service application on a three-car train. With an eight-pound reduction of train-pipe pressure, the triple will instantly respond, and with auxiliary pressure sufficient to overcome the resistance of the spring, why the delay?

In answer to G. H., January issue, question second contains the statement that "when the lever of the engineer's brake and equalizing discharge valve is thrown to the emergency stop, both gauges are shut off from their supply of air."

This error must have been intentional and to excite discussion. The red pointer of air gauge is connected direct with main reservoir pressure, and its supply of air can not be shut off by any movement of the brake-valve. Applying the brake at either service or emergency stops will relieve the governor and allow the pump to increase its speed, running up a higher excess pressure in main reservoir, which must be and is registered by the red pointer.

## A Lubricator Puzzle.

*Editors:*

I have a little conundrum for the boys concerning a lubricator. It puzzled me for a while, and I would like to hear what the lads have to say on the subject.

I made the run of 85 miles; my lubricator worked all right for that distance; when I arrived at the end of the division I unscrewed the feed-valves and cleaned out the glasses, my fireman shut off all the connections and filled the lubricator. When we were called to go out about six hours later, our lubricator was only two-thirds full; my fireboy asked me if I had let any of the oil out of the lubricator while our engine stood in the roundhouse. I told him I had not. We thought that some of the roundhouse men had let it out, but got out of the house and hooked on to our train. From the yard for 7 miles is a heavy up grade; when I got to the top of grade the oil was all gone out of my lubricator. I could not account for the disappearance of the oil, for I knew that it had not gone out of the feed-valves.

I refilled the lubricator and tried it again. Before I had gone 10 miles it was all gone, but this time I watched it and found out what was the matter, and fixed it in ten minutes. Now what was the matter with it? Would say that the lubricator is a Detroit of improved pattern.

## Conger's Puzzle.

*Editors.*

In answer to C. B. Conger's puzzle No. 1, in January issue, would say that after the eccentric strap bolt broke it allowed the strap to spring open, and as a consequence the eccentric could not move the bottom rocker arm back a sufficient distance to uncover the front steam port to the exhaust, which resulted in the advancing piston compressing the imprisoned steam up to a pressure sufficient to blow out front cylinder-head.

As to puzzle No. 2, would suppose that top gauge-cock stood full of condensation, and owing to the small opening at boiler end it took some time before it would show steam.

G. P. CASS.

*Monett, Mo.*

*Editors:*

In answer to C. B. Conger's puzzle regarding the broken cylinder-head. When the bolt parted it would leave the front port open, the strap being so loose on the eccentric, the valve would not travel far enough forward to open the exhaust, and the piston going forward on the steam contained in the cylinder caused too much pressure for the weakest part—the head—and blew it out.

E. A. SIDDALL.

*Oxford, N. S.*

*Editors:*

The steam that was between the piston and cylinder-head could not get away. The momentum of the engine forced the piston against the steam, compressing it until there was more strain on the cylinder-head than it could withstand, and it gave way. I have known the same thing to occur, and could not account for it in any other way. Some persons would say that the steam would force the valve off its seat.

W. W. L.

*Hampton Junction, N. J.*

THE ANSWER.

*Editors:*

In regard to the two easy puzzles on page 17, in the January number, there may be a difference of opinion as to the cause of the cylinder head breaking. After the eccentric-bolt broke at top of strap and let the strap open out the valve stopped in back end of steam-chest leaving the forward port open to the live steam and piston traveling against it. This made a great strain on the front head, as it was the weakest place it gave way.

Right here I would like to inquire if it is possible to have valves set so as to give excessive compression after exhaust closure and shear the bolts in forward end of main rod?

The gauge-cock (second question) was stopped up at the end inside the boiler, so there was a very small hole in it; it was then almost full size for 2½ inch and very small at seat of valve. Possibly this passage filled up with water from condensation, so it showed clear water when first tried, and after that was blown out the

steam came through so small a hole in the end it condensed some before getting out. This cock was bored out clean the entire length and gave no more trouble, so it is fair to charge its peculiar action to being stopped up with scale. This case emphasizes the danger of allowing gauge-cocks to become stopped up, as the correct water level will not always be shown.

## Square Engines.

*Editors :*

It has cost railroad concerns a lot of money to get and keep their engines exhausting square, keeping them to suit the delicate ear of their engineers. There has been much thought on this subject and much ingenuity displayed to attain this "ideal" of perfection.

The remedies used have been legion and I will name a few.

There are some that have put on square exhaust-nozzles thinking, no doubt, that it must sound square coming out of a square hole. Others, finding that this was not a panacea, thought that it was not the outlet that should be square, but that it was the steam itself that should be made in square chunks, and to do this they use a Belpaire fire-box, which is square in the place where most of the steam is made; and when this failed others used the square fire-box and nozzles both, and are not happy yet.

Now it is right here that I would like to make a few suggestions. When the square fire-box is used and the steam is generated in square chunks, the things have a good start and ought to succeed, and probably would if these square chunks of steam did not get their corners knocked off when going through the steam pipes which are all made round. Why not make them square, also the cylinders the same. You know the ports are all right without any changing. Now if this will not accomplish the desired end, why not?

It seems a pity that this matter should stop short of final success after so much expense. Unless one can get good square steam from a Belpaire fire-box it will never pay to use them, for their first cost is much more than other makes and repairs are much more; for example, out of twelve engines on the New York Division of the P. R.R. which are comparatively new, they have nine or ten patches on them up to this date, and the standard engines which are doing the same service and have been for years are without a patch on them. Why is the Belpaire boiler used?

## Air-Brake Points.

*Editors :*

I like the interesting discussions on the knotty air problems in your valuable journal, and if I could get my arguments on paper in a composed or readable shape, they might be of some benefit to some straying ones that have fallen short of a clear understanding of the quick-acting air. But as a writer I fear I am a failure. G. H. makes a very plain statement on air in the February number, but he must not persist in drilling that hole through close to the seat of feed-valve 21, or he will do just what us farmers would call opening a slip gap in a G-rail fence between the goats and the sheep; both become one common herd; besides he would throw a good twenty-pound spring out of a job.

The answers to the question as to what causes the blow from train-pipe exhaust after handle has been thrown back to full release, after a service application of brakes, is plain both in question 1, January, and G. H. in February. Take a engine and tender with no train, exhaust 10 or 15 pounds of air, service stop; when stopped push engineer's handle to full release; air is restored into train-pipe from main drum through large cavity in rotary valve in a single flash, and, of course, comes around under piston 17, raising it off its stem of the seat and holding it off, causing the blow, until air going more slowly down through the two small holes into chamber D, on top of piston 17, and filling the little drum under foot-board, then equalizing pressure, getting the most pressure on top of piston 17, and seating it; this blow will be long or short, in proportion to the air exhausted in service stop.

Some good air manipulators have claimed that this blow was caused by a wave. When the engineer's handle was pushed into full release, air from main drum would go with a rush against angle-cock at rear end of tender, coming back in a wave and unseat piston 17, but this can not be, for no wave can come against main drum pressure.

Here is where a wave comes in, and it will knock off two, three or five brakes next to the engine in a fairly long train. Bring engineer's handle around and give a quick dip into emergency and stop on lap; this starts a rush of air out of train-pipe emergency port, and cutting it off so quick, not letting enough air out to start emergency valve, and stopping the rush out all of a sudden a wave is thrown back by the pressure concentrating at the hole it was escaping at, and throws off the triple-valve, releasing brakes on the cars next to the engine.

Here is another way of throwing a wave back, and some enginemen make the mistake of doing it, mostly in long trains. Take a train of fifteen to thirty cars, all equipped with quick-acting brakes; it requires the weighing or letting out of 6 to 8 lbs. at preliminary port for a service stop for a train of twenty or thirty cars, but as it only required a little over 8 lbs. of train-pipe air to run out at train-pipe exhaust port for one car, it will require for a 30-car train thirty times as long for the air to run out of train-pipe exhaust.

The engineman gets uneasy at this long-continued blow or exhaust of train-pipe air, thinks he is losing his train air and pushes his handle from "on lap" to between running position and lap, with the handle spring on the bridge or lug between running and lap position; this immediately stops the rush of air out at train-pipe exhaust port, and the air being cut off again so suddenly at its exhaust hole it piles up and waves back again, raising the triple pistons and releasing brakes on the cars next to engine.

As this stopping of flow of train-pipe air and kicking off the first brakes at front end of train is not exactly done in the same way, but with the same effects that dipping into emergency air has as explained.

Will some one handling the improved equalizing discharge-valve on long trains see how near he can come to explaining just how and just what stops this air in its mad rush to get out and causes the wave back? It is plain when understood.

## Diagrams of Locomotive Starting.

The indicator diagrams here shown, for prints of which we are indebted to Mr. Theo. N. Ely, General Superintendent of of Motive Power of the Pennsylvania Railroad, give an interesting illustration of the defects of the link motion as a valve-gear for locomotives. The engine from which the diagrams were taken was class A of the Pennsylvania Railroad, with cylinders 18x24 inches, the purpose of the experiment having been to determine the difference between valve ports 16 inches long and 17¼ inches long.

When the diagrams shown in Figure 1 were taken the reverse lever was put in a notch, where cut-off at one end took place at 10⅛ inches, and the other end at 8¼ inches. The engine was started with the lever in this position, and the full line diagram marked 1 was taken in starting. Diagram 2 was taken after 10 seconds, with 5 revolutions per minute; diagram 3 was taken after 20 seconds, when the engine was making 14 revolutions per minute; diagram 4 at the end of 30 seconds, with 26 revolutions per minute; diagram 5 at end of 40 seconds, while the engine was making 40 revolutions per minute; diagram 6 at the end of 50 seconds, with 58 revolutions per minute.

One of the leading stereotyped objections raised against the link motion is, that when the link is drawn up to cut-off early the point of release is made so soon that loss of power and loss of steam result from the valve being opened long before the piston reaches the end of the stroke. If an engine was worked at the slow speed made in the first revolution, this objection would hold good. Release takes place at A (Fig. 1), when the piston has more than one-quarter of its stroke to move, and the steam escapes so quickly

*Fig. 1.*

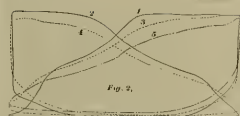

*Fig. 2.*

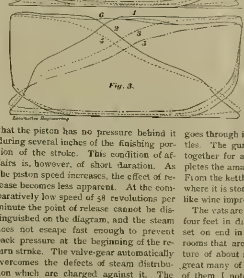

*Fig. 3.*

that the piston has no pressure behind it during several inches of the finishing portion of the stroke. This condition of affairs is, however, of short duration. As the piston speed increases, the effect of release becomes less apparent. At the comparatively low speed of 58 revolutions per minute the point of release cannot be distinguished on the diagram, and the steam does not escape fast enough to prevent back pressure at the beginning of the return stroke. The valve-gear automatically overcomes the defects of steam distribution which are charged against it. The successive diagrams show a highly interesting picture of how perfect steam distribution is brought about.

In Figures 2 and 3 the pencil that formed diagram 1 was applied after the engine had made two revolutions. Figure 2 was taken with the lever in the 12-inch notch. The point of cut-off being more protracted, the period of release comes later than in the other cards, and so the drawbacks of early release are not so pronounced. In the cards shown in Figure 3 the cut-off does not occur till about 15 inches, and the release is then delayed until there is just merely time for the steam to escape from the cylinder before the return stroke commences. Increase of piston speed with this late cut-off soon shows back pressure at beginning of return stroke.

We regard these diagrams as new testimony to the merits of the link motion. They demonstrate that the motion is only defective when worked in a way never followed, and that it automatically improves as speed increases.

## Where They Make Fine Varnishes.

Travelers who keep their eyes open will see, when passing up the Detroit River, a village of buildings to the left about two miles north of the Michigan Central ferry at Detroit, with "Berry Brothers Varnishes" displayed in conspicuous lettering. There are few railroad shops where the product of these works are not known, and it may interest our readers to learn some particulars about the place.

Varnish does not appear to be a complex article, yet a visitor to these works finds out that there are a great many processes connected with its manufacture. The first impression one receives in wandering about the establishment is its great magnitude, then we admire the extraordinary precautions that are taken to guard against fire. All the material handled is of a highly inflammable nature, and it is controlled and treated as if it was ever starting into flame. Here we find fire-proof buildings worked out to perfection, for nothing is left in them that will burn except the material manufactured.

The fine varnish used for passenger car work is made from copal gum, grown in Australia and Africa. The first considerations in the production of a good, durable varnish are first-class gum and the best of linseed oil. That is the combination. If it is worked out by skillful hands the best kind of an article will be produced. Copal is an expensive article, and there are many substitutes employed with varying degrees of badness down to common resin. The inferior varnishes, that are not unknown to railroad business, are made from the cheap material that graduates from copal to resin.

In the Berry Brothers' works a visitor can examine endless packages of copal as they come from the ship, and he can watch the careful manipulation that the article goes through in its way to the boiling kettles. The gum and linseed oil are boiled together for a certain time, which completes the amalgamation of the materials. From the kettles the varnish goes to vats, where it is stored for aging, like wine, and like wine improves with age.

The vats are cylindrical iron tanks about four feet in diameter and eight feet long, set on end in rows in vaulted fire-proof rooms that are maintained at a temperature of about 100 deg. Fah. There are a great many of these storage rooms. One of them I noted had a capacity of 85,000 gallons.

Connected with the works is a finely equipped chemical laboratory, where all material used is tested or analyzed. Samples of all kinds of the varnish made pass through the hands of the chemists, and the quality of all goods sold is on record.

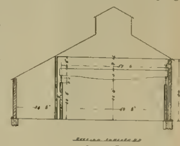
The A. French Spring Co., have introduced a practice of sending out outline prints of their springs with spaces for entering leading dimensions of the springs to be ordered. The blank contains all particulars that must be known, such as length between centers, number of plates, with dimensions, size of hangers, size and form of bands, weight on engine or truck, etc. The blanks are printed in copying ink and all particulars of an order can be easily copied.

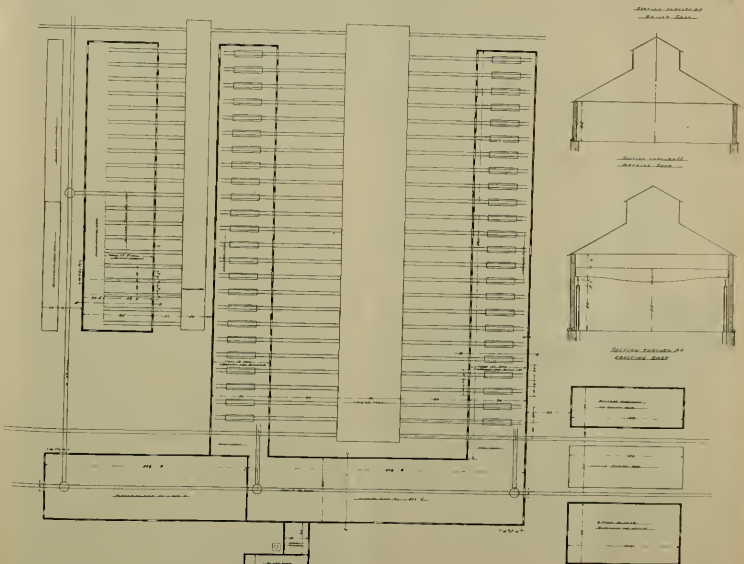
A coroner's jury in the case of the locomotive boiler explosion at St. Clair, Pa., have rendered a verdict fixing the responsibility on the Philadelphia & Reading Railroad Co.

## New York Central New Shops.

The annexed engravings show the ground plan and end elevations of very large shops about to be built near Buffalo by the New York Central for the repair of locomotives. The size of these shops will be readily understood when it is seen that there is erecting shop accommodation for forty-eight locomotives at once, and that facilities will be provided for sending fifty engines through the place every month. This will be the largest and most commodious repair shop for locomotives in the country.

The main plan is two erecting shops set parallel with a transfer table between them. At the end of these shops and at right angles to them is the erecting shop with the blacksmith shop to the left. In a separate building, parallel to the erecting shops, is the boiler shop, which is also served by a transfer table. The transfer tables will be operated by electric motors, and all the shops will be served by overhead traveling cranes. The best tools and other appliances for doing work economically will be supplied to the shops. The shops were designed by Mr William Buchanan, superintendent of motive power.





## Dangers of the Compartment Car.

The railway passenger car used in Europe is an enlargement of the hack or hackney coach so long used in the stage coaching period. When the railway age came it was considered by British engineers the right and natural thing to put a hackney coach on flanged wheels and make it a railway passenger car. The line of development followed was putting a number of these coaches on one frame and calling them compartments. Britain gave the whole of Europe the type of rolling stock, and all that part of the world suffers from the inconveniences of the compartment system.

The English say that the compartment system suits the insular tastes of old country people, since it secures greater privacy than the open car. This privacy is obtained at the expense of dreadful drawbacks. It is impossible to make efficient means of communication between a closed compartment and the trainmen, consequently murders, robberies and outrages are constantly perpetrated in these carriages, and no effectual means can be devised to prevent them. The following incident of travel told in a Manchester paper strikingly illustrates the dangers to a lone lady in a compartment car.

A lady who has been traveling abroad relates an adventure which befell her in Italy in a railway train. Her husband put her into a compartment alone, and went to attend to the baggage. After he had gone a villainous-looking fellow got in, and presently the train started off, the husband not appearing. The lady was naturally a good deal disturbed, and the way in which the stranger looked at her did not tend to diminish her agitation. Suddenly, still with his eyes fixed upon her, the man took from his pocket a large claspknife and opened it. Then he rose, and deliberately cut from the window blinds their cords, and began to knot them together.

The lady was terrified almost to death. She expected to be strangled on the spot, and began appealing to the stranger to spare her. He only laughed brutally, answering her in Italian, of which she did not understand a word. Then he pulled off his coat and waistcoat, and just as the terrified woman was almost prepared to fling herself out of the compartment of the swiftly-moving train, he knotted the cords so as to piece out a broken suspender, put on his coat and waistcoat, and sat quietly down in a corner, where he went quickly to sleep.

## Improved Car Journal Lubricators.

When a man goes along the side of a freight train and examines the oil-boxes of the cars, it strikes him as strange that a better bearing, a better oil-box and a rational means of lubricating the journal are not employed. Truly, the things in use form a crude combination, but somehow they do the business fairly well.

The method of oiling the journal is really the worst and leads to much heating, cutting of journals, and in consequence breakage and wrecking of trains. The remedy seems simple enough. The common practice is to pack the box with cotton waste and saturate it with oil This is all right as long as the waste keeps up to the journal, but the vibration of the car soon packs the waste solid in the bottom of the box, the journal gets dry, and heating ensues. A natural remedy is to put some spring arrangement under the waste that will prevent it from sagging away from the journal. A prettier and theoretically more perfect plan is to put in a roller held to the bottom of the journal by means of springs. As the journal revolves, the roller revolves, and the bottom being down in the oil, the lubricant is constantly supplied to the moving journal.

The improved methods of oiling would be all right if they were properly cared for, but under existing methods they are no good. The galvanizer walks along the side of a car looking for dry oil boxes. He opens one of these fancy packed concerns, and seeing no sign of grease-begrimed waste, he lifts a supply out of his basket,

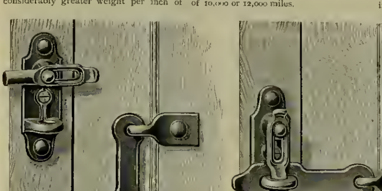
dabs it into the box, stirs the mixture with his packing iron, goes on to the next victim, and the identity of the improved car-journal lubricator is lost. The rough-and-ready methods of American railroading are hard on many improvements, and others besides the lubricator, while theoretically correct, fail to pass the practical ordeal.

With the heavy freight cars coming into general use the defective methods of lubricating is growing a serious matter. Journals of larger size are coming into general use, but the 60,000-pound car is much more liable to have hot boxes than the 40,000-pound car of a past decade, and it was troublesome enough. The heavy car puts considerably greater weight per inch of bearing surface upon the journal, the greater diameter increases the journal speed, and the train speeds, as a rule, are faster than they were ten years ago. Under these circumstances it is not surprising that hot boxes should be causing delay to so many freight trains that the business of some roads is seriously impeded thereby. The problem of preventing hot boxes has generally come up in connection with passenger trains. It has now to be solved in connection with heavy freight cars. The simplest remedy would be to use an elastic material for packing that would not sag easily away from the journal. Hot boxes have been cured on the passenger cars of several roads by this simple improvement. Its application to freight cars might prevent a general demand for an improved form of oil box.

## Long Search for a Car.

Freight cars do not get lost so often now as they used to do when construction companies were in the habit of stealing cars and using them in out-of-the-way places, but a car goes astray yet and gives chasers a long search. A bad case of this kind was lately related to a reporter of the *Globe-Democrat*:

"One of the best jobs in car-tracing that was ever done in this country was completed about three weeks ago by a car-tracer of the New York Central. That road had lost a car and sent out the tracer to look it up. He followed it West to Pittsburgh, then to Cincinnati, then to Chicago, and from there to St. Louis. Here he lost track of it, but after some search found it had been in an accident and had been repainted. By some oversight the number had been changed, but, taking the new number, he chased the car to Kansas City, where he found it had been loaded and sent on to Galveston. To Galveston he went, and there found that, after taking a fresh load, the car had gone to San Francisco. He went after it, but on reaching San Francisco found the car had gone back to Galveston. By this time his blood was up, and he made up his mind to find that car if it took the balance of his natural life, so he went back to Galveston, and, to make a long story short, followed that car to New Orleans, to Mobile, to Atlanta, to half a dozen places in Florida, then back to New Orleans, to Galveston again, and thence to Kansas City, and from there to Chicago. He had now been on the hunt for over three months, but had got so close to the runaway that just as he came into Chicago by one road the car left it over another on its way to Buffalo. Its load was consigned to that point, and when he ascertained the fact he telegraphed on to have the car held and and took the next train for the East. At Buffalo he came up with the car and caught his first sight of it. He had traveled almost constantly for over thirteen weeks, traversing a distance of 10,000 or 12,000 miles.



## A New Car-Door Fastener.

The National Malleable Castings Co., of Cleveland, O., have recently put upon the market a car-door fastener of new design, and possessing some advantages.

This device is illustrated herewith, the cuts showing its application and position, both opened and closed.

The principal improvement is in fastening the pin to the plate, so that they are to all intents and purposes one plate, and there is never the annoyance of a lost pin.

This fastener is complete in three parts, there are no chains, staples nor separate pins to purchase and apply.

## Flexible Metallic Tubing.

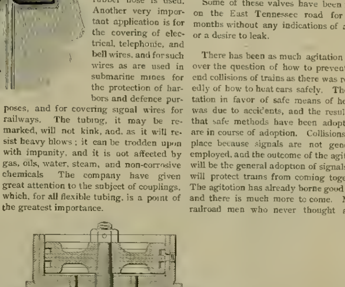
There are numerous purposes about locomotives and cars where a flexible metallic tubing would be of the very greatest service. Rubber is good in its way, but it soon wears out and heat disintegrates it very rapidly. Flexible metallic tubing is badly needed. Several forms of metallic tubing have been offered, but they were dependent upon rubber strips to form a tight seam. That made the article weak in the line where all rubber fails.

The *Practical Engineer* had lately a description of a new form of flexible metallic tubing put on the market in England which seems to fulfill all requirements. The tubes are produced by a machine from strips of metal of the required length, width and thickness. These strips, in passing through the machine, are corrugated longitudinally with a large and a small corrugation side by side, and the tube is formed by the corrugated strip being coiled spirally round a mandrel in such a way that the small corrugation enters and interlocks with the large one, thus forming a flexible joint. This kind of flexible tubing was previously made steam and water tight by means of a strip of india rubber inserted in the interlocking corrugations, and although this answered well for many purposes, yet it was found in some cases that the substance passed through caused the india-rubber to deteriorate. In the new form the absence of india rubber does away with this difficulty, and thus solves the problem of manufacturing a cheap, effective flexible metallic tube, which is unaffected by the passage of ordinary liquids or gases.

These tubes at all times sustain great internal pressure. For instance, under a hydraulic strain of 1,000 lbs. to the square inch, $\frac{3}{16}$-inch tubing retained its flexibility and tightness. Tubing 1 inch in thickness stood the same pressure, finally giving way on a trial of over 1,600 lbs. to the square inch. The tubing is also tight at low pressures.

The uses to which such tubing can be applied are almost legion. One of the railway companies has recently adopted it for carrying petroleum gas used in lighting their carriages. This gas is conveyed from a reservoir to the carriages at a pressure of about 150 lbs. on the inch.

For steam the tubing has been used at varying pressures up to 200 lbs. on the square inch. It has also been employed for pumping petroleum from barges, for cooling rifle barrels, and it might, in fact, be added for nearly all purposes for which rubber hose is used. Another very important application is for the covering of electrical, telephonic, and bell wires, and for such wires as are used in submarine mines for the protection of harbors and defence purposes, and for covering signal wires for railways. The tubing, it may be remarked, will not kink, and, as it will resist heavy blows; it can be trodden upon with impunity, and it is not affected by gas, oils, water, steam, and non-corrosive chemicals. The company have given great attention to the subject of couplings, which, for all flexible tubing, is a point of the greatest importance.



## Independent Double Disk Throttle-Valve.

Men who have had trouble to keep throttle-valves ground tight and know the nicety of work necessary to have both seats of a common balanced throttle-valve ground to a fit, will appreciate any improvement that promises to abate the annoyance.

The valve shown herewith was invented and patented by Master Mechanic J. B. Michael, of the E. T. V. & G., at Knoxville, Tenn. Mr. Michael had so much grief with leaky throttles after the advent of high steam pressure, that relief was necessary.

As will be seen, the top valve carries on its upper side a box into which a piston is packed, the stem of the piston extending loosely through the valve, and being fastened to the lower disk, which seats, as usual, from the inside. The lower valve and the piston above the larger one can be lifted half an inch before the upper valve is moved. The interior of the box or case on top of the upper valve is lined with brass, and two packing rings are carefully fitted, with lap joints, to the piston. Holes are drilled through the upper valve to the cavity under the piston, so that when the lower valve is lifted pressure enters below the piston and helps to balance it and aids in keeping the upper valve to its seat, these also prevent leaks from throwing the valve out of balance. This valve can never "fly open," and can be easily handled, its principal advantage, however, lays in the independence of the two valves of each other. Each can be ground to its seat and can always get there regardless of what the other one does, or how much the case expands or contracts.

The lower valve, when opened to the point that the steam commences to move the upper valve, gives an opening of 42 per cent. of the area of the dry pipe, which is enough to run the engine under ordinary circumstances, and prevents wear of the upper disk by not using it except where very heavy throttling is necessary.

Some of these valves have been in use on the East Tennessee road for some months without any indications of a leak or a desire to leak.

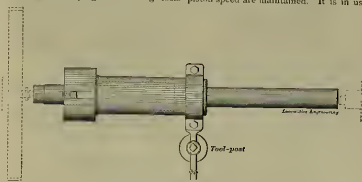
There has been as much agitation lately over the question of how to prevent rear end collisions of trains as there was repeatedly of how to heat cars safely. The agitation in favor of safe means of heating was due to accidents, and the result was that safe methods have been adopted or are in course of adoption. Collisions take place because signals are not generally employed, and the outcome of the agitation will be the general adoption of signals that will protect trains from coming together. The agitotion has already borne good fruit, and there is much more to come. Many railroad men who never thought about signals are now getting educated to the necessity for this means of increasing the safety of train operating.

There was a good meeting of the New York Railroad Club last month. Arrangements have now been made for this club to meet regularly at the rooms of the Society of Mechanical Engineers. This is a popular arrangement. At last meeting a variety of subjects were discussed, the members taking a much more active part than they have done for a long time. President R. C. Blackall makes an excellent presiding officer, and he is working outside the meetings to make the club a success.

## A New Boring Bar for Lathes.

The engraving accompanying this article is a plan view of a very neat and efficient boring bar recently designed and patented by Jackson Richards, M M. of the P. & R. shops at Philadelphia.

The head carrying the cutting tools slides on a ground arbor or bar, and is moved out and in by the connecting lug that is fast in the tool-post of the lathe, thus using the regular carriage feed. Anything that can be clamped to and revolved by the face plate can be bored out. Several sizes of this tool in a repair shop would be very efficient for boring out air-pump cylinders, driving-boxes, etc.



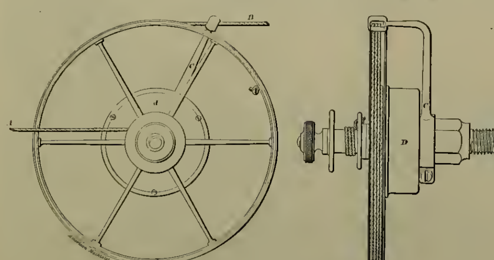
Boring Bar for Lathes.

## Motion Reducer.

The introduction of compound locomotives and the growth of intelligence are making the application of the steam-engine indicator to locomotives so common, that any improvement which aids the engineer in the operation of taking indicator diagrams is worthy of attention. For this reason we bring to the notice of our readers the reducing wheel for engine indicators shown in the annexed engravings. The ordinary methods of reducing the travel of the cross-head to that adapted for the drum of the indicator are nearly all crude, and cause inaccuracy due to the swing of the moving parts. This wheel appears to be free from the objectionable features of other motion reducing devices. The rim of the wheel is aluminum and is made to combine lightness with strength.

The wheel can be mounted on the back cylinder head in such a position that a cord connected with a small rod secured to the cross-head and extending to the wheel will move parallel with the guide-bars. The arrangement makes a very short cord connection between the wheel and the indicator, and the motions being in straight lines the diagrams taken are certain to be correct.

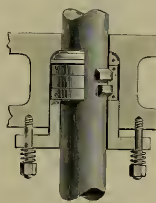
The apparatus is made by Webster & Parks Tool Co., Springfield, O.



Motion Reducer for Indicators.

## The "Silver Bronze" Metallic Packing.

The illustration herewith shows the arrangement of rings in a form of metallic packing that has become quite popular where excessively high steam pressure and piston speed are maintained. It is in use on the fast double-screw boat "Monmouth" of the Sandy Hook line. This boat is driven by a pair of triple expansion engines running with a piston speed of 800 feet per minute with steam at 160 pounds—the boat making from 20 to 23 knots per hour.



"Silver Bronze" Packing.

The packing is used on the "John G. McCullough" and other boats in this harbor.

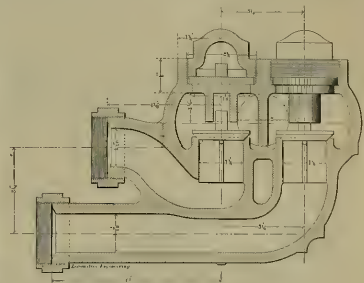
The advantage is that it can be applied to an old stuffing-box, using the old gland and without disconnecting the rod. The two inside rings, the ones in contact with the piston rod and taking the wear, are made of "silver bronze," and by renewing these the packing is entirely renewed. There are no springs inside the box, but two small ones are located on the studs outside of the gland.

This packing is being made and sold by the Forrest Silver Bronze Packing Co., of 115 Liberty street, this city.

## Both Injectors on One Side.

The Louisville & Nashville people are putting both injectors of their locomotives on the right-hand side and passing the water from both into the boiler by means of a single check-valve designed by Mr. P. Leeds, Superintendent of Motive Power.

There are several reasons why this change is made as explained by Mr. Leeds. In the first place, the engineer has the whole of the feeding apparatus under his hand. Then he can use the injectors alternately, which keeps them both in good order, a condition that does not always prevail when one injector is on the left-hand side, and the right-hand injector is sufficient to feed the boiler at all times. Another advantage is, that only one check-valve is used with one opening into the boiler. This takes away half the danger from having check-valves knocked off.



L. & N. Double Check.

When we had listened to all these reasons in favor of the two injectors being on one side, we cordially admitted that Mr. Leeds had made out his case.

---

The superintendent of motive power of an important railroad is reported to have said at a public meeting that he did not use iron brake-beams because he was afraid they would give trouble breaking. This man might obtain useful information from the experience of the New York Central with brake-beams When they were using the wooden beams on passenger trains the breakage was about one hundred beams a month, the quick-action brake nearly always breaking a beam when applied. This was too expensive for the company and they adopted iron beams.

## COMBUSTION.

### Plain Explanation of a Cloudy Subject.

By M. E. WELLS.

I have been interested in the efforts of a prominent Western road, in educating their engineers and firemen on the subject of combustion. A little study of the chemistry of combustion proves interesting, and is not so difficult to understand as might be imagined at first sight. I am sure the little effort it takes will more than repay you, besides being a great help toward economical and good firing. The earth is composed of about sixty-eight simple elements which exist, in their free state, in the smallest divisible quantities of matter called atoms.

These atoms of matter are represented by their chemical symbol, as carbon (C), oxygen (O), hydrogen (H). They also have what are called chemical affinities or powers to unite with other atoms in certain fixed proportions.

Hydrogen (H), has a chemical affinity of one, oxygen (O) has a chemical affinity of two. To make it simpler, an atom of hydrogen has one hand or grasping power, while oxygen has two It is perfectly plain then that oxygen with its two hands can unite with two atoms of one handed hydrogen, thus; $\begin{matrix}H\\H\end{matrix}{>}O$ or $H_2O$ which is the chemical formula for water. We see from this that the union of two gases (oxygen and hydrogen) forms water, and farther on we will discover that a little light and a great amount of heat are produced by the union.

An important point to be realized as we go on is that the power of a locomotive is derived *entirely* from heat, and that this heat is obtained by the combustion of fuel (principally coal nowadays). The chief elements entering into the chemistry of combustion are carbon (C), hydrogen (H) and oxygen (O)—carbon and hydrogen being found in the coal, and the oxygen coming from the air. It might be well to state here that one-fifth of the air is oxygen, while the remaining four-fifths is nitrogen; these two gases being only mechanically mixed to form the air They are not chemically united Ordinary soft coal contains from 50 to 65 per cent. carbon, from 25 to 40 per cent. hydro-carbons (which are the gases given off) and 10 per cent. moisture ($H_2O$) and non-combustible matter called ash. When fresh coal is thrown upon the fire the intense heat drives off the gases. These gases (hydro-carbons), as the name indicates, are composed of hydrogen and carbon, and as they are the first to burn we will first consider their combustion.

The oxygen coming through the grate, when heated to the igniting point, has so much stronger an attraction for the hydro-

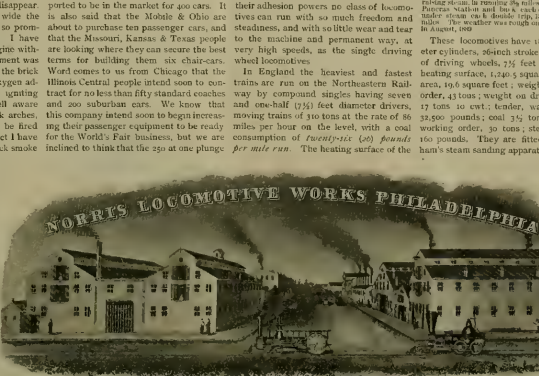
gen than for the carbon of the hydro-carbons that they are separated—the atoms of hydrogen clashing with the atoms of oxygen producing great heat, and water ($H_2O$) by their union—thus $2H+O=H_2O$ as shown above. When you take away the hydrogen from the hydro-carbons of course you have free carbon left. It is this carbon that makes the black smoke so often seen coming from our locomotives. If there is sufficient oxygen admitted through the grate and above the fire this carbon will be consumed; but, as you all know, a large per cent. of it is usually wasted. It is this carbon that collects as soot in our stove pipes In order to burn this black smoke (carbon) successfully, a brick arch is very necessary, and also some means of admitting a limited amount of air (oxygen) above the fire. Too much air above the fire will destroy the combining effects of what comes through the grate, because it cools down below the igniting point and combustion ceases, followed by a great waste of fuel.

I used to perform an experiment for the entertainment of any visitor we might have riding on the engine that proved the truth of the above. I was firing a common everyday locomotive on a common everyday freight train. She had a brick arch in fire-box and no means of admitting air above the fire except a few small holes in fire-door and an occasional hollow stay-bolt that had not filled with ashes or otherwise stopped up.

I would put one or two scoops of coal on a bright fire and close the door; the black smoke would commence to roll; I would then watch the stack and open the fire door just a little; the black smoke would disappear. By closing the door again the black smoke would show; open a little again the black smoke would disappear. And then by opening the door wide the black smoke would show, but not so prominently as with the door shut. I have often tried this with the same engine without the brick arch, but the experiment was not so successful. This is because the brick arch heats the gases and the oxygen admitted above the fire up to the igniting point, and they burn. I am well aware that all engines do not have brick arches, and also that all engines cannot be fired without lots of black smoke—in fact I have seen firemen who thought the black smoke very necessary to steam-making. If you have not got a brick arch you can make a great saving in your fuel account by light feeding on a light fire. There is a certain amount of oxygen passing through your fire all the time, and if you feed your fire by light installments smaller amounts of hydro-carbons are given off each fire. This gives the oxygen some chance to burn the hydro-carbons as they pass off, whereas, with heavy firing, the work for the oxygen is not well distributed, and large portions of the hydro-carbons pass through the stack unconsumed.

The chemistry of the combustion of carbon I will give in a subsequent article.

*Deadwood, S. D.*

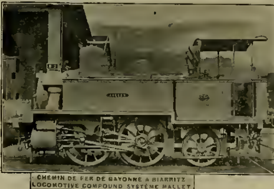


NORRIS LOCOMOTIVE WORKS IN 1853—NOW PART OF THE BALDWIN WORKS

No more subscriptions can commence with January; the entire edition of 30,000 is exhausted. We can commence some 1,500 subscriptions with February. We hardly expected 13,500 paid subscriptions to come in before March, but such has been the fact. The progressive men are with us.

## The Ancestor of Compound Locomotives.

The small locomotive shown in the annexed engraving is interesting, because it was the first of the race from which the compound locomotive has sprung The engraving was made from a photograph sent us by the well-known French engineer, Mr. Anatole Mallet, and represents the first locomotive which he designed. It was one of three built by Schneider & Co., of Creusot, for the Bayonne & Biarritz Railroad, in France, and to its successful working was due the movement in Europe which resulted in so many compound locomotives being built.



CHEMIN DE FER DE BAYONNE A BIARRITZ LOCOMOTIVE COMPOUND SYSTÈME MALLET

The locomotive was a very small machine, the cylinders having been only 9½ and 15¾-in., with 17¾-in. stroke. The ratio of high pressure and low pressure cylinders is high, being as 1:2.79 The engine had the cylinders placed outside the frames, and like all Mallet's compounds, were so designed that they could be worked simple any time when the engineer so desired.

These engines gave so much satisfaction that the entire road where they were introduced on is now worked by compound locomotives.

## Comfort for Manufacturers.

The New York & New England are reported to be in the market for 400 cars. It is also said that the Mobile & Ohio are about to purchase ten passenger cars, and that the Missouri, Kansas & Texas people are looking where they can secure the best terms for building them six chair-cars. Word comes to us from Chicago that the Illinois Central people intend soon to contract for no less than fifty standard coaches and 200 suburban cars. We know that this company intend soon to begin increasing their passenger equipment to be ready for the World's Fair business, but we are inclined to think that the 250 at one plunge is beyond the courage of the finance department There is a good reason for believing that the Savannah, Florida & Western will soon award a contract for building fifteen coaches. The New York, Ontario & Western we have reason to believe will soon order five locomotives and 500 cars.

## Locomotives for Hauling Fast Trains.

By WM. BARNET LE VAN

The tendency at the present time is to build locomotives to move passenger trains at the rate of a mile a minute continuously for a distance of 150 miles. To accomplish this high speed with safety and economy, a single pair of driving wheels must be resorted to. It is impossible to couple a pair of driving wheels by parallel rods that will remain alike The lateral disturbing forces at high speeds produce unequal wear which adds additional friction. It is well known, and has been shown by the experiments made by M. Regray, the superintendent of the Eastern Railway of France, that the frictional losses in locomotives amounts to over *twenty-five per cent.* of the total indicated horse-power when "coupled" by parallel rods.

Single locomotives with large driving wheels make better time and consume less coal per train mile than coupled ones. Heretofore the objections urged against single drivers was the want of sufficient adhesion in starting the train and the climbing of inclines, but this is now overcome by the introduction of steel rails and followed by the "steam sanding" apparatus now in general use on the majority of the best and fastest English trains, it has been demonstrated that a single pair of driving wheels can carry as much as twenty (20) tons where formerly fourteen (14) tons was the maximum load. The above improvements have brought the single locomotive into favor and enabled heavy loads to be put on their driving wheels as witness the Caledonian Railway. Mr. Drummond's seven feet diameter single locomotives during the great railway race between London and Edinburgh, in 1888, averaged between Carlisle and Edinburgh 59.9 miles per hour for one hundred (100) miles, climbing two inclines of 10.15 and 870 feet, on the former grade, averaging 42.7 *miles for ten miles up a 133 per cent. grade.*

It is undeniable that for trains within their adhesion powers no class of locomotives can run with so much freedom and steadiness, and with so little wear and tear to the machine and permanent way, at very high speeds, as the single driving wheel locomotives

In England the heaviest and fastest trains are run on the Northeastern Railway by compound singles having seven and one-half (7½) feet diameter drivers, moving trains of 310 tons at the rate of 86 miles per hour on the level, with a coal consumption of *twenty-six (26) pounds per mile run.* The heating surface of the boiler being only 1,130 square feet and the fire surface twenty (20) square feet, cylinders 20 and 24 in. by 28 in. stroke This performance has never been paralleled on any railroad.

The low coal consumption per train mile is extraordinary as compared to the coal burned in this country. Take the fuel consumption per train mile of either the Pennsylvania Railroad or the Bound Brook branch of the Reading Railroad on their fast trains between Philadelphia and Jersey City and the coal consumed per train mile never falls below fifty (50) pounds except in the case of the Webb compound on the former road

When the statement is made of the fast time and small coal consumption, you are met with the cry that their trains are lighter than those in America, but the facts are to the contrary, as will be seen by the following, from their printed statements The Midland Railway Company, England, for the month of August 1889, Samuel W. Johnson, Locomotive Superintendent.

COAL CONSUMPTION AND WORK DONE BY LOCOMOTIVES OF THE 1853 CLASS FOR THE YEAR ENDING SEPTEMBER 5, 1889:

| Locomotives, No of | Miles | Coal consumed Lbs | Coal consumed Lbs. per mile | Aver No of Carriages |
|---|---|---|---|---|
| 25, 28 30, 31, 32 and 34 | 168,027 | 3,483,840 | 20.7 | 9½ |

WORKING OF LOCOMOTIVES NO. 28 AND 34, RUNNING THE SCOTCH EXPRESS AUGUST, 1889, BETWEEN LONDON AND LEICESTER AND RETURN.

*Double Trips.*

| ITEMS | Aug. 5 to 9, 1889, 8 25 p m London to Leicester and 6 18 a. m. Leicester to London Average double trips 4½ | Aug 19 to 17, 1889, 8 25 p m London to Leicester and 6 18 a. m Leicester to London Average double trips 5 |
|---|---|---|
| Total miles run ..... | 839 | 992 |
| Coal consumed per mile in pounds .... .... . | 25.7 | 25.9 |
| Pounds of water evaporated per pound of coal. | 8.9 | 9.1 |
| Number of coaches . ... | 16 | 15.7 |
| Weight of coaches in pounds .... .......... | 347,312 | 304,112 |
| Weight of Locomotive and trains in pounds .. | 537,040 (239 tons) | 546,896 (244 tons) |
| Actual speed run in miles per hour . ... .... ... | 50.7 | 48.3 |

NOTE —The fuel in the above includes all used in raising steam, in running 3½ miles from shed to St Pancras Station and back each day Total time under steam each double trip, 13¾ hours for 198 miles The weather was rough on the dates given in August, 1889

These locomotives have 18½-inch diameter cylinders, 26-inch stroke, a single pair of driving wheels, 7½ feet in diameter; heating surface, 1,240.5 square feet; grate area, 19.6 square feet; weight in working order, 43 tons; weight on driving wheels, 17 tons 10 cwt.; tender, water capacity, 32,500 pounds; coal 3½ tons, weight in working order, 30 tons; steam pressure, 160 pounds. They are fitted with Gresham's steam sanding apparatus

On London, Nottingham, and Leeds branch they are timed at 53½ miles per hour, with loads of from nine to thirteen coaches, and have been for the last four years performing this work, with an average consumption of from twenty to twenty-three pounds of coal per mile, and have frequently taken trains equivalent to

from thirteen to sixteen coaches without loss of time.

In this country, up to within a short period, the fastest running was between Philadelphia and Jersey City, a distance of 90 miles, and the actual speed run in miles per hour is 48, the coal consumption per mile run being 52 pounds, average weight of train 210 tons; the difference in fuel consumption being 50 per cent. in favor of the single locomotives of the Midland.

The amount of adhesion required to turn to account the whole power which a locomotive is capable of developing varies, inversely, as the speed at which the locomotive is run—*the higher the speed the less being the adhesion required.*

Again, there is another important factor in the utilization of the gases evolved by the fuel—*that is the allowance of sufficient time.* A large diameter driving wheel, combined with a long stroke of cylinder, reduces the number of revolutions per mile, thereby allowing the products of combustion time, thus prolonging the passage through the flues, resulting in the giving up the greater portion of the heat evolved, thus effecting a higher evaporation per pound of coal burnt, which is shown by the performances of the Midland's locomotives.

By compounding and increasing the stroke we reduce the back-pressure on the pistons, the occurrence of which is one of the great drawbacks to high speeds.

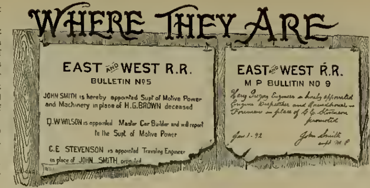
### Central Vermont Shops.

Any person traveling over the Central Vermont Railroad at this time will be impressed with the good condition of both the motive power and equipment generally, and the writer distinctly notes the improvement over a year ago. The superintendent of motive power has succeeded in centralizing his shops by bringing all the repairs to St. Albans. A recent addition of 250 feet, giving a machine shop 500x50 feet, helps very materially in keeping up with the repairs to cars. A number of new tools have been added, such as a heavy planer for car-sills, and a molding machine for car ceilings and roofing, a Rogers end tenoning machine, a three-spindle car-boring machine, and a gaining and cutting-off tool, and a hollow chisel and mortising machine. The company further contemplates adding to the machine shop and putting in a transfer table, greatly facilitating the handling of work through the different shops.

Mr. Robertson has 180 engines to look after, which are doing severe and trying service. The freight engines make 400 miles per 24 hours, and passenger engines 250 miles per 10 hours, which reflects very creditably upon the thoroughness in the mechanical department. That engines turned out by them some time since (light 16x24 8-wheelers) make 250 miles per day, or a run of 125 miles, in 4 hours and 15 minutes each way, with 28 stops, with six heavy cars, including a Wagner parlor car, and does that twice a day, and continuously during five winter months, without missing a trip, is surely excellent work. The road is crooked, about one-half of it being composed of grades, and where it crosses the Green Mountains the grades run as high as 48 feet to the mile.

The burning of the barrel factory of the Standard Oil Company at Bergen Point, N. J., made it necessary to get thousands of barrels from the Western factories. Superintendent C. A. Smith met the transportation question very promptly by dismounting the tanks on some hundreds of cars and putting on racks that carried safely 280 barrels.

One of the new Baldwin compounds had to be taken out of service last month owing to a badly laminated sheet in the fire-box. Some of the steel now offered for locomotive boilers is as unreliable as iron came to be. Inspection and tests of this material cannot be too rigid.



Mr. John Wells has been appointed purchasing agent of the Ohio & Mississippi.

Mr. E. L. Moser has been appointed mechanical engineer of the Philadelphia & Reading.

Mr. D. C. Horn, a conductor on the Northern Pacific, has been promoted to the position of assistant superintendent.

Mr. John Henry has been appointed master car builder of the L., N. A. & C., with charge of the car-shops at Monon, Ind.

Mr C. Palmer has been promoted to the position of general foreman of the Chicago and Northwestern Railway shops at Janesville, Wis.

Mr. F. P. Boatman has been appointed master mechanic of the Queen & Crescent, with charge under Mr. Meehan of the shops at Ludlow, Ky.

Mr. Fred Winkles has been appointed master mechanic of the Louisville, New Albany and Chicago, with charge of the shops at Monon, Ind.

Mr. Joel H. Hills, general agent for the Granular Metal Company, has removed his office to 55 Oliver street, Boston, where he wishes to see his many friends.

Mr. F. H. Stark, general car foreman of the Wheeling & Lake Erie, has been promoted to be master car builder, with charge of the shops at Ironton, O.

The Central Railroad Club and the Western Railway Club have both passed resolutions of sympathy with the family of the late William F. Turreff on the death of the husband and father.

Col. William G. Rice, President of the Consolidated Car-Heating Company, was married at Albany, N. Y., last month. His wedding was one of the most fashionable affairs ever held in Albany.

Mr. Frank Bruce has been appointed master mechanic of the Great Northern, at Barnesville, Minn. Mr. Bruce was formerly on the Santa Fé, and subsequently on the Chicago and Eastern Illinois.

The employees of the Grand Trunk shops at London, Ont., and numerous friends, presented Mr. J. D. McIlwain, lately superintendent there, with a gold watch and other testimonials of regard.

Mr. Jas. S. Mather, formerly of Danville, Ill., has been promoted to the office of General Foreman of the Chicago & East Illinois Railroad Co., and is now located at Thirty-third street roundhouse, Chicago, Ill.

Mr. Ross Kells, superintendent of motive power of the Erie, is said to be rapidly recovering from the illness which has prostrated him for several months. It is expected that he will return to duty about the beginning of April.

Mr. James T. Furber, general manager of the Boston & Maine, died on January 27, after a short illness. Mr. Furber was an able railroad man of the rough, swearing type. A scandalous roughness of manner covered a warm and generous heart.

Mr. J. C. Clarke, one of the most active friends of LOCOMOTIVE ENGINEERING on the Santa Fé system, has been made roundhouse foreman at Woodward, Indian Territory. Mr. Clarke has been running out of Newton, Kan., for some years.

Since the death of Mr. Furber, Mr. John W. Sanborn has been acting general manager of the Boston & Maine. Mr. Sanborn is 70 years old and is not likely to be made permanent general manager. His strength lies on the financial side of railroad business.

Mr. Joseph Shrimpton has been appointed general car foreman of the Chicago and Eastern Illinois. He left the position of joint inspector at Toledo, O., to accept the appointment named. Before going to Toledo he was joint inspector at Niagara Falls.

There is a great deal of talk in New England to the effect that Mr. Payson Tucker, general manager of the Maine Central, will be appointed general manager of the Boston & Maine. Mr. Tucker is considered one of the ablest railroad men in New England.

Mr. Samuel F. Prince, Jr., has been appointed mechanical engineer of the Long Island Railroad. He has been for several years chief draughtsman of the Philadelphia & Reading. He is a graduate of the Pennsylvania Railroad, and is recognized as one of the rising men of the day.

Engineer George King, of the Wabash road, claims to have made the largest mileage with his engine, in one month, ever made in the country—6,627 miles. Other engines have made larger mileage, but no other engineer has ever made such a mileage in the same time with a single engine. —*Ex.*

Mr. Lucius Tuttle, for the last two years General Manager of the New York, New Haven & Hartford, has been elected Vice-President in place of Mr. Reed, deceased. Mr. Tuttle is one of the broad-gauge class of railroad managers whose upward progress brings pleasure to all classes of railroad men.

Mr. L. B. Butler, Master Mechanic of the New York, Providence & Boston, has been taking a much-needed rest. He did not take to his room voluntarily, although an unusually busy season had given him a good excuse. La grippe took a hold of his limbs and intimated that a brief period of repose was imperative.

Mr. John Heath, for some time foreman of the Chicago & Northwestern shops at Janesville, Wis., has been promoted to the position of master mechanic of the Wisconsin division. We are glad to see Superintendent of Motive Power Smith finding men on his own road to promote when vacancies occur in higher positions.

Mr. John McCurdy is one of the oldest engineers on the Michigan Central. He has run an engine between Jackson and Michigan City for forty-four years, and it is figured that he has traveled 2,400,000 miles, being a distance of over ninety-six times around the globe. He has never been hurt, and every limb of his body is as sound as ever.

Mr. William Garstang, Superintendent of Motive Power of the Chesapeake & Ohio and one of the vice-presidents of the Railway Master Mechanics' Association, was offered the position of Assistant Superintendent of Motive Power of the Erie but declined it. The Chesapeake & Ohio management gave him material inducement to remain where he is.

Mr Samuel A. Beardsley, of Utica, N. Y., has been appointed Railroad Commissioner of New York in place of Mr. W. E. Rogers. Mr. Beardsley is an able politician, and will be entirely at home in the New York Board of Railroad Commissioners. Mr. Rogers was considered the ablest man of the Board; but his ability was manifested almost exclusively in talk.

Mr. Daniel W. Sanborn, since 1884 superintendent of the Eastern Division of the Boston & Maine, has been made general superintendent of the system, a new position. He has been in railroad service 33 years and rose through train service, having been brakeman and conductor. He has the reputation of being an excellent practical railroad man and may be made general manager.

Charles L. Sullivan, who for the past three years has been Superintendent of the Boyden Brake Company's shops, at Baltimore, has resigned that position to accept the Superintendency of the Northwestern Equipment Co. of Chicago, who manufacture brake-beams and other supplies. Mr. Sullivan is a B. & O. boy, having come up through all the stages, finally leaving the service while occupying the position of Engineer of Tests. He is one of the educated mechanics who has gone through the mill, and got his theory and practice to mix and equalize.

We have received from the Lukens Iron and Steel Co. a notice of the appointment of Coolbaugh & Pomeroy to be general agents. These gentlemen scarcely need an introduction to our readers. Mr. F. W. Coolbaugh is an old train dispatcher from the D., L. & W., and Mr. L. R. Pomeroy was secretary of the New York Rapid Transit road. Both of them are the kind of men railroad officers like to meet, for they can always be depended upon to tell something of interest about their own business, lightening it with yeast consisting of all the latest news of railroad circles.

Mr. William Gibson, who has been for some time secretary to the General Manager of the Cleveland, Cincinnati, Chicago & St. Louis, has been made superintendent of a division of the road. Mr. Gibson began railway work on the North British Railway in Scotland. He came to this country with Mr. John Scott, who was for some years General Manager of the Queen & Crescent. When Mr. Scott left that road, Mr. Gibson went to be chief clerk for General Superintendent Rockwell, of the Columbus & Hocking Valley, which he left to go to the Big Four.

Last month, in announcing the death of the master mechanic at Mandan, N. D., on the N. P. road, we got the name J. W. Goodman, when it should have been Gardner. J. E. Goodman is alive and still filling the position of road foreman of engines. Mr. Gardner was at one time shop foreman of the C. St. P. M. & O., and afterward general foreman of the St. P. & K. C., at So. St. Paul, from this position he went to Missoula on the N. P. as general foreman of the Rocky Mountain division, and from there was promoted to be master mechanic at Glendive, Mont., being transferred last August to Mandan. He was a very popular shop manager, and his death is deplored by those under him.

# Cast Steel Works of FRIED. KRUPP, ESSEN, Germany.

**Represented by THOMAS PROSSER & SON, 15 GOLD ST., NEW YORK.**

These works cover an area of 1,200 acres, employ about 18,000 men, have the most improved plant, and stand unique, from the fact that they have their own Ore and Coal Mines, Blast Furnaces, etc., and that *every* stage of manufacture is under their own supervision, and are not (like others) dependent on the open market for a miscellaneous assortment of crude material; which, in connection with 75 years' experience, enables them to turn out a product of a very superior quality, second to none, and at the same time the different grades of Steel are always of the *same uniform* quality.

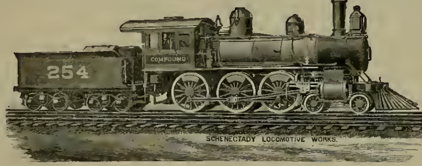
Locomotive Tires, Crank Pins, Piston Rods, Spring Steel, Steel-Tired Wheels, Etc.

After a test of over 25 years the "KRUPP TIRE" has proved itself the best in the market. If a reliable article is wanted, which will give satisfaction, get KRUPP'S.

# SCHENECTADY + LOCOMOTIVE + WORKS,

**SCHENECTADY, N. Y.**

LOCOMOTIVES OF STANDARD DESIGN FOR ALL CLASSES OF SERVICE,



OR FROM DESIGNS FURNISHED BY RAILROAD COMPANIES.

## COMPOUND LOCOMOTIVES,

**Showing an Economy of 15 to 30 Per Cent. in Fuel and Water.**

**ANNUAL CAPACITY 400.**

# THE SAFETY CAR HEATING AND LIGHTING CO.,

**160 Broadway, New York.**

**HEATING SYSTEMS.**—By hot water circulation and direct steam with regulating devices. Reliable and uniform heat. Economical and rapid circulation. Gibbs automatic coupler of Westinghouse type, absolutely steam-tight.

**LIGHTING SYSTEM.**—The celebrated Pintsch compressed oil gas method. In use on over **40,000** cars in Europe and America. Adopted by the U. S. Lighthouse Board for lighting Buoys. The best, most economical and only safe light for Railroad purposes. In brilliancy and cleanliness unsurpassed.

All GENUINE INGOTS & MANUFACTURES BEAR OUR REG. TRADE MARKS.

## PHOSPHOR-BRONZE

INGOTS, CASTINGS, WIRE, SHEET &c.

THE PHOSPHOR BRONZE SMELTING CO. LIMITED

512 ARCH ST. PHILADELPHIA PA. U.S.A.

ORIGINAL MANUFACTURERS OF PHOSPHOR-BRONZE IN THE UNITED STATES AND SOLE MAKERS OF "ELEPHANT BRAND" PHOSPHOR-BRONZE.

## RICHARDSON & ALLEN-RICHARDSON,

BALANCED SLIDE VALVES.

New Patent, April, 1891.

10,000 Locomotives Equipped. In Use on 175 Railroads.

Manufactured only by

**M. C. HAMMETT,**

Successor to Estate of F. W. RICHARDSON, Troy, N. Y.

# ELMORE JOURNAL BOX LID

Has No Bolts, Nuts, Springs or Hinges. No Loose Fastenings. Makes a Perfectly Tight Cover.

E. A. CURTIS, Manager. 324-335 PHENIX BUILDING, CHICAGO, ILL.

**Keeps all Dust Out of Front of Boxes. Keeps Oil in the Boxes. Made of Pressed Steel or Malleable Iron. Cannot Jump Up or Down while Car is in Motion. If Left Open it will Close Itself.**

Another veteran railroad man, who climbed from the scoop and worked upward to a high altitude, has passed away. Last month, Edward M. Reed, Vice-President of the New York, New Haven & Hartford, died at New Haven, Conn. Mr. Reed was born in Pennsylvania in 1821. When quite a lad he went to work in the repair shops connected with a coal-pit, and he continued for several years to follow this kind of work. In 1843 he went firing on the Baltimore & Ohio, and after a few weeks was made engineer. Mechanics were then very scarce, and the mechanical training Reed had received recommended him for rapid promotion. After two years on the road, he was offered the position of master mechanic of the Philadelphia & Reading, and accepted. A couple of years afterward he received a tempting offer to go to Cuba and take charge as superintendent of a railroad under construction out of Havana. This he accepted, and remained in Cuba for two years. On returning to the States he accepted the position of master mechanic of the Hartford & New Haven road. There he rose to be superintendent and eventually vice-president of the line forming the principal artery of travel between New York and New England. To the last Mr. Reed took an active interest in the mechanical affairs of the road.

Mr. Amos R. Barrett has been promoted from the position of Division Master Mechanic to that of Superintendent of Motive Power of the Boston & Maine. Mr. Barrett is a native of East Boston, and he learned the machinist trade in the Eastern Railroad shops, now part of the Boston & Maine system. After learning the trade he went firing for a short time, and then was duly promoted to the right-hand side. From this he was made assistant master mechanic and held the position nearly 20 years, with a break of 9 months when he held the place of master mechanic on the Sandusky & Dayton Railroad. Ten years ago he received and accepted an offer as division master mechanic on the Atlantic & Pacific and was there for three years, having been stationed successively at Williams, Peach Springs and The Needles. Returning to New England seven years ago, he was appointed master mechanic of the Worcester division of the Boston & Maine, from which he has now been elevated to the head of the mechanical department.

The rapidly increasing business of the Consolidated Car-Heating Company has made it necessary for them to enlarge their plant. Heretofore the factory which they have occupied they have leased, but recently they purchased a tract of land at the north end of the city of Albany, and have already let contracts for the erection of a new factory and warehouse. The first floor of the new building will be used exclusively for a shipping-room and wareroom for all finished material. A portion of the second floor will be used for offices and the remainder for lathes. The third floor will be used for drills, brass lathes and hand work in putting up their various apparatus. The fourth floor will be used exclusively for tests and experimental work. This floor will especially be equipped so that all apparatus furnished by the Consolidated Car-Heating Company will be thoroughly tested before leaving their factory, so that defects in all material supplied by them will be reduced to a minimum. Their factory will be equipped with the latest improved and best machinery for doing their work, the greater part of which is special. Aside from this will be the engine-house and auxiliary buildings. The contractors for the building are already at work, and the buildings will be rapidly pushed to completion. The Consolidated Car-Heating Company will probably occupy their new building on or about June 1.

## WHAT'S GOING ON.

The Pennsylvania Railroad Company have contracted for twenty-five new day coaches.

The Atchison, Topeka & Santa Fé have placed orders for fifty coaches with Barney & Smith.

The Long Island Railroad are about to make a large increase to their freight car equipment.

There were more orders for cars placed during the month of February than in any month for years past.

The Pennsylvania Railroad people have just ordered a ten-wheel compound locomotive from Baldwin's.

In our recent review of "Grimshaw's Engine Runner's Catechism," we quoted the price as $1 50, it should have been $2.00.

The Chesapeake & Ohio has ordered fifteen 10-wheel engines and ten consolidations from the Richmond Locomotive Works.

The Peninsular Car Works are building 100 platform cars for the Burlington, Cedar Rapids & Northern. They will have Williams' couplers.

The Missouri Pacific people are about to contract for fifty locomotives. Mr. George Gould is attending personally to what will go on these engines.

The Rock Island people have placed orders with Pullmans for thirty coaches, and Barney & Smith are building twenty passenger cars for this road.

The Central of New Jersey have placed orders for 1,000 gondola cars of 50,000 lbs. capacity, and for 250 box cars. All the cars will be equipped with Westinghouse air-brakes and Janney couplers.

The Rock Island has lately received six 10-wheelers from Brooks, and are about to give out contracts for the building of twelve more. The latter will weigh 131,000 pounds and will have cylinders 19x24 inches.

The Louisville & Nashville have just given contracts for new cars as follows: The Ensign Manufacturing Co., 250 fruit cars, the Mt. Vernon Car Mfg. Co., 500 box cars, the Elliott Car Co., 500 box cars and 250 gondolas.

The New York, Susquehanna & Western have ordered 250 box cars. They will be equipped with the Smillie coupler, and will have Lee composite roofs. The company contemplate placing another order for cars soon.

The Schenectady Locomotive Works have within the month received orders for sixteen engines for the Duluth & Iron Range, and sixteen for the Chicago & Alton. At present writing the latter road has ten more engines to give out.

The Mowry Car Wheel Works, Cincinnati, have been very busy since the New Year. Among the roads they have been making wheels for are the Pennsylvania, the Cincinnati Southern, the Ashland Coal & Iron Co., and a variety of other southern roads.

The Bridgeport Machine & Tool Works are building an addition of 80x100 feet to their machine shop, the increasing business making an enlargement imperative. The Sturtevant system of heating and ventilating has been introduced for the whole of the works.

The contract awarded by the Chicago & Northwestern to the Hall Signal Co., to equip nearly 90 miles of road with block signals, interlocking switches and crossing alarm signals, is said to have been the largest contract ever awarded to a signal company at one time.

Mr. Marvin Hughitt, president of the Chicago & Northwestern, is reported to have said that his company has saved more than enough to pay for the air-brakes and close-couplers put on the freight cars by the prevention of wrecks alone. The saving of life and the acceleration of trains is regarded as clear profit.

It is reported that the Panhandle car shops at Columbus, O., are about to begin work on a large number of passenger cars for the Southwestern system of the Pennsylvania. These shops are as well equipped for doing work of this character as any railroad shops on the continent, but it is doubtful if they can compete successfully with contract shops.

The Nashville, Chattanooga & St. Louis are getting eleven fine passenger cars built at Jeffersonville. The Chicago & Grand Trunk have ordered ten suburban cars, the Louisville, New Albany & Chicago eight day cars, the New Orleans & Southern four passenger cars, and the Cincinnati, New Orleans & Texas Pacific five postal cars from the Ohio Falls Works.

The New York Central have contracted for the 2,000 freight cars which we mentioned last month as being in the market. There are 1,000 gondolas and the same number of box cars. All the cars will have vertical plane couplers and air-brakes. The builders bidding on these cars asked about $50 a car extra if required to put in the Fox steel truck. They did not get it.

The passenger trainmen on the Pittsburg Division of the Pittsburg, Cincinnati, Chicago & St. Louis have been directed to state, in announcing the name of a station, on which side of the train the platform is located.—*Ex.* How much better and safer it would be to adopt platform gates and only open them on the station side.

The Mount Vernon Car Works are building 500 box cars for the Louisville & Nashville, and some 60-foot flat cars for a St. Louis company. The latter cars will be painted white and made very attractive. The Mount Vernon company report that they are making a great many cast-iron wheels for railroad companies, and are receiving gratifying records from those in service.

The Pennsylvania Railroad people at Altoona have lately put five sets of Fox pressed steel trucks, similar to those illustrated in our January number, under the tenders of fast passenger engines. It is rightly concluded that the trucks will receive a more thorough test for strength and durability in this service than in any other. If the truck gives satisfaction it will be largely adopted for freight cars.

We learn that the Canadian Pacific are very busy in their car shops at Montreal. The repair work is unusually heavy, and they are building a good many new cars. Among these are some emigrant sleeping cars, in which several changes from the usual standard have been made, and it is said that all the colonists' sleeping cars hereafter built will be similar to the new type. The cars will be vestibuled, and there will be fixtures between the berths, to divide them more effectually. Stout leather covered seats will be provided in place of the old wooden seats.

The Chicago & Northwestern have adopted the Hall Electric Signal as standard, and have ordered enough to entirely block all the lines for some thirty miles out of Chicago — eighty-seven and one-half miles of track altogether. This requires 201 block signals, 52 road-crossing signals, and 157 switch connections. This is one of the largest orders ever given for block signals at one time. Green will be the safety color, and the system is what is known as the automatic electric block signal, using a wire circuit. The Northwestern evidently intends to get into shape to do a heavy and safe business during the World's Fair, and their example can be followed with profit by all the other lines without exception. Block signals are the true safeguard, and all large roads must adopt them. All honor to those that lead!

## Engine on the Brain—A Driver's Wild Ride.

"I was loafing around the streets last night," said Jim Nelson, one of the oldest locomotive engineers running into New Orleans, "and as I had nothing to do I dropped into a concert, and heard a slick-looking Frenchman play a piano in a way that made me feel all over in spots. As soon as he sat down on the stool, I knew that by the way he handled himself that he understood the machine he was running. He tapped the keys away up one end, just as if they were gauges and he wanted to see if he had water enough. Then he looked up, as if he wanted to know how much steam he was carrying, and the next moment he pulled open the throttle and sailed out on the main line as if he were half an hour late.

"You could hear her thunder over culverts and bridges, getting faster and faster, until the fellow rocked about in his seat like a cradle. Somehow I thought it was old '36' pulling a passenger train and getting out of the way of a 'special.' The fellow worked the keys on the middle division like lightning, and then he flew along the north end of the line until the the drivers went around like a buzz saw, and I got excited. About the time I was fixing to tell him to cut her off a little, he kicked the dampers under the machine wide open, pulled the throttle away back in the tender, and—Jerusalem jumpers! how he did run! I couldn't stand it any longer, and yelled to him that she was pounding on the left side, and if he wasn't careful he'd drop his ash-pan.

"But he didn't hear. No one heard me. Everything was flying and whizzing. Telegraph poles on the side of the track looked like a row of cornstalks, the trees appeared to be a mud bank, and all the time the exhaust of the old machine sounded like the hum of a bumblebee. I tried to yell out but my tongue wouldn't move. He went around curves like a bullet, slipped an eccentric, blew out his soft plug, went down grade fifty feet to the mile, and not a confounded brake set. She went by the meeting point at a mile and a half a minute, and calling for more steam. My hair stood up like a cat's tail because I knew the game was up.

"Sure enough, dead ahead of us was the head-light of the 'special.' In a daze I heard the crash as they struck, and I saw cars shivered into atoms, people mashed and mangled and bleeding and gasping for water. I heard another crash as the French professor struck the deep keys away down on the lower end of the southern division, and then I came to my senses. There he was at a dead stand-still, with the door of the fire-box of the machine open, wiping the perspiration off his face and bowing at the people before him. If I live to be a thousand years old I'll never forget the ride that Frenchman gave me on a piano."—*N. O. Times-Democrat.*

Some years ago a rich planter of Cuba ordered a lot of cars from the Ramapo Works, and came to see Mr. Snow about them himself. He wanted things fixed up just right to insure the best results in his country. He made no inquiry about the wheels, axles or other ironwork, didn't care whose coupler was used or what paint, but demanded a sworn statement from the cutter that all the timber was felled "in the decline of the moon."

(22) A. G. C., Trotwood, O., asks

How do you find the number of revolutions per minute a locomotive will make? *A.*—By counting.

(23) W., Selma, Ala., writes

Please give me the rule in regard to putting water-gauge cocks into locomotive boilers. Distances from crown sheet. *A.*—There is no rule, the practice is to put the lower gauge from six to eight inches above the highest point of crown sheet.

(24) G. H., Detroit, asks:

1. What is the spring on tumbling shaft for and what advantage is there in its use? *A.*—To make the lever handle easier by counter-balancing the weight of the links and rods. 2. Is eight feet too high for center of boiler for safety at high speeds? *A.*—There are many locomotives this high running with entire safety.

(25) G. L. T., Detroit, asks:

1. To what extent has steam reversing gear been applied to locomotives in this country and England? *A.*—In this country very little, the P. R. R. and Reading have some in use, the former road threw away some of the rig when balanced valves became a success. 2. What is the approximate ratio of volumes of boiler and cylinder in new 8-wheel passenger engines. *A.*—Varies according to engine; take general dimensions given from time to time and figure it out yourself—it will be time wasted, however. 3. Why is cylinder center higher than driving-wheel center. *A.*—To get cylinders up out of way of truck, out of snow, etc. 4. Is it practical to compound a 3x4 cylinder engine? *A.*—It can be done.

(26) C. S. W., Madison, Wis., writes

Will you please state in your paper the proper position for deflecting plate and petticoat-pipe in extension front of a soft coal burning locomotive, and also what effect the raising and lowering of them would have on the fire, and also what part of the fire by so doing would be effected the most? *A.*—This depends so much on the arrangement of the front that it is impossible to answer. 2. What size stack (a straight one), petticoat-pipe and nozzles should a 15-inch cylinder have, other things being all right. *A.*—About 14 inches.

(27) J. A. S., Selma, Ala., asks: 1. Why is the pin in the link-block not in the center of the link? *A.*—It is thrown out to equalize the cut-off distorted by the angularity of the main rod. 2. What is meant by exhaust clearance. *A.*—When the exhaust cavity of the valve is wider than the exhaust port and both bridges. 3. What is meant by the angular advance of an eccentric? *A.*—The amount that the throw of the eccentric is advanced from a point at right angle to the pin toward the pin—if the pin is on the center, the amount that the eccentric is placed ahead of the quarter is the angular advance.

(28) W. C. H., Moncton, N. B., writes: 1. Has there been a standard height of freight car draw-bar adopted by the M. C. B. Association If so, what is it? *A.*—The standard height of draw-bars for freight cars is 33 inches, measured from top of rail to center of drawbar when car is empty. 2. Has there been a standard strength of spring adopted for freight cars, or anything to regulate the depression of the springs per some unit of weight? *A.*—No standard relating to this has been adopted.

(29) A Fireman, Buffalo, N. Y., writes.

Our road, the D. L. & W., has adopted the extension front end, and are having considerable trouble in making them a success. We used the single nozzle, and in making alterations to get the engine to steam the M. M. ordered a double 3-inch nozzle. My engineer claims that with the double nozzle the engine will carry her water better, and I fail to see what difference it makes. *A.*—The kind of nozzle used has about as much influence on the water level as a horseshoe hung under the headlight, or the fact that the windmill that pumped the water saw the new moon over its left shoulder.

(30) C. F., Winona, Minn., asks.

1. Suppose you place a piston in the center of its cylinder so that a line drawn through the exact center between the two cylinder heads would evenly divide the thickness of both the spider and follower plate, where will it place the crank-pin? *A.* The pin will be a little ahead of the quarter, this is on account of the angularity of the main rod; if it were disconnected from the pin and dropped to the axle it would bring the center of its bearing to the center of the axle, the greater the length of stroke the more the effect of angularity is manifest. 2. Which end of a cylinder uses steam the furthest, front or back? *A.*—Practically the same. 3. Does the lead of valves wear away? I am firing an engine, 17x24. When she came out of the shop she had a 32d lead in her valves; when she was out a year we found she was getting logy, and could not make the time. They run her valves over and found she lost a 64th lead. *A.*—The wear on the valve motion caused it to open the port a little slower—this needs no explanation. Think. 4. Is the pressure in the top and bottom of the boiler alike or not? *A.*—The pressure at the bottom of the boiler is greatest on account of the weight of water, the steam pressure is elastic and the water transmits it to the bottom of the boiler, but adds its own weight.

---

Those who have endured the misery of riding in a European railway carriage in winter or during cold weather will understand why some of the Parisian papers are expressing joy that the Northern Railroad Company, of France, have determined to warm their carriages. They seemed never to have dreamed of attempting to make the boiler of the locomotives supply heat for the cars. The warmth is to be provided by means of acetate of soda placed in boxes. The chemical is put in a solid state into the boxes, and these are then plunged into hot water of about 100 degrees. The effect is that the soda becomes liquid. On being taken out of the water the boxes are wiped dry and put into carriages. By degrees the soda solidifies, and as long as that operation lasts—that is, for about five or six hours—it gradually gives off the heat it has absorbed in the melting process.

---

We have received from the Otley Mfg. Co., Chicago, a small pamphlet lately published, setting forth the merits of the Eureka steam packing cement made by the company. This cement is used for joints of all kinds, and we know from experience that it is an excellent material for the purpose, being much better than lead or rubber. Nothing has ever been tried for smoke-boxes and other parts where great heat is present that has approached this cement in making a tight joint. The use of the material is reported to be increasing greatly. It is a case where merit is winning success.

---

Another boiler exploded on a Reading locomotive on January 28th. The engine was slowly pushing a long train, eighty-six empty coal cars, up a grade near St. Clair, Pa., when the explosion occurred. The entire crew were instantly killed—five men. The boiler that exploded was one of the 72-inch straight ones, with narrow fire-boxes, only four years old, and was the fourth out of five of this class to explode. It is maintained by the men that these boilers were seldom if ever inspected, that broken stays are the rule not the exception, and that 180 pounds of steam was carried on them where 150 was originally intended, the fifth engine has been shopped for a new boiler. The back, or fire-box end of a locomotive boiler is of something the same shape as a Burdon gauge spring tube. Every time it is subjected to great varying pressure, there is more or less of a movement that has a tendency to bend and finally to break stay-bolts. In the use of such pressures as 180 pounds per square inch, eternal vigilance is the price of safety. Inspect!

---

The postal authorities of Germany sent some men to this country some time ago to study our railway mail service, and especially our mail cars. They reported that the cars used by the C., M. & St. P were in their estimation the best in the world. The result of this was that the German government asked the C., M. & St. P. road to build them two models of their cars. These models are now finished and on their way to Germany. They are complete cars, built just one-sixth the full size, and are complete in every particular, and the interiors contain all the racks, mail-throwing devices and mail catchers, as well as a full complement of sacks. These models are 12 feet long and were exhibited in Milwaukee before being sent away. They were built at the West Milwaukee shops.

---

In a paper read by Mr. D. L. Barnes to the Western Railway Club on "Recent Progress in Car Construction," he said The freight car in use twenty years ago was in appearance not unlike those we now use; but the difference in construction is considerable. The most important change has been, of course, in the increase of capacity. The old cars were adapted to carry 24,000 pounds, and weighed 20,000 pounds, or 8-10 pounds of dead weight per pound of rated useful load. The present car weighs about 30,000 pounds, and has a capacity of 60,000 pounds or 5-10 pound of dead weight per pound of rated useful load. The car of twenty years ago had a capacity of 1,000 cubic feet, or about 20 pounds of dead weight per cubic foot, or a rated capacity of 24 pounds per cubic foot. The recent cars have a capacity of nearly 2,000 cubic feet, or 15 pounds of dead weight per cubic foot, and a rated capacity of about 30 pounds per cubic foot. From this it is seen that there has been 37 per cent. decrease in dead weight of box freight cars per ton of full rated load; 25 per cent. decrease in dead weight per cubic foot of capacity, and 25 per cent. increase in the full rated load per cubic foot of capacity.

---

The wisdom of legislators was well illustrated when a public demand arose many years ago to pass laws that would help to secure the safety of steam boilers. The Government inspectors reported in favor of the use of charcoal-iron being exclusively employed for making boilers. A law to this effect was passed and makers of charcoal-iron were advised to put the stamp C on the plates. All makers of iron plates then began using the C stamp, and as no penalties were imposed on those who used this stamp upon other than charcoal-iron, it took years to amend the law to make it useful.

---

In a discussion on air-brake matters before the New York Railroad Club, when questions relating to the oiling of brakes were receiving attention, an inspector of air brakes mentioned that brakes were sometimes oiled by pouring a liberal supply of black oil into the hose. Others corroborated this, and the impression was given that the practice was common. At this rate, it is not surprising that sticking and slow-acting triple valves are common. The general conclusion was that, as a rule, too much oil is used, even when applied in the proper way

## The Station-Master and the Goat.

One of the most imposing personages to be seen when traveling in Belgium is the station-master. He appears to combine the dignity of a field-marshal with the importance of the village bailiff, so graphically portrayed by Dickens. He wears an ostentatious military uniform, and he is distinguished from all lesser railway lights by a blazing red cap. All train movements at a station seem regulated by the wave of the station-master's arm, and all and sundry regard him with awe mingled with fear. The altitude of this official must be understood in order to appreciate an event which happened lately at Charleroi.

In the seclusion of private life the station-master is not always performing an heroic part. It appears that the station-master at Charleroi is owner of a goat, and that this wife of Aries provided a supply of milk for the family. This particular goat had all the evil propensities of its kind, and was noted for kicking and butting those with whom it was not on amicable terms. The relations between the goat and the station-master were not cordial.

It happened that Mrs. Station-Master went from home one day, and during her absence the problem of securing the supply of milk from the goat came up for solution. The juvenile members of the family were in distress for want of milk, and the supply must be drawn from the goat. The station-master tried his most winning and seductive arts as a milker, but the goat would have none of him. Being a man of fertile resources, as becometh an old railroader, he conceived the idea of personating his wife, and making the goat believe that the regular milker was operating upon it. He donned his wife's attire, and was just preparing to deceive the goat, when, to his consternation, the whistle of a passenger train was heard. There was no time to change his attire, and for a passenger train to stop at the platform without the station-master being there to receive it was without precedent.

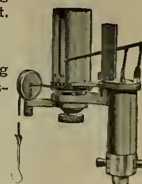
Again he acted promptly. His wife's bonnet was thrown aside, and hastily putting on his red cap that none might mistake who was there, the station-master strode out to his acustomed place, skirts, waist, bustle and other parts of the female outfit making an incongruous combination with the bearded face, red cap and military bearing. In vain the station-master gave his signals with unusual austerity and dignity. Some of the passengers laughed, but the prevailing impression was that the station-master had suddenly gone crazy. He was promptly marched off to prison. The case is undergoing investigation.

# THE ASHCROFT MANUFACTURING COMPANY.

Our double Bourdon Spring Gauge is the only one with actuating mechanism independent of the case. Case, dust and steam tight. Large figures.

Locomotive Steam Gauge.

The Tabor Indicator has the lightest reciprocating parts, and is the only accurate instrument at excessively high speeds. It has no equal.



Tabor Indicator.

**OFFICE AND SALESROOM:**

**111 LIBERTY STREET, NEW YORK.**

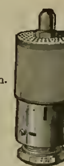
New Works: BRIDGEPORT, CONN.

# Richardson's Patent Safety Valves and Mufflers.

THE MUFFLER IS A SIMPLE ATTACHMENT TO RICHARDSON'S WELL-KNOWN ENCASED

## SAFETY VALVE.

Encased "Pop" Valve.



Muffler.

**THESE VALVES HAVE STOOD THE TEST OF YEARS.**

The Valve and Muffler have been adopted by many of the largest railroads, and are giving entire satisfaction.

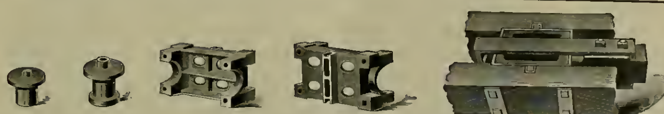
MADE IN THE FOLLOWING SIZES: 2¼ INCH, 2½ INCH, 3 INCH.

*Sample Valve and Muffler will be sent on trial, Subject to Approval.*

THE CONSOLIDATED SAFETY VALVE CO.,

SOLE OWNERS AND PROPRIETORS,

Salesrooms: 111 LIBERTY ST., N. Y. Works: BRIDGEPORT, CONN.



# BUTLER DRAW-BAR ATTACHMENT.

This Company guarantees its device for One Year from application against breakages. If the Yoke or Strap Style is used, we guarantee against Spring breakages and Pulling out of Drawheads or Couplers.

*No other device offers as many good features as the Butler.*

**IT HAS THE FEWEST NUMBER OF PARTS.**

**IT HOLDS THE DRAFT TIMBERS TOGETHER.**

**Simplicity and Strength are thoroughly combined in this attachment.**

These Elements reduce breakage to the lowest point and make repairing easy.

**It requires the least number of bolts and costs less to apply.**

Is being applied to more CARS than any other device on the market.

Butler Draw-Bar Attachment Co., Cleveland, O.

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

VOL. V, No. 4. NEW YORK, APRIL, 1892. PRICE, 20 Cts. Monthly. $2 00 per Year.

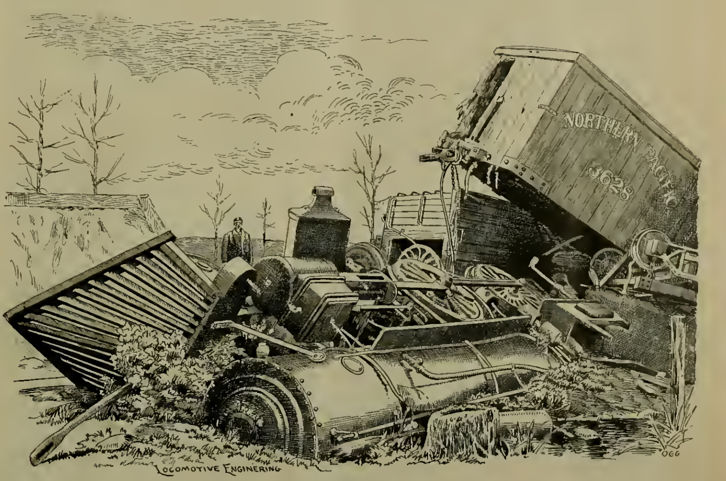
## Under the Wreck.

The occurrence illustrated in the accompanying engraving is one of those sad incidents of railroad operating that render the life of a railroad trainman so much like that of a soldier in active service. This is the line of industrial warfare that claims many victims. In this case three men went down to the Valley of the Shadow of Death.

About midnight a train of north-bound fast merchandise was speeding along on a railroad in the Northwest. No train was ever run under circumstances more promising for reaching the terminus on time. There were twenty loaded cars, most of them being equipped with air-brakes, and a first-class engine that handled the train as if it were merely load enough to steady the power. They were speeding along at about thirty miles an hour when, without the least warning, the engine's wheels dropped from the rails. They were entering upon an embankment and a small bridge was in front, which the engine passed over on the ties. Then she turned over, the cars broke down the bridge, and engine, cars and bridge were mixed in a confused wreck with three precious human beings beneath. The Northern Pacific car that stands up so prominently in the picture was away from home.

The engineer was pinned under the tank alive, and it took five hours' work to get him relieved. He died three hours after being taken out. On the train stopping the conductor ran ahead, and on the way met the fireman stark naked on his way back to the caboose. He had been badly scalded, and tore off all his clothes in his agony. The head brakeman was found standing knee-deep in water, which was so hot that they had to put down a plank to reach him. He and the fireman both died from scalding.

The rumor was circulated that the wreck was caused by obstructions laid on the track, and the railroad company offered a reward of $1,000 for the arrest and conviction of the train-wreckers. New ties had been distributed for some time to be put in the track where the accident happened. The coroner's jury investigated the case, and returned a verdict to the effect that the accident happened through the spreading of the rails, due to the presence of rotten ties. This was the common-sense view of the cause of the derailment. The road where the accident happened is well managed, but there was a weak link somewhere that permitted worn-out ties to remain in place.



UNDER THE WRECK.

## Simple Test of Coal.

Railroad men do not need to be told that there is great diversity in the quality of coal bought for steam making. It is no uncommon thing for the fuel from one set of coal mines to have ten per cent. or more carbon than the coal from another source of supply. As the carbon is the vital element in the coal, care ought to be taken to choose the best quality of coal. As the price is generally about the same, a little care might result in important saving of fuel.

There is a very simple form of test for coal that ought to be known to everybody interested in fuel. It is based on the quantity of pure lead that will be released from its oxide by a given weight of carbon. Litharge is oxide of lead, and contains 34.5 units of lead to one of oxygen. When finely powdered coal mixed with oxide of lead is heated to the combining temperature, the oxygen of the compound unites with the carbon and leaves the metallic lead. The quantity of lead precipitated gives the means of determining how much carbon there was in the coal used.

Let a sample of coal be heated with forty times its weight in pure litharge. The weight of the lead formed will give a basis for ascertaining the purity of the coal. The weight of lead will vary from twenty to thirty times the weight of the coal. If the weight of lead is twenty-five times the weight of the coal employed, the per centage of carbon in the coal will be about $\frac{85}{100}$. This is not absolutely correct, but it is near enough for all practical purposes.

A plan of making this test, devised by Prof Monroe, is to fit up a piece of 2-inch iron tube, about 2 feet long, with a threaded cap on one end and a reducer at the other, to which is fastened a piece of ¼-inch gas pipe about 3 feet long and open at the ends. One ounce of finely powdered coal, mixed with about forty times its weight of pure litharge, is placed in the tube. This is placed in a hot fire, with the gas-pipe slanting outward. The mixture will boil quickly, giving off a stream of gas which can be felt by the finger. As soon as the gas stops escaping, the tube should be removed from the fire. A sharp rap will send the lead to the bottom of the tube. The weight of the lead button found will, by the calculation given, show the per centage of pure carbon in the coal.

## Florida Central & Peninsular.

The Florida Central & Peninsular Co. operates 650 miles of road, the main portion running east and west across the northern part of the State of Florida. They have but forty-five locomotives, these, however, being double-crewed and chain ganged.

The main shops are located at Fernandina, on the eastern coast, but they have a moderate-sized shop at Tallahassee.

The old shops at Fernandina burned down some three or four years ago and were never rebuilt. A few boards were stuck up over one lathe and an old engine, fast to the side of a dead boiler, drove it and a fan for the blacksmith shop and a small foundry. The pits were under a shed, and the work done under many disadvantages.

New shops are already up, and will soon be equipped with tools and ready for business. With the facilities enjoyed, it is a wonder to me that the motive power has been kept running at all.

Mr E Burton, who has but recently become master of machinery, has been for some time past general foreman of the shops at Tallahassee, and is now hard at work trying to bring order out of chaos. Mr Burton is one of the large class of railroad motive-power men who graduated from the B & O.

The fuel used on the road is pitch pine, and engines carry those homely balloon stacks. Most of the power is comparatively new and of modern size and style.

Colored firemen are sprinkled in with the white ones, and seem to make very good men. They are without the incentive to work for promotion, and therefore evince little interest in learning other than their firemen duties. The engineers prefer them to the white fireman, who is credited, in this part of the country, with getting a bad dose of "throttle fever" after having been exposed for about three months on the left side.

J. A. H.

The practice of taking links and pins from cars standing on side tracks is almost universally followed, and is frequently a source of delay and annoyance. General Superintendent Brown, of the Fall Brook Railroad, is opposed to this practice and vigorously enforces rules against it. The standing penalty is prompt and permanent dismissal. Yet dismissal is a rare penalty for offences on that road. But they will not stand link and pin-stealing.

## Samuel L. Moore—the Career of an Old-Time Engineer.

By HARRIS TABOR.

The modern traveler has become so accustomed to the luxuries of the "vestabuled Pullman" that he does not realize what railroading meant to the pioneers of a generation ago. He may touch the electric button at his side to order a lunch or a

cocktail, with never a thought of the men on the foot-board or their predecessors of a few years ago. He may sit listlessly under the barber's razor, with no fear of losing a portion of his face, or he may lie in the bath-tub until, if gauged by cleanliness, he is fit for the highest Heaven. If he happens to be a literary man, or one with the nightmare of unanswered letters on his mind, he may summon a stenographer and talk to his heart's content, with a certainty that his garrulity will come back to him on a neatly printed sheet ready for his signature. He may enjoy his after-dinner cigar, and take a turn with some favorite author in apartments that will satisfy the most fastidious dude in the "Four Hundred." If it be his good fortune to travel with his wife, a lady's maid is at his beck to relieve his clumsy fingers of the little details of her toilet, and to pass the final judgment, which would otherwise fall to him, with a certainty that it will be better done. Everything, in fact, that comfort can suggest is at his command while traveling at a speed that would have been considered impossible a dozen years ago, and at a cost that is reasonable when compared with the better hotels. He is literally living in a hotel on wheels, wherein he may enjoy himself as he likes. This is modern railroading, with which all who travel are familiar. It is an evolution that has been brought about by untiring industry, pluck, ingenuity and skill, coupled with a perserverance in danger and difficulties that would make heroes of men in time of war. Indeed, many men have had knighthood and medals thrust upon them for less exhibitions of courage than pass unnoticed every day on American railroads. This is not strange. Frequent occurrence destroys sentiment, and makes all things commonplace. The every-day hero is soon buried beneath the multitude of brave deeds.

In the early days of American railroads, when the whole number of locomotives in in the country would come well within the dozen, it meant something to be an engineer, he was brakeman, as well, and to his other accomplishments must be added the skill of the machinist, with a capacity to spike down "snakeheads" as they raised and threatened the train. In those days there were none of the wrecking appliances now in use, no double tracks, and few sidings to fall into play in case of a wreck, and when one did occur it must have taxed to the utmost the few resources of the road.

There are but a few of these "old-timers" left, and their number is fast growing less. It has been suggested by the Editor that his readers have an interest in anything pertaining to these veterans of the rail, hence this letter.

It has been the good fortune of the writer to meet, almost daily for the last two years, one of the oldest, if not the oldest, railway master mechanic in America, Mr Samuel L. Moore, president of the Crescent Iron Works and Shipyard, Elizabeth, N. J. Mr. Moore is a hale and hearty old gentleman, eighty-nine years of age. His age is a long time for a man to live and retain his mental activity; it covers three generations, and a period of time which represents the industrial progress of the world. Mr. Moore was born in Crosswick, N. J., one year after the Cornish miner, Trevithick, patented his high-pressure locomotive with fly-wheel on the crank-shaft, and nine years before John Stevens, of Hoboken, memorialized the Legislature of New York, urging the budding of railways, and showing their advantage. He was twenty-six years old when Stephenson built the "Rocket," which was the beginning of the world's system of steam railways. When he began his railway career there were only 1,000 miles of railroad in the United States, and of this probably not 200 miles used locomotives.

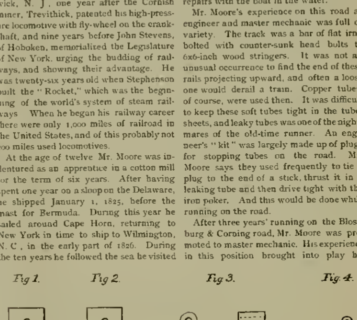
At the age of twelve Mr. Moore was indentured as an apprentice in a cotton mill for the term of six years. After having spent one year on a sloop on the Delaware, he shipped January 1, 1825, before the mast for Bermuda. During this year he sailed around Cape Horn, returning to New York in time to ship to Wilmington, N. C., in the early part of 1826. During the ten years he followed the sea he visited the west coast of Africa and Napoleon's grave at St. Helena, and was shipwrecked twice. He arrived in New York January, 1836, from the west coast of Africa. One month later he became fireman on the Trenton & Philadelphia R.R., where he remained until the following October, when he accepted a similar position on the New Jersey R.R. & Transportation Co. Here he remained as fireman, running between Jersey City and New Brunswick, until some time in 1837, when he became engineer on the same road. He ran on the N. J. R.R. & Transportation Co. road as fireman and engineer about five years, and then, in May, 1841, accepted a position as engineer on the Corning & Blossburg road, with instructions to take the new locomotive "Tuscarora," built by Rogers, of Paterson, to Corning via canal boat. The "Tuscarora" was the third locomotive built by Rogers. She had four 4-ft. drivers and 12x16 in cylinders. Rogers was to put the "Tuscarora" on the boat in Jersey City. When he saw the boat, a double-ender—commonly known as chunkers—he did not consider her safe, and would guarantee nothing beyond the loading. The locomotive was put in one end of the boat, the tender in the other, with Mr. Moore's household goods between. Mr. Moore, with his family, took passage on one of the then famous canal "packets," which bore about the same relation to the ordinary canal boat that a Mississippi steamer now does to a Fall River liner. The trip was up the Hudson to Albany, thence via Erie Canal to Geneva, Seneca Lake to Jefferson, now Watkins, and from there to Corning by stage. Mr. Moore has many pleasant recollections of this trip. At Corning Mr. Moore could get no tidings from the "Tuscarora." He returned to meet her, finding the boat at Schenectady. The delay was caused by staving a hole in the boat which compelled unloading for repairs. Mr. Moore then took charge and remained with the "Tuscarora" until her arrival at Corning. At Geneva another snag was encountered, and another hole resulted. Mr Moore made the repairs with the boat in the water.

Mr. Moore's experience on this road as engineer and master mechanic was full of variety. The track was a bar of flat iron bolted with counter-sunk head bolts to 6x6-inch wood stringers. It was not an unusual occurrence to find the end of these rails projecting upward, and often a loose one would derail a train. Copper tubes, of course, were used then. It was difficult to keep these soft tubes tight in the tube-sheets, and leaky tubes was one of the nightmares of the old-time runner. An engineer's "kit" was largely made up of plugs for stopping tubes on the road. Mr. Moore says they used frequently to tie a plug to the end of a stick, thrust it in a leaking tube and then drive tight with the iron poker. And this would be done while running on the road.

After three years' running on the Blossburg & Corning road, Mr. Moore was promoted to master mechanic. His experience in this position brought into play his capacity to do in cases of emergency. In our days a copper tube is a very simple, long hole, which is within the reach of any man who can pay for it. Then it was different. None were carried in stock nearer than New York or Philadelphia, and during the winter season wagon freights were enormous from these points. The soft, sulphurous coal used on that road would destroy a set of tubes in two or three years, making replacing necessary. In some cases, when tubes were not obtainable, Mr. Moore has made them, doing his own brazing and drawing into shape afterward, for entire boilers. When he was master mechanic of this road the locomotive "Chemung" was bought from a New Castle, Del., concern. She had one pair of drivers, with the weight pretty evenly distributed over them. Her first attempt at pulling a train developed a disposition to lift in front and leave the track. Mr. Moore put pony trucks under her rear before she became serviceable. One cranky locomotive on a road to-day would mean nothing, but if twenty-five per cent. of the motive power was on its bad behavior there might be trouble. The "Chemung" comprised just one quarter of the motive equipment of the Blossburg road.

In May, 1847, Mr. Moore engaged as superintendent of a machine shop building wood planers, in Albany. He remained here only a few months. In November,

*Fig 1.* *Fig 2.* *Fig 3.* *Fig. 4.*



EVOLUTION OF THE IRON BRAKE-SHOE.

1847, he accepted the position of M. M. of the Elizabeth & Somerville road (now part of Central of N. J.), and moved his family to Somerville. The following year he moved to Elizabethport, where he has since lived. When Mr. Moore came on this road its car equipment comprised, all told, about fifteen cars. The motive power consisted of four locomotives with 10x16 inch cylinders, single pair of drivers, all built by the Baldwin Locomotive Works. The length of track was 26 miles. When Mr. Moore took charge of the mechanical branch, he says that the only tools in the shop that had a rotative motion were a grindstone and a blacksmith's crank drill. He soon secured a lathe for turning driver tires, and one smaller, but had nothing to give them motion. A steam-engine for driving these tools was then out of the question. He had lathes, but unless they could be made to revolve they were useless. He was equal to the occasion. He put a set of rollers in the track so that the driving wheels would revolve them; from these rollers he took his motion to his lathes. When an engine came in from her run to Somerville she was put to the treadmill duty of turning off the tires of some sister engines, much the same as the farmer uses his dog for a churn motor. This was his shop power until the "Speedwell" became useless on the road and was "jacked up" in the shop for permanent power.

Mr. Moore has been an important factor in the evolution of the present cast-iron brake-shoe. I believe he was its inventor. At any rate, when he adopted it it was new to him and his road. When he came on the Somerville road the common braking appliance was a piece of wood suspended to the car, like sketch No. 1. This was found too short-lived, and an effort was made to add staying qualities by the addition of old leather next to the wheel. Old harness traces were found to be better than anything in the leather line on account of their firmness. This was unsatisfactory, and bar iron was substituted with but little better results. It was found that the wrought-iron became so hot that the wooden beam would burn. Sketch No. 2 shows the application of wrought-iron. In the fall of 1850 Mr. Moore designed the form shown in sketch No. 3, which he found very satisfactory. Later on No. 4 was substituted on account of its cheaper form. The comments made on the introduction of the cast-iron shoe by the trainmen were numerous and generally adverse. It would wear the wheel badly, and in cold weather its braking capacity would be limited by frost.

Castings for the road were difficult to get. There were no foundries nearer than Jersey City and Newark. At one time a foundry in New Brunswick made the castings. The constant annoyance from being so far from the foundry led Mr. Moore, in company with his brother and Isaac Field, to start a small foundry in 1854. That small beginning was the nucleus of the immense shops and ship-yard of which he is now president.

In the car equipment, when Mr. Moore came on this road, there were no two cars alike No two axles would interchange.

The foundry business grew to such an extent that in 1858 Mr. Moore resigned his position as master mechanic and took charge of his own shops, adding a machine shop. In 1869 the interests of the other partners were purchased and his son Douglass G. became associated with him, under the firm name of S. L. Moore & Son. In 1886 the present company of S. L. Moore & Sons Co. was incorporated and the works moved to the present site in new shops. The officers were. President, Samuel L. Moore; Vice-President, Douglass G. Moore; Secretary and Treasurer, Miller F. Moore.

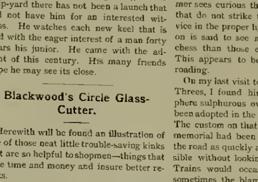
It is a noteworthy fact during the time Mr. Moore was a locomotive runner his trains had no brakes.

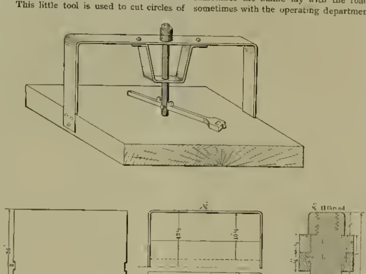
It has fallen to the lot of few men to look back on so long a life well spent. Integrity, pluck and perseverance have been well rewarded. Mechanical and social distinction, as well as political preferment, have centered around him. He was a member of the City Council ten years, and for two terms represented his district in the State Legislature at Trenton. After a busy life, reaching almost to a century, he is still active, and visits the shops daily. Since the beginning of the ship-yard there has not been a launch that did not have him for an interested witness. He watches each new keel that is laid with the eager interest of a man forty years his junior. He came with the advent of this century. His many friends hope he may see its close.

## Blackwood's Circle Glass-Cutter.

Herewith will be found an illustration of one of those neat little trouble-saving kinks that are so helpful to shopmen—things that save time and money and insure better results.

This little tool is used to cut circles of glass for head-lights, signal-lamps, etc., always insuring a round job and preventing cracks from running out of cutter. The tool is one devised by General Foreman Blackwood, of the South Carolina shops, at Charleston, S. C.





BLACKWOOD'S CIRCLE GLASS-CUTTER

The general view shows the tool complete, except the diamond-holder, which is held in the slot at end of bar.

On the bed or platen they draw circles of all the standard sizes of round glass used, and in cutting it is only necessary to see that the glass covers the circle used and the tool placed over it. On the tool used by Mr. Blackwood he has a common wooden one-foot rule set into the base from the center out so that the tool can be set to cut any given size without measuring.

In some earlier forms of the cutter made by Mr. Blackwood trouble was experienced from the cutter chattering, but this is entirely avoided by the form of bearing at top of spindle, plainly shown in the detailed drawings; on which sizes are given enabling those interested to make the machine.

On a recent visit to the Charleston shop the writer saw a large glass cut into rings about an inch wide; these had been put together again without breaking through, so accurate is its work done.

## What a Railroad Drummer Sees and Hears.

KICKING AGAINST THE PRICKS—A SENSELESS SUPERINTENDENT.

BY SAM SHORT.

It appears to me that a railroad drummer sees curious things about railroading that do not strike the men in active service in the proper light. The man looking on is said to see more of the contest in chess than those engaged in the game. This appears to be the case also in railroading.

On my last visit to Gratsam, of the Twin Threes, I found him making the atmosphere sulphurous over new rules that had been adopted in the operating department. The custom on that system from time immemorial had been to get the trains over the road as quickly and comfortably as possible without looking closely into delays. Trains would occasionally be late, and sometimes the blame lay with the road, sometimes with the operating department and at other times with the machinery department. There had been no systematic reports of delays made, and it was not clearly understood what department was most at fault, but each agreed that the other was the greatest sinner. There was not much blaming or hard feeling about the matter, for they were all practical railroad men and understood that delays would occur in the best regulated department. No kettle was much inclined to call black bottom to the pan.

But a change has come o'er the spirit of the dream. A new general superintendent has appeared on the scene, and his ideas are rattling the dry bones out of their sockets. This new superintendent declares that guess-work is not good railroading, and he demands reports of all irregularities. When I went into his office, Gratsam was praying in his peculiar way over an assortment of slips calling for explanations about delays due to defects of engines and cars. My friend was moved all over with wrath, not at the shortcomings that had caused the delays, but at the new order of things that pointed them out. He was exasperated because nothing had been said about numerous delays he was familiar with by bad train-dispatching, blocking of the tracks in the yards, and the slow handling of baggage. "Everything is heaped upon the mechanical department," he declared, "railroading is going to the dogs with all these theoretical dudes pretending to manage things."

What I gathered from the conversation that ensued was, that Wilt. Gratsam had made up his mind to throw every obstacle in his power in the way of the new general superintendent. Wilt. thinks the road cannot run without himself looking after the department that has grown from almost nothing under his charge. It will be a terrible blow to the old man if the management turn him out, but I am afraid that is what will happen.

One meets with a great many cases similar to this, where men in charge of motive power are inclined to resent the introduction of what are really business methods. Opposition of this kind generally proves bad for the kicker.

In Gratsam's case the general superintendent is in the right and the master mechanic in the wrong; but in my travels, I frequently find things the other way. While in Cincinnati last week, I heard a story talked about that reflects very badly upon the general superintendent of an Eastern railroad.

It seems that a rumor had been going around that the master mechanic of the Eastern road was about to quit, and a Cincinnati railroad man wrote to the general superintendent recommending one of his friends for the position. The G. S. answered that he was anxious to get rid of the master mechanic and had tried to get him to quit without success; that he believed the man would cling to the position till he was driven out with a club.

I know both parties intimately, and feel certain that the master mechanic is by far the most capable and efficient of the two.

## Work at Schenectady.

The Schenectady Locomotive Works are not shouting very loud about the number of compound locomotives they are building, but they seem to be hauling in sufficient orders to satisfy the advocates of the newer type of locomotive. After a satisfactory trial of a number of compound locomotives in different kinds of service, the Southern Pacific Company have lately ordered twenty-seven new compounds from Schenectady. As far as we know, this is the largest number of compound locomotives ever called for in one order. Seven of the engines are intended for passenger service, and have cylinders 20 x 29 x 26 inches. They are ten-wheelers. The remaining twenty engines are twelve-wheelers of the form illustrated in LOCOMOTIVE ENGINEERING for January.

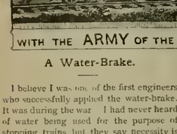
These works have two mogul compounds for the Adirondack & St. Lawrence about ready for delivery. They have just received from the New York Central an order for one hundred locomotives.

## Alabama Midland Railroad.

One of the new and struggling roads of the South which is rapidly lifting herself up out of the mud, where it was left by the construction company and turned over to the Plant system as a gilt-edged property, is the Alabama Midland, running from Montgomery to Brauntree, through perhaps the most valuable timber and farming land in Alabama and Florida. What has been accomplished in this direction has been done through the perseverance and indomitable will of Col. Bradford Dunham. As a manager of Southern railroad properties where economical methods are essential for dividends, Col. Dunham has few equals. His success is based on a comprehensive system of management and direct supervision of details. Elaborate system in transportation, mechanical and roadway departments cannot be successfully saddled upon roads south of the Ohio In the South success depends to a great extent upon the personal attention and vigilance of the manager.

### A Water-Brake.

I believe I was one of the first engineers who successfully applied the water-brake. It was during the war I had never heard of water being used for the purpose of stopping trains, but they say necessity is the mother of invention. It was so in my case. I arrived at Cowan, on the N. & C. R R , with thirteen cars, Engine 17, L. & N., Robert McKallipp, conductor , Robert Warnock, fireman. The pusher assisted us up the hill. In the tunnel I felt the slack run out, thus knowing we were to get



Work of Sherman's Destroyers.

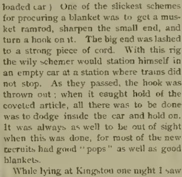
down the mountain alone. We went down in a hurry Before we were fairly out of the tunnel I could feel the train bumping the engine and called for brakes, but felt none About this time McKallipp came over the train bareheaded, shouting to me to hold her as they had only three brakes and had broken two of them I had been trying to slack them by reversing previous to this, but had let up on them two or three times for fear of blowing steam-chest covers off. Not knowing what might be at Tantalon, I was at a loss what to do Then my good angel came to my aid. We were flying I turned on the left-hand pump. Warnock set it to work by opening the pet-cock With both pumps working it did not take long to get a full boiler When she showed water in the whistle I reversed and opened the throttle, with a fervent prayer that the steam-chest covers and cylinder-heads would stand the pressure of the water. They did, but we passed Tantalon a little faster than I want to ride under such circumstances

The railroad company abandoned Tantalon as a meeting station after the war, as there were several disastrous wrecks there by reason of trains running away on the mountain.

### How Trainmen got Home-made Blankets.

When President Lincoln called out the one hundred days men many of them were furnished with fine double all-wool blankets by their friends in the North Now, the aforesaid blankets looked very tempting to the Government trainmen. As it was getting along toward winter when these men were sent South, many schemes were devised by them to secure one or more of the much-coveted coverings for their bunks. As the soldiers had to ride on the top of the cars they were compelled to use their bedding to keep warm (No soldier was allowed to ride inside of a loaded car ) One of the slickest schemes for procuring a blanket was to get a musket ramrod, sharpen the small end, and turn a hook on it. The big end was lashed to a strong piece of cord. With this rig the wily schemer would station himself in an empty car at a station where trains did not stop. As they passed, the hook was thrown out ; when it caught hold of the coveted article, all there was to be done was to dodge inside the car and hold on. It was always as well to be out of sight when this was done, for most of the new recruits had good "pops" as well as good blankets.

While lying at Kingston one night I saw the tables turned. One of our conductors had a Mexican blanket "serape." He had been showing it to some soldier friends of his who were in his caboose, where they spent the evening. About ten o'clock the conductor made up his bed, spreading his serape over him. I was on the station platform, close to his car, when I saw a soldier sitting between the trucks immediately under the car-door. As there was nothing unusual about this I did not pay any attention to the man until a passing train came by, when he got up and made ready to board the train, which he easily did. About the time he dodged between the cars I saw an object flutter out of the caboose, and start up the track after the train. It was Steven-



Badly Kinked.

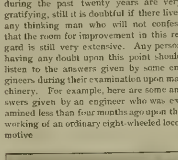
son's "serape" at the end of a cord , he fired one or two shots after the train. said a few cuss words, and crawled under an old Government gray.

James H. Hevey

The writer recently measured the depth of sand on a break-beam on the tender of an L. & N. engine, running between Pensacola and River Junction, Fla. The engine had run the 162 miles, and was covered with sand, that on the beam being an inch and an eighth deep This division lays through white sand wastes , at night it looks like a slight fall of snow. Not very good for machinery, and awful bad for tires. The only thing that could be said in its favor is that it causes the brakes to take hold in business earnest.

### More Education for Engineers.

What means can be employed to more fully impress upon the minds of machinists and locomotive engineers and firemen the great importance of education in their business? While it must be acknowledged that the results of effort in this direction during the past twenty years are very gratifying, still it is doubtful if there lives any thinking man who will not confess that the room for improvement in this regard is still very extensive. Any person having any doubt upon this point should listen to the answers given by some engineers during their examination upon machinery. For example, here are some answers given by an engineer who was examined less than four months ago upon the working of an ordinary eight-wheeled locomotive



Burning and Raiding.

Question—How long have you been employed as locomotive engineer?

Answer—Thirty years.

Q.—Where does the steam go after it has completed its work of driving the piston to the opposite end of the cylinder?

A.—It goes to the cylinder on the opposite side of the engine.

Q.—Where does it then go?

A.—Back to the other cylinder.

Q.—Does any of it get out of the stack?

A.—Yes, a portion of it.

Q.—What becomes of the balance?

A.—It keeps going from one cylinder to the other.

Q.—Did you ever read any upon the subject of steam and the steam-engine?

A —Naw I don't go much on readin' books. Experience is good enough for me.

And this man ran a locomotive for thirty years. Think of it If he had pulled the regulation trains for thirty years with the steam acting in this manner, what a fuel record-maker he must be. Can any one believe that had this engineer read Locomotive Engineering regularly and carefully he would have made the above answers? No. And should he begin now to read and study upon matters connected with his business he would wish to be re-examined quickly.

Examples of such ignorance as the above answers indicate are becoming more rare each year, and this desirable result is brought about by the men taking more time to read and study such literature as Locomotive Engineering, "Sinclair and Forney on the Locomotive," etc. An engineer should never be examined upon the subject of machinery without an effort being made to impress upon his mind the fact that he cannot afford to neglect the study of such works as these

Oh, engineers and firemen! what would become of us should the physicians of this country give no more study to their business than did the engineer, a part of whose examination you have just read. And what will become of the machinists, engineers and firemen who do not study and endeavor to keep thoroughly posted upon subjects pertaining to their business?

Not many years ago, if a special was to be run over a road, the general manager or superintendent would inquire, "What conductor can you give us" Now the question oftener is, "Who is engineer?" And if he is a sober, careful, intelligent man all is satisfactory, and the official retires with the feeling that all will go well with the special. We must not lose sight of the fact that brains count more in railroading now than formerly. Good, sober, energetic men of brains are those whom the general managers are looking for to fill positions of trust. Experience is a good thing and should not be underestimated, but experience, coupled with careful thought and study, is a better thing.

The days of the ignorant engineer and fireman are numbered. They would not now be chosen to fill important positions ; and the day is not far distant when they will no longer be allowed to stumble blindly along, gaining all their knowledge by experience alone, but they will be dropped out as being utterly useless.

L. C. Hitchcock

### Lining Guides.

BY A. HOLBEER.

In your February number we notice an article by Mr. L. C. Hitchcock upon method of hanging guides We have no fault to find with the method, except that as Mr Chas. Graham once expressed to me, after he had examined our method of squaring an engine, and we had asked him if it was not correct, "Yes, it is correct enough, but is all-fired awkward." So with Mr. Hitchcock's elaborate method. It is all right but in this age of get there it is decidedly slow.

Our method is :

1st. Have your guides straight.

2d. Have your piston turned and fitted to crosshead, keyed firmly to place. Then put your piston and crosshead on planer ; clamp the piston-rod in "V" block, which are, of course, fitted to slots of planer. This insures that any cut taken on the crosshead is in line with piston-rod ; then plane up the crosshead. Have gland ready to slip on the piston ; this gland should fit the stuffing-box at back cylinder-head. Now everything is ready for guide hanging.

Next put your piston in the cylinder; push it back until it is in the center of cylinder ; slip the gland to its place. Then if your spider does not fit the cylinder accurately line to center of cylinder by strips of tin or thin wedges ; next key on the crosshead and level it , then clamp your guides to the crosshead, using a liner of heavy paper between the wearing parts of guide and the crosshead. A bit of thought will show you that your guides are now in their proper place, and the process of fastening them to this place is next. We believe it best to have guide-blocks that are considerably thinner than crosshead. Put them in place, and put liners on top and bottom of guide-blocks to fill up whatever space may be left. Now clamp both ends of the guides firmly to these blocks, ream out for bolts, and put bolts in place. Then loosen up all bolts and take out the paper liners used between crosshead and guides, and tighten up bolts When this is done, unless your liners have been very accurate, your guides will be sprung up or down ; relieve this by paper until the crosshead and piston move freely.

This is all there is to it Do not fool with a line, or take measurements where you can avoid it.

In Mr. Hitchcock's method a line is used to represent the piston, and if guides are not central with cylinders (as most of them are not) a complicated calculation is needed. By this method you put the piston and cross-head in place, and fit the guides to it. We know from practical experience that when you tighten up your guide-bolts in this method you are liable to spring the guide So you will by the method as explained by Mr. H ; but you can depend upon this, that your guides are reamed right, and any relief you may have to make by liners is not going to affect the alignment.

In this connection, allow me to say that it is folly to attempt to hang guides too closely. When a young man I worked in a shop with a friend who, I think, was the most careful and painstaking man I ever met, and he used to hang guides on one side of an engine and I on the other. When we were through I used to feel cheap, as my guides did not look like his; but after the engine had been in service a few days mine looked the best, for there was usually trouble with his guides cutting. Why, because they were not in line? No, but because they were hung too close, and would not admit of proper lubrication.

*Rochester, N. Y.*

## The Golden Rule—of Brass.

It's a strange thing that a man can have two consciences; can do right in one walk of life and wrong in another; can be honest with Smith and dishonest with Jones—a Dr. Jekyl on Thursday and a Mr. Hyde Thursday night.

There are a whole lot of people who would cut their right hand off rather than do any man a wrong in private business, but who, as railroad officers, will enter into disreputable schemes to work injury to other roads or other people and think that they are doing their duty and "managing" for the company.

The writer recently sat in the office of the master mechanic of a Southern road when a "drummer" appeared; he had a thing that he called a car brass, it had an iron stiffening piece in it which was surrounded by a little brass and lead lined; it looked fairly well.

He only asked ten cents per pound for it and the M. M. at once said that a reliable brass could not be made for that money. Then he explained the iron center. M. M. said he didn't want them; would wear down to iron and cut the journal; then an ordinary brass was worth something for scrap, this bastard nothing.

Then the drummer opened his clinching argument. People don't buy them for their own use, but to put into foreign cars; they get off your road all right, and it makes 30 per cent. difference for renewal of brasses on foreign cars.

The M. M. said he always had and always would put the same kind of brasses into foreign cars that he had in his own—treated his neighbor as he hoped to be treated—and that he didn't want any snide brasses or any cast-iron coupler knuckles, or any culled car wheels to put on cars to annoy, rob or kill other people; said it wasn't right and he wasn't sure but that it was criminal.

Several days later the writer ran across the drummer in another city, and he said he was doing a good business. No railroad officer can do this kind of work and remain an honest man.

## Compound for Cleaning Paint.

Firemen who are anxious to keep neat looking engines will be interested in anything that will tend to lighten their labors, and cleaning paint-work is labor.

The following mixture is used on the South Carolina road for cleaning all varnished paint, and neater looking tanks, cabs, etc., are hard to find:

To four gallons of water add one pound of borax and one quart of lard oil. This is rubbed on the paint and then wiped dry with clean waste. It does not dim the luster of varnish by repeated use, and comes off easily, but it should not be left on very long; rub half a dome or sand-box with it and then wipe off before it is partly dried.

A coat of this once or twice a week will keep a tank shining. It does not darken gold-leaf letters, costs almost nothing, and is effective. Try it.

## The First Agreement between Locomotive Engineers and a Railroad.

As is, perhaps, well known, the South Carolina Railroad was one of the first in America, having been chartered in 1827 and built in 1832, it had the first hundred miles of continuous track in the world, and was, up to 1838, the longest road in the world—its main line is no longer now.

This road put into service the "Best Friend," the first locomotive built in America, and in 1835 had *eight* locomotives in daily service.

During a recent Southern trip I had the pleasure of looking over many old drawings and records from "ye olde, olde, very olde rode,' and had I but time and space could give you something of interest from all of them.

In the front of the time-book for engineers and firemen for 1835 was found what I believe to be the earliest "contract" or "agreement" between engineers and a road, and it is here reproduced from the original, full size and exact.

Pay of Engineers

While in Charleston $2.00 pr. day

passengers laying over at the place on Sunday — 2.00 do.

With Freight. $9 for trip of 3 days

" Passengers. 5.50 for do 2 days.

If detained at Aiken for repairs $2 pr day

If the Engineer returns without completing the trip nothing will be allowed for the time absent unless the trip be lost in consequence of Breakage of the road and exchange of trains or from other cause than the failure of the Engine - When thus detained on the road $2 per day for the time exceeding the proper time of the trip. Engineers running for wood or timber will be allowed $2. pr. day.

The most interesting clause is the one providing that when the engine broke down, and had to return without finishing her trip, the engineer got no pay. That was the day of the "machinist runner," when he did all the repairs and often helped to build his engine.

Verily, "over-time," "delayed time," "lay-over pay," "pay by the trip" and "agreements" are not modern inventions.

J. A. H.

---

Our neighbor the *Railway Review* shows up an old picture of one of the Camden & Amboy eight-footers, and moralizes a little on the probable details, wondering if drawings still exist, etc. In THE LOCOMOTIVE ENGINEER for February, 1889, the detail drawing of the first of this class of engines, the "John Stevens," was shown from plates taken from the original drawings, giving dimensions, etc. The engines were designed by Isaac Dripps, and the original drawings were made by a son of Richard Norris, who is still alive. The big wheel was a correct principle for fast speed but there was not sufficient power behind it.

## Courage of Trainmen.

Some of the courageous scribblers who sit in their secure dens and reel off words for the daily papers at $5 a column are very courageous on the subject of train robbers, and abuse trainmen for quailing before a loaded pistol or shot gun. The *Railway Conductor*, edited by a man who has been compelled to interview robbers and ruffians in actual service, has this to say respecting a paragraph in a New York paper reflecting on the courage of trainmen:

"We would like to see a fair test made of the courage of the writer of such a paragraph. He is either thoughtless, ignorant or a braggadocio. We do not believe there is a train running in America that has not one or more in the crew who, with anything like an even chance, would not fight in defense of the property in his care. Railway employés are not deficient in courage as they demonstrate every day; the most of them do have a little common sense though, and they do not consider that they use good judgment in throwing their lives away in defense of the express company's or even the passengers' cash. The train crew are the ones first looked after by the robbers, as a rule, and they know that they are marked, and that a move means death."

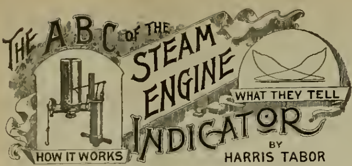
## A Thing-Man.

On a recent trip in the South, the writer stumbled upon one of those characters who make you disgusted with being human, and causes you to half wish you were a girl baby or a baboon. This specimen claimed to be a lawyer from Chicago, and was particular to mention that he was a neighbor of George M. Pullman. He had a letter asking Pullman employés to show him every courtesy. He rode in the sleeper a short distance, simply paying a seat fare, the berth being sold to other parties. When it became late enough for people to go to bed, the conductor asked him to sit in the smoking-room, so that the berth could be made up—he had been in there a long time before. To this he made no objection at the time, but when most of the people were in bed he commenced to abuse the conductor for moving him. He was funny, sarcastic and insinuating, but the conductor kept his temper, and even asked the "thing's" pardon, but he was madder the longer he talked, and finally said he should make a complaint and have the conductor discharged. "I want your job for this, that's the way I'll fix you," were his words. To this threat the conductor replied that he could no doubt accomplish that end if he tried, but that it was a mean spirit for a man to exhibit. The conductor told the writer afterward that he had been in the employ of the company for thirteen years. The Pullman Co. ought to require conductors, in a case of this kind, to take off their uniforms and punch the head of the animal needlessly insulting them and threatening to deprive them of their means of livelihood. There are stock cars for such things, a sleeper is too good for them. We do not know the name of the "man who lives neighbor to Pullman," but the conductor's name is W. B. Ellison, and he runs between Jacksonville and New Orleans. If the Pullman Co. discharge him for this complaint, it will punish the wrong man. He was a gentleman—the other was not.

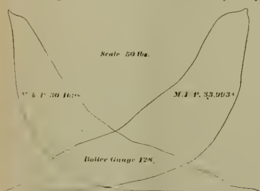
## Divisibility of Gold.

It is said that a Southern Pacific officer has induced the Pullman Car Company to make a reduction on the quantity of gold leaf used on the exterior decoration of the cars, and that it has resulted in a saving of $80 per car. We suppose that the report is correct, but it seems a big saving for one car, for gold leaf is very thin, and an ounce goes over a big surface.

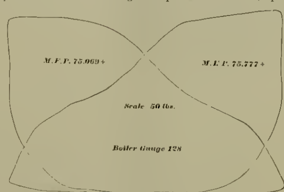
Few people realize how thin gold can be spread. In the manufacture of gilt wire used for embroidery the amount of gold employed to cover a foot of wire does not exceed the 720,000th part of an ounce. Those fond of figuring know that if the 720,000th part of an ounce is used in covering 1 foot of wire that in an inch there is only the 8,640,000th part of an ounce. We may divide this into 100 parts and yet see the gold quite distinctly with the naked eye, and find that the 864,000,000th part of an ounce of gold is visible, and the exceedingly minute particle possesses all the characteristics of a large piece.



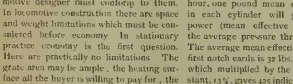
The locomotive is a machine that is largely influenced by extremes. These extremes often work in opposite directions, or in antagonism to each other, seriously affecting the economy of the locomotive as a steam motor. This point may be illustrated by referring to the series of diagrams published in the preceding number of this journal. We know that the cards taken when the reverse lever was in the first and second notch are much more economical in the use of steam than that taken with the lever in the seventh notch. We also know that the boiler will steam much better under the latter condition, for the reason that this condition is favorable to a larger coal consumption. A more economical result might be obtained from coal if the draft conditions would warrant slower combustion, but they do not, and the locomotive designer must conform to them. In locomotive construction there are space and weight limitations which must be considered before economy. In stationary practice economy is the first question. Here are practically no limitations. The grate area may be ample, the heating surface all the buyer is willing to pay for, the natural draft may be made to suit any requirements that appear. As a result of this freedom in design a pound of coal burned under a stationary boiler will produce more power than we can ever hope for from a like amount burned in the fire-box of a locomotive.



14.75 Miles per hour.
Reverse lever in 1st. notch.
Throttle open
Grade 30 ft. per Mile.



7.37 Miles per hour.
Reverse lever in 3rd. notch.
Throttle ½ open
Track level.



34.31 Miles per hour
Reverse lever in 2nd notch.
Throttle open.
Grade 30 ft. per Mile.

The running conditions which must always govern the locomotive is another factor against the highest coal economy. There will always be grades which mean extremes in loads, and frequent stops. Anything like a uniform load, which is one of the conditions of good economy, will always be out of the question. With the stationary engine the load rarely varies beyond the limits of economy.

Enthusiasts who would revolutionize the present locomotive practice do not give sufficient thought to the limitations that must be met. If we analyze the card taken with reverse lever in the first notch, and its effect upon the boiler, we meet one of the obstacles in the way of high economy when compared with the more favored stationary engine. This card, considered independently from the boiler, shows excellent results. Its steam consumption is low, and the drain upon the coal pile necessary to supply the steam would be very satisfactory. With 62-inch drivers, running at a speed of forty miles per hour, one pound mean effective pressure in each cylinder will give 13¼ horse-power (mean effective pressure means the average pressure through the stroke). The average mean effective pressure of the first notch cards is 32 lbs. per square inch, which multiplied by the horse-power constant, 13¼, gives 425 indicated horse-power. The heating surface in this boiler will not exceed 1,400 sq. feet, or 3.3 feet to the horse-power. In stationary practice the builder of a single-valve automatic engine which would make an indicator card similar to this would not think of recommending less than 10 sq. feet of heating surface per horse-power, and he might call for 12 feet. Under natural draft conditions favorable to the highest steam economy, our first notch card, from a stationary engine, would call for from 4,000 to 5,000 sq. feet of heating surface in the boilers to do the same amount of work that is done on the road with 1,400 sq. feet.

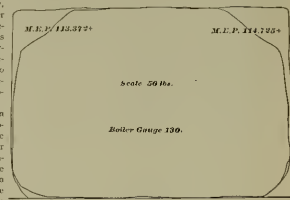
The indicated power shown by the second notch cards, at a speed of forty miles per hour, is 586, which brings the heating surface per horse-power down to 2.38. The stationary engine, with practically the same valve gear, would require 6,000 feet of heating surface to develop the same power. The slower combustion under the stationary boiler compels a much larger grate area.

The mean effective pressure of third notch cards show, at forty miles per hour, 1,000 horse-power, which cuts the heating surface per horse-power down to 1.4 feet. This result is often obtained.

The great drain made on locomotive boilers by the engines calls for very rapid combustion in the fire-box, and an unusually large amount of coal to be burned on each square foot of grate surface. This means a strong draft, which must come from the exhaust of the engines; hence, the card which shows the greatest terminal pressure (pressure at the end of the stroke) and exerts its influence through the greatest portion of the stroke, represents the conditions which give the boiler its greatest steaming capacity. On the other hand, it may be said that the card which gives the greatest mean effective pressure with the lowest terminal indicates the conditions of best economy in the engines. Here we find one of the conflicting extremes which will bear analyzing.

If we refer to the first notch cards, we see that the terminal pressure, on account of expansion and early release, runs down to the atmosphere. There is no impulse to the draft from the pressure of steam. We have a vapor of the pressure of air, which is forced through the exhaust by the piston, to produce draft. An examination of these cards reveals the fact that we do not get this current through the entire stroke; the exhaust is closed before the piston has reached the middle of the stroke, thereby shutting off all communication between the exhaust side of the piston and nozzle, and stopping the forced draft during the latter half of the stroke. We see at a glance why the boiler will not respond to the call of the engines under first notch conditions, notwithstanding they are making a light demand. The second notch cards show the same conditions, but in a less degree. These are very economical cards. Their terminal pressure is somewhat greater, and the increased speed has raised the "back pressure" or exhaust to 4 lbs., the exhaust closure takes place later in the stroke, thus giving a longer communication with the nozzle. The steaming conditions here are much better than shown by the first notch cards, but it is doubtful if the draft would be sufficient for a long run. These cards represent conditions showing extremes in engine economy and limited steaming capacity in boiler. As the terminal pressure is higher and exhaust closure delayed, the coal combustion will be increased.

The other extreme may be accounted for by the lines on seventh notch card. In this case the valve is at its greatest travel and the ports are fully uncovered. The terminal pressure is 94 lbs. The effect of this pressure, admitted through full port to the exhaust nozzle, on the fire can be appreciated only by studying the firebox. The flow continues until the return stroke is nearly completed, when exhaust closure takes place. We have here—first, a greater terminal pressure; second, a larger port opening for its escape to the nozzle; third, an uninterrupted flow through the nozzle during a greater portion of the stroke. Every change in the conditions tends to a greater coal consumption. These cards represent the maximum steaming capacity of the boiler. They also represent the greatest cost, per horse-power, in pounds of coal. The compound locomotive corrects, in part, these extremes or antagonisms. A comparison of compound and simple cards will be made later in this series.



9.22 Miles per hour.
Reverse lever in 7th. notch.
Throttle ⅓ open
Grade 47⅓ ft. per Mile.

Harris Tabor

## Bessemer-Steel Axles.

We have several times had occasion to speak disrespectfully about Bessemer steel as a material for axles. We do not think that the roads which accept Bessemer-steel axles care for anything beyond getting a bar that will fasten the wheels together to start them rolling. When Bessemer-steel axles are subjected to the M. C. B. test before being accepted, and the test conscientiously made, the rejection of axles is something appalling. That is, it is appalling in the light of our knowledge that many roads are using just such axles, and have let them pass into use without examination. We would like to see the men who specify Bessemer-steel axles, and accept them without tests, compelled to ride on the cars carried on such unreliable material.

Those who think of trying Bessemer-steel axles should find out the experience of the B. & O. people with some 1,500 such axles furnished by Carnegie, Phipps & Co.

The Rhode Island Locomotive Works are comfortaby busy, but not rushed. They are working on an order of twenty-seven locomotives for the Boston & Albany, twenty of them being the standard eight-wheel engine, four consolidation engines and three switchers. They are also working on a large order for the Wabash, embracing ten-wheel, eight-wheel and switching engines. There is in the erecting shop a very fine heavy Forney engine for the Wheeling Bridge Terminal Co. The engine will be well adapted either for switching or surburban train service. The New York, New Haven & Hartford have ordered fifteen engines from the Rhode Island Works, and the Union Pacific has placed a large order. Besides these, there are several smaller orders on hand. During the slack time ten of the company's standard moguls have been built, and they are still on hand, but the probability is that a customer will soon be found.

## The Bursting Pressure of Cylindrical Boilers.

Several correspondents have recently asked for an explanation of the rule for finding the bursting pressure of boiler shells. The following article, says *The Locomotive*, is offered as a general answer to all of these inquiries:

Fig. 1 shows an end view of such a shell, with the thickness purposely exaggerated. Let us assume that when the shell bursts it will separate along the line $AB$, so as to come apart in the manner indicated in Fig. 2. Now, although the steam pressure acts perpendicularly to the curved shell at every point, as indicated by the arrows, yet, so far as blowing the two halves of the boiler apart is concerned, the effect is the same as though the steam pressure acted vertically against a flat plate equal to the boiler in length, and equal in width to the diameter of the boiler. To make this plain let us consider Fig. 3, which shows each half of the boiler with a flat plate welded to it along its open side. Now, it is a matter of common experience that a structure like one of these halves will not move upwards or downwards when steam is admitted to its interior. That is, if it were put on a pair of scales the pressure of the steam against its inner surfaces would not make it weigh

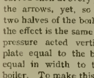


Fig. 1.

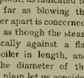

Fig. 2.

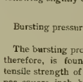

Fig. 3.

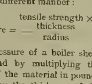

Fig. 4.

less or more than before. It follows, therefore, that the total upward pressure of the steam against the shell is precisely equal to the total downward pressure against the flat plate; the greater area of the curved shell being exactly compensated by the obliquity of the pressure against it.

Let us now consider Fig. 4. The total upward pressure of the steam against the upper half of the shell is equal, as we have seen, to the pressure against a flat plate, such as that shown in the cut, extending across the middle of the boiler. That is, it is equal to

Pressure per sq. in. × area of flat plate.

But the area of the flat plate is equal to the length of the boiler multiplied by its diameter, so that the total upward pressure, tending to blow off the upper half of the boiler, is equal to

Pressure per sq. in. × diameter × length.

This upward force is assisted by the strain on the boiler shell, as indicated by the arrows at $A$ and $B$. The total strain on the shell is equal to the strain on 1 square inch of sectional area multiplied by the number of square inches of sectional area that would be broken across if the boiler should burst. The area of the fracture along each side of the boiler would be

Thickness of boiler × length of boiler,

and since there is one such strip on each side of the boiler, the total area broken across would be

2 × thickness × length,

and, therefore, the total strain at $A$ and $B$, tending to hold the boiler together, is

2 × strain per sq. in. of section × thickness × length.

So long as the boiler does not burst, the force tending to blow it apart must be exactly equal to the force tending to hold it together; so that

Pressure per sq. in. × diameter × length = 2 × strain per sq. in. × thickness × length.

This is equivalent to saying that

Pressure per sq. in. × diameter = 2 × strain per sq. in. × thickness.

And this, again, is equivalent to saying that

Pressure per sq. in. × radius × 2 = 2 × strain per sq. in. × thickness.

That is,

Pressure per sq. in. × radius = strain per sq. in. × thickness.

Now, when a boiler bursts, it does so because the strain on the shell has become equal to the tensile strength of the material; so that in this case our last formula becomes

Bursting pressure × radius = tensile strength × thickness.

This is the ordinary rule for finding the bursting pressure of a cylindrical boiler, except that it is usually expressed in the following slightly different manner:

$$\text{Bursting pressure} = \frac{\text{tensile strength} \times \text{thickness}}{\text{radius}}$$

The bursting pressure of a boiler shell, therefore, is found by multiplying the tensile strength of the material in pounds per square inch, by the thickness of the shell in inches, and dividing by the radius in inches.

In this demonstration we have assumed the shell to be a solid sheet of metal, without joints. In practice the strength of a boiler is reduced exactly in proportion to the strength of its longitudinal joints, so that we must multiply the result obtained by the foregoing rule by the decimal representing the efficiency of the joint. The foregoing formula therefore becomes

$$\text{Bursting pressure} = \frac{\text{tensile strength} \times \text{thickness} \times \text{efficiency of joint}}{\text{radius}}$$

which means that in actual boilers we find the bursting pressure by multiplying the tensile strength of the material by the thickness of the plate *and by the efficiency of the joint*, and then dividing by the radius.

In conclusion we shall give a few numerical examples of the use of the foregoing formula and rule:

EXAMPLE 1. What is the bursting pressure of a steel boiler (tensile strength 55,000 lbs.), 48 inches in diameter and $\frac{5}{16}$ inch thick, with single-riveted longitudinal joints whose efficiency is 56 per cent? ANS.—The radius of this boiler is 24 inches, so that the rule gives

Bursting pressure $= 55{,}000 \times \frac{5}{16} \times 56 \div 24 = 401$ lbs. per sq. in.

EXAMPLE 2. What is the bursting pressure of a steel boiler (tensile strength 55,000 lbs.), 60 inches in diameter and $\frac{3}{8}$ inch thick, with double-riveted longitudinal joints whose efficiency is 70 per cent? ANS.—The radius is 30 inches, and the rule gives

Bursting pressure $= 55{,}000 \times \frac{3}{8} \times 70 \div 30 = 481$ lbs. per sq. in.

EXAMPLE 3. What is the bursting pressure of a steel boiler (55,000 lbs. tensile strength), 66 inches in diameter $\frac{3}{8}$ inch thick, with triple-riveted longitudinal joints whose efficiency is 75 per cent? ANS.—The radius of this boiler is 33 inches, and the rule gives

Bursting pressure $= 55{,}000 \times \frac{3}{8} \times .75 \div 33 = 469$ lbs. per sq. in.

EXAMPLE 4. What is the bursting pressure of a steel boiler (tensile strength 55,000 lbs.), 72 inches in diameter and $\frac{3}{8}$ inch thick, with double-welt butt longitudinal joints whose efficiency is 87.5 per cent? ANS.—The radius is 36 inches, and the rule gives

Bursting pressure $= 55{,}000 \times \frac{3}{8} \times .875 \div 36 = 501$ lbs. per sq. in.

After we have found the bursting pressure, the safe-working pressure may be found by dividing the bursting pressure by a suitable factor of safety. We consider 5 to be the best factor of safety when all things are considered, though we sometimes allow $4\frac{1}{2}$ when the workmanship is known to be first class, and the materials of which the boiler is made have been carefully selected and tested. With a factor of safety of 5, the safe-working pressures in the foregoing examples are as follows: Example 1, $401 \div 5 = 80$ lbs; in Example 2, $481 \div 5 = 96$ lbs.; Example 3, $469 \div 5 = 94$ lbs.; and in Example 4, $501 \div 5 = 100$ lbs.

## Air-Brake Matters.

Mr. W. C. Parsons, of San Antonio, Texas, finds fault with the answer we gave to a correspondent to the effect that no pump gets up 130 pounds pressure in service. He says: "In my experience as fireman, I have often seen the air-gauge register 130 pounds in main reservoir in cases of train parting or hose bursting." In such a case, the first thing an engineer does is to place his brake-valve on lap, in which position the pump-governor is cut out, and the main reservoir pressure will go up very nearly to boiler pressure if the pump is good and the connections tight.

This extra pressure is necessary to fully recharge train-pipe and auxiliary reservoirs so as to be able to go as soon as the train is coupled up. This extra pressure must be admitted into the train-pipe gradually, so as to avoid bursting hose next to engine, for we must bear in mind that the air has to pass into the auxiliary reservoirs through a very small opening, and it takes some little time to recharge them.

The necessity for time to permit the auxiliary reservoir to recharge is well illustrated in cases where brakes are released too quickly in making a stop at a water-tank. The attempt to apply them at once after release often results in running past the water-tank, and the blame is laid on the equalizing discharge-valve, when it should be laid to the fact that sufficient time was not given for the auxiliary reservoir to be recharged with air.

In answer to another question, you say by having air in train-pipe of the rear car, the train would be stopped before damage could be done in case the rear car broke off. Would not brakes have been applied just as quickly if the cock had been turned on rear car behind hose-coupling, leaving cock next to it open so as to have air in hose, but not in train-pipe of rear ear? Of course, in this case the conductor's valve would be useless.

[It is not good practice to let the air go up to 130 pounds pressure. It is not desirable to have a car at the end of a train with the conductor's valve useless.—ED.]

## Western Railroad of Alabama.

Marked improvement in the roadbed and equipment, as well as a corresponding improvement in speed of trains throughout the South is noticeable on every hand. They have shown a disposition to "tread closely upon the heels" of Northern roads in adopting the most advanced appliances, and in some cases they lead our Northern roads. On no road is this tendency "to be abreast of the times" shown in a more marked degree than on the Western Railroad of Alabama, or what is more generally known as the Atlanta & West Point Railway. Under the management of Captain E. L. Tyler this road has acquired an enviable reputation throughout the entire South for excellent track, gravel and stone ballasted throughout, safety switches, switch lamps, 48-inch double angle bars, 68-pound steel rails and semaphore signals. On this substantial and well-maintained structure there is run first-class locomotives and cars that would be a credit to any railroad.

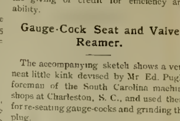
The extended experience of Captain Tyler in different departments of railroads fits him particularly well for the general manager of a Southern road. His experience embraces that of machinist, locomotive engineer, master mechanic and superintendent. One source of his success might profitably be imitated by other railroad officers. It consists in displaying keen appreciation of valuable service and the giving of credit for efficiency and ability.

## Gauge-Cock Seat and Valve Reamer.

The accompanying sketch shows a very neat little kink devised by Mr Ed. Pugh, foreman of the South Carolina machine shops at Charleston, S. C., and used there for re-seating gauge-cocks and grinding the plug.

As will be seen, it is intended to be used with cocks having a straight stem, with thread in outer nut.

The cutting tool is a round piece of steel of the same diameter as the stems to be ground; one end is made in the shape of a



rose-bit, as seen on the right of sketch. This is used to true up the seat. The other end has cutting edges, as shown at the left, made the same angle as the cutter on the opposite end. This end of the tool is held in a sleeve by a pin, as shown, the sleeve serving as a guide, into which the plug of the valve is inserted and rotated to form a new bearing. This is a simple little hand tool that can be carried in the pocket. It is not necessary to remove gauge-cocks from the boiler in order to renew the seat, and the whole set can be put in good shape in a few minutes without any "grinding in."

## The Boring Bar is Old.

We are every day receiving new illustrations of the truth of the saying that "there is nothing new under the sun." Our latest information bearing on this is from Mr. T. B. Purves, Jr., assistant master mechanic of the Boston & Albany, who writes us:

In your March issue, page 97, you illustrated "A New Boring Bar for Lathes." I fail to understand why it is called new. The Schoharie Valley car shops used a bar of this description over twenty years ago for boring car wheels, and there are quite a number of jobbing shops in Albany and vicinity that have had them in use for almost as long a period.

In the Boston & Albany shops we have been using a bar about ten years that we consider an improvement over the "new" one. Instead of holding the bar on its true centers in lathe, we throw them out one-half inch, and with suitable rig attached to tail stock we get one inch movement of the sleeve to which the tool is attached, making it unnecessary to move the tool in sleeve throughout the whole operation; at the same time doing it with as much speed and accuracy as if the tool was held in post. We also have a bar that will bore an oval hole of any diameter that lathe will swing.

When the car cleaners and repairers look over a S. P. car at New Orleans or Houston, they paint the hook of the Miller coupler and the buffing irons with a heavy grease that prevents wear and noise. This practice has obvious advantages over the dry system of letting them cut, file and squeak.

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

## Special Notice.

We can commence no more subscriptions with January or February papers, and only a few hundred with March.

When the present owners enlarged the paper and doubled the price they naturally expected some falling off in subscriptions—estimated at 25 per cent.

They printed 30,000 copies in January, using many for specimens, and the regular edition of 16,800 for February.

The subscriptions did fall off in a few localities, but others took their places, and many clubs increased. This called for an increase of edition in March. The subscriptions continued to flow in, and to-day, March 25th, the paid list is larger by some hundreds than it ever was. Our agent in Australia has almost doubled his order, the News Company have increased their order twice since February, and so the April number goes to press to-day with 20,000 copies, and the May number will be increased to forty pages.

Provision will be made to supply back numbers hereafter, so in sending names please have them commence with March or April.

For this prosperous condition we acknowledge indebtedness to the support of the railroad men of the country and to the business houses who have patronized our columns.

We believe the interest taken has been, in a measure, deserved; we have tried to make a good paper; we are now in better condition to make an interesting paper than ever, and no trouble or expense will be spared to keep LOCOMOTIVE ENGINEERING "the most interesting railroad paper printed"—that is the reputation we are striving for.

ANGUS SINCLAIR,
JOHN A. HILL.

## Electric Motors against Locomotives.

The electrical press with one accord has been predicting with intense persistence for several years back that the steam locomotive must give place to the electric motor, and not a few electricians of more or less eminence have expressed themselves to the same effect. If a doctrine is preached persistently enough it is certain to secure converts, and it is not surprising that the prophecies about the coming triumphs of electricity should meet with believers among railroad men. Some railroad men of high degree even have been so much carried away with contemplation of the coming greatness of electricity that they have themselves turned prophets and foretold that the steam locomotive is about to disappear from the railroad scene.

It is not surprising that electricians and those who depend on electrical business for a livelihood should come to entertain extravagant expectations as to the future of electricity, but it is strange to see railroad men beguiling themselves with beliefs that have so little solid foundation. A long-headed prophet studies the facts before he makes predictions. When this is done he is liable to tell correctly how the thing will come out. When a man prophecies in accordance with unreasoned predilections he is likely to miss his mark; when he says that a thing will happen the way he wishes a thing to come out there is a very good chance that he is mistaken. The last two classes of prophets are the men who have been informing the world regarding the future of electricity as railroad motive power. Their inspiration is one-sided.

The moving of ordinary railroad trains by electricity is merely a question of expense, and on this basis alone will the question be settled. There have been so many improvements effected on electrical motors in the last few years that it is probable sufficient power could be transmitted to move high-speed trains; but it is certain that the work could not be done at twice the expense now incurred with steam locomotives. Cost is the real obstacle in the way. Should the day come round that trains can be moved cheaper by electric motors than by locomotives, the latter will soon pass away.

A particularly able electrical expert talking on this subject to the writer lately said, that the prospect of moving ordinary trains by electricity is about as good now as the prospects of lighting cities by electricity were before the discovery that electricity could be generated by a dynamo-electric machine. Previous to the introduction of the dynamo, it was well known that electric lights could be made with powerful batteries, but the zinc and copper that constituted the fuel of a battery were too expensive to make electric lighting anything more than a curiosity. The dynamo effected a revolution by cheapening electricity. If another improvement equally radical should be made over the present methods of generating electricity, it would open the way for operating railroad trains more cheaply by electricity than by locomotives. The radical improvement looked for is the direct generation of electricity from the energy of coal. So long as coal has to be burned in a furnace to make steam for an engine to drive dynamos for the generation of the electricity used, there is no probability of electric transmission being cheaper than hauling by locomotives.

The success of electric street cars is often pointed to as a precursor of what is going to happen on surface railroads. The cases are not parallel. The electric motor competing against horses is very different from the same motor competing against a steam locomotive. With all the boasting of what will be done next year to transport passengers at unheard-of speed by electrically operated railroads to the World's Fair, there was not an electric company in the country that would enter into a guarantee to operate the elevated railroads of Chicago as cheaply with electric motors as it can be done by steam locomotives. Electricity for railroad motive power and oil for locomotive fuel stand on the same basis. They are both practicable, and in some respects both are desirable, but it will not pay to use either, except in special cases where other considerations overbalance expense of operating.

## Need of Better Trucks.

There is no important member of railroad rolling stock that so much evil could truthfully be said about as the diamond truck that is almost universally used under freight cars and tenders, yet no part of car and tender mechanism has met with more general adoption. It is curious how this kind of a truck ever came to meet with the favor that led to its general introduction. It has only one merit, and that is that it can be made cheaply. A second merit might be found in the fact that the cheapest kind of labor can be employed in repairing it.

The general introduction of such a defective carriage as the diamond truck was due to the peculiarities of railroad management that neglects one department and pampers others. Cars are the articles that earn money, the engineering department is given entirely to devising means of expending earnings. As a natural consequence, with managers not noted for much foresight the car department is popular and the engineering department the reverse. The diamond truck was an article that car builders liked because it was cheap and easily put together.

The engineering department might protest that the diamond truck was like a huge sledge hammer battering over the track and their remonstrances went unheeded. Eminent engineers, who were responsible for maintaining the track in good order, have repeatedly exposed the vicious tendencies of the diamond truck; but their information was distasteful, and the authors were treated as theoretical cranks. The diamond truck is itself heavier than the cars were that first brought to light the necessity for freight cars being carried on springs, and the greater part of its weight is below the springs. With this heavy truck pounding over the track at the speed now becoming common, it is no wonder that rails are hammered out of shape with small mileage. It is a common thing to hear railroad managers complain that the steel rails supplied now-a-days are greatly inferior to those supplied when Bessemer steel first was put on the market, and that they do not stand near the same tonnage. We believe that the rails supplied to-day are better than they ever were, and that the cause of their not enduring the same tonnage before wearing out is due to the uncushioned blows from the vicious form of truck carrying the heavy car loads at increased speed.

Had the engineering departments enjoyed their proper influence in the councils of railroad managers, we believe that some more mechanical device would have taken the place now held by the diamond truck, and that it would have been greatly to the profit of railroad stockholders. The cheapest and worst, however, was chosen, and railroad companies are paying for the short-sighted policy followed.

The diamond truck may have been chosen because it was the best to be had at a time when there was little else to select from. It looks now, however, as if railroad men would soon have improved forms of trucks to select from, and the indications are that there will be a general movement in favor of a truck that would carry its load without undue injury to the track. At two railroad club meetings last month the subject of car trucks was discussed, and decided favor was manifested for the Fox pressed steel truck. This is a very simple form of truck, and puts all the load above the springs, as may be noted by an engraving of the truck published in our January number. Railroad companies are exhibiting a decided inclination in favor of the Fox truck, and a great many are already in use under tenders and heavy cars. If it proves durable, the diamond truck will pass away as rapidly as the link and pin coupler. If the Fox truck fails to meet the requirements, some other improved truck will be forthcoming, for the writing on the wall reads that the diamond truck is found wanting, and, like the rascals, must be turned out.

## One-Sided Judgment.

There are very few engineers who will not do something to get rid of a fireman who is obnoxious to him. He may be ever so good a fireman, the oldest on the road; but if the engineer doesn't get along peaceably with him, and the companionship is not congenial, he goes to the proper official and asks to have him "changed off."

This is almost always done, for officials know that the good of the service depends in a measure on the men getting along together. Let the officer refuse to change off a fireman whom his engineer dislikes, and the engineer will soon seek evidence to secure his dismissal from the service. We believe that the official does wrong where he does not make the change upon request. The company needs the energy used in fighting each other in its own service.

We believe that engineers and firemen should seek divorce where the union is unsatisfactory to either side.

But the old saying, "What is sauce for the goose is sauce for the gander" should be true in this case.

An engineer goes to the master mechanic and asks for the removal of his fireman, and thinks he gives ample excuse for the change—which he does—when he says, "I am in charge of that engine and can't do the work well or satisfactorily with a poor, insubordinate or drunken fireman. If I am responsible, I want another man."

This very same engineer will breed a riot if the same measure is applied to him.

If the master mechanic says, "I am in charge of these engines, and I can't make a show with poor engineers; those who are insubordinate or who drink whisky. I can't seem to get along well with you, and you must go on another division or on another road."

War is declared then and there.

The engineer who will stand up and refuse to argue the point when he is accused of being a poor engineer, let alone the poorest, has not been found yet.

Is it just right, when we are so free to pass judgment on those below us, that we demand the right to reverse the decision of every court above? Do we not, as engineers, owe to the officers next above us the same kind of loyalty and interest in *results* that the fireman owes to the engineer? Can we consistently be arbitrary and swear we are right when we are on either side of the fence? Has a chronically insubordinate, incompetent engineer any right to kick for the removal of a chronically insubordinate and incompetent fireman who is under him?

If he has that right, has he the right to kick against the removal of himself by a master mechanic or superintendent who is over him?

Can we not afford to be just? Can we afford to be unjust?

## Steel for Boilers.

The manufacture of the mild steel best adapted for standing the intense heat and strains that result from the rapidly varying temperature of a locomotive firebox has been so well developed during the last fifteen years that makers have no difficulty in producing a satisfactory article. That is, there is no difficulty if the proper skill and care are employed on suitable material. We regret to say, however, that within the last two months our attention has been drawn to failures of firebox steel, which leads us to believe that some of the concerns supplying railroad companies with boiler steel are offering an article that is not well suited for high-pressure boilers.

We mentioned last month the case of a firebox having failed in a new engine, and we have since learned of several other cases on New England roads.

Many railroad companies order steel that will come up to certain specifications, but rarely make the test to determine whether or not the article furnished is of the quality paid for. Owing to this practice, makers are not kept up to tension, and they become careless, with the result that inferior articles are furnished for a purpose where the best is never good enough. A year or two ago the Massachusetts Institute of Technology had an experience with firebox steel that ought to have roused railroad men to new vigilance in the examination of the steel purchased. The Institute ordered firebox steel having a tensile strength of not less than 55,000 pounds, and not more than 60,000 pounds per square inch. The elongation was to be not less than 20 per cent. in a gauged length of 8 inches, and the limit of elasticity to be not less than 30,000 pounds per square inch. The steel had to bend double cold, red hot and at a flanging heat without cracking. No lamination was to exist in any specimen of the plates. From each sheet four test pieces had to be furnished, two cut lengthwise and two cut across. Every specimen of the steel furnished failed, principally on account of lamination when bent cold.

The defect which caused the rejection of the sheets under the careful tests made by the Institute are the kind most fatal to the life of a firebox, and they are the defects that led to the failures we have recently heard about. We are persuaded that if every master mechanic who reads this article would make careful tests of the sheet steel he has on hand, he would find out some things that would surprise him. There is active competition in the sheet-steel business these days, and some of the cheap stuff put upon the market deserves the most vigilant inspection. This necessity for great care does not exist concerning firebox steel only. The shells of boilers have to stand such enormous pressure nowadays that the margin of safety is none too high, even with the best material. When a firebox sheet fails it cracks or laminates, putting the engine out of service for a time. If inferior material should lead to failure in a sheet belonging to the shell, the notice of defect is likely to be of a more violent character. Every sheet that goes into a boiler ought to be up to the ordinary specifications, which are established to secure the requisite strength and durability. The man in charge who fails to find out how near steel purchased agrees with the specifications, is neglecting an important duty. In no department of railroad engineering does the saying eternal vigilance is the price of safety apply more truly or directly than in the inspection of material that goes into boilers.

## Another Reading Boiler Explosion.

It is difficult keeping count of the boiler explosions that happen to locomotives belonging to the Philadelphia & Reading Railroad. A month has seldom passed during the last year without some explosion on this road that resulted in the killing of some one. The State of Pennsylvania holds the lives of its citizens at painfully low account, or there would be some one suffering before this time for the homicides committed by rotten boilers going to pieces. A boiler explosion is the result of criminal carelessness. When the boilers belonging to one company kill nearly twenty persons within a year in one State and nobody is prosecuted for the crimes committed, it is high time that the law officers of the State were indicted for neglect of duty.

The latest Reading boiler explosion happened near Shamokin, Pa., on March 15. The boiler of an engine pulling a freight train blew up, killing the engineer and fireman. A rustic jury will no doubt sit on the case, and decide that the explosion was due to some unknown cause and that nobody is to blame. If a rotten plank of a scaffold gives way, or worn-out ropes break, letting men fall to the street, coroners' juries sometimes find out that the accident was not of a mysterious nature, and the guilty parties find themselves in an awkward position. It is about time that the average juryman was plainly informed that sheets and stay-bolts of a boiler are liable to the deteriorating influences that make the fastening of scaffolds unsafe. There is no more mystery about the average boiler explosion than there is about the falling down of scaffolds. Boilers fail because the material has worn out, and in too many cases no effort is made to find out how the progress of weakness go on.

## NEW BOOKS.

HOW TO RUN ENGINES AND BOILERS. By Egbert Pomeroy Watson, editor and proprietor of *The Engineer*, New York. Price $1.50.

This is a very unpretentious little book, written by a man who is thoroughly familiar with the first principles and traditions of the business of a working engineer. The author is careful to mention that no man can be made an engineer by reading books, practical experience is the capital that makes an engineer valuable, but there are certain facts about the business which can be learned most readily from those who have gone through the mill, and he proceeds to tell some of the things he learned. They are the kind of points that a well-posted engineer would bring out if he was given a list of subjects and told to sit down and write what he knew about them. There is a good deal said about boilers and their attachments. This embraces the keeping of boilers clean and keeping them in safe condition as far as stays, braces, etc., are concerned. The notes about boiler attachments take in mud-drums, feed-pipes, grate-bars, tubes, bridge-walls, and all the principal fittings. Considerable space is profitably devoted to bearings and how to keep them running smoothly. Eccentrics, cranks and the slide-valve occupy a great portion of the book. The young reader will find this a highly interesting part. The book is full of the information essential for a good engineer in charge of an important steam plant. It is full of valuable facts and is notable for the absence of things that are not so.

THE MECHANICAL ENGINEER'S POCKET-BOOK. By D. Kinnear Clark. D. Van Nostrand Co., New York. Price $3.00.

Engineers who require to use books of reference are nearly all ready to admit that Clark's "Manual of Rules, Tables, etc.," is one of the most useful and comprehensive books to be found, but it is a large volume fit only for the library. "The Mechanical Engineer's Pocket-book" is designed to furnish the great variety of information needed by engineers in a shape convenient for the pocket. The high reputation of the author insures the reliability of the work. It is difficult giving an idea of the contents of such a book as this, for it deals with everything that a mechanical engineer is likely to need information about, and that embraces a vast field. It contains a great many tables and rules furnishing information about electrical engineering which we have not seen in any other pocket-book. A strong point about this book is the index. The table of contents is also unusually comprehensive. These are of great importance to a man looking for information.

## Tipping Dining Car Waiters.

An officer of the Santa Fé is reported to have made the statement that the no-tip system for waiters of dining cars which that road has inaugurated works successfully. "Of course," said the officer, "there are those who do not take any note of such trifles, but the majority of travelers are not of that class. When we adopted the no-tip system we found that we had to discharge our colored help, for they refused to work without opportunity to gather in the futures. We employ white waiters, and by not employing so many to each car we pay them good wages, and they give the best of satisfaction. We find that two waiters, as a rule, are sufficient to each dining car, and where they get no tips and know they cannot accept any, we find that they attend to the wants of our patrons well. If there happens to be a crush now and then on the diner, the conductor of the same takes a hand and helps out on the rush."

We consider that the management of the Santa Fé system deserve the gratitude of travelers for the stand they have taken on this question. Instead of aiding to discourage the extortion on travelers by the tip system in dining cars, the majority of roads do all they can to aid the practice of drawing gratuities that are not earned. The duty of a conductor of a dining car used to include the collecting of the payment for meals, but the general practice now is to require the waiter to collect the money. This is done to enable the waiter to impose upon the traveler by making a mute appeal for a tip. During a recent trip over the Lake Shore we had made up our mind to stop tipping, but the waiters were so distressing in their appeals for help that we had not strength of character to refuse.

## Larger Driving Wheels.

We understand that two of the ten-wheel locomotives under construction at the Schenectady Locomotive Works, for the Chicago & Northwestern Railway, will have 60-inch wheel centers, and all the others 57 inches. This is, we think, a change that has been made since the engines were ordered, as the first purpose was to have them all 57 inches. The cylinders are 19 x 24 inches. From what we have seen of large driving-wheels on other roads lately, we would venture the prediction that the engines with the larger wheels will give the greater satisfaction, especially on passenger trains. The road where they are going is fairly level, and the work done is nearly uniform. The 3 inches extra diameter of wheel will give the engines a decided advantage at high speed, and the repairs will be made lighter. Several roads are now running engines with driving-wheels 6 feet in diameter and over. Where such engines come in competition with those having smaller wheels, it is found that the ability to make time, economy in fuel, and wear and tear to engine and track are all in favor of the big wheels. Our railroad men are only beginning to understand the advantage of large driving-wheels.

On March 3, William E. Lockwood, described as managing director of the Shaw Locomotive Company, of Philadelphia, made an argument before the Committee on Railroads of the House of Representatives, at Washington, in favor of a bill to appropriate $25,000 to enable the Franklin Institute, of Philadelphia, to test the force of the reported hammer blow of locomotive driving-wheels. The press report of this proceeding asserts that the bill has been recommended by the American Railway Master Mechanics' Association. This will be interesting news to the members of the association. If there is any one thing that the Railway Master Mechanics' Association has been particularly careful about, it is that of refusing to permits its name or influence to be used in promoting private interests. There is not the smallest foundation in fact for the claim made that the association favors a raid on the national treasury for any purpose whatever, more especially for the testing of a style of locomotive that most of the members hold in contempt. The hammer blow has been tested sufficiently to give a good idea of its magnitude. Those who are most strongly impressed with the subject have no intention of resorting to the Shaw form of locomotive as a remedy. If the national treasury should be drained of $25,000 to make new demonstrations of the force of this hammer blow, the money would be wasted, for it would lead to no change in locomotive construction.

The publishers of *Cassier's Magazine* have got up a particularly convenient envelope for filing advertising contracts. It has the names of all the leading technical papers on the outside, with columns to note the space taken, the time of beginning and the amount to be paid. We would recommend firms doing advertising to send for these contract envelopes.

In our correspondence pages there is a letter on standard bolt-heads by Professor Sweet, which will be read with interest by every one who has paid any attention to standard sizes. When the movement was in progress which led to the establishment of the United States standards of screw-threads and the sizes of nuts and bolt-heads, Professor Sweet proposed that wrenches and not nuts and bolt-heads should be made standard. He favored making the wrenches ¼-inch, ¾-inch, 1-inch, etc., regardless of the nut, which, of course, would have been made to suit the wrenches. Had this plan been adopted, its practical effect would have been to reduce considerably the number of wrenches necessary to keep on hand. This would have been a great convenience, and, although it is now too late to change, we consider it a pity that Professor Sweet's proposal was not adopted.

One of the meanest, most selfish and most unreasonable things we have heard of lately is an agreement that the engineers of a certain road have asked the management to sign, providing that no firemen shall be promoted and all engineers hired. This is not right and won't work. It won't work because it isn't right. It is the hope of promotion that stimulates men worth something to be good firemen, without hope of promotion dead men only will fire. Why don't these men start a society for the strangling of all women, so that no children can be reared to take their places. Engineers asking this are like the old Know-Nothings—only more so. We believe in hiring some engineers and promoting some—no hard and fast rule to the advantage or disadvantage of any man or class of men. Honest men do not want advantage, they want justice.

Under the caption "A Thing-Man" we publish elsewhere particulars of a case of abuse of a Pullman conductor that is representative of many that are daily occurring. There is a belief abroad that the Pullman Palace Car Company deal very severely with employés against whom complaints are made, and this encourages a mean, cowardly class of traveling hogs, disguised in decent apparel, to treat Pullman employés with contumely without any cause. The sleeping-car conductor and porter are frequently made to bear wicked treatment of people who have no right to mix with any class higher in the social scale than hogs, but the ill-usage has to be meekly borne. Every discomfort of traveling and every delay of trains brings down upon Pullman conductors and porters the wrath of unreasoning occupants of cars, who find relief in abusing the helpless men who dare not reply with a little wholesome truth. The Pullman Co. ought to make some effort to relieve decent travelers from the annoyance of listening to the domineering talk of the brutes who try to make all within their reach miserable.

## Wouldn't Ship Under False Colors.

The Central Railroad of Georgia use a line flag on their ships and the same device on certain fast freight cars as well as on their stationery—a trade mark.

The flag has a white ground with cross-bars of blue running from corner to corner with the initials of the line and a star or two in red.

One of their traveling freight hustlers dropped into a Chicago house not long since to solicit business for the line and sent in his card, which bore the trade-mark flag.

The "old man" of the house was one of those fire-eaters of the North who had never been south of Peoria, and believed that the war was only over temporarily. He came right out. "Young man," said he, glaring savagely at the freighter, "you've got the damndest secession gall about you to come into my office and ask me to ship my freight over a treason-infested dam road that does business under the dodrotted rebel flag! Not by a damsite, not by a damsite, young fellow, my uncle Abner was in the war! Go back to Savannah and Jeff Davis with your rebel rag line, and try and set up slavery again. If there is a man in Chicago that ships as much as a can of lard under that Libby Prison rag I'll have him fired out of the Board of Trade, damfi don't."

## An Improvement in Springs.

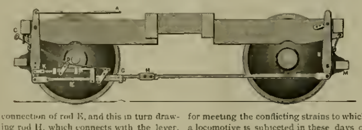
The Charles Scott Spring Co., Philadelphia, have introduced an improvement in locomotive springs that promises to be highly popular with railroad men. The usual practice in spring making is to weld a pad on the ends of the upper leaf to make bearings for the hangers. Those having to deal with locomotives are aware that breakage of the spring very often takes place at the weld of the pad. Recognizing this fact, Mr Ellis, of the Chicago, St Paul, Minneapolis & Omaha, introduced the practice of forming the pad by pressing the upper spring plate to the required form. The practice increased the durability of the springs so much that it was made standard on the road. The Charles Scott Spring Co have now adopted the improvement for all their locomotive springs and have special dies and presses for forming the hanger seat.

Within the month we have received from the inventors of two distinct new car couplers the offer of heavy proprietary interests in the inventions if we would devote our efforts to putting them on the market. As this thing is getting a little monotonous, we wish to intimate to all whom it may concern that we are engaged in getting up readable matter for a railroad journal, and that we intend to depend on that for a livelihood or starve. When we see starvation as certain in our chosen vocation we will be ready to consider an offer to sell car couplers.

## Brake Slack Adjuster.

At the present time there is expressed by all railroad men who have anything to do with the air-brake system, the want of a slack adjuster for the brake-rods. Mr. E. G. Desoe, the air-brake inspector of the Boston & Albany R. R., has designed a slack adjuster which has been found practicable. Following is the description.

The rod A connects directly from the cylinder with the lever B, pulling with it the brake-beam C and through the lever



connection of rod E, and this in turn drawing rod H, which connects with the lever, and sets beam M through the dead lever N. When there is any wear on the shoe, the auxiliary rod K is pulled forward with the motion of the lever B, thereby catching up as many teeth of the ratchet D as are necessary to compensate the wear on the brake-shoe. When the brake is released, the auxiliary rod K holds the two beams together, all that has been taken up by wear and the lower rod E is then shortened by ratchet G. The ratchet D simply takes up the wear and holds it, so that when the brake is released the rod E will shorten.

Further particulars of this arrangement can be obtained of the Mason Regulator Co., Boston, Mass.

We hear it reported that there is a movement on foot to form clubs of railroad employés in several Southern States for the purpose of opposing legislation and political action prejudical to railroad interests. Clubs of this kind have exerted a wholesome influence in some of the granger States. When legislators force down rates till the earnings are not sufficient to cover operating expenses, as has been done for some railroads in Texas and elsewhere, it is time that railroad men generally should stand up and demand that they be counted. The railroad man continues to be a citizen whose interests are entitled to respect.

A school of Marine Engineering has been established in connection with Cornell University. Everything relating to marine engineering and architectural construction will be taught in the new college, which is the first of the kind in America. Railroad interests are much greater in this country than those connected with the sea. The establishing of a school of Locomotive Engineering would appear to be next in order. It offers a great opportunity for the munificent individuals who have built monuments of wealth out of railroads. Our railroad magnates are much more given to acquiring than to distributing wealth.

We have never examined specimens of boiler making for locomotive work that appeared so strong and mechanically sound as the Belpaire boilers that they are now building at Altoona for Pennsylvania Railroad locomotives. The design appears to be ideal for meeting the conflicting strains to which a locomotive is subjected in these days of high pressure. The flat surfaces are stayed to flat surfaces so that all movements and stresses are met by direct binding. Stays and braces are put in wherever there is a surface that requires support. As we finish examining the newly-finished boiler and fail to find a weak point, we naturally conclude that this is a perfect boiler for a locomotive. Yet we find that nearly all the boilers of this type in service have been patched; some of them after a very few months of work. The weak point is the junction sheet between firebox and shell.

Mr. E. J Whittington, who resigned the position of master mechanic of the Chicago & Alton a month ago, died at Denver on March 20th.

Mr. M L. Butler, superintendent of motive power of the New York, Providence & Boston, has been nominated for State Senator by the Democrats of Providence, R I.

We have not recently seen more truth in small compass than what we found lately in the letter of a high railroad official whom we were urging to apply for the management of a road badly in need of the labors of a live, energetic railroad man. "It is a better and more independent course to let the place search for the man. When I look around, and see the large number of blokes, shams, frauds and humbugs that are holding positions on leading railroads of this country, men who merely get in and ride without attempting to lead, it makes me weary."

## Success of the Rotary Snow Shovels.

During the month of March there was a heavy fall of snow in the Mohawk Valley and the northern portions of New York State, and the high winds that prevailed drifted the snow badly, causing great obstruction to some of the railroads. The New York Central made good use of the rotary snow shovel which they have. With this machine they opened a division in a few hours that would have been closed for several days had the old methods of snow handling been the only ones relied upon. The rotary was used to good purpose in opening up the Rome, Watertown & Ogdensburg division of the New York Central which was badly snowed under. During the single storm the rotary easily earned its cost a thousandfold and the Central people consider themselves very fortunate that they had the machine on hand. It had waited six years in the engine house without being used; but like a wrecking outfit, it is one of those things that earn most when lying idle.

The S. P. switchers around the wharfs of New Orleans have a flat car behind each sloping tank. These cars are painted and striped like the engine, have steps around each end and on sides, and carry a headlight, tool box, the frogs and replacers, switch ropes, etc. They can be seen over, and often act as a long light arm to reach down upon some boat and take a car without having the engine leave solid ground.

## FARMING IN THE SOUTH.

It is not astonishing that hundreds of Northern farmers have settled in the South at points on, or adjacent to, the southern division of the Illinois Central Railroad within the past five years, nor is it remarkable that instead of confining themselves to the cultivation of cotton exclusively, they are diversifying their crops with gratifying results. One of the important questions in the mind of any Northern farmer who contemplates locating in the South is: "What crops can be profitably grown in that latitude?" The passenger department of the Illinois Central Railroad will, on application to Mr. J. F. Merry, Assistant General Passenger Agent, Manchester, Iowa, mail free the following pamphlets: "Southern Home Seekers' Guide," "How to get Rich in the South," "Truck Farming," and "Farmers' and Fruit Growers' Guide to McComb City, Miss." These publications contain valuable information and should be read by every farmer looking for a Southern home.

### Standard Bolt Heads.

*Editors :*

I see by LOCOMOTIVE ENGINEERING that the Master Car Builders have up the question of bolt heads and nuts. I should like to get before them the argument we use to justify ourselves for adopting certain proportions, and in order to give my position some weight will say that for two years previous to the time the Committee of the Franklin Institute had the question under consideration, I had been connected with a large bolt and nut works in England as draughtsman, designing machinery, etc. The question of sizes had been under discussion, and the conclusion reached that the thing to do was to make the *wrenches* the standard and not the *bolt heads and nuts.*

This at first sight will appear like a distinction without a difference, but I will try to show that the difference is a matter of prime importance.

I hoped to get the result of our conclusions before the Franklin Institute at the time, but doubt if it was presented with the force it deserved ; and to give it more force now let me recount the reasons that led up to the question.

Whitworth had succeeded in introducing his pitches of threads to a considerable extent, by putting on the market the best "screw tackle," that is screw plates, taps, and dies, then to be had in England, and had promulgated a set of sizes for nuts and bolt heads, the worst that man could well have devised, and that was to make the size of a hexagon nut across the corners just twice the diameter of the bolt. One of the easiest things in the world for the draughtsman to deal with, and an impossible thing for the machinist to measure across the flats. Square nuts and bolt heads were on some other formula, and the number of wrenches required for an ordinary machine twice or more than necessary.

The Franklin Institute system is better as to measurements, but bad in this that it calls for one set of wrenches for rough nuts and another for finished. The United States Engineers accepted the Sellers threads, the Franklin Institute pitches, but not the separate sizes for finished nuts, making the size of finished nuts and rough nuts the same. This, it will be seen, reduced the number of wrenches in the engine-room by one-half. Another point comes up. The size of the standard nut—one and a half the size of the bolt plus one-eight inch—is large enough to look well, and if as thick as the diameter of the bolt, is doubly strong, but a bolt head of the same size is larger than necessary, costs more, and to have the head of one bolt the size of the nut of a smaller bolt, gives this advantage—with one set of wrenches the workman always has one wrench to hold the bolt from turning and another to turn the nut.

The head of a ¾-inch bolt the size of a ⅝-inch nut is large enough, looks right, and has this wrench advantage.

My original proposition was to make the wrenches ¾-inch, ⅞-inch, 1-inch, 1¼-inch, etc., regardless of the bolt head or nut, so that one could use a flat or thin head or nut or a thick and small one for any size, which would have reduced the number of wrenches still more, but the present standards are now too well established to change. The United States standard, 1½ plus ⅛ inch the size of bolt for nuts, and the size of bolt and cap screw-heads the size of nut one size smaller, makes a rule that any workman can remember, brings the number of wrenches down and looks well. I understand no bolt ever ought to be put in so as to require holding to screw on or off the nut, but they are, and the trouble is a constantly recurring one.

### Slipping Without Steam.

*Editors :*

A heavy ten-wheeled passenger engine running on the North Shore limited created quite a sensation here recently by slipping so badly that it was impossible to hold her on the rail upon any train after a speed of forty or forty-five miles per hour was attained without using sand to do so. I wish it to be understood, however, that upon a good dry rail she would run along all right and cause no trouble. When the trouble did exist was when the rail was either slightly wet or frosty. When first turned out of the shop a box of sand would last a week, and the greater portion of that would be used in stopping. One morning, after she came in on the limited express, I met the engineer who had run her that trip, who for convenience we will call Ike, he stopped me and said : "Mac, that engine will slip after she has been shut off, and won't stop till you put the sand under her."

Of course, I thought my old friend was trying to have some fun with me, and just said, "She must have the Devil in her, Ike," and passed on.

A few moments later I met the M. M., and he also asked me if I heard of the mogul being ghosted. I replied that I had, and we enjoyed a laugh at the expense of our friend Ike. There were two engineers for this engine, she being double-crewed, her regular mileage for month of thirty days being ten thousand and eighty miles. The other engineer, also a veteran, had the same trouble as Ike, but was just holding back for Ike to break the news and be laughed at.

This engineer, who for convenience we will call George, was to take her—the mogul, I mean—out on the North Shore limited on the morning in question, so I concluded to take a ride on her to see for myself. It was quite early, not yet sunrise, when we coupled to the train and there was a heavy white frost. Everything passed off pleasantly until about the time the sun began to start the frost from the rails, and I had just fixed myself for a quiet and comfortable smoke, and had about concluded that I was the victim of one of my old friend's practical jokes, and was wondering how I was going to get even, when we entered into a piece of woods about three-quarters of a mile in length, when all without warning the old hag tripped. She was then running about fifty-five miles per hour. The racket she made was something deafening. The engineer had shut her off instantly upon her letting go, but the racket still continued, and after running about half a mile down the grade George pulled the sand-lever open, which stretched her out O.K. After the noise was over I looked at George, and he said "That is just a little one," which I afterwards found was a logical remark on his part. The engine in question had 68-inch wheels, 19x24-inch cylinder, carrying 160 pounds steam, built at Schenectady Works. She has been through the shop since and the evil has been remedied. What was the trouble with her? MAC.

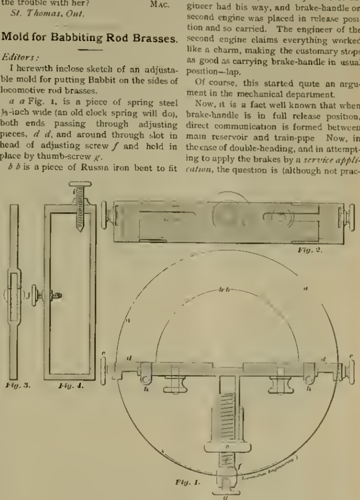
### Mold for Babbiting Rod Brasses.

*Editors :*

I herewith inclose sketch of an adjustable mold for putting Babbit on the sides of locomotive rod brasses.

*a a* Fig. 1, is a piece of spring steel ⅜-inch wide (an old clock spring will do), both ends passing through adjusting pieces, *d d*, and around through slot in head of adjusting screw *f* and held in place by thumb-screw *g*.

*b b* is a piece of Russia iron bent to fit inside of brass, with the sides cut to a taper. Care should be taken before getting ready to pour the metal, to have the mold adjusted to diameter of boss on brasses and everything ready ; then, after heating and tinning the brasses (one at a time), the mold can be put in place and the Babbit poured in before the brass gets cold.



MOLD FOR BABBITING ROD BRASSES.

When there is no boss on brass, and only a flat surface, the mold can be adjusted to size and clamped to brass by clamps shown in Figs. 3 and 4. These clamps, which are hinged to adjusting pieces *d d*, at *h h*, swing around to back of brass, and are held by screw *i*. The band, *a a* is held to brass by screws *j j*.

This mold has been in use here about two years, and has proved a very handy device. I send the sketch in hopes that it may be useful to other readers of LOCOMOTIVE ENGINEERING. N. W. SLATTER.

### Both Engines Supplying Air.

*Editors :*

The divisions north and south from this point (A. T. & S. F., Las Vegas, N. M.) are, to a certain extent, quite mountainous, and it necessarily becomes a common occurrence to double-head both ways, passenger as well as freight, and in doing so the general practice is for the second engine to carry engineer's brake-handle at lap, using the pump on second engine to help charge train, thereby lessening the work for the pump on first engine.

A short time ago one of our passenger trains (north) double-headed from this point, the engineer on second engine carrying his brake-handle, as usual, at lap, pump working, and occasionally charging train. One or two stops were made in this way, when engineer of first engine requested the second engineer to carry his handle in full release position.

The latter protested, saying it was impossible and act ; but finally the first engineer had his way, and brake-handle on second engine was placed in release position and so carried. The engineer of the second engine claims everything worked like a charm, making the customary stops as good as carrying brake-handle in usual position—lap.

Of course, this started quite an argument in the mechanical department.

Now, it is a fact well known that when brake-handle is in full release position, direct communication is formed between main reservoir and train-pipe. Now, in the case of double-heading, and in attempting to apply the brakes by a *service application*, the question is (although not practicable), is it possible to run with a first-class pump on the second engine and brake-handle in full release position?

Not being satisfied that it was, I experimented with two light passenger engines, coupled together and standing in yard. I pumped up a pressure of 80 pounds, both main reservoirs being in communication with train-pipe. The pressure on both engines registered alike.

The pump on second engine was in first-class order.

I then reduced about 1 pound (service application) on first engine, and *moved brake-handle to lap*. There followed a strong blow from service exhaust port, and, of course, *continued to blow*, while pumps began working on both engines.

At the expiration of 2½ minutes I gave it up, being convinced that the pump on second engine was supplying system with air as fast as it was being exhausted from service exhaust port on first engine.

Upon this small data I advanced the theory that it would not work in practice if the pump on second engine was a good one, or in first-class order, and explained why I thought it would not.

Some suggested that if the same operation were tried on forty cars we would get different results, as the pump in the case of two light engines would supply same quicker than forty cars.

I grant this is correct if the pressure is once lost, and in attempting to regain it ; but the area of service exhaust port being the same in brake-valve with either two light engines or forty cars, 80 pounds pressure in both cases, and the pump on second engine being able to supply system as fast as it is allowed to escape through service exhaust opening on first engine (brake-handle at full release on sec-

ond engine), I fail to see but what brakes would remain off in the forty car case just as long as on two light engines, regardless of the difference in *volume*.

In the forty car case I would reduce a larger *volume* of air (in comparison to two light engines) in reducing *pressure* sufficiently to bring governor on second engine into play; but after this point was accomplished, the reduction that had taken place would be just small enough to start my pump on second engine, but not enough to push brake-pistons past leakage grooves in cylinders, and after pump has been started, it appears to me, would keep *pressure* stationary. Of course, in both cases I am presuming areas of *service exhaust openings* are the same.

I would like to have the opinion of some air men on this subject No doubt there are faults in my method of reasoning, but should like to have them pointed out.

## Ingenious Remedy for Broken Air-Pipe.

*Editors:*

To settle a controversy, please give your opinion as to the feasibility of the following remedy for an accident to the air-brake.

The pipe that connects the brake-valve reservoir to brake-valve was broken, and a blind gasket was put in pipe at connection. With the brake arranged in this manner, it was impossible to make a good stop, for the reason, as I contend, that with the loss of the brake-valve reservoir there was such a very small volume of air above the piston 17 (W A B. Catalogue) that controls the discharge of air from train-pipe in making a service stop, that it was all exhausted by the first movement of brake-valve lever to service stop position. The train-pipe pressure would then force piston up and escape, and would continue to escape until the handle was returned to full release or running position.

In case of an accident of this kind, would it not be advisable to put a plug in discharge-pipe from brake-valve, a blind gasket in the connection of the ruptured brake-valve reservoir-pipe at brake-valve, and then regulate the discharge of air from the train-pipe through the emergency ports only? Would this method of handling the valve not render it the same in its operation as the old style three-way cock, and is there any reason why a good, smooth stop could not be made with valve in this condition, provided the valve was handled with good judgment?

E. P. BISHOP.
*Birmingham, Ala.*

[Mr. Bishop has hit the matter with a degree of intelligence that is unusual. The purpose of the 10 x 12-inch reservoir, in connection with the engineer's brake-valve, is solely to give volume to the chamber which is above the equalizing piston in the brake-valve. In order that the pressure may be reduced in this chamber sufficiently slowly, so that the engineer can make any desired reduction, a certain relation must exist between the volume of the chamber and the size of the port through which the air is permitted to escape from it

There are three ways to do this. One is, to leave the volume just what it naturally is, and make an exceedingly small preliminary discharge-port. The objection to this is, that a small discharge-port would become easily clogged with dirt, and a very small amount of dirt would very materially alter the rate at which the air could discharge through the port. The second method is, to make the discharge-port as large as is necessary to prevent difficulty from the accumulation of dirt in it In doing this, it is necessary to have a chamber of much larger volume, which might be accomplished by making a very bulky brake-valve. Of course, the natural objection to this is, that one does not wish a very large mechanism in the way, at the point where the brake-valve usually has to be placed. The third method, and the one employed by the Westinghouse Air-Brake Company, is to make the preliminary discharge-port of a sufficient size to prevent irregularities from collection of dirt, and to make the volume of the chamber above the piston, in the brake-valve, sufficiently great for such size of discharge-port, but adding in some convenient position, out of the way, a reservoir communicating directly with this chamber, and giving it the necessary volume.

It is at once apparent that under these circumstances, if anything should happen, such as Mr. Bishop speaks of, which would necessarily cut off this reservoir, the volume in the chamber above the piston is very small in proportion to the size of the discharge-port, and when the engineer opens the discharge-port to let the air out, it would issue so rapidly that it would be impossible for him to make a small reduction of pressure in it, and it would be almost impossible for him to do good braking by its use. It would therefore be much better for him to close the opening through which the air usually discharges from the train-pipe in making service stops, than to depend upon careful discharge of air from the train-pipe through the emergency port in the brake-valve. He is quite right in supposing that this may be done. The brake-valve then simply becomes a three-way cock, so far as discharge from the brake-pipe is concerned. We all know that a train of quick-action triple valves can be nicely handled, as to graduation, by the three-way cock; but it requires skillful handling, and one that in practice cannot be at all relied upon with the average engineer. At the same time, under such circumstances, this method proposed by Mr. Bishop would be the only proper one.—EDS.]

## Breakage of Cylinder-Heads.

*Editors*

C. B. Conger's explanation of front cylinder-head breaking is not satisfactory. Most likely made to excite discussion.

He says when bolt broke valve stopped in back end of steam-chest, leaving forward port open to live steam and piston traveling against it. If such were the case compression would equalize with boiler pressure, which pressure cylinder-head was calculated to stand.

If forward port was closed to exhaust and chest, as I suggested, compression would run up enormously, depending on amount of steam in front part of cylinder, for the reason that you have, say, 20 square inches of valve exposed to pressure due to compression, tending to raise valve, while you have about 150 square inches of valve surface exposed to boiler pressure, tending to hold valve to its seat, and, of course, valve could not raise.

A few years ago I was running a locomotive that sheared bolts in forward end of main rod at top and strap breaking at bottom. I always thought it was caused by reduction of clearance space, brought about by the adoption of larger packing rings, which materially increased the thickness of piston.

In answer to C. B. Conger's query in March issue, as to whether valves could be set so as to give excessive compression after exhaust closure and shear bolts in forward end of main rod, would say That excessive lead would necessarily be followed by early exhaust closure, especially so when working the engine cutting off close, and too much inside lap, together with restricted exhaust-nozzles, would all aid in running the compression line up and forming that loop in the indicator card which Brother Tabor is now telling us about; and if the bolts in front end of the main rod were the weakest link in the chain, I see no reason why they would not be the first to show signs of distress.

A few years ago Mr James Meehan, of the Cincinnati, New Orleans & Texas Pacific, experimented with an Allen valve, and found by cutting out some of the inside lap of the supplementary passage it allowed compression to equalize with chest pressure without advancing the period when compression began.

## Wrong Material.

*Editors:*

Under the above caption I wish to make a few comments on the rules of the M. C. B. Association, not through criticism, but with the hope that they may be discussed, modified and amended at their next convention

When going over the road I find many cars set back for wrong material It may be a wrong hanger, a wrong brakehead, or a wrong drawhead, the material is as good as that of the company owning the car, but the connecting line, trying to make matters as disagreeable as possible for their neighbors, keep an expert at that junction who exercises the potential powers of the M C. B. rules in chalk marks on the side of a car, regardless of delays or losses to his own or the connecting line. The interchange of cars is necessary, and a car that is properly cared for as to defects that do not impair its usefulness or endanger its going through to its destination should be received, or the company receiving required to pay a fine. Such fine to be decided by a committee of arbitration.

Rule 4 says "A car with defects which do not render it unsafe to run, or unsafe to trainmen, must be accepted." This rule should be enforced; but it is daily violated by some smart crank who wants to make it disagreeable for his neighbor There is here a wide field in which the members of the M C. B. Association can measure harmony and co-operation. A sounder and more expansive policy is necessary to secure perfection. Enforcement of present existing laws are unfair, and in many cases unjust, and gives inspectors too broad a field to exercise their authority. Let us hope that the next convention will eliminate all unfair rules and recommend a uniformity of inspection, and not allow cars to be set back for trivial defects. Rules 4 and 6, if complied with, will not hamper or check the movement of cars, and will cause a better feeling among connecting lines than now exists Iron-clad rules of their own making should not be tolerated when they have agreed to comply with the rules of the association There are only three defects that it is fair to reject a car for, *i e.*, bad trucks, bad wheels, or draft-irons in bad order The rules should be modified and made so explicit that every car foreman can understand them, so plain and so emphatic that a wrong construction cannot be placed upon them

## Defective Triple Valve.

*Editors:*

The question asked by Mr. Wood in the last issue of your paper is not perfectly clear. The defective condition to which I had reference was a broken pin in the graduating valve, said pin in normal condition performing the service of opening the graduating valve on the first movement of the triple valve piston in applying brakes.

If the pin is broken of course the valve cannot open, the auxiliary reservoir pressure holding it shut, and the result is that the pressure on the inner side of the triple valve piston finds no relief until the slide valve is forced far enough to open the supplemental port that affords passage for air from the auxiliary reservoir to the cylinder in emergency applications, when, of course, the quick action valve also opens.

The duration of time that elapses before this application takes place depends, of course, on the amount of pressure drawn out of the train-pipe and the rapidity or slowness of such reduction.

This action can be very easily obtained on a testing rack by plugging up the port in the slide through which graduated applications are made, and reducing the train-pipe pressure gradually and slowly, when it will be found that all the brakes except the altered one will begin to set before that one makes any movement, until finally when it does set, it goes on with a heavy blow. The inference that Mr Wood draws is scarcely warranted by my statement. Ordinarily, on a three-car train, seven or eight pounds reduction should be sufficient to actuate the emergency valve in any triple in which the graduating port did not open. The fact remains, however, that a defective valve of this kind will not act under such conditions as promptly as the rest in the train.

## Lubricators Acting Unevenly—A Bent Side-rod.

*Editors*

I have run fifteen or twenty engines equipped with Nathan lubricators, and all except one feed faster when *not* working steam in cylinders. This one exception always feeds the same, working steam or not. Now, what is the cause of this one working with such regularity and the others not?

I have another nut for some one to crack. I was running an eight-wheel engine working at a wreck one night Some time in pulling I sprung the right-side rod out 3½ inches I backed up one mile to sidetrack after it was done and did not notice it The brakeman came along with lantern and noticed it. He looked up at me with a "Say, mister, do they run that kind of rods on this road?" I looked down and sure enough it had the bow-gee I got down with torch, expecting to find something wrong on the other side, but everything was all right. Engine had been out of shop six months, was in train, and rods always free on all points. Nothing wrong except rod sprung. What was the cause?

J. F. WALLACE.
*Corry, Pa.*

## Does the Air Surge or Equalize?

*Editors*

Mr De Long's air-wave theory in the March number may give a wrong impression to some who read his letter, the more so as his argument is backed by the Westinghouse instruction book, which states that the abrupt opening and closing of the three-way cock will, on a long train, cause a violent surge of air forward, releasing the breaks at the head end of the train

The instruction book aims at brevity in giving this very plausible reason, but the fact is it doesn't surge, it equalizes. Air wil flow from a brake-valve at emergency, or from a three-way cock, quicker than it can equalize in a lengthy train-pipe

In working a long train line carrying 70 pounds of air, make a sudden reduction of train-pipe pressure with a three-way cock, drawing off enough air that, on closing the cock, the gauge will show a reduction of 8 pounds While the air flows from the train-pipe, the black pointer will fall away back to 50 pounds or less, indicating that the pressure in forward end of train-pipe is so reduced that some of the brakes at the head end will go full on, their auxiliary pressures expanding to about 50 pounds When the discharge of air has been stopped by placing the cock on lap, the train-pipe pressure will immediately equalize, and the black pointer run right up and stop at 62 pounds. A train-pipe pressure of 62 pounds, with initial help of the compressed graduating spring, will overbalance 50 pounds auxiliary pressure, force up the triple piston and release the brake, this operation being the same as "dipping into emergency" with the engineer's brake and equalizing discharge-valve as mentioned by Mr De Long.

The correspondent also refers to a service application where the handle is

brought back half way between lap and running position before air stops blowing from equalizing discharge-valve, and claims that the air "piles up" and releases the brake. Now, with the use of 1¼-inch angle-cocks, air will flow through the train-pipe about as fast as it can pass out at the equalizing discharge port, the brakes are applied uniformly, and the sudden closing cannot release the brakes. The question is asked why do they release? When the valve handle spring is upon the shoulder, between running and lap, the valve is in the running position, but the ports have a very slight opening; train-pipe pressure fills the large cavity in valve fare, and passes down through the partially-opened equalizing port to the equalizing discharge-valve, which it forces down, stopping the flow of air from train-pipe, at this point the rotary valve slightly uncovers the feed-valve port, and main reservoir pressure will pass through the feed-valve to train-pipe, and release all the brakes, if held in that position long enough.

WILL W. WOOD.

*Terre Haute, Ind.*

## Mistake in Expansion Curve.

*Editors:*

I would like to try to tell Mr. Fickinger where the mistake of one pound is in Mr. Tabor's expansion curve. The piston is supposed to have no weight or friction with atmospheric pressure above and below it. We now put weights on piston, forcing it downward two inches or one-sixth, which will give us ⅚ of the pressure that was under the piston before it started to move, which is 18 pounds, or 3 pounds above atmospheric pressure. We now put on more weights, forcing the piston ⅕ of the remaining distance, which will give us ⅘ of the pressure we had at the first move, which will be 22½ pounds, instead of 21½, or 7½ pounds above atmospheric pressure.

ONE OF FIEK'S BOYS.

*Roanoke, Va.*

*Editors:*

In answer to the question of "Where is it?" regarding the expansion line as shown by the Tabor Indicator, should say that the mistake was in the third position of the piston, which should read 22½ lbs. in place of 21½ lbs., as it now is.

F. C. EMERY.

*McComb, Miss.*

## Casting a Patch on a Cylinder.

*Editors:*

In your experience and observation have you ever known of a piece being successfully cast in a cylinder—piece having broken out in service? Would you accept the statement as being gospel, and gulp it down as did the writer, or propose him for full and non-assessable membership in the Ananias Club? Inclosed please find card for reply.

MEMBER OF FLAT WHEEL CLUB.

[The thing might be done, but the chances of a permanent job would not be very good.—EDS.]

## Wood for Plugs.

*Editors:*

In a recent issue you direct a correspondent to use soft wood plugs for broken gauge-cocks. In my experience I have found hard and dry wood the better. I was once firing a passenger engine when our whistle blew out. The engineer had just shut off to roll down a hill, when away went the whistle. I started the left injector and he pulled his pump on full. Then I covered the fire over with fresh coal. When we stopped at the foot of the hill we had a glassful of water and 15 pounds of steam. We made a plug out of an oak block and drove it in the hole, which was 2 inches in diameter. Steam was then raised, and we took in the train with the full pressure of 140 pounds without the least escape of steam from the plug.

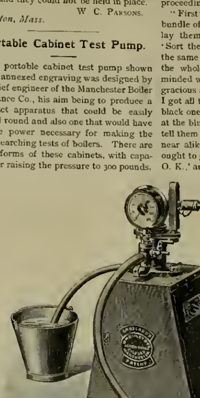
I have seen soft wood tried to plug up holes and they could not be held in place.

W. C. PARSONS.

*Boston, Mass.*

## Portable Cabinet Test Pump.

The portable cabinet test pump shown in the annexed engraving was designed by the chief engineer of the Manchester Boiler Insurance Co., his aim being to produce a compact apparatus that could be easily moved round and also one that would have all the power necessary for making the most searching tests of boilers. There are three forms of these cabinets, with capacity for raising the pressure to 300 pounds, 400 pounds and 1,000 pounds respectively. The device has been patented in this country, and the proprietors, Crosland & Bailey, wish to dispose of the patent rights. They can be addressed through this office.



PORTABLE TEST PUMP.

## Color-Blind Tests.

BY CLINTON B. CONGER.

My friend "Doc." came up from Indianapolis last week to visit me, and gave me a graphic account of an examination he passed a few days previous, which is given in his own language:

"There has been quite a hubbub on our road amongst the boys about a test of our eyes. Ike, that's our traveling engineer, called me into the office the other day, and gave me a letter to a young doctor to examine my eyesight.

"'For the land's sake,' says I, 'my eyes ain't giving out, are they?'

"'No,' says he, 'but that is what I got orders to do. Now, you go down to his office, give him this letter, answer his questions, do as he tells you. Let him try your eyesight any way he wants to, hold your temper and don't say any more than is required. I am sending you down first because I know you will get along all right.'

"'Ike,' says I, 'what is he going to do?'

"Says he, 'I can't say just how he will do it, but what he wants to know is whether you are short sighted or got weak eyes, if you can tell red, green and white signals apart, and how far off you can tell a brakeman with a flag from a section-man with a tamping bar.'

"So I went down to the doctor's office, give him my letter and sat down. He read the letter and got out a big memorandum book and says, 'How old are you?' 'Forty-seven,' says I. 'How long have you been running an engine?' 'Twenty-four years,' says I. 'Have you ever had any disease of the eyes?' 'Not as I know of,' says I. 'Have your parents always had good eyesight?' 'Don't know,' says I. 'Both of them died when I was a kid,' says I.

"So he telephoned for another young Sawbones to come in and help him and the proceedings began.

"First thing they did was to get out a big bundle of little bunches of colored yarns, lay them down on the table and say, 'Sort them out and get all the skeins of the same color together.' I wanted to ram the whole bunch down his neck, but I minded what Ike told me and went at it as gracious as a schoolma'am at a quiltin' bee. I got all the red ones together all right, the black ones and white ones, but when I got at the blue ones it pretty near beat me to tell them from the green ones, they was so near alike. Says I, 'A man of my birth ought to get the green ones picked out all O. K.,' and I sorted them in good style.

"The doctor looked over the pile, and says to the other fellow, 'I guess this is a good test. Now we will give him something harder. Hold your hand over your right eye and look at this card with your left eye.' I looked at the card. It was less than fifteen feet off, but I couldn't read any on it. Then he made me cover the other eye and look at it, that wasn't any better. It kind of worried me, till I got it in my hands after he laid it down to get something else. It was a blank card. Then he had me read fine print at all sorts of distances, and tell the letters on a big card across the room. Every time he gave me something fresh to do his helper would write something in his book, so I saw why he wanted a big one. One thing he did was not fair, and I told him so, too. He set a postal card up on top of the lower sash, right in the middle of the only window of the room, so you had to look against a bright light to see it, but I beat him at that, for I see it before he picked it up.

"He sat down and made out a certificate that my eyes were all right, and give it to me. I waited a minute while thinking about what Ike told me, and says I to myself, 'I'll go him one round anyhow, if I get fired for it.' Says I, 'Doctor, do you think it is a fair way to test a railroad man's eyes—on a lot of girl's yarns and a few fine-print cards? We have to see colored flags and lights, and look down the track a long way, and know for sure whether a man is waving a flag at you or just walking along, and your sight has got to be fine enough to read orders and time-cards without any specs. Some of the orders we get the man that wrote them can't read after they get cold. Now,' says I, 'what do you know about all these things? Have you ever been out on an engine and seen what is required of an engineer's eyes?'

"He allowed he had never been out that way, but it was a scientific fact that some eyes were defective when the men could not tell it themselves.

"'Scientific grandmother,' says I, 'come down into our main passenger yard and I will show you something.' He laughed and said 'All right.' So we went down in the yard, and I says, 'What is the shape of the first switch-target beyond the Twenty-second street depot?' I had to explain to him what a switch-target was. A nice outfit of knowledge he had to test railroad men with!

"'Round,' says he. 'What color is it?' say I. 'White.' 'Any yarn on it?' says I. 'Now just ask me questions about those targets, engines and tracks you see down there. I don't care how far off they are, I can see just as far as any one.'

"It was pretty well along to six o'clock then, so we staid till the switch-lights began to show good, and says I, 'Can you tell which of them lights are on main line switches and what color they are when set right?' I'll bet there was more than a hundred switch-lights and signals in sight from where we stood, and he did not say a word.

"Says I, 'Don't you think your examination of railroad men is a little lame? Suppose you take the next fellow that is sent up to you, scared out of his wits for fear he is marked to lose his job, out on the road and try him with the signals he has to work with.' The other young doctor says, 'He has got you in a tight place if you are an ophthalmologist.'

"The upshot of it was he allowed the right way to test eyes was to try colored lights instead of yarn. I took my certificate down to Ike and told him the whole proceedings. Says he, 'Now you see why I sent you first. You will likely be the last till he gets his kit of tools fixed up to suit him. The doctor is all right as far as he goes, but he don't go far enough. He ought to try you on colored lights instead of colored yarns. You will pass.'"

Doc asked me what I thought of it, and was told that I had rather not say anything either way about the matter till he had seen something more. I said to him, "Doc, we have an eye-tester here in town that uses the Pennsylvania Railroad system and appliances. We will go down and see him after supper. We went down and found a set of cards with different sized letters printed in good plain black type, the usual pile of yarns of various colors, but something else took Doc.'s eye, there were eleven incandescent lights with colored glass slides in front of them. When the current was turned on these lights, any color could be shown or all lit at once. The glass shades could be changed so that at one time a certain light was green; at another it showed red, without the glass, it was white. Doc. said to me, "This is something like. If we have got to be tested, let it be with lights not with yarn."

I told him that the doctor in charge of it knew a good deal about railroading and the wants of railroad men. His aim was to give the men a practical test in their own business as well as a scientific one.

One of our best and most intelligent engineers who was up here with me the other night, was examined himself, to see how it was done, and came away satisfied that it was what it claimed to be—a practical test of ability to distinguish colors both by day and night.

There is a good deal of prejudice against the color-blind test, because the men do not think it is fair to go through the form of sorting yarn or reading fine print, especially when a man fails on this test when he can tell red from green and white lights. When the tests of eyesight first commenced twelve years ago, if they had been a little more practical, *maybe* it would have worked better.

Doc has not said a word about it since we came out of the office, but he will have something about it the next time I see him. He is not one of the fellows that can keep still long. Tests and examinations of a man's ability are all right, if they are fair and practical. No one that can pass them need be afraid. If they are not fair and honest, we do not need them.

The drawings for the New York, Susquehanna & Western new shops at Paterson are about completed, and work will be commenced in a few weeks, and will be pushed forward to rapid completion. This company will order in a few weeks some additional power. Their order for 300 coal gondolas and fifty box cars has been let.

---

The Lukens Iron & Steel Company report a good and steadily increasing railroad trade, having recently booked steel orders from the Lehigh Valley, N. Y., Susquehanna & Western, N. Y., Ontario & Western, Del., Lackawanna & Western, K. C. F. S. & M., Central Vermont, Buffalo, Rochester & Pittsburgh, N. Y., Providence & Boston, South Carolina, Missouri Pacific, etc. It has been specified on eight engines building by Cooke Locomotive Works for the Louisville & Nashville Railroad, and for fifty engines building by the Baldwin Locomotive Works for the Missouri Pacific Railway.

---

The Louisville & Nashville Railroad have placed a large order for new locomotives with the Cooke Locomotive Works, Paterson, N. J. These works are very well equipped for doing good construction work, and the proprietors appear determined to do their best on the fine engines designed by Superintendent of Motive Power Leeds.

---

The New York, Ontario & Western have ordered five consolidation engines from the Dickson Locomotive Works. These works are also building eight engines for the Delaware, Lackawanna & Western.

---

On the Warren branch of the Richmond & Danville road they still have in use some of the old U section rail; it was taken up from the main line years ago.

---

The Illinois Central have placed an order with the Rogers Locomotive Works for forty-two locomotives. The engines will all have the same kind of Belpaire boiler as Leeds uses on the Louisville & Nashville locomotives.

---

The Brooks Locomotive Works are building some 10-wheel engines for the Toledo & Ohio Central. The compound which these works built about the beginning of the year is now at work on the Lake Shore & Michigan Southern and is giving satisfaction. The engine is of the 2-cylinder type.

---

The Pittsburgh Locomotive Works have delivered the lot of engines ordered by the New York Elevated Railroad and they are doing very well. The officers of the road say that the work done on these engines is better than anything they have previously had from contract shops.

---

The Baldwin Locomotive Works are crowded with orders. Among orders of most recent date are: Central Railroad of Brazil, six compounds. This follows an order for seventeen sent out last summer. Western Railroad of Cuba, one compound; Missouri Pacific, thirty 10-wheelers, simple; Grand Rapids & Indiana, sixteen consolidations and seven passenger engines, all simple; Missouri, Kansas & Texas, six moguls, one of which is a compound; Southwestern Company, nine moguls, simple, Chicago, Rock Island & Pacific, five passenger 10-wheelers, simple; Chicago Street Railway, two compound motors.

---

On the St. Louis and San Francisco road no paint is furnished for front ends and stacks, but instead plumbago or black lead is used. This is lighter in color, but makes a very neat front, and causes no scale. A scaly, patchy front end and stack are the reverse of neat and cleanly in appearance. Don't use tar.

The practice throughout the South of putting a spittoon at every seat in all cars tends to make the cleaning of coaches an easier matter, and prevents in a great measure the coloring of dress trains to the shade of navy cut plug.

---

Put a three-way cock in the exhaust pipe to your air pump, and arrange it so that the engineer can open it from the cab and start with the exhaust going under the engine instead of throwing a shower of wet soot on the engine—this discourages the firemen.

---

The Rhode Island Works are building forty-seven locomotives for the Wabash.

---

## Texture of Steel and Iron Axles.

The annexed engravings are etchings of locomotive axles. One is steel and the other is iron. The character of the two kinds of material can readily be understood by an examination of the etchings. The iron is a conglomerate mass formed into a rough unit by the blows of the hammer and the pressure of rolls. Working the iron fails to eliminate the whole of the clay, and some of the pieces that make up the pile from which the axle is formed

IRON AXLE.

are improperly welded, so that the elements of disintegration are present from the time the forging leaves the hammer.

The texture of the steel axle, on the other hand, shows a homogeneous material, not a collection of fragments indifferently stuck together. The steel axle ought to be better than iron if made of the proper material. There have been many failures of steel axles, and there is not a little prejudice against them, but most of it comes from using Bessemer steel, which is decidedly unsuitable for axles, just as unsuitable as it would be for boiler plates or firebox sheets.

---

Mobile, Ala., has a unique institution in the shape of a Railroad Social Club. The club has been established for about a year, and promises to be a decided success financially and in the attendance of members. We do not see why railroad social clubs cannot be established in the leading cities. The common interests that spring from being engaged in the same business has formed many social clubs, and it is strange that men who travel so much as those engaged in railroad work have not established more centers of gravitation in the form of clubs.

---

The suburban passenger service of most of the Chicago railways is excellent in respect to equipment, frequency of trains and speed, and the rates are so low as to afford little if any profit, but still improvements are liberally added. The Chicago & Eastern Illinois Railroad, although required by city ordinance to carry passengers between Chicago and Englewood, six miles for five cents, has just added ten suburban cars which probably are not surpassed for such service. The cars are fifty-two feet long and are equipped with Hale & Kilburn high-back seats covered with maroon plush, have a seating capacity of sixty-four passengers each, and are lighted with the best improved lamps.—*Railway Age.*

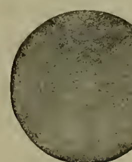
In a boiler that had recently had a hot crown sheet, it was found that around each stay there had been wiped a packing of good cement to insure a tight joint. The stay-bolts were well headed over, but the cement did the water-tight business. When the crown sheet was dropped, this cement was hard enough to remain on the stay and clean enough to show the finger-marks made in applying. Is this practice carried to any great extent?

---

Mexico has certainly the most luxurious, if not the most comfortable, railways in the world. The rails of the Mexican Gulf Railway are laid on sleepers of mahogany, and the bridges are built of white marble. On the west coast of Mexico there is another line which has sleepers of ebony and ballast of silver ore drawn from old mines beside the track. The reason for this apparent extravagance is that the engineers had no other materials on the route, and found it cheaper to use these than to import the ordinary plant.—*Galveston Paper.*

---

The Secretary of the Railway Master Mechanics' Association has issued a circular calling upon members to answer cir-



STEEL AXLE.

culars. This is about the time of the year when the circulars received from committees are generally drawn out of the loop-holes where they have been placed for "consideration." We would suggest that the season of consideration is about finished. Get them all out and send in all the information you can.

---

We have received from Mr. Wm. Montgomery, master mechanic of the Central Railroad of New Jersey, some ends of boiler tubes that had the copper ferrules and iron ends nearly all corroded away. It looks as if the corrosion were caused by galvanic action. An analysis of the water showed that chlorides and sulphuric anhydrides were present in large quantities. The latter impurity would be sufficient to account for the very rapid destruction of the tube ends.

---

It is a long time since differences of opinion arose between the public and railroad companies as to the equity of transportation charges. In an English publication, under date of 1846, we find an answer from railway directors to a charge that the fares were excessive. The directors say "It is true we charge you twice or thrice the fares exacted in other countries, but you paid more on stage coaches before we enabled you to travel on railways comfortably. We have accelerated your journey and given you every luxury that a traveler could desire, and carrying free three times the amount of baggage you could have taken on a stage coach. What right have you to complain of high fares when you enjoy so many advantages in return? If you dislike our charges, you are not compelled to pay them. You are at perfect liberty to use the turnpike, and if you prefer the old coaching practices, introduce them again. Only in God's name stop uttering your complaints against the benefactors of the country."

## Long Mileage.

The claim made by Engineer George King, of the Wabash, of having made the longest mileage ever reached in this country is contested by Engineer John E. Baird, of Wymore, Neb. He tells that he has run engine No. 20 on the B. & M. Railroad, in Nebraska, and in the month of January made 6,824 miles, and in February 6,268 miles. The auditor of the road claims this to be the longest mileage ever made in Nebraska.

Mr. Geo. M. Hankinson, time-keeper of the Michigan Central Railroad at St. Thomas, Ont., writes us:

"In reading over the March issue of your paper I noticed where Engineer Geo. King, of the Wabash, claims to have made the largest mileage with his engine in one month ever made in the country—that is, 6,627 miles—but we have an engineer here on the Canada Southern Division of the Michigan Central Railroad who leaves brother King in the rear by 601 miles. The distance between St. Thomas and Buffalo, via Niagara Falls, is 139 miles, and in January last Engineer John Nolan doubled this distance twenty-six days or fifty-two trips over the division, leaving St. Thomas at 2 o'clock A. M. and returning at 4 50 P. M. Total mileage, 7,228.

"There were five days during the month that he did not work. He had the same engine all the time, and handled two of the heaviest passenger trains that are pulled over the line."

---

We happened to call on a master mechanic lately who was ordering new locomotives that were to have highly-pressed boilers, and he had agreed that a steel should be used which is noted for nothing but its cheapness. He was highly elated with the tests stood by the steel as shown by the makers' figures. On our suggesting that he should have tests made for himself, he protested that it would be casting suspicion upon reputable men. There are some reputable men who are worth looking after in business, and the infant who thinks otherwise is not fit for the head of a railroad mechanical department.

---

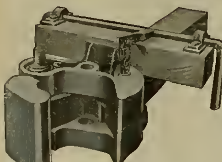
A discovery is reported at Helsingfors of an ancient chest, containing a lot of curious pieces of iron machinery with a mass of parchments, the latter being a treatise on the possibility of applying steam to mechanics, while the machinery is a very tolerable approximation of the steam-engine of a century ago. Both iron-work and documents purport to have been made by Suger, the famous abbott of St. Denis and administrator under two kings of France in the twelfth century. Great interest will, of course, attach to the investigation of authenticity of these antique remains. If they really are Suger's he will have a new distinction as antedating all the other pioneers of steam application by hundreds of years.

---

We have a long article from a fireman in Nashua, N. H., proposing a reformation in the handling of locomotive firemen. The proposal is made that firemen be relieved from the work of scouring brass, blackening boiler-heads and similar menial duties, and that the time of these men while in the engine-house should be devoted to the learning of an engineer's duties, the engineer to act as instructor. We do not consider that railroad companies or even engineers are quite ready to agree to this change, and we must postpone the publication of our correspondent's letter until it is likely to meet with more support than it would receive in this benighted age.

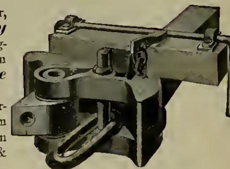
We have received a pamphlet giving some points about grinding tools by J. Wendell Cole, Columbus, O. It deals in a comprehensive way with the advantages of using the Sellers tool-grinding machine for grinding tools. Those who read this pamphlet and have had any experience with tool-grinding machines are likely to acquire a hard opinion of the poor old grindstone.

# THE STILGER & STROSLER AUTOMATIC CAR COUPLER



Is the Cheapest, Safest and Strongest Coupler, on account of its durability. The *only* Automatic Coupler that has a lateral swinging hook and couples with the link and pin proper, ***and pulls direct from the center at all times.***

This coupler has been in use on the Birmingham Division of the L. & N. R. R. seven months without a break. We take pleasure in referring to the Supt. Motive Power, L. & N. R. R., as to its merits.



For any information, photographs, models, or sample couplers, address **No. 310 FIFTH ST., LOUISVILLE, KY.**

---

Price, $1.00. Sold at this Office.

## The Shaw Electric Traveling Crane.

Until within a few years nearly all the cranes in use in machine shops and foundries in this country were of the jib type, despite its serious limitations as to area of floor served and the large proportion of floor occupied by the mast and thus rendered useless. A few traveling cranes had been built, but they were generally so crude in design and workmanship, and consequently so slow and jerky in their movements, that they met with little favor, especially in foundries, where smoothness of action was most important.

The comparatively late development of the traveling crane was undoubtedly due not only to the fact that a higher order of design and better workmanship was required to produce a traveling crane which would operate satisfactorily than to construct a jib crane which would work with equal steadiness, but also to the difficulties connected with the transmission of power from an external source to a moving machine. This necessitated either a square shaft with its cumbersome and expensive tumbling bearings, or rope transmission, which in practice has proven expensive to maintain and liable to unexpected breakdowns.

With the advent of electric transmission of energy, the latter difficulty was at once done away with, and the invention and introduction of the system of applying an independent electric motor to each movement by Mr. Alton J. Shaw, then of Milwaukee, Wis., so simplified the mechanism and increased the smoothness of action and the delicacy and accuracy with which the traveling crane could be handled and controlled, that now the electric crane, constructed on this system, is easily first for nearly all purposes.

The first triple-motor electric traveling crane put in practical operation anywhere is believed to have been built from the designs of Mr. Shaw by the Edw. P. Allis Co., and erected in their foundry in Milwaukee, Wis. Although an experimental machine and naturally somewhat crude in many of its details, it was at once pronounced by all who saw it in operation to be superior to anything previously produced. The molders were especially enthusiastic in its praise, as it was far smoother and steadier in its movements and capable of much more accurate handling than the power cranes in use at that time.

While the mechanically driven cranes had but two speeds of traverse and four of hoist, the electric crane had an indefinite number, and any movement could be smoothly and gradually accelerated or retarded or maintained at any speed between the highest and lowest at the will of the operator. All this was accomplished without clutches or mechanical disengagements of any kind.

Next to the smoothness of action the simplicity of this crane was the first feature to impress one accustomed to the intricate mechanism of the older machines. Instead of six, eight or more friction clutches, four or five dozen gears and diverse square shafts and tumbling bearings, it had but twenty-two gears and no clutches or square shafts. The remainder were replaced by three electric motors, each of which had but one moving piece—the armature.

THE SHAW ELECTRIC TRAVELING CRANE.

There have since been installed in the works of the Edw. P. Allis Co. two more electric traveling cranes built by the Shaw Electric Crane Co., one crane of thirty tons capacity, operating on the same tracks with the first, and the other of fifteen tons capacity, in the Alliance Works No. 2 Erecting Shop, an interior view of which, taken from a photograph, is shown in the accompanying cut.

This crane, while not as rapid in its movements as some which have since been constructed, was, when put in, much faster than the majority of cranes then in use. It has a maximum hoisting speed of twenty-five feet, a bridge or longitudinal traverse speed of three hundred and fifty feet, and a trolley or transverse traverse speed of one hundred and twenty-five feet per minute. The speed of each of these movements may be raised from nearly zero to the maximum simply by moving the reversing lever a greater or less distance either side of its mid-position. As but one lever is required for each movement, the manipulation required is of the simplest possible character. The crane is fitted with incandescent lamps of six hundred total candle-power, which brilliantly illuminate the floor below whenever the crane is used at night. This crane, as are all those built by this company, is fitted with duplex automatic brakes, to which, in large part, is due the accuracy with which the load can be handled in hoisting and lowering. These brakes not only insure against the accidental dropping of the load from any cause other than breakage of parts, but absolutely prevent any possibility of "racing" in lowering.

These brakes are entirely automatic in their operation, and do not depend for their action on the skill or vigilance of the operator. One of them is applied continuously by the reaction of the load itself, the power with which it is applied being proportional to and increasing with the load, and released by the pull of the motor. The other is applied by a powerful spring, and is always "on" except when withdrawn by the action of a solenoid in series with the hoisting motor. Without the mechanical brake the crane would "race" in lowering, as the magnetic brake is then withdrawn by the current which actuates the motor, and both the motor and the load act in the same direction. Without the magnetic brake the load could not be stopped promptly after either hoisting or lowering, on account of the momentum of the armature. Without the capability of instantly checking the movement of the load, accurate handling would be impossible, as, when the current is thrown off, it would always go either a little too far or not far enough. The two brakes acting in combination give great accuracy of control, which, together with the extremely slow speed at which the crane may be run, enable the heaviest loads within the capacity of the crane to be set with absolute accuracy.

All truck wheels are cast from charcoal iron and the treads are chilled deep and hard and ground true. These wheels are considered by the makers to be better than steel, as the hard surface insures great durability, while the accuracy attained by grinding causes the traverse movements to be extremely free from vibration.

All the shafts are large and the bearings are unusually long. Great attention is given to the matter of accessibility, the machinery being so arranged that all important details may be removed and replaced readily without disturbing other parts. Bearings are capped wherever possible.

The girders are very rigid, laterally as well as vertically, and have a large margin of safety.

These cranes are built by the Shaw Electric Crane Co., Muskegon, Mich., and are handled by Manning, Maxwell & Moore, New York.

## A Texas Car-Wheel Foundry.

While on a recent visit to Houston, Texas, I was very much interested in the modern foundry of the Dickson Car-Wheel Co. These works were established some years ago by the present president of the company, Mr. John T. Dickson, then general superintendent of the Texas & Pacific Railway.

Mr. Dickson's attention was first called to the great strength and the chilling quality of the brown hematite ores then melted with charcoal at the old furnaces in Marion County, Texas. After leaving the road, Mr. Dickson established wheel-works, and has made large numbers every year since.

No mysterious "mixtures" are indulged in—plain Texas ores and old wheels are alone used.

The shops at Houston are new, and of modern plan—wood, covered with iron, there are five "floors," of eighteen flasks each, set in a circle, and each floor served by a crane of its own. The melting is done in two Byram-Colliau cupolas of the latest form, and so arranged that one elevator serves both charging floors. In the charging-room, instead of doors in the cupola, the feeding apertures are only closed with a wire screen on a light frame, the air going through this keeps it cool, while it is almost impossible to keep the fire-brick lining on the ordinary door.

The foundry is fitted up with the Barr contracting chill, steam being used to expand the chill until the moment of pouring, and the contracting being done by the substitution of cold water for the steam. The works have an independent water supply and electric light plant.

The usual test of car-wheel mixtures is to take a piece of the iron two inches square and fourteen inches long, support it twelve inches apart, and apply a load in the center, the usual breaking strain being 18,000 to 26,000 pounds. Reihle Bros., makers of testing machines, at Philadelphia, recently tested six bars of the Texas metal, and found that it required a breaking strain of 27,000 pounds to break the poorest of the specimens and 32,000 pounds to break the best.

The Dickson people have great faith in their wheel, for they give a guarantee exceeding the requirements of the M. C. B. standard guarantee, who only ask 60,000 miles in passenger service and four years in freight. The Dicksons guarantee 70,000 miles in passenger and five years in freight service.

At one end of the shop are arranged the annealing pits and the machine to grind the tread; this last device takes all the chill fins off and insures a round, true wheel.

Most of the roads in Texas and the Southwest in general have some of these wheels in service, and we see no good reason why the works cannot be doubled by properly pushing the merits of the wheel. Certainly the works are in fine shape to do good work and do it cheaply—everything is new.

J. A. H.

---

Sand is an item of considerable expense to a great many roads, and good, gritty sand is a mighty scarce article. We know of roads that haul sand for more than 500 miles. This is expensive, yet it is the using of large quantities under trains that costs fuel-money. It would pay any road to make a trial of some of the jet sand distributors now on the market. They are very economical of sand, put it where wanted, and spread it evenly.

The Northern Pacific are building 100 street cars in their shops at Tacoma, Wash.

The Southern Pacific Refrigerator Co. is building 100 patent refrigerator cars of their latest pattern for the Schoenhoefen Brewing Co.

The Hale & Kilburn Manufacturing Company have, within the last eight months, equipped about 700 passenger cars with their seats.

The Erie Car Works has begun the delivery of 500 cars which it is building for the Pennsylvania. The first 300 built have been ordered for the Philadelphia & Erie Division.

The Wells-French Company are building a number of Rodgers ballast unloaders, including an order of 150 for the Great Northern. They are also building 125 ore cars for the Duluth & Iron Range.

The New York, Susquehanna & Western has placed orders for 300 gondolas and 50 box cars. They will have Smillie couplers, Lee composite roofs and Cambria steel axles made by the Coffin process.

The Mount Vernon Car Manufacturing Company of Mount Vernon, Ill., have contracted to build 200 refrigerator cars for the Frost Proof Car Company. These cars are to be operated over the Canadian Pacific Railway.

The Safety Car Heating & Lighting Company have recently equipped twenty-five Wagner palace cars and fifty passenger cars of the New York, Lake Erie & Western, and twenty passenger cars for the Jersey Central with their heating system.

The Ohio Falls Car Company of Jeffersonville, Ind., have just completed 300 fruit cars for the Alabama Great Southern and are delivering 300 thirty-ton hopper coal cars for C. N. O. & T. P. Ry. This company has also closed contracts for 550 freight cars for the L. N. A. & C. Ry. and 500 for the Pennsylvania lines.

The Burlington & Missouri River have just received ten handsome passenger cars from the St. Charles Car Co. They are finished in mahogany and have the Scarritt high-back seats. The same car company are working on orders from the Missouri, Kansas & Texas, and the Atchison, Topeka & Santa Fé. They are very busy.

We have received during the month several circulars from committees of the Master Car Builders' Association calling for information. There seems to be great activity among the M. C. B. Committees. We understand that most of the Master Mechanics' Association Committees are collecting without the aid of circulars the information required to make up reports.

The Standard Oil Company now own and operate nearly 8,000 tank cars, the latest ones holding 8,000 gallons of oil. Crude and refined oil weighs about $6\frac{6}{10}$ pounds per gallon. The company also have a large number of very small tanks for handling acid; acid weighs from 13 to $16\frac{1}{2}$ pounds per gallon. Some of these cars, loaded, got knocked off a float in the harbor at Baltimore recently and the men in charge could not account for the small cars sinking so quick—they went down like lead.

## Plant Freight Cars.

The Plant system of roads have lately ordered a great many large freight cars for carrying fruit, and one of them as finished is shown in the annexed engraving. The cars are built in first-class style and equipped with all the most approved attachments. They have Janney couplers and Westinghouse air-brakes. The cars are 33 feet 6 inches long and have comfortable room inside for a 30-foot rail. The cars are all painted yellow, and have the striking figure seen on the side which is put only on cars belonging to the road which has all the latest improvements.

PLANT VENTILATED FRUIT CAR

The Missouri Pacific people are about to make important additions to their rolling stock. They have ordered fifty locomotives from Baldwins, thirty of them being ten-wheelers, intended for fast freight. An order has also been placed with the Ensign Mfg. Co. for 500 Canda cattle cars, and one with the St. Charles Car Co. for 1,000 box cars and 500 coal cars.

## Work at Pullman.

Among recent car building work done by the Pullman Car Co., Chicago, is: One private car for the Baltimore & Ohio. Twenty-two coaches for the Southern Pacific. Six parlor cars for the Chicago & Northwestern. One passenger coach for the Chicago & Eastern Illinois R. R. Co. One private car for the Pecos Valley. One private car for the Minneapolis, St. Paul & Saulte Ste Marie. Twenty-five passenger coaches for the Central Railroad of New Jersey. One parlor car for the Windsor & Annapolis Railway Company of Canada. Twenty-five passenger coaches, ten express, ten baggage and five postal cars for the Norfolk & Western. One hundred passenger coaches for the Philadelphia & Reading. Two passenger cars and two dining cars for the Chicago, Rock Island & Peoria. One thousand box cars and four hundred coal cars for the Norfolk & Western R. R. Co.

The street car department has been unusually busy during the month. The principal demand is for motor cars and the fine center vestibule double-decked cars designed a short time ago by Mr. C. L. Pullman.

The committee appointed by the Master Car Builders' Association to report on compound locomotives are getting the apparatus in shape for making complete tests of a compound ten-wheeler of the Vauclain type with a single-expansion engine of the same dimensions, with the exception of the compound cylinders. A dynamometer car is nearly completed, which will be a duplicate of the one used by the Chicago, Burlington & Quincy Railway. It is expected that the latest improved apparatus will be used in making all readings in connection with the tests which are intended to be complete in every detail. The plan is to make tests of the compound every day for a week, and the following week make the same tests with a single-expansion engine, and to follow out this plan for a period of about three months.—*Railway Review.*

The adoption by railroad companies of the M. C. B. type of coupler appears to be proceeding very satisfactorily, but it looks as if Congress intended to spur on the railroads to greater energy in this line of improvement. There are several bills before Congress proposing to compel railroads to adopt automatic couplers within a certain time. The most practical and sensible of these measures is one introduced by Senator Allison, which proposes to have railroad companies decide by letter ballot upon the type of coupler. The vote will be based upon the number of cars owned by each railroad company. The Board of Interstate Commerce would be required to receive and count the ballots. In the event of no decision being arrived at by the votes of the railroad companies, the M. C. B. type of coupler would be made the legal standard. We see no objection to the enactment of this measure. A great many railroad companies do not require any urging to adopt safety appliances, but others do. Compulsory measures of a mild kind would do no harm to progressive roads, and they would have a good effect upon the companies that will do nothing until kicked into action.

## Prompt Repair of Moving Cars.

By EUGENE CHAMBERLIN.

At all times, but more particularly when railway traffic assumes unusual proportions, a company will find it necessary to keep in service as large a percentage of its freight equipment as possible. The problem is presented as to how the execution of car repairs may be facilitated and cars kept moving.

To successfully accomplish this, particularly in localities where freight yards cover an extensive area, and the arrival, shifting and making up of trains are carried on simultaneously in several sub-yards, and at widely separated points, and always at some distance from the shop, requires no small amount of study, patience, and above all perseverance. We will assume that inspection is promptly cared for on the arrival of each train, by competent men working intelligently under the wise provisions of the M. C. B. rules, and bearing forcibly in mind that the object to be accomplished is the rapid movement of freight *en route*, and that all things must be subservient thereto.

The first step to consider is the necessity of making all repairs possible "in train"—keeping cars in line—and thus avoiding the expense of shifting out many cars which are condemned by inspectors, and the consequent delay to freight which would be caused by hauling these cars to some convenient point for repairs. In making "train repairs" it has been found wise to employ a sufficient number of repairers and others to follow the inspectors closely, and thus avoid holding trains for any length of time after inspectors and oilers have performed their respective duties.

In many instances defects are found upon loaded cars which can be readily repaired in train, providing the seals of car are broken and doors opened, and much delay to freight avoided if a sealer, or some person authorized by the freight department to break seals and take records, works in conjunction with the repairers. It should be borne in mind that every facility should be afforded the men making "train repairs," the basis of their supplies being the repair branches, at which point the repairers may be returned for duty, in case trains do not arrive in sufficient numbers to occupy all their time. Having thus executed all that may reasonably be expected in the matter of "train repairs," and having kept in line many cars that under ordinary circumstances would be cut out and sent to shop, there still remains in train a number of condemned cars, upon which repairs cannot be made until cars are separated and placed in a more convenient position to handle. As a matter of convenience, we will call this the second stage of repairs, as here shifting becomes necessary. Very satisfactory results have been obtained and much delay avoided by establishing repair branches at convenient points, and always as near as possible to the tracks where inspection is made to trains—in the larger freight yards.

If possible, these repair branches should consist of two tracks, one for empty and one for loaded cars, with ample working room between, and having connection at both ends with the main freight yard, so that cars for repairs placed in at one end may be taken off repaired at the opposite lead, and thus avoid filling and pulling from the same lead. An ample store-room is necessary, and in it the stock classified, plainly marked, and placed so that any kind of material sought for can be readily obtained. Too much stress cannot be laid

upon the necessity of keeping the stock, and all appurtenances of the repair branch in systematic shape. As this store-room is also to be the basis of supplies required by train repairers, it serves a double purpose, as also does the repair branch, which becomes the working-place of the train repairers when not on duty with trains.

It will also be observed how readily cars repaired upon these branches may be delivered back to freight yards, in many instances taking the same train or group before it is ready for delivery from freight yards to connecting lines, thus obviating the delay which would necessarily occur if the crippled car was hauled some distance to a shop and brought back to freight yards after being repaired.

If these repair branches are properly conducted, it will be a pleasant surprise to find what a variety of work—much of it of a heavy character—can be accomplished thereon, and the fact of having one of the repair tracks reserved for empty cars gives constant employment to the force in case there is a falling off in the number of loaded cars to be repaired.

From the foregoing it is of course discovered that many empty cars and nearly, if not all, loaded cars arriving in a crippled condition have been repaired and returned to service or sent directly to the transfer-house with but little delay and without unnecessary shifting, and that the shops have been reserved for more extensive repairs or rebuilding, of which there is always plenty at hand.

## Speed of Fast Trains.

The fast Empire State Express run daily on the New York Central between New York and Buffalo continues to excite great interest in England, which long held the broom for fast trains. The correspondent of a London daily lately made the following comments about fast trains:

"A comparison between the runs made by the Empire State Express and those made on English roads shows that that train is entitled to the palm for long runs. From New York to Buffalo, 439½ miles, the run is made by the Empire State in 8 hours and 40 minutes, an average of 50.71 miles per hour including stops, and the engine draws a train weighing about 175 tons. From Euston to Perth, Scotland, 450 miles, the run is made in 9 hours and 50 minutes, with an average time of 45.76 miles including stops, weight of train 80 to 130 tons. From King's Cross to Perth, 439 miles, the run is made in 9 hours and 55 minutes, with an average of 44.27 miles per hour including stops, by a train of about 130 tons weight.

## The Latest Locomotive Humbug.

The picture of a locomotive, with all the wheels of engine and tender resting on other wheels secured in separate trucks, has been sent us by a correspondent. Beneath the picture we read: "Should the standard locomotive now being constructed on this plan prove a success, as is expected, and the five dollar non-assessable fractional shares now being sold increase 150 times, as is proposed, a five dollar investment would amount to $750 at par value. Address H. J. Caldwell, Mankato, Minn."

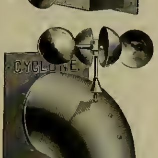
We consider that the post-office authorities ought to look after Mr. Caldwell if he is sending that circular through the mails. The whole thing is a palpable humbug. It looks like an attempt to use a mechanical monstrosity as a means of obtaining money that might as well be burned up. The unfortunate feature about the thing is, that any oddity is certain to attract attention, and a plausible advocate can make ignorant people think that they risk little perhaps to gain much by taking stock in a scheme like this. It has strong lottery elements.

## Cyclone Car Ventilation.

We illustrate in this issue, two styles of the Cyclone car ventilator just being placed on the market by M. C. Hammett, of Troy, N. Y., the manufacturer of the well-known and popular Richardson and Allen-Richardson balanced slide-valves.

The Cyclone as it was very properly named by Superintendent of Motive Power Blackall, of the Delaware and Hudson, after seeing it tried, is the invention and design of W. S. Rogers, Superintendent of the works of M. C. Hammett, who is thoroughly familiar with the question of car ventilation and has made it a study to contrive something that would be of practical value and at the same time not be so complicated that it would be too expensive and impracticable for adoption by railways. The ventilator is placed on the side of the deck of the car in the same manner as the ordinary ventilators generally in use.

The semi-spherical vanes actuated by the currents of air caused by the speed of



the moving train, rotate an exhaust fan in the body of the case and mechanically withdraws all foul air and gases from within the body of the car.

The methods employed in arranging the fan and the vanes together makes them sensitive to the slightest air currents, so that when the cars are standing still, the lightest breeze will cause the ventilator to do what all ventilators are supposed to do, and keep the atmosphere within the car pure and clean.

On cars of modern construction they are placed outside the movable deck sash or outside the screen guards. Their construction is such that they will run for years without requiring attention and care more than is ordinarily given to such apparatus, and any one can apply them in very short order without revamping or changing the present deck arrangements. They are furnished by the manufacturer all ready for putting on the coaches.

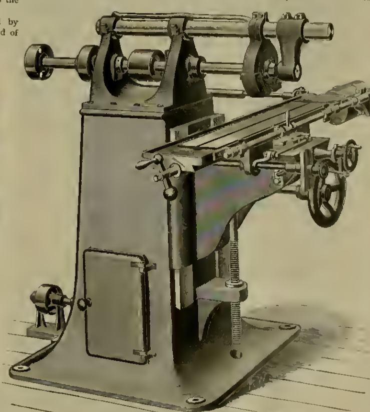
Coaches equipped with the Cyclone ventilator need not have the windows made to raise and lower. Neither can currents of air blow in through the deck windows from the outside and cause annoyance to passengers, all air within the car being drawn upward and forced outward by the fans.

On one of the Delaware & Hudson Canal Co.'s smoking cars on a local train, ten Cyclones have been put on and twenty-six of the ordinary ventilators taken off. From forty to fifty pipes and cigars have been seen lighted and being puffed at once, the smoke being at once taken away and the air left clear and pure. A more severe test than this could hardly be required.

Its simplicity and quick application should commend it to the entire railway community of presidents, managers, car-builders and passenger department alike without reference to its saving in cost over present methods with such superior results.

## Emery Wheel Surface Planer.

The tool illustrated herewith is intended for doing with an emery wheel a portion of the work usually done with a file, planer, shaper, milling machine or similar tool. It will do flat and true surface grinding and finishing, thus proving an effective substitute for filing and stoning. The entire cost of files and three-quarters of the labor usually expended on these operations are saved, besides obtaining better surfaces upon the work done. It is especially adapted for surfacing iron in the



rough where but a small amount is taken off, and for finishing and cutting down work where the material is of a hard nature, as the surfaces of hard iron, chilled iron, steel dies, punches, etc.

On tempered work it saves drawing the temper and rehardening, and is true when done, while, if finished on an iron planer, on hardening it will spring, warp and twist out of shape. It is also adapted to finishing work that has been roughed off on a planer where it is desired to take out the tool marks. The emery wheel cuts as fast when carriage is running backward as when running forward, while an iron planer cuts only one way. It will grind the very hardest castings made freely, so stronger and less expensive iron can be used than with an iron planer. Castings have only to be made a little above the actual size they want to finish, as the emery wheel only needs to remove enough stock to bring the work to a nice finish, while with the iron planer it is necessary to go under the scale to plane it. The work can be fastened on the table by chucks, draws and straps, same as in common milling machines and iron planers.

The machine is very substantially made, and great attention has been directed to convenience of operating. It is made by the Springfield Emery Wheel Co., Bridgeport, Conn.

The Boston & Maine Railroad Company are putting in some good new tools into their locomotive shops at Boston.

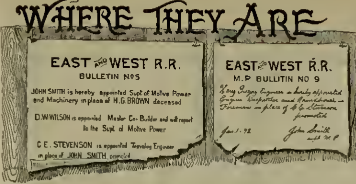
## Fast Running.

There is a Baldwin compound locomotive on the Central of New Jersey that is making remarkably fast running. She has been on a train leaving Philadelphia at 5:15 P. M., which makes the run of 89.4 miles to New York in 2 hours and 13 minutes and makes seventeen stops. At one place a run of 13 miles has to be made in 15 minutes, including the start and stop. The fastest running is done on this stretch. A report of an engineer who was indicating the engine made out that one mile on this part of the run was made in 39¼ seconds. As the catching of the mile-posts is a matter of some delicacy, we should be inclined to let the ¼ second go and make it 39 seconds.

The writer timed the engine during one trip and was very much struck with the speed capacity displayed. The second mile after leaving the starting point was run in 61 seconds; then the time for succeeding miles was 51, 50, 50, 55, 53, 50, 44, 41, 47 seconds. The last mile was made as the engine was slowing down for the purpose of losing some of the time gained. The train consisted of four cars. When running at the highest speed the engine rode very steadily and with little jar. When running one mile in 50 seconds, the steam popped at the safety-valve, showing that there was no difficulty in keeping up the pressure. When running one mile in 41 seconds, the speed is 88 miles per hour. Having in mind at the time the possibility of making a speed of 100 miles an hour, we concluded that such a velocity was within the capacity of this locomotive.

In the matter of high speed a compound locomotive has no advantage over a simple one, unless it be that there is less drain of steam from the boiler. With very high piston speed the difference is likely to be on the side of the simple engine. This engine has two pairs of coupled driving-wheels 6½ feet in diameter.

Our correspondent, Mr. W. De Sanno, mentions a curious engine accident, and assures us that the case is not intended for our Ananias column. It was an upright stationary engine. The piston-rod key broke, and the piston went up like a rocket through the sky-light, turned over and dropped into the cylinder with the head reversed.



Mr. Samuel F. Prince, Jr., has been appointed superintendent of motive power of the Long Island Railroad.

Mr. C. L. Aiken has been appointed division master mechanic of the Boston & Maine, with headquarters at Worcester, Mass.

Mr. J. Conroe, formerly traveling engineer of the Atchison, Topeka & Santa Fé, has been promoted to be master mechanic at La Junta, Col.

Mr. J. T. Lord has been appointed master mechanic of the Northern Pacific at Mandan, Dak., in place of George W Gardner, deceased.

Mr. Theodore P. Jacobs has been appointed master mechanic of the Toluca & Acambaro subdivisions of the Mexican National, including the Patzcuaro branch, with headquarters at Acambaro.

Mr. Alfred Child, formerly general foreman of the car department of the Northern Pacific, has been appointed division master car builder of the Chicago, Rock Island & Pacific.

Mr J. L. Greatsinger, who has lately been made general manager of the Duluth & Iron Range Railroad, began work for the company as master mechanic. He attended several of the conventions and took an active part in the proceedings.

Mr. Porter King, of Springfield, Mass., has just left the throttle after running locomotives for forty-eight years on the Boston & Albany. He was previously on the New Jersey Railroad, and there guided the restive steed when the road was operated by horses.

Mr. C. A. Thompson has resigned from the position of superintendent of motive power of the Long Island Railroad. Mr. Thompson has been crowded out by what are reputed to be progressive influences. No railroad company ever lost the services of a more faithful and devoted servant.

Hon. Judson C. Clements, of Georgia, has been nominated by President Harrison as Interstate Commissioner. Mr. Clements is a lawyer and successful politician. His knowledge of railroad matters has not yet been demonstrated, but it is probably as profund as that of the other members of the board.

Mr William Voss, master car builder of the Burlington, Cedar Rapids & Northern, at Cedar Rapids, Ia., has been appointed superintendent of the Barney & Smith Car Works at Dayton, O. Mr. Voss is one of the ablest men in his line and is very well fitted to be superintendent of a manufacturing concern.

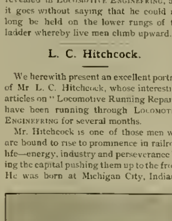
We desire to present the strongest evidence in our power to the good judgment and literary taste of Mrs. J A Baker, Oakland, Cal. In renewing the subscription of LOCOMOTIVE ENGINEERING for her husband this lady has the sense to remark "The paper was always good, but since its enlargement, it seems to me from the way I see it studied you might as well call it 'The Engineer's Bible.'"

Mr. W. E. Symons has been promoted to the position of master mechanic at Raton, N. M., on the Atchison, Topeka & Santa Fé. Mr. Symons has been an active agent in spreading the gospel of mechanics as revealed in LOCOMOTIVE ENGINEERING, and it goes without saying that he could not long be held on the lower rungs of the ladder whereby live men climb upward.

## L. C. Hitchcock.

We herewith present an excellent portrait of Mr L. C. Hitchcock, whose interesting articles on "Locomotive Running Repairs" have been running through LOCOMOTIVE ENGINEERING for several months.

Mr. Hitchcock is one of those men who are bound to rise to prominence in railroad life—energy, industry and perseverance being the capital pushing them up to the front He was born at Michigan City, Indiana,



May 4th, 1853. In 1869 he entered the service of the Michigan Central Railroad Co., in the capacity of locomotive fireman. In the fall of 1871 he went into the machine shop at Michigan City as machinist apprentice under Master Mechanic A. P Farrar In the spring of 1876 he went to work as machinist in the shops of the C. B. & Q Railroad at Beardstown, Illinois, under Master Mechanic Henry Whiting In March, 1878, he went to work in the Northern Pacific Railroad shops at Brainerd, Minnesota, first under Mr. Farrar and later under Superintendent of Motive Power George W Cushing and Master Mechanic H. J. Small. While there he had charge of the air-brake and water-pump repairs and locomotive valve setting In December, 1887, he was made roundhouse foreman at Minneapolis, Minnesota. In October, 1889, he left the service of the N. P. Railroad and entered that of the Minneapolis, St. Paul & Sault Ste Marie Railway as roundhouse foreman at Minneapolis, at which point he is at present employed as general foreman of their main shops.

Col. R. E. Ricker, general superintendent of the St. Louis & Iron Mountain Railroad, is spoken of as general manager of the Boston & Maine. Col. Ricker is a Maine man, and began his railroad career in New England He has few equals as a railroad man, and he is very familiar with all branches connected with railroad operating. He has been chief engineer, superintendent of transportation, superintendent of motive power and general manager.

President Oakes, of the Northern Pacific, and a party of railroad officers were concerned in an accident at Nork Yakima, Wash., last month, which came near being fatal to several of the party. A wagon in which they were fording a stream was overturned by the current Mr. Oakes succeed in reaching a shallow point, Mr. Mellen was able to swim to the shore, but Mr E. V. Smalley, editor of the *Northwest Magazine*, was rescued only after sinking twice.

Mr. James E. Greensmith has accepted the position of general manager of the Portland Locomotive Works, Portland, Me Mr. Greensmith received a good training in locomotive building under William Mason. He has been with the Pond Machine Works for six or seven years. It is the intention of the Portland Works people to put a good equipment of modern tools in the shops, and Mr. Greensmith proposes to follow the most approved methods in the manufacture of locomotives.

Mr James M. Foss, general superintendent of the Central Vermont, has been appointed assistant to the president of that road. Mr. Foss rose through the mechanical department. He learned the machinist trade in the Concord Railroad shops, where several men graduated who have risen to distinction in the railroad world. The upward grades were through the positions of engineer, foreman, master mechanic and superintendent Mr. Foss stands high among the railroad men of New England.

Railroad repair shops are not, as a rule, kept in a condition to impress visitors with the idea that order and cleanliness are considered important, but there are many shining exceptions. Nearly every section has some shop that the railroad men within range point to with pride. In the South the shops under the charge of Mr. C. F Thomas have been noted for the evidences of good management No matter what kind of a shop he takes charge of, it soon becomes a model of neatness and order. Those who have these surroundings have good evidence that their work is carried on under favorable conditions. A man who habitually keeps a dirty shop and slovenly surroundings has no reason to complain if he is taken for a slouch.

Mr. E B. Wetmore, for some years superintendent and master mechanic of the Rapid Transit Railroad of New York, has been appointed superintendent of the elevated railroads of Chicago Mr. Wetmore is one of the most successful railroad men of our acquaintance, and combines in a most happy manner the faculty of making it pleasant for both stockholders and employés. He made an excellent record on the Rapid Transit road for economy of operating, and no railroad officer was ever more popular with the men under him. Mr. Wetmore is a man of ripe experience in railroad work. He entered railroad employment in the Hartford shops in 1850, and remained there five years Then he went West and ran on the Ohio & Mississippi for eight years, until severely injured in a collision. After recovering, he went running as conductor, and continued in this service for four years. In 1867 he returned to the New Haven & Hartford road and took an engine under Mr. E. M. Reed, who was then master mechanic. In 1879 we find him running an engine on the New York elevated railroads, and a year later was made engine dispatcher. From that he was advanced to be trainmaster. In 1887 he was appointed superintendent and master mechanic of the Suburban Line On leaving this road to go to Chicago he was presented by the employés of the road with some handsome testimonials to indicate their respect.

## R. W. Bushnell.

When we received from Mr. R W Bushnell, general master mechanic of the Burlington, Cedar Rapids & Northern, the highly interesting article about the old locomotive "Pioneer," which appeared in our March number, we tried to get a portrait of Mr. Bushnell to accompany his sketch, but the engravers disappointed us and the portrait is now shown.

Mr Bushnell is one of the best educated of our older master mechanics, but a retir-

ing disposition and want of confidence have kept him more in the background than his abilities warrant. His article indicates a man of considerable literary ability. By personal contact the writer knows that Mr Bushnell is well informed on applied mechanics and on engineering science

Richard W. Bushnell served an apprenticeship to the machinist trade in the Rogers Locomotive Works at Paterson, N. J. He remained there for some time after learning the trade, but afterwards became seized with the "go-West-young-man" fever and went to Chicago. He naturally turned towards railroad work, and found employment in the Galena & Chicago Union shops. Here he rose through the usual grades to be division master mechanic. In 1872 he accepted the position of general master mechanic of the Burlington, Cedar Rapids & Minnesota, a small, struggling road with a few locomotives that were kept running by the personal ability to make something out of nothing The requirements of the master mechanic's position were toiling day and night, with the merest sheds for shelter, and tools that could be produced by labor and ingenuity without cost. The road has grown and prospered, and Mr Bushnell has grown with it. He is the kind of man who makes many friends and few enemies.

Mr J H Ruxton has been appointed division master mechanic of the St Louis and Kansas City divisions of the Chicago & Alton Railroad, with headquarters at Slater, Mo., to succeed Mr E. J. Whitington, resigned. He will have supervision of all engine and car work on these divisions, subject to the orders of the superintendent of machinery and the master car builder of the car department.

Mr. M C Leonard, master car builder of the Chicago, Rock Island & Pacific shops at Chicago, has resigned. Mr Wilson, the head of the department, has been making numerous changes in the shops, among them being the introduction of a piece-work system. Mr. Leonard did not feel that he could support the new plans cordially, so he resigned This was a much more manly course than that frequently pursued of retaining the position and covertly opposing the methods introduced

Mr. W H. Whyte has been appointed master mechanic of the Eastern Railroad of Minnesota.

Mr. S. J. Johnson, who was formerly business manager of the LaFayette Car Works has gone to be assistant superintendent of the Allison Mfg. Co., Philadelphia.

Mr. F. D. Casanave, superintendent of motive power of the Pennsylvania Lines at Fort Wayne, Ind., has been offered the position of general superintendent of motive power of the Reading system.

Mr. James E. Keegan has been appointed master mechanic of the Grand Rapids & Indiana. He will have charge of the locomotive and car departments and relieves the road foreman of engines of the charge of roundhouses.

Mr. T. A. Bissell, general manager of the Wagner Car Works, at Buffalo, has been in bad health for some time. He has gone to Bermuda for a few weeks in hopes that the sea breeze and the change of climate may prove of benefit.

Mr. Walter G. Chase, general manager of the Mason Regulator Co., of Boston, and Mr. Charles H. Barnes, son of the general manager of the Boston & Albany Railroad, went to Europe last month. They expect to be away for three months.

We thoroughly sympathize with Mrs. James M Dickson, Moberly, Mo., who writes us: "My husband was well pleased with LOCOMOTIVE ENGINEERING, and certainly would have renewed his subscription, but I am sorry to say that he lost his life in a wreck."

Mr. M. L. Hinman has been elected president of the Brooks Locomotive Works. Mr. Hinman began work in the establishment of which he is now the head when it was used as repair shops for the Erie. The prosperity of the works has been in a great measure due to the business capacity of Mr. Hinman, and his elevation to the highest position in the Company is a just recognition of what was due.

Mr. Lewis Gleason, who has been running a passenger engine on the Eastern division of the Atchison, Topeka & Santa Fé, has gone to Brazil in the interests of the Brooks Locomotive Works. Mr. Gleason spent several years in South America before. The Brooks people expect to push their locomotives upon the railroads in all South American countries and Mr. Gleason goes as an *avant-courière* with two of the engines.

Mr. J. N. Lauder, Superintendent of Rolling Stock of the Old Colony Railroad, has been visiting Mexico and the southwestern portion of the United States during the greater part of last month. Mr. Lauder was Superintendent of Motive Power of a Mexican railroad for some time, and he went to visit old friends and note the progress of the country. He thinks Mexico to be in a very hopeful condition. "The country is falling into line," as he expresses the situation.

Mr. Walter G. Oakman, lately vice-president of the Jersey Central, was elected president of the Richmond & West Point Terminal Co. last month, which makes him the head of a large Southern railroad system. Mr Oakman is becoming one of the railroad magnates of the country. Not many years ago he was a poor division superintendent of the Delaware, Lackawanna & Western. With no backing of position or family he had the audacity to fall in love with the daughter of the late Senator Conklin. Like young Lochinvar, his suit was denied, but he followed the Scotch hero's example. The energy that won a bride in the face of hopeless opposition seems to be pushing him to the highest pinnacle of professional success

## Ross Kells.

In the March number of LOCOMOTIVE ENGINEERING we announced, on what seemed to be the best authority, that Ross Kells, superintendent of motive power of the New York, Lake Erie & Western, who had been sick for some months, was so far recovered that he would return to duty about the beginning of April. The disease from which Mr. Kells was suffering

was of a very deceptive character. Instead of getting better he was merely passing through the temporary revival of energy which in kidney complaints often precedes rapid collapse. An unexpected bad turn came on about the beginning of last month and he died on the 10th.

Mr. Kells was born at Steubenville, O., in 1840. He learned the machinist trade in the shops there of a road that became part of the Panhandle. On this road he rose to be foreman, general foreman and master mechanic, leaving it only to take the higher position of superintendent of motive power of the Nickel Plate. While on the Panhandle Mr. Kells was associated with Mr. S. M. Felton. When the latter gentleman became general manager of the New York & New England, he induced Mr. Kells to take charge of the mechanical department. The New England road did not prove a permanent position for Mr. Kells any more than it has for many others, and he went into the railroad supply business for a time, but returned to railroad work in 1887 as superintendent of motive power of the western lines of the Erie. He became head of the department two years later. His forte was shop-work and the management of men.

## Exploded Shop Boilers.

The writer visited the scene of the explosion of the boilers at the shops of the S. F. & W., at Savannah, Ga., which occurred on February 29.

The boilers were nearly new, 14 feet long and 54 inches in diameter, they had thirty-four 4-inch tubes each, the shell sheets were $\frac{11}{32}$ of an inch thick, and the tube sheets $\frac{1}{2}$.

The two boilers are connected to a steam drum 24 inches diameter and 10 feet long, having 3½-inch gate-valves in the upright connections.

Sunday the boilers were washed out, and it is now supposed that the engineer packed these valves and left them closed, for after the explosion they were both found closed. The safety-valve and steam-gauge were attached to the steam-drum instead of to the boilers themselves; this was the only fault.

The workmanship of the boilers was good, and the wreckage showed no weak point; in some places the sheets tore, double and single-riveted seams alike gave way, rivets sheared off, stays broke or sheared off their rivets—the rupture was universal.

The damage done to shops was considerable, the pattern storage rooms, which were almost over the boilers, were totally destroyed, and all the patterns came down in the shape of kindling wood.

One piece of the boiler struck the track and sheared off a sixty-pound steel rail, and another struck a pair of wheels on a flat car and broke the axle short off.

The shops looked as if they had been bombarded.

The engineer and two colored men, one of them the fireman, were killed.

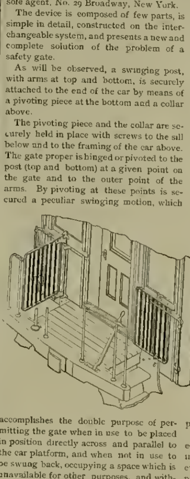
## Wood's Car Platform Gate.

We show the accompanying illustration of the Wood Car Platform Gate, manufactured by the R. Bliss Mfg. Co., Pawtucket, R. I., and introduced by J. B. Goodwin, sole agent, No. 29 Broadway, New York.

The device is composed of few parts, is simple in detail, constructed on the interchangeable system, and presents a new and complete solution of the problem of a safety gate.

As will be observed, a swinging post, with arms at top and bottom, is securely attached to the end of the car by means of a pivoting piece at the bottom and a collar above.

The pivoting piece and the collar are securely held in place with screws to the sill below and to the framing of the car above. The gate proper is hinged or pivoted to the post (top and bottom) at a given point on the gate and to the outer point of the arms. By pivoting at these points is secured a peculiar swinging motion, which



accomplishes the double purpose of permitting the gate when in use to be placed in position directly across and parallel to the car platform, and when not in use to be swung back, occupying a space which is unavailable for other purposes, and without interference with any existing condition of platform, step, brake-staff or coupling-lever.

Attached and pivoted to the gate is a "grab iron brace-bar," which extends to and is pivoted to the outer corner of the car by means of pivoting pieces, which are securely fastened to the framing with screws. The "grab iron brace-bar," when the gate is in use, securely holds the same in position, serves as a hand-rail and is an important factor in holding the gate in place when it is folded back. Particular attention is called to the fastening of the gate when open or closed, which is secured by one double-acting latch attached to top of post, as shown in cut. No fastenings are required on the buffer beam end of gate or platform, thus permitting of an adjustment to all widths of openings.

The gate closes to within 5½ inches of the platform and is parallel with same, and it may be particularly observed that the swinging motion of the gate is inward, towards the car platform, not outward.

To operate the gate, the latch is turned, the gate swung, when it will automatically lock itself in the opposite position and *vice versa*. The standard gate is made strong and simple in design, as shown in cut, and is adjustable to all cars and widths of car platforms.

In this simple but effective device is secured a practical safety gate that fulfills in every respect the requirements for which it is designed. A large number have been placed during the season of 1891 (practically the first year of business), and in every case are giving perfect satisfaction, as may be shown by the numerous requisitions which have followed trial orders.

## Work at Alexandria, Va.

At the Alexandria shops of the R & D. —one of the old Government shops during the war—they are doing some work in a little different way from that done elsewhere. Men who have to depend much on makeshifts of their own become inventors. One of the men in the shop has gotten up and they have built a screw machine with several entirely new features. One, the changing of tools instantly and maintaining the same length of tool, is a neat and novel feature. Screw machine makers should look this device up.

Having no tool to slot out forked rod ends, knuckles, etc., they made a disc some 14-in. in diameter and set tools in its periphery, this was put on the drill press spindle and revolved, the rod being fastened to the table.

Chris. Thomas, who by the way is one of the best shop managers we have seen, is making solid ended rods of I section finished all over and ready for service for $101 per pair.

In the car paint shop a system of steam heating has been adopted, the pipes being laid just inside the rails and directly on the floor, no trouble is had from it, and the heat is where wanted, both sides of the car getting the same amount, which is not true where ordinary radiators are used.

Much trouble has been experienced here from the cracking of driving-wheel centers on some classes of engines, and a new pattern of wheel is being introduced. The same engines were found to be some eighty pounds short in counter-balance weight for main wheel and an increase has been beneficial.

There is at this shop an old Smith & Perkins engine built shortly after the war, and is yet able to do a fair day's work.

The stationary engine was built by the Government, and some of the old tools used thirty years ago are on the pension list.

The R. & D. people recently had an economical fit and cut the number of men in this shop down to a baker's dozen, but even then they seem to keep the power in pretty good shape.

## Conflicting Reports of an Accident.

An accident happened to a locomotive in the yards of the Pennsylvania Railroad near Philadelphia a month ago, which gave the daily paper reporter an opportunity to spread himself tangental to the facts.

Among the headings directing attention to the accident are the following 1st. Four frightfully scalded—The water-jacket of a locomotive blown off with serious results. 2d. An engine explodes—Locomotive explosion about midnight. 3d. Injured in an explosion—The drawbar of a boiler bursts and four men are scalded.

The drawbar of a boiler bursting is worthy of Mrs. Partington The facts were that a switch engine backed into some cars hard enough to break the pin in front end of drawbar between engine and tender, and the blow sent the drawbar through the casting into the boiler, permitting the steam and hot water to escape into the cab.

The Congdon Brake Shoe Co. is erecting an iron building 200 x 110 feet, which will contain a twelve-ton open-hearth steel furnace and a twenty-four pot crucible steel furnace. It is expected that the plant will be in full operation by June 1, making general steel castings and material for the Ross-Meehan shoes.

## Familiar Spirits.

"Speakin' o' ghosts," said the old-timer, crossing his lean shanks at the end of the row in the Ananias Corner, "speakin' o' spirits reminds me of a gaak we put up on old Terrence Costhello, out at the front—which, incidentally, gentlemen, are the place to see life.

"Old Ted was night wiper in the roundhouse—the biggest one on earth, had the bull sky for a roof—and every time the pay car came in the old o' the moon Ted saturated his hide with sheep-dip and was among the missin' for about forty-eight hours.

"Ted owned a small shanty and a large wife, who—the wife, I mean—always hunted for him when he was burdened by a 'jag,' and invariably wept on finding him, declaring that he had her heart scalded.

"Well, me an' Baldy Hooten, Flat-Wheel Davis an' Stutterin' Jim, we went to the old woman and 'lowed we'd help her to scare Ted so's he forgit to drink enny more. Ted war powerful superstitious.

"We got the old woman to dress up in sheets, like a made-a-purpose ghost—only she was sorter a bad build for spookin'—and stand in a dark corner of the path, and then we hunted Ted up, threw a bracer inter him, and started him fer home.

"We sneaked around to hear the interview, knowing that the old woman had learned her part well.

"Ted was a-hummin' 'Wearin' o' the Green,' and stumblin' along the path, when alter onct he slammed up agin the ghost.

"'Oi cum, oh, dammed bibbler of a pizened stew, to take away thy carrion sowl,' says the ghost, with an accent that gave away its nativity.

"Ted started as if stabbed, clapped his hands to his head, never takin' his eyes off the ghost, that pointed its finger at him.

"Finally he found his blarney spiggot and says

"'Who, in the name of the Howly Mother, are ye?'

"'Oi am the divel!'

"'The divel!' says Ted, kinder thinkin' like, 'the owld divel hisself? Well, sir,' (advancing an unstiddy step), 'shake hands wid Ted Costhello, *I'm married til a sister o' yourn!*'"

## A New Air-Brake.

"Speaking of your Ananias column," said the division superintendent, sitting down in the "sleepy hollow" of the holy of holies, "Speaking of the literature of prevarication, I have got a conductor who will some day shine as a gilt-edged liar.

"His studied lies I know nothing of, but for an extemporary-spur-of-the-moment liar I will match him against all-comers.

"He gets into more scrapes than all the other men together—too good a liar to be good at anything else—but call him up on the carpet and he would make you believe that he left a switch open to prevent an accident, and he'd prove it. And gall—why, my dear sir, it was sublime.

"I determined to dispense with his services the first time he crossed the dead line, and waited for him.

"One day I saw his train making forty miles an hour down a long grade, with half the car doors in the train open, some of them swinging—strictly against rules and a recent bulletin order. I ordered him up.

"'Mr. Prevaricator,' said I, looking as severe as possible, 'I guess we will have to get along without your services hereafter; you seem to read rules and bulletins so that you can understand how to disobey them.'

"'What rules do you refer to?' said he.

"'I saw you come down Cumming's Hill, heleytarrup, with half your doors open—I won't stand that.'

"The liar turned around, carefully deposited his chew in a spittoon, and answered

"'Opened 'em a purpose.'

"'What for, I'd like to know!'

"'Jest to prevent an accident, and save money and reputation for this company. I knowed we had but half the cars braked; that the rail was frosty and the men green, but there was a heavy quarterin' wind a blowin', and so I told the boys to open some of them box-car doors and let the wind get a holt to help us, and we got down nicely. Don't you want a man to use his own judgment to save trouble?'

"I just turned around to my porter and said, 'Jim, take that spittoon out of this office; give one of the north-end conductors a chance to spit and he'll lie out of an accusation of having been born.'"

"What did you do with him?" we asked.

"Gave him a cigar and a passenger run, but I expect to lose him, now, pretty soon, one of these railroad newspapers has got onto him, and are bound and determined to make him an advertising agent, he's an artist in his line."

## A Bad Piece of Engineering.

"Oh! dear me, is this tunnel safe, George, is there anything wrong with it?" she exclaimed as the train dodged under the Bergen Hill. "Yes, darling," he whispered, "It's too short by half and altogether too light."

## A Mixed Recommendation.

"When I was on the Kansas Pacific," said President Mackenzie during a recent session of the Flat Wheel Club, "I had an engineer named Con Consadine (Double Con, the boys used to call him), who was one of the best men I ever saw with an engine, but he got into bad habits. When he was all right there was no more reliable man than Con, for there was nothing about railroading that he was not away up in, and men of that stamp were valuable in a country where good engineers were scarce. Feed water that was all froth as soon as it entered the boiler, was supplied at the most of the water stations, and engines were rushed so much that many of them were in bad shape. An engineer that can be depended to take his train through with drawbacks of that kind will be excused for a great many shortcomings. Con was excused a great many times, and lightly punished for numerous other lapses, but all would not do. He went from bad to worse so that he was full nearly all the time, and I was compelled to let him go.

"Con was a hail-fellow-well-met man and highly popular with everybody, which did much to lead him into drinking habits. The droll stories he told and the funny 'bulls' he was constantly making kept the division in fun. But with all that to shield him he was finally discharged

"A few days after he got his time Con came to me sober for once and asked for a letter of recommendation. I wrote out a good letter telling that he was a first-class engineer Con looked it over and said 'Faith, sur, would not ye's put in that I was a sober and industrious man of poor but honest parents?'

"'Well, Con,' I replied, 'I do not mind putting in the poor but honest parents, but I can't say anything about your being a sober man.'

"'Well, sur,' he said, 'you might put down that I was sober frequently.'"

## A Developed Hero.

"Man in the undeveloped condition," remarked the secretary of the club, clearing his throat for a yarn, "is very much like the diamond when first seen among other gravel in the mine.

"This truth was very forcibly brought home to me by the heroic act of a Scotch engine-driver that happened a good many years ago. The papers were full of the thing for weeks afterwards.

"This driver, whose name is David Wilkie, was walking through a yard on his way to the engine-house, when an alarm was raised that a switching engine had started up the down main line with no one upon her. Great excitement ensued, for a passenger train was nearly due. A rush was made towards the station-house for orders from the station agent, men being trained by rigid rules and habit to do nothing without orders. When the others were paralyzed for want of orders, Wilkie acted. He jumped on to a switch engine that was near, and, under the protests of the man in charge, took possession and started after the runaway engine.

"Those familiar with the story will remember that the engine was overtaken; that Wilkie climbed on to the runaway and reversed the engine. That the heroic act was scarcely in time, for the coming passenger train struck the engine when she was getting into speed, and that Wilkie was badly injured.

"It may not be so well known that this man was mildly censured by the officers of the company for acting without orders, but that he was excused on account of previous good character By special favor the act was not allowed to prejudice his prospects in the service, and he was permitted to resume his old engine and run when he recovered from the illness resulting from his injuries.

"I cannot think of Wilkie's truly heroic action without seeing him doing other things that partook more of the ridiculous than the heroic.

"One April morning, in what was the springtime of my own life, I was sitting in the office of the foreman of the locomotive department at Arbroath when an overgrown lad of about seventeen years came in and reported that he had come ready to begin work He was an ungainly looking youth of great size, composed mostly of legs and arms. His rosy face and general demeanor betokened rustic raising. He was dressed in a suit of the white duck overalls much affected by the British workman, and appeared to be proud of the snowy whiteness of his apparel. This was the introduction of David Wilkie to railway life, and to me.

"The foreman directed the youth to go to the engine-house and ask for a man he named, who would set him to work wiping.

"He went to the engine-house, as directed, and the first one he met was Jack Moncrieff, a lad whose purpose in life seemed to be mischief and deviltry.

"'Are you Mr. Speedyman?' asked the greenhorn.

"'No,' said Moncrieff, taking in the situation, 'I'm Mr Speedyman's assistant, is there anything I can do for you?'

"'A dinna ken', replied the rustic, 'may be there is, am come tae be a cleaner.'

"'Oh, yes,' said Moncrieff. 'I understand. You will be under my orders Come along,' and he led the youth outside the engine-house, cudgeling his brains in the meantime what trick he could play on the new-comer. An engine was standing on the pit outside, and a bright idea struck Jack.

"'Do you know what the first duty of a cleaner is?' he asked his victim.

"'No, a hinna ony idee,' said Wilkie.

"'Well, the first thing you have to do, is to sweep the lums (chimneys) of the engines.' This seemed reasonable enough, as all house chimneys have to be swept of soot regularly in Scotland.

"'Now, come, and I'll help you to make a start,' said Jack.

"With that he got a broom out of the engine-house, and led the new wiper to the front of the engine standing on the pit

"I happened upon the scene a few minutes afterwards, and found Wilkie pushing a broom up the chimney of the engine, his long legs were sprawling all over the buffer beam, his head and arms were inside the smoke-box and the soot was showering all over the white overalls. Jack was shouting directions with merely a quiet smile on his face. I fell down and roared.

"Wilkie looked round and seeing me laughing, concluded something was wrong. His red cheeks had received several patches of black, and his big nose looked like the handle of an ebony cane. His appearance was so ludicrous that Jack could not maintain his rôle of serious overseer, and he began to laugh.

"Wilkie slowly emerged from the smoke-box and his slow powers were roused to anger. His first act was to seize Jack by the axis of his trousers and push him into the smoke-box. Looking round, he saw a bucket of the yellow grease used for anointing the bearings of British cars. With his hand, which held as much as an ordinary shovel, he scooped up a 'gob' of this grease and plastered it over Moncrieff's head and face.

"Jack, who was a natural boaster, never blowed about making Wilkie sweep an engine's chimney.

"It came to pass that two years afterwards, when I was beginning to have some experience in engine-driving, this Davie Wilkie was firing for me. He was growing into a big man, and his leading characteristic was an inside void that could not be filled. A lunch basket is a poor substitute for a big basin of porridge

"On returning light one evening after running an excursion train, we stopped at a junction refreshment bar for lunch. They had small buns cut in two to make sandwiches. I ate two or three of them and felt satisfied. Davie said

"'These things do not make a good bite. I could eat twenty of them.'

"David, my boy,' I remarked, 'you have a fine appetite, but you should not slander an institution of the road by saying that you could eat five of the lunches set up for a hungry public.'

"'Oh, get out,' said Davie, 'I only wish somebody would pay for twenty of them to give me a fair meal.'

"'David,' I said, 'it is not in my nature to encourage excess, but if you eat twenty of those sandwiches in ten minutes, I shall pay for them. If you fail, you may pay for your own feast.'

"He readily agreed to the terms. There was a crowd of trainmen and others in the place, and great interest was manifested in the gastronomic feat Judges were duly appointed, watches were pulled out and David began to eat. He ate leisurely, but he finished the last sandwich nine minutes after starting.

"Then he said, 'Will you bet that I cannot eat twenty more?' I answered sadly, 'No, not if you make it a hundred.'"

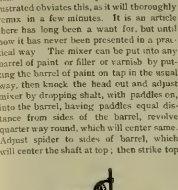
## Wheeler's Adjustable Barrel Paint-Mixer.

There has always been an objection with master painters to buying paint in bulk, for the reason that it takes so much time to "reincorporate" the paint, also a great deal of exertion. The paint-mixer here illustrated obviates this, as it will thoroughly remix in a few minutes. It is an article there has long been a want for, but until now it has never been presented in a practical way. The mixer can be put into any barrel of paint or filler or varnish by putting the barrel of paint on tap in the usual way, then knock the head out and adjust mixer by dropping shaft, with paddles on, into the barrel, having paddles equal distance from sides of the barrel, revolve quarter way round, which will center same. Adjust spider to sides of barrel, which will center the shaft at top; then strike top



of shaft several times, so as to drive points on the step into bottom of barrel. Turn up set-screws to fasten spider to sides of barrel, and adjust collar on shaft to close under upper bearing.

This mixer makes it practicable for painters to carry paint in bulk, saving cost in cans. It can be adjusted in a few minutes to any ordinary sized barrel, and will thoroughly combine or agitate the paint in much less time than by the old way of mixing with a paddle by hand, saving time, which is money. It is reversible; it is simple; it is durable, it requires no experience. A boy can use it with perfect ease. Besides the paddles, there is a two-edged scraper attached, which will break up all settlings that form in the bottom of the barrel. It is the only practical adjustable barrel paint-mixer in the market.

This mixer is controlled by the Senour Manufacturing Company, Chicago, who are manufacturers of a high grade of freight-car paint, ready for use or in paste form, to be thinned with linseed oil, and who furnish the mixer to their patrons.

---

The March greeting of the Jos. Dixon Crucible Co. was highly appropriate, and even prophetic. A storm of pencils is flying round propelled by the breath of Old Boreas. The sting from the sharpest of them would hardly equal the stings sent out by the piercing winds of last March.

---

A joint grievance committee of the Brotherhood of Railroad Conductors and of the Brotherhood of Railroad Trainmen has been in conference with the Santa Fé officials on the adjustment of wages for trainmen. All the grievances were amicably settled. A schedule of wages was agreed upon that will give passenger conductors and brakemen between Coolidge and Denver $5 more per month. Freight conductors will receive an average raise of a quarter cent per mile west of Coolidge. Brakemen east of the Missouri River will receive a raise of $5 per month. Two brakemen will also be put on passenger trains east of the Missouri River. The rules were revised in a manner that the employés considered beneficial to them.

(31). W. E. B., Galesburg, Ill., asks

Who invented the water-glass. *A.*—Thos. Watt.

(32) P. E. N., Sycamore, Ind., asks

Who ran the first locomotive in America? *A.*—Horatio Allen, on August 9, 1829.

(33) C. K., Pittsburgh, Pa., asks

What is the highest pressure you know of carried in a locomotive boiler? *A.*—200 pounds per square inch.

(34) Reader, Pine Bluff, Ark., asks

Where are the heaviest locomotives in the United States? *A.*—St. Clair tunnel, between Canada and Michigan.

(35) B. C. R., Buffalo, writes

What do you consider the safe limit for locomotive tires before being turned? *A.*—One well-known railroad has made the limit $\frac{3}{8}$ inch. We think from that to $\frac{1}{4}$ inch as much as can safely be used.

(36) C. L. S., Detroit, Mich., writes

Is the traction force of an engine increased when the pop is blowing off? I have heard it said that the friction of the escaping steam upon the atmosphere causes a downward pressure. *A.*—There is a downward pressure, but not enough to be perceptible.

(37) G. A. G., Chicago, asks

Do the drivers of a locomotive slip in rounding a curve, and if they do, is it those on the outside or inside that do the slipping? *A.*—As the wheels on the outside have to travel further than those on the inside, the latter do the slipping. Model wheels and track ought to be experimented with to settle questions of this character.

(38) W. H. P., Vicksburg, Miss., says:

Please give me through LOCOMOTIVE ENGINEERING formula for calculating the hauling capacity of locomotives running at a speed of twenty or thirty miles per hour on level track or on any grade. *A.*—A detailed answer would take too much space. Full particulars can be learned from Forney's "Catechism" or Sinclair's "Locomotive Engine-Running."

(39) H. H. K., Ennis, Texas, says

If 120 lbs. pressure has been pumped in main reservoir and brake-valve is put in full release, is there any place for air to escape to the atmosphere? *A.*—There is no means for the air to escape. Pumping to high pressure is bad practice. It is apt to damage the diaphragm of the pump-governor, and it puts such high pressure into the reservoirs of the direct brake and tender that there is difficulty in releasing them after coupling on to the train.

(40) Subscriber, ——— ———, asks

What do you think of an M. M. that will order a man out to his office about two miles from his home, after coming in one night, to find out why he did not estimate the cost of a coupling-pin between tank and engine in his report of a broken one? *A.*—We think this M. M. a good deal like the new policeman who arrested his old chum. "Pat," said he, "it's not that I hate ye that I have to bate ye into submission—it's because av the aut'ority I have over ye!"

(41) S. S., Mantua, Pa., writes:

I would like to have you give the reason why that brakes applied to the front part of a train will stop it quicker than if the same amount of brakes were applied to the rear part of the train? I would also like to know how much sooner a train of fifty cars, with ten of them loaded, with air-brakes on the loaded cars only, would stop than if the ten loaded cars (with air-brakes) were placed on rear part of train? *A.*—It would not make any difference. This applies to both questions.

(42) F. S. H., Denver, Col., writes

1. Did you not make a mistake in answering 27. Is not the link block pin always in the center of link slot? *A.*—Yes, we should have said *saddle* or *suspension* pin. 2. You say that exhaust clearance is the amount the cavity of valve is wider than the exhaust port and both bridges, this is wrong. *A.*—We fail to see how wrong; if the cavity were less than the width of both bridges and the exhaust cavity it would have inside lap, if it were exactly the width stated it would be line-and-line. Point out the mistake.

(43) Fireman, Waukesha, Wis., writes

We had an argument about plugging flues, and some one said it would take more pressure to force out a plug if it was pointed at the end than it does to blow out a blunt plug. Can you tell us why the plugs are not pointed to make them hold better? *A.*—It would not make any difference. A pointed plug would offer as much hold for steam as one with a flat end. The idea that a pointed plug would offer reduced area for pressure is a fallacy long exploded, but it seems to deceive the inquiring minds of every new generation.

(44) L. H., Johnstown, New York, writes.

Will you tell me how to figure thread-cutting on a lathe. The screw is 4 threads to the inch, and the gear on it has 144 teeth used for all threads. Gear on spindle has 96 teeth and is stationary, while the stud carries two gears which can be changed. *A.*—Divide the number of threads to be cut by the pitch of the feed-screw, and multiply the quotient by the number of teeth on one of the gears and the product by the number of teeth on the other gear; then any divisor that will leave no remainder to this last product is the number of teeth in one of the gears required and the quotient is the other. Remembering which is required to run the fastest, the spindle or the lead-screw will easily determine how the two gears found are to be placed on the intermediate stud.

H. H. F., Huron, S. D., wants to know the average crank leverage of an engine with 24-inch stroke. *A.*—The average leverage is as .6366 is to 1. The length of the crank being 12 inches, the average leverage is 12x.6366=7.64 inches.

A. G. C., Trotwood, O., is not satisfied with an answer given in these pages directing how to find the horse-power of an engine. He cites directions from a hand-book which he thinks different from ours, and asks which is correct? *A.*—They are both correct, except that we use the indicated pressure, and the other uses two-thirds of the boiler pressure.

## Training of Mechanics.

A contemporary greatly given to guessing says that the future mechanic will be a very different person from the present and past mechanic. The engine of human regeneration, according to our contemporary, will be the training-school, which is going to develop skill and sense much more rapidly than the shop. The boy in the shop goes and works on a machine and sees the work done without asking the reason why. The boy in the training-school will be taught all the whys and wherefores, therefore the conclusion is come to that he must be the more valuable workman.

We think there has been a lot of senseless gush written on this subject. If training-schools could alter the nature of boys and convert them all into the material from which first-class mechanics are made, there would be a great improvement in the future mechanic. As it is, a boy intended by nature for a dry goods clerk passes through the training-school for mechanics and comes out a hopeless incompetent. The training-school does him no more good than the shop does for similar graduates.

The boy cut out for a mechanic comes out of the shop as well equipped to perform the duties of a workman as he would be if subjected to years of training-schools. The special advantages enjoyed in a training-school are those needed by the men who become foremen and leaders in the business. Only a small number of the workmen can reach this elevation. The man with the natural parts for a foreman generally manages to acquire the knowledge necessary, even when his experience is confined to the shop. When we find a better place than the shop for the training of good mechanics, we will write it up for the benefit of our readers.

---

The New York Central Railroad people have decided to rebuild the "De Witt Clinton" for exhibition at the World's Fair. This was the first locomotive run on a railroad in New York State, the road having been the first link of what is now the New York Central Railroad. There is very little of the original engine preserved, but Mr. Buchanan has the drawings from which the engine was built. It will now be in order for the Baltimore & Ohio people to build for exhibition a reproduction of Peter Cooper's locomotive "Tom Thumb." This was really the first locomotive used on an American railway, and ought to excite as much interest among us as the "Rocket" does among Englishmen. The "Tom Thumb" performed as important a service for American railroads as the "Rocket" did for those of Europe.

---

The Boston & Maine people are fitting driver-brakes upon all their locomotives as fast as they can be put on. Numerous other practices lately introduced indicate that there are men at the helm who wish to steer in progressional waters.

---

Notice has been given that the Grand Union Hotel, at Saratoga, will be opened for the accommodation of the Master Car Builders' and the Master Mechanic' conventions. The headquarters for both associations during the conventions will be at Congress Hall Hotel.

---

The most enthusiastic advocate of the compound we have as yet met is Mr. C. H. Hudson, general manager of the E. T. V. & Ga. After a full year's experience his statements, based upon a most carefully kept record, must naturally entitle him to the position of one speaking upon authority. Figuring at cost of coal on a basis of 90 cents per ton, calculating relative cost of repairs, etc., 100 compounds would effect a saving of $110,000 per year. A discussion on the relative merits of the two types with Mr. Hudson will prove to be most edifying to those who may have this privilege.

## FREMONT'S PASS.

**The Highest Railway Point in North America, 11,540 Feet Above the Sea.**

The upper picture on this page shows one of the Denver & Rio Grande's narrow gauge consolidations with her train on the summit of Fremont's Pass, on the Continental divide.

The lower picture was taken looking east from the summit down the 211-foot grade; the track makes a big loop in the basin shown in the upper left corner of the picture, and a high trestle-work can be seen in the valley there; from this the track comes back directly under the one in the foreground and below the line of trees.

This pass is noted for snows in winter and beautiful flowers in summer, and the branch on which it is located is a popular picnic route.

The great Arkansas river heads in this gulch below the pass, and starts on its 2,000-mile journey to join the Father of Waters, having in all a fall of over two miles, over half of this being lost in 162 miles, to Pueblo, at the edge of the plains.

The bald-headed old storm-king in the lower picture always has a crown of snow, and the trains on this pass are often above the clouds.

From the western slope of this pass on a clear July day, the Mount of the Holy Cross shows its white symbol of Christianity, fifty miles away, and this is the only spot where the cross can be seen from the railroad.

The D. S. P. & P. branch of the U. P. road have now a line over this pass, and the grade has been made a little higher at the summit to get to the highest point.

The Rio Grande built over this pass in 1880, in order to reach the mines at Robinson and Kokomo, and the tie timber along the upper waters of the Blue river.

HIGHEST RAILWAY POINT IN NORTH AMERICA, 11,540 FEET ABOVE THE SEA.

LOOKING EAST OFF FREMONT'S PASS. GRADE 211 FEET PER MILE.

---

There is at McAdam Junction a water-tank eighty feet high which is supported on a trestle of rails designed by Mr. George A. Haggerty, master mechanic at that place. The posts, beams and braces are all made of old rails. The structure is very stiff, and shows little vibration during the severest gales.

---

At a railroad division shop in New Brunswick we recently examined a pile of broken Nashua tires that had failed on driving wheels. Nearly all the fractures were circumferential, the species of failure so common with this make of tire. The making of steel suitable for tires is now so well understood that there is no excuse for offering to railroad companies tires that will fail in service. The company that buys tires of this kind assumes a very serious responsibility.

---

The Plant System's new refrigerator cars, 500 of which have just been turned out by the Madison Car Works, will have part of the series equipped with the Smillie Coupler, the rest with the Janney.

---

Cy Warman, of the *Western Railway*, Denver, has sold out that paper and started a daily at Creede, the new, red-hot mining camp of Colorado. We sincerely hope that Cy "gets there," but a little experience of eight months as owner, editor, manager and slave satisfied the writer that working in a treadmill or sawing wood was a snap as compared to work on a daily.

---

At the Phœnix Foundry, St. John, N. B., they have lately finished the construction of a fine 17x24 eight-wheel engine of the same pattern as the standard engines belonging to the Intercolonial Railway. The place is an ordinary jobbing machine shop with an able superintendent, who has made small facilities go a long way in producing good machine work.

---

A very simple and ingenious form of journal-box lifter has been invented by Emery E. Taylor, Minneapolis, Minn. It consists of a bracket which is hooked on the top of the wheel and a chain that can be passed under the box. By turning a nut on a screw which fastens the chain to the bracket the journal-box is raised up, the wheel acting as the support. We are inclined to think that this will be a decided improvement on the small screw-jack usually employed for lifting axle-boxes when a brass has to be put in.

## On the Oldest Road.

[Editorial Correspondence.]

As is probably well known to the readers of this paper, the South Carolina road was the first one of any consequence built in America, and employed the locomotive "Best Friend," the first railroad locomotive made on the Western hemisphere. This engine was built at the West Point Foundry, in this city, to the designs of Allen Hallard, and Horatio Allen, the civil engineer of the road, and the man who ran the "Stourbridge Lion" on her trial trip.

EARLY ENTERPRISE.

The business men of Charleston must have been foresighted fellows in those days, for they planned to build up their city by making it the center of a great transportation system. This was before the days of practical railroads, river steamboats and canal barges were the best. The people of Charleston took hold of the railroad idea with a hurrah, and took out a charter for the South Carolina & Hamburg R. R. in 1827. A little later the plan was proposed to push through lines of road to the Mississippi and Ohio rivers and make Charleston a great seaport. In 1835 a charter was secured for the Louisville, Cincinnati & Charleston R. R. These were consolidated in 1843.

THE FIRST 100 MILES.

The South Carolina road was completed to Augusta, Ga., 137 miles, in 1833, and was for some years the longest road in the world—the main line is the same length yet.

The gauge was five feet, but this was changed after the war, and the road rebuilt—having suffered fearfully from the destructive ravages of the soldiers. The rebuilding and changing of gauge put the road fearfully in debt, from the effects of which it is suffering yet.

IN EARLY DAYS

the road was operated by South Carolina men, who, of course, had no experience or precedent to go by. That the mechanics who had charge of the engines and cars were able men there are many evidences extant. Some of the old drawings are preserved, not only of locomotives and cars, but machine tools as well, and better drawings are not made to-day.

There were some inventors here who were men for emergencies, but none of their inventions that I know of ever came into general use, unless the credit of the eight-wheeled car can be placed here—which is doubtful.

Long years ago, in the '40's, they used barrel cars, the bodies being made up of staves hooped, the car being cigar-shaped; this car was illustrated in *The Locomotive Engineer* for April, 1891.

The roadmaster recently dug up an old flanged car wheel with a 12-inch tread and in the shop yard there are still a few of the old iron U rails.

THE ROAD

runs through a swampy country, and in an old report to the stockholders, made in 1831, Chief Engineer Allen and his associates devote considerable space to explaining why the road cost more than at first estimated—not unlike present practice.

THE MOTIVE POWER

was horses at first and then sail-cars, and there are still alive people who rode in these old sailers; and one man lives in Charleston who was a conductor on one.

THE "BEST FRIEND"

was used here. Her colored fireman held down the safety-valve one day and the boiler exploded, and after that they hauled a flat-car next to the engines loaded with bales of cotton as a sort of a breastworks to protect the people in the coaches.

THE SHOPS

as they now stand were built in 1854, and are very large for the size of the road—about the only case I know of where they have too much room. The buildings are of red brick, put up very substantially, but are somewhat scattered.

THE EARTHQUAKE

of 1886 did considerable damage to these buildings, as it did to most of those in the entire city; some of the cracks were cemented up and some left alone, these latter have closed up very much since the "settlement." While on the subject of the 'quake let me call your attention to the photographs of the two wrecks caused by the shake. In many places the track was thrown off the grade, but in only these two did trains find the breaks too late. In each case the fireman lost his life

WAR MEMORIES

cling around these old shops; the Confederates used them as gun-shops during the war, and most of the tools there are of the Whitworth make and came from England on blockade runners "endurin 'de wah." One man is still running a large lathe on which he bored out guns in the '60's.

The Nasmyth steam-hammer, now pursuing its arts of peace in the blacksmith-shop, was dropped overboard in the harbor to prevent capture and was afterward fished out.

SLAVE RAILROADERS.

The S. C. road owned its own trainmen in early days and had a great deal of money invested in humanity. They had special quarters for these men and provisions for feeding them.

In the old-time records still preserved in the shops it is not unusual to see reference to an accident giving the names of those hurt, but behind some say "company man." In the time-books the words "company man" often appear where the rate of wages and time put in should appear. They still employ colored firemen, some of them putting in long years tossing fat pine.

THE ENGINES

are mostly 8-wheelers, and the average of them are comparatively light, 16 and 17-inch cylinders, and very few of them are so awfully old, though I guess there are six or eight that ought to vote.

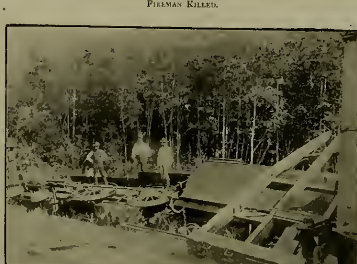
THE CARS

are mostly modern ones, but there are some old-timers, most of them made here, a great many of them with cross-framing, and some odd old draft gears. There is an old

WAR CAR

here, built entirely of iron, and once used by General Thomas as headquarters of the Army of the Tennessee. This car is very strong, has cross-framing and no truss rods, but it has been lifted on jacks at the center without springing, and it has been in the ditch repeatedly, but never hurt. The outside panels are pressed out and riveted up to cleat pieces over an iron frame with wood filling; the inside of the car was finished in the same way. The car was so insufferably hot that some years ago it was sealed inside with wood. It is now painted like a box car, and is used to take the colored laborers out to the phosphate works around the city.

EARTHQUAKE WRECK, TEN MILES NORTH OF CHARLESTON, AUGUST 31, 1886. FIREMAN KILLED.



EARTHQUAKE WORK AT PATH, S. C., 130 MILES NORTH OF CHARLESTON, AUGUST 31, 1886.—FIREMAN KILLED.

SOME OLD RULES.

I got hold of an old book of rules issued by General Superintendent H. T. Peake, in 1860, that contained a few odd rules. Here are extracts from some of them:

"Any person engaging himself, and the owners of slaves employed shall, if required, sign articles of agreement releasing the company of all liability for damages in case of injury to the person or loss of life occasioned by accident while in their service."

"Smoking not allowed and positively prohibited on freight trains carrying combustible material * * * Any person in the service using profane or obscene language in the presence of a passenger will be dismissed."

"* * * Each conductor must keep a watch."

"At end of trip conductor and train hands will clean the cars."

"In meeting trains of the same class the one to the right takes siding."

"Engineers leaving engine under steam will throw the engine out of gear, screw down the tender brake and leave the fireman in charge."

Part of rule 7 for engineers: "When there is a possibility of a collision with another train the speed must be reduced to four miles per hour * * *"

"It will be a particular part of an engineer's duty to see that all switches and turnouts are right before crossing them; to insure which, it will be necessary to approach all switches, water stations and depots at such speed as will enable him, on discovering a switch out of place or any obstruction on the track, to bring his engine to a stop in day-time; and at night he must not cross a switch or turnout until he assures himself it is right by stopping and getting off his engine to examine it, if so dark as to render that necessary."

"* * * When there are more trains at a turnout than can get into it they will stand on the main line, and the conductor of the forward one will shift the gate to let the meeting train into turnout, he will then shift the gate back to main line, and the conductor in the turnout will shift the gate to let his own train out and then replace it to main line."

"* * * When two trains running in the same schedule, and can not see more than a quarter of a mile, on account of fog or other reasons, the second train will go into a turnout and wait for the next schedule. In the case of a train in this schedule the delayed train will go on, and if still foggy the last train will wait in a like manner."

"15. Freight trains will not leave Aiken without a brake-car, when they have over ten cars."

"* * * Foremen of shops must never suffer a locomotive to go out without a fender or cow catcher to remove cattle and other obstructions."

"Engineers and conductors are forbidden to strike their firemen or brakemen, either free or slave."

NOW

the men in charge are trying to operate the road on modern principles, and not on its "before the war" history. The superintendent of machinery, Mr. E. M. Roberts, formerly occupied the same position on the Ashland Coal & Iron Co.'s road, and lately the position of master mechanic of the E. T. V. & G. at Atlanta. Mr. Roberts wears a very handsome watch that was presented to him when he left the East Tennessee which bears the inscription: "From the Boys."

G. H. Grambling is the master car builder, and has been with the road a long time. J. T. Blackwood is general foreman, and came there from the L. & N., while the machine shop is looked after by E. Pugh, a Pittsburgh mechanic.

THE ROUNDHOUSE

is, like most of those in the South, an outside circular wall and a roof; no doors or inside wall in the house. They have a little crane mounted on an old engine truck, this is used to lift stacks, cabs, air-pumps etc., and to handle tire. I must tell you about their

TIRE HEATER,

which is simple and effective; the plan is used on several roads, but is new in most places. The burner is formed as shown in the sketch, Fig. 1; the lower pipe is perforated on its upper half with small holes, and the connection is made to the center of the upper pipe; this connection is carried away some twenty feet to an upright pipe some twelve feet high, and is there connected to a ten-gallon can. A globe valve in the vertical pipe, which is ½-inch, serves to control the flow of oil, a cheap quality of crude oil being used; the flame from the small jets heats the upper pipe, and the oil passing through it flashes into gas, making an intense blue flame.

This burner is placed under a tire and a sheet metal shield placed around the top half of same; this serves to guide the flame around the wheel

After the pipe is h[illegible]

nish from actual work, and to tell the make of material and age at a glance whenever the stock is noticed on the road.

WOOD BURNERS

are still employed here as on many roads

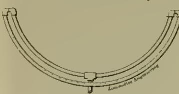

Fig. 1.

in the South, but they are fast working in coal burners.

A FEW BRAKELESS CARS

are still to be found on the road, and it is only two years since they stopped hauling empty brake cars up the incline at Aiken in order to hold others down with them.

Several things of especial interest are illustrated elsewhere. J. A. H.

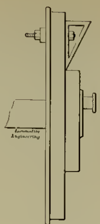

Fig. 2.

dred dollars in Confederate money, and the highest wages were for mechanics who had trades, as many of the South Carolina slaves had.

This roll is for outside slaves hired from owners, and is probably about the last one made out.

The Emancipation Proclamation shortly after announced that the cancer of chattel slavery had been cut out of the fair body of the Union by the sword, and the wound washed in the blood of her sons.

## One Cause of Leaky Flues.

An intelligent boiler-maker who had been for years engaged on contract work of flue-setting in a locomotive building shop, in a conversation with us lately about methods of doing work, revealed the secret of a practice which might account for a good many leaky flues. The price paid for setting flues is surprisingly low, and we expressed surprise that living wages could be made by the workmen. "Well," he said, "there are ways that we can help ourselves out."

"What kind of ways?" was the inquiry "Do you mean that you can slight the work and deceive the inspector?"

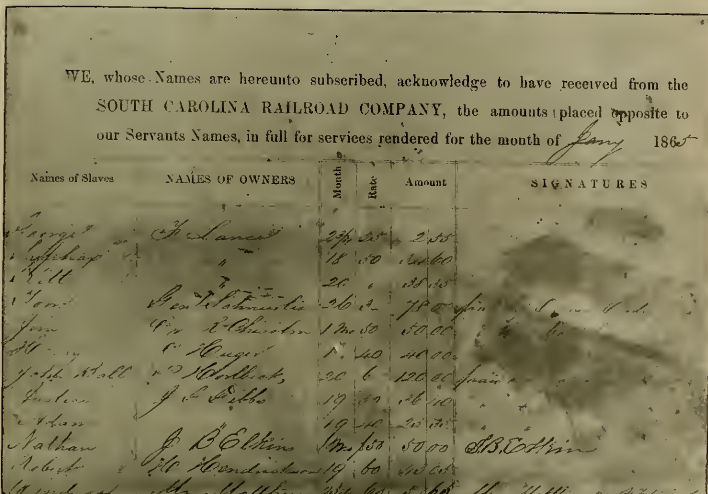
"No, not exactly that," said the boiler-maker. "I'll tell you how it is done. When the holes for the flues are drilled the exact size the flue is hard to center, and there is loss of time placing it. A few seconds lost on each flue counts at the end of a day. The plan we followed was to go to the man drilling the flue-holes and quietly get him to make the hole $\frac{1}{16}$-inch larger than the size called for. It does not make any difference to him and it helps the boiler-maker wonderfully."

We took occasion afterward to measure a variety of holes in flue-sheets, and always found that they were drilled too large. Some of them measured as if they had been intended to hold a copper ferrule, when they had nothing but the bare flue to fill the hole.

Some conductors belonging to the Pittsburgh & Western have seriously proposed that a part of the baggage car be partitioned off as a pen for the accommodation of drunken and unruly persons. We think it is a very good idea, but it would be difficult to consign all the persons to such a place who infest railroad trains and yet are unfit to mix with respectable people. When a railroad has regular passengers who require accommodation of the kind suggested, we would ask, What is the matter with a stock car? The human hogs would be nicely provided for in a strong stock car, with plenty of straw to soak up tobacco refuse.

The S. P. road, Atlantic system, recently put into service some fine Schenectady passenger engines having the Pennsylvania standard sand-box—in the front wheel cover. After six months' trial they have been voted a nuisance all around, and ten new engines of the same class now building will have the old-fashioned sand-box on top of the boiler. The P. R. R. box is made of sheet metal, and is down where it gets no heat from the boiler, and, the boys say, is constipated.

General Superintendent Voorhees, of the New York Central & Hudson River, announced on the 4th of April that the plans had been completed for the establishment of block signals along the entire line of the road from this city to Buffalo. The work, he thinks, should be completed to Albany by the 1st of August, and to Buffalo by the 1st of November. This is, on the whole, a very prompt application of the lesson taught the company by the disaster of Christmas Eve and by others of less magnitude. The plan, when completed, will put the management of the road, in point of safety, where it already is in other regards—abreast of the times. It has only lacked block signals to give those magnificent 870's a chance to show what is in them.



WE, whose Names are hereunto subscribed, acknowledge to have received from the SOUTH CAROLINA RAILROAD COMPANY, the amounts placed opposite to our Servants Names, in full for services rendered for the month of Jany 1865

## On Tick.

There are 900,000 miles of telegraph lines in the world with approximately 2,500,000 miles of separate wires. Europe alone has 67,465 telegraph stations out of the total of 465,000. The world's yearly messages are put down at 296,000,000. From this number 57,500,000 are messages transmitted from one country to another. The total receipts for the world's telegraph service amount to upward of $450,000,000.

When you want to cut rubber gaskets wet your knife-blade in water, or better yet, in potash and water, and you will find it cuts much easier and cleaner. In putting rubber gaskets into steam-tight joints coat them with black lead and they will not stick to the metal when you want to take them down. If you have no black lead common chalk is a good substitute.

## The Last Slave Railroaders.

While in Charleston, S. C., recently, the writer ran across an old pay-roll of the slaves employed by the S. C. R. R. Company. Perhaps it is not well known that for many years this company owned their own firemen, brakemen, switchmen, cleaners, etc.—some sixty persons. These were housed, fed and clothed by the road.

In looking over the old time-books of the company, such entries as follow were on every page:

Engine 11, Engineer, Allen, 26 days, $70.60

" 11, Fireman, Mose (Company man).

There are to-day old colored men in the South who fired locomotives for more than thirty years.

The pay-roll, one quarter of which is exactly reproduced here, is double, both sides used. The wages in some cases are very high, but it will be remembered that this was just at the close of the war, when a pair of boots was worth five or six hun-

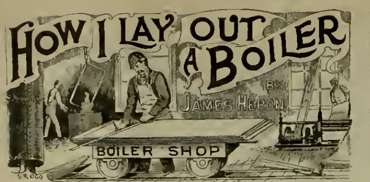

Figure 6 shows plate to form throat-sheet. By referring to engraving of boiler you will find the height of this sheet where it connects to belly of boiler to be 2 ft. 11¾ in.; the height to top of wing C D is a matter of taste. Some boiler-makers run them up to center of boiler; I prefer to make them as short as possible, as it requires less manipulation in flanging and less riveting, and makes a stronger and neater job; this sheet when flanged should be the same width as back-sheet, as in Fig. 6, last paper. But, as we have double-row of rivets in flange, 1¾ in. more must be added, each side, as double-rows of rivets have 1¾ in. between center, as at Fig. 8.

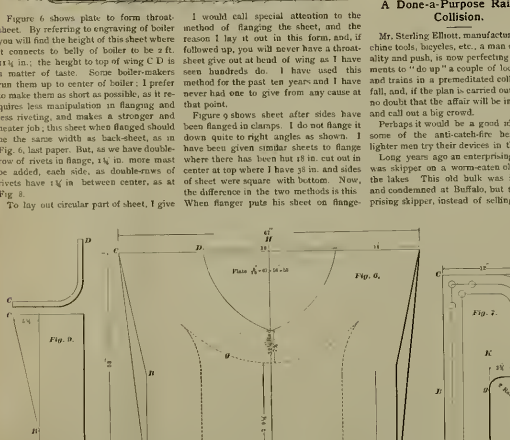
To lay out circular part of sheet, I give height to where ¼ circle commences as at g, Figs. 6 and 7, to find the height; the sheet we are working on is 9-16 in., but to simplify matters, I make it ½ in., height from bottom of mud-ring to belly of boiler, or bottom connection sheet, 2 ft. 11¾ in.; radius of corner as at g, Fig. 7, 2 in. inside, 2½ in. outside; 2 ft ½ in. from 2 ft. 11¾ in. will be the height as at g, Fig. 6. Now you want to find amount of material required to form ¼ circle and straight part of flange. Where you find the abbreviation radius, it means radius in all cases where you get a given inside diameter, you must add thickness of material to diameter to find circumference. We have here an inside radius of 2 in., which means a diameter of 4 in., adding thickness of material ½ in. or the equivalent decimal .50, make 4½ in. or 4.50×31.416 = 14.137 or 14⅓ divided by four, as we only require length of ¼ circle 3½ in., to this add 2½ in. for laps and 1¾ in. for center, between knit-holes, length required 7¾ in.

Note radius at H 32¾ in., plan of boiler, shows radius 2 ft. 5¾ in.; this should be the radius of circle when finished, but I have added 2½ in. to that radius because my line on sheet is to guide flanger showing him where his bend commences.



I would call special attention to the method of flanging the sheet, and the reason I lay it out in this form, and, if followed up, you will never have a throat-sheet give out at bend of wing as I have seen hundreds do. I have used this method for the past ten years and I have never had one to give from any cause at that point.

Figure 9 shows sheet after sides have been flanged in clamps. I do not flange it down quite to right angles as shown. I have been given similar sheets to flange where there has been but 18 in. cut out in center at top where I have 38 in. and sides of sheet were square with bottom. Now, the difference in the two methods is this When flanger puts his sheet on flange-block to flange circular part, and comes down with the mauls—or what is more generally to the deterioration of the material, sledges—on point D, Fig. 9, down goes the wing at point C with it, and I have seen sheet heated four times after flange was down to hammer back that wing so as to have edge straight as at A B C, Fig. 7. Now this is the cause of so many throat-sheets giving out at point marked K, Fig. 7. That is the point where the sheet has the most strain in flanging, as it has to stretch both ways—down and out. Then knocking wing back point K, as a center, has to stand the blunt of all the hammering, and is very often burned at that point in trying to get material as hot as possible, so as to get wing back to its place with least amount of work, which is no easy job.

Now, by having sheet wider at top and cutting to shape as at A B C, Fig. 6, point B is a weak point and when flanger strikes on point D, Fig. 9 wing at point C goes down with D and I have the material there to let it go, so needs no knocking back.

I insist on flanger bringing point C straight with A B, to do this he has to come down with heavy sledges at C on edge of plate. It is plain to see the 5½ in. at point C has to be upset in flange where it has to stretch the most, and sheet is not reduced by heating so often. By this method of flanging you can scarcely perceive a difference in thickness of material when cahpered.

I will take up connection sheets in the next paper, as requested by letters from several of your readers, 2½ in. *loss* in last paper should read 2½ in. lap.

J. Heron

## A Done-a-Purpose Railroad Collision.

Mr. Sterling Elliott, manufacturer of machine tools, bicycles, etc., a man of originality and push, is now perfecting arrangements to "do up" a couple of locomotives and trains in a premeditated collision this fall, and, if the plan is carried out, there is no doubt that the affair will be interesting and call out a big crowd.

Perhaps it would be a good idea to let some of the anti-catch-fire heater and lighter men try their devices in the trains.

Long years ago an enterprising Yankee was skipper on a worm-eaten old brig on the lakes This old hulk was inspected and condemned at Buffalo, but the enterprising skipper, instead of selling her for old wood, advertised to let her go over the falls of Niagara if enough spectators, at a dollar ahead, would come. He was the original inventor, and got enough out of the exhibit to buy a new ship.

Perhaps Mr. Elliott's plan will open up a new way to sell old engines and cars, teach an object lesson, and at the same time leave on hand as much scrap as if the exhibition had not taken place.

Mr. Elliott is an interesting humorous writer, as the following article from the *Bicycling World* will bear witness

"At the suggestion of any extensive and elaborate amusement enterprise the average mind turns at once to P. T. Barnum. Barnum and the show business are synonymous. He was to the amusement world what Napoleon Bonaparte was to war, or what Bob Ingersoll is *not* to the Orthodox church. Given some extremely odd and unusual freak and little Jimmy Jones, of Dead Horse, Dakota, says the same thing that little Ralph Waldo Browning, of Boston, would utter, viz.: 'Why, Barnum ought to have that.' *Why Barnum?* Because Barnum stands not simply as the name of a man, but as an idea, and that idea embodies all that is startling enough to warrant a charge for the privilege of seeing it. Barnum has 'strut his brief hour upon the stage' and passed away. Who will be his successor? Of course we know who succeeded to his show business, but who is to be the 'bright, particular star' that will outshine all the firmament of amusement managers? Who is to 'take the cake,' so to speak, that will be baked by our grandchildren? Will it be some man who began at the foot of the amusement ladder and patiently toiled his way along, who perhaps even now has reached a respectoble mediocrity and will win by slow degrees? *I don't believe it.* It seems to me that he will come tumbling into the ring with a jolly 'Hi, hi, here we are again'' and not only begin where Barnum left off, but leave the genial old godfather of Thomas Thumb several lengths to the rear on the first lap.

"Now my natural modesty makes it hard for me to say it, but do you know I believe I am that man. I have got an initiatory scheme that would have made Barnum turn pale. Something which will make Jumbo and the sacred white elephant look like a couple of dwarf rats. Something as compared with which the 'Last Days of Pompeii' and the 'Fall of Babylon' would be absolutely noiseless. What do you think? *A railroad collision.* Not one of these tame affairs where both engineers are doing their best to stop, and where at most but a few human lives and a few thousand dollars' worth of engines and stuff are lost, but a real, genuine done-on-purpose collision with full steam and everything right, and have them come together smack square in front of the grand stand; every man at his post and no half-way business about it. Haven't you traveled miles to see the wreck or even the location where such a thing happened, and haven't you carried away slivers and things and had them labeled and put on the 'whatnot' in the front room? Haven't you bragged for years that you went to the scene of the wreck and personally—'Yes, sir, personally,' and with your own hands pulled off a piece of the smoke-stock, or whatever, and brought it away with you? What wouldn't you give to sit in a comfortable chair in the grand stand and see such a magnificent sight as two beautiful trains of modern vestibule cars coming at full speed around a specially constructed curve, each engineer blowing his whistle like the last trump, and the other pretending not to hear it. A flagman wildly waving the wrong color, an open switch, 'the hot breath of the engine,' the customary, 'Oh, my God, we are lost!' the usual 'dull sickening thud, and all is over.' Then the train is cut up into small bits and sold to you (probably 100,000 of you) and the affair passes into history as the greatest thing in the amusement line the world ever saw. *How do you like it?* I am negotiating with a prominent railroad to furnish the road bed and rolling stock with every prospect of success. The hitch, if any, will be the selection of the passengers. There are some who say they would like to be on board and yet others that we are waiting to hear from. If you want to be in the first premeditated smash-up that ever happened, please file your application at once. Details and prospectus later.

"P. S. The peanut, lemonade, and undertaking privileges are to be sold to the highest bidder.

"P. S. No. 2. The same engineers will not be allowed to enter such tournaments often enough to become professionals."

## Car Building in New Brunswick.

The J. Harris Co., Limited, of St. John, N. B., build cars of all kinds. The place originated as a foundry and gradually developed into a manufacturing establishment, where any kind of mechanical work was undertaken. The specimens of cars which we examined showed that they can do first-class work, but it must be done under great disadvantages, for there is scarcely any machinery in the place adapted for car building. After going through the place the reflection of a mechanic naturally is, if these people can get paying prices for cars, wouldn't we like to build cars in competition, with the facilities of a first-class American shop.

A big business is done in making cast iron wheels, and the facilities for this business are fairly good. They are putting in machinery to roll and cast iron wheels under great pressure while they are hot. From experiments made by the process there is reason to believe that it will greatly strengthen the wheel and make it more durable. If I am not mistaken, the process is an American invention. It is also claimed that when the wheel comes out of the rolls it will be perfectly round.

## Boilers for High Pressure.

BY PULASKI LEEDS.

In answer to an inquiry about boiler matters Mr. Leeds sends the following exposition of his views:

In regard to combining safety and high pressure in boiler construction, I find that with boilers carrying 160 pounds of steam there are more broken stay-bolts than there was when the pressure was lower. The breakage of stay-bolts occurs mostly near the top of the firebox, and at both forward and back corners. With the 62-inch shells and firebox 120 inches long there is a great deal less trouble in every way with the Belpaire form of boiler than with any other that I have had experience with. The Belpaire I consider the proper form of firebox, because the flat surface is stayed to a flat surface, and it is possible to strengthen all points that are weak in in other forms of firebox.

With boilers having radial stay-bolts there is a tendency in two ways to break the upper rows of stay-bolts toward the top of the inside box. First there is the pressure of the steam, putting direct tension on the bolts, and then there is a tendency of a bad form to change its shape. The sides of the firebox become like a Bourden tube, and the pressure is always trying to straighten it out. If you cut out a narrow strip from the transverse section of a radial stay firebox, with the water leg passing down between the frames, it will be seen that the strains coming upon it must be of a very complex character. The tendency of this section to straighten out the part that is seen as concave from the outside, puts side strains on the upper stay-bolts that must soon prove destructive, and is, no doubt, in a great measure the cause of so much breakage of the stay-bolts in this form of boiler.

Another objection to the radial stay firebox is that it is nearly impossible to put heads on the inside of the crown-sheet on the two or three outside rows of stay-bolts, and I do not consider a crown-sheet properly or securely fastened unless the stays have heads to hold the sheet in case of the buckling of the same or of the stretching of the holes. The slight riveting of the stay-bolt sometimes practiced is not reliable.

My idea of the best boiler for high pressure is the "Belpaire type," braced at the corners in such manner as to prevent any tendency to assume a circular form over the water space in front of the firebox, and to relieve forward row of crown-bolts of any excessive strain due to the unstayed space at that point with sufficient "T's" or angle-irons across roof sheet to stiffen it and resist the tendency to assume a cylindrical form. The stay-bolts should be passed directly through the inside sheet without thread. The bolts should have spacing-thimbles between roof and crown sheet, so that they can be drawn securely and solidly against the head under crown-sheet, and against the thimble. In this form we receive the full benefit of the direct stays between the two parallel sheets of crown and roof sheet. The parallel sheets should be sloped the same, say three inches in twelve feet. By this method of construction, in case one of the crown-bolts breaking, the danger would be discovered at once by leakage in the firebox, and before enough of them had become broken to render it dangerous. With the present general form of construction of Belpaire boilers, no one knows when a crown-bolt breaks until others surrounding it give way and let the sheet bulge. This is the case in both the radial stayed boiler and the Belpaire. Most assuredly no one will advocate the desirability of the thread through crown-sheet, except to save the cost of the thimbles. Perhaps it would be well to screw through roof sheet, so that if bolt breaks there should be no danger of steam enough escaping through the top to injure any one, as might possibly be the case if the bolt passed directly through both sheets. This danger, however, would be almost nil, inasmuch as the thimble would protect the hole from any great escape of steam, while it would not protect the lower end enough so but that it would indicate by leakage that the bolt was broken.

## How to Counterbalance a Driver.

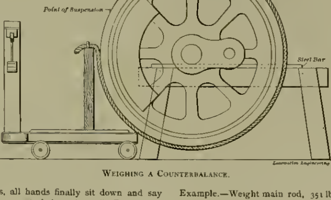
When a bad-riding engine has had her valves altered a few times, her spring rigging overhauled, and a few other well-known home remedies applied without results, all hands finally sit down and say "Her counterbalance is out." That is usually the end of effort to make her a good-riding engine.

"It must be in her counterbalance," seems to relieve the minds of many foremen and shift the responsibility off their shoulders.

The rules for determining the proper amount of counterbalance weight needed in a locomotive driving-wheel are very misty and discouraging to look at, so that most mechanics let them alone.

Down on the South Carolina road they had an old 14x24 engine that gave all the boys the horrors, she rode so badly. Superintendent of Machinery Roberts took her in and removed 80 pounds of counterweight from her main wheels and 56 pounds from her back wheels, and then she rode splendidly, and the boys bragged on her.

The plan employed by Mr. Roberts is used on several roads and is simple, quick, and requires no special apparatus.



WEIGHING A COUNTERBALANCE.

He lets the journals of the pair of wheels rest on steel bars on horses leveled up carefully, the wheels being free to turn. Passing a rope partly around the wheel, as shown, it is fastened to the tire at a point nearly at right angles to the crank-pin, bringing it around under the wheel and up to a post set on the platform of an ordinary pair of scales. The pin on one side is exactly plumb with the center of axle, this brings the pin on the side to be weighed on one side of the axle and the counterbalance on the other side; the weight, of course, tends to go to the bottom and shows the extent of this tendency on the scale. The rule followed is here given.

For Main Wheels.—Take one-third the weight of crosshead, piston and front end of main rod, add weight of back end main rod and front end of side rod; multiply this by half the stroke, and divide this by the distance from center of axle to point of suspension. (If tires are on, the point of suspension will be the outside of tire.)

For Back Wheels.—The same as main wheels, but leave off weight of back end of main rod.

Note.—Pin on opposite wheel from one being weighed must be exactly plumb. Trestles must be exactly level both ways.

Example.—Weight main rod, 351 lbs.
" side " 291 "
" piston and crosshead, 324 "
996 "

$996 \div 3 = 332 \times 12 = 3864 \div 30''$ radius of wheel = 129 pounds—129 pounds being the proper weight for counterbalance.

## A Quarry Railroad.

The annexed illustration shows the quarrying of huge granite blocks as performed on the Barre Railroad in Vermont, which is a peculiar road. General Superintendent Stanyan writes:

The road was chartered in 1888 and work commenced immediately from Barre to the granite quarries, and at the present time has twenty miles of track, including switch-backs, with one and a half miles of track additional now graded to East Barre. The road is standard gauge, is thoroughly ballasted and laid with 60-lb. steel rails and safety switches, tamarack and hemlock ties, laid 20-inch centers and Servis tie-plates. All water-ways and under-passes are of solid granite masonry. Maximum grade, 264 feet per mile, with switch-backs 300 feet grade. Curves, 10 to 20 degrees. Highest elevation above Barre reached is 1,020 feet in distance of four miles. The road runs directly under the derricks of thirty quarries. The same derricks used in lifting the granite from its natural bed place it on the cars, thereby saving transfers or rehandling.

SIXTY-FOOT GRANITE SHAFT ON TWO CARS.

The rolling stock is all new and built especially for this company. Platform cars 20 and 28 feet long, 50,000 lbs. capacity, with double hand-brakes and Westinghouse air.

Three locomotives, built by the Baldwin Locomotive Works 1889-90. Saddle tanks. Soft coal burners. One 37-ton, four drivers, one lead and one trail truck. One 48-ton, six drivers, with one trail truck only. One 50-ton, six drivers, no trucks, built as follows: Cylinders, 16x24 in., steel firebox, 60x34 in.; straight boiler, 48 in. diameter; 140 2-in. flues, diameter of drivers, 46 in.; wheel base, 10 ft., total length, 37 ft. Supplied with two No. 6 Sellers improved injectors, Detroit sight-feed lubricator, United States metallic packing, pistons and valve stems, Richardson balance valves. Capacity of tank, 1,000 gallons; capacity of coal bunker, 2,000 lbs. Weight on drivers (total weight), 100,000 lbs. Westinghouse quick-action air and Le Chatilier water-brakes. Ross-Mehan shoes. This engine will draw ten empty cars up our 264-foot grade at a speed of six miles an hour.

One thousand tons of granite have been drawn from the quarries in a day. The road also does quite an excursion business during the summer, as extended views of the surrounding country are had for miles in all directions, aside from the interesting and instructive knowledge gained of the methods of quarrying and handling the huge blocks of granite. Several millions of paving-blocks are shipped each season in addition to the regular monumental granite shipments.

---

Hammering an air-pump on its head with a monkey-wrench, and pounding a check-valve case with a coal pick, are both evidence that the engineer ought to be working in a stone quarry.

---

The Long Island road lost another locomotive in April through a boiler explosion. The fireman and brakeman were killed and several others badly hurt. The "48" was, it is said, one of the oldest on the road, and had been reduced to the rank of switching. When will it become the practice to throw away old boilers?

---

During a recent visit to St. John, N. B., we examined a train of cars and a locomotive pulling it which were all built under the supervision of Mr. George A. Haggerty, master mechanic at McAdam Junction. The work on both locomotive and cars was all first-class. The cars were, to a great extent, built of the wood of the district, and they were finished inside in the native birch, which makes a unique and striking style of car decoration.

---

Professor Goss, who has charge of the mechanical engineering laboratory of the Perdue University at Lafayette, Ind., has consented to permit the committee ("Exhaust pipes, etc.,") of the Railway Master Mechanics' Association to make experiments with the locomotive that belongs to the University. The intention is to make experiments with different forms of exhaust pipes and nozzles and note the results. As the engine is jacked up and can be worked in any way that the investigators think desirable, it is likely that much more reliable results can be obtained than are possible with locomotives working under the varying conditions of ordinary service. It is understood that Mr. Robert Quayle will conduct some of the experiments. He has devoted a great deal of attention to the subject of exhaust nozzles and steam passages, which will be of great service in the experiments to be undertaken.

---

An engineer of the C., H. & D. writes us about the item of big mileage, and says that they have the engines that double 131 miles every day in the year, this is 7,860 miles for month of thirty days, and is big mileage, but not extra large for passenger service. Six thousand miles on freight per month is heavy work.

Pedrick & Ayer's New Railroad Tool Factory.

## A Model Manufactory.

There are very few railroad men in the mechanical department who do not know the special machines and tools for repair work made by the firm of Pedrick & Ayer, Philadelphia, Pa.

In 1870 an old locomotive engineer by the name of L. B. Flanders started a little shop in Philadelphia and commenced to bore out steam engine cylinders "in position" by the use of a boring bar of his own invention. Mr. Flanders was a genial, whole-souled man and made many friends. He invented, besides the cylinder boring bar, a radius link planer attachment, portable railroad frogs, a spring piston packing and the crank-pin turning machine.

The portable boring bar, now so common, was developed here and put upon the market, yet a large part of the work was in boring out cylinders of all kinds and sizes with these special tools instead of in selling the tool.

Mr. Flanders died in 1877, and the business was conducted by H. C. Ayer, acting as attorney for the estate, with D. W. Pedrick in charge of the shop.

In a short time the title of the concern was changed to L. B. Flanders Machine Works and D. W. Pedrick acquired a small interest.

In 1881 Mr. Pedrick and Mr. Ayer purchased the business.

These two men made up the firm of Pedrick & Ayer and found themselves with two special tools to build, the portable boring bar and the valve-seat planer—both illustrated herewith.

These tools were advertised so thoroughly and so persistently, guaranteed so well and were so much of a saving that they at once met a fair sale; once tried on a road, more were ordered for other shops, and to-day there are more than a thousand of each in use, and boring bars are made with a shaft 10½ inches in diameter and 20 feet long, capable of boring out a cylinder 110 inches in diameter.

New tools were added to the shop and new work secured to build, and it soon became known that the firm could introduce and push new tools for repair work better than anybody else, and they soon had the refusal of new devices.

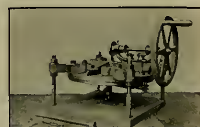
They commenced to build heavier machines, notably milling machines, and more recently the Richards planer which bids fair to overrun the shops or call for a special plant of its own.

Two years ago the old shop on Hamilton street was given over exclusively to the local repair department and the concern moved into their new shop at 1001 Hamilton, running clear through to Buttonwood street.

This shop is shown in our large illustration, and a view given of each of the floors, that describe them far better than can be done by words.

The office of this shop is fitted up like the library of some gentleman of leisure, while the shop is considered by all who see it as a model one for a small factory.

Every convenience is furnished the men; splendid light day and night; steam heat



Cylinder Boring Bar and Valve-Seat Planer—the Start.

in winter and cooling fans in summer; the best of tools and appliances.

In the busiest time they work about 116 men, and from that down to 70, depending on the volume of business.

All the tools are served by cranes, and power sliding devices are used to move heavy parts, being fitted by scraping.

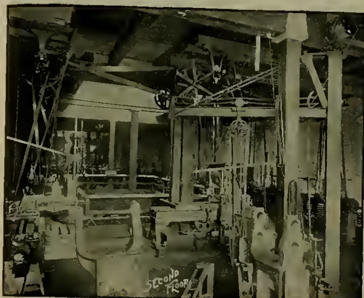
Mr. Ayer is the business man, attends to all the business affairs and oversees all office work, while Mr. Pedrick is at the head of the mechanical department; he came through the shop himself, can do any job done in the works and knows when a man does it well.

The success of this concern shows well what can be done by pushing, energetic work in one line. They made their name and goods known by the use of ink, and they made the reputation their product enjoys by doing honest work

## A Florida Railroad.

The Jacksonville, Tampa & Key West road, in Florida, is the best one on that great coral peninsula. Its roadbed is like the others, sand and swamp, but it is laid with 55-pound steel rail, and operates the best looking and most modern power and rolling stock.

There are some 200 miles of standard-gauge road, and the Florida Southern, under the same management, is narrow gauge, and strings out 307 miles.



The shops of both narrow and standard-gauge roads are at Palatka, Mr. Wm. Rutherford being master mechanic of both.

The shops are of wood, but are covered with corrugated iron and neatly painted. Florida shops, as a rule, are composed of a roof and a few posts. The narrow-gauge shops are separate from those of the standard and some distance away from them.

All the tools in the shops are painted blue and kept scrupulously clean, as are the yards around them.

The narrow-gauge engines have a great deal of brass, but the firemen keep them

looking like jewelry. White firemen are employed.

The most noticeable thing about the standard engines is the extension front and straight stack on wood burners.

This plan is being tried on several roads in the South, but is a success, so far as we could see, only on this road.

The fuel is pitch pine, and the smoke from it is as black and dense as that from soft coal, the pitch makes it very difficult to use any netting of small mesh, as it stops up with a tar-like substance. Mr. Rutherford uses perforated plate with openings ½ x 1 inch.

The writer rode on one of these engines on a six-car passenger train, behind time, and a better steamer, doing heavy work, would be hard to find. Of smoke there was plenty, but there were no sparks or cinders thrown out.

The truly remarkable thing about the use of wood this way is that a cord of it goes further than a ton of coal, a cord being about equal to a ton and a quarter of soft coal. The reverse of this is generally true where wood and coal are burned on the same road.

Many of the engines here had a high exhaust stand without a partition, and a change in pattern helped the steaming very perceptibly.

Florida has drawn the color line in passenger cars, and most of them have a partition through them, and a person "off color" is not allowed to ride in the special partition reserved for the other race; it is said that the colored folks are very particular to kick against the intrusion of the whites.

The principal freight business of the road is phosphates and oranges, and they had handled nearly two million boxes of oranges up to the middle of March.

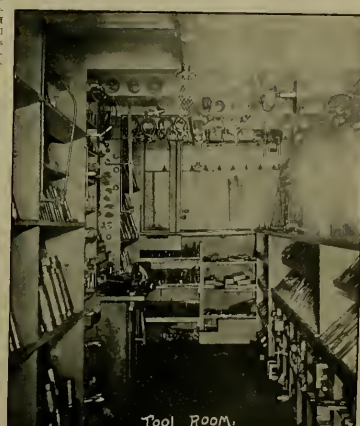
## Effects of Water Purifier.

We have received from Mr. C. F. Lape Master Mechanic of the Wabash Railway, a report of the performance of engine 69, which was equipped with the Barnes water purifier on February 18, 1890, and ran till March 31, 1892, without the boiler having any of the flues removed for cleaning. During 1890, the engine ran 35,912 miles and was washed out eleven times; in 1891, she ran 43,834 miles and was washed out thirteen times; while during the three months of this year she ran 12,270 miles and was washed out twice. The total mileage made was 92,066 or about 3,500 a month, which is good steady work for an engine. She was washed out once for every 3,500 miles run, which is remarkable for an engine using Illinois water.

In commenting on the performance of the engine Mr. Lape says: "Engine 69 was taken into shop on account of bad tires. Condition of boiler and flues would warrant six or seven months additional service, but, owing to the fact that engine was in shop for repairs, we took out her flues. The crown-sheet and crown-bars are apparently as clean now as when engine first came out of shop. The boiler had about three bushels of fine scale such as is usual in boilers without purifier, that have had five or six months' service. When the water is let out of engines to do necessary work on boiler or firebox, we wash engine out at that time to save holding engine in at some future time for washing out. This explains why this engine was washed out at shorter intervals than at other times."

Mr. Lape justly attributes a considerable share of the success of the purifier to the care bestowed upon it by the engineer, Mr. Leroy Killmer. This is an equation that cannot well be left out on any improvement that is applied to a locomotive.

Master Mechanic Briggs, of the K. C. M. & B. road, speaks very highly of the Luttgen's stack damper, and says that by its use in passing cotton platforms and other places where fire is liable to be set no danger is run, it prevents tearing fire when starting and opening the door to cool the engine down.



The Morris Box Lid Co., Pittsburgh, are manufacturing the Roberts dummy air-brake coupling illustrated in a recent number of LOCOMOTIVE ENGINEERING.

LOCOMOTIVE ENGINEERING.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } Editors and Props.
JOHN A. HILL, }

J. W. CURRAN, Manager Advertising Department.

Subscription Price.

$2.00, postage paid to any part of the world. Single Copies, 20 cents.

## Special Notices.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary—always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as Second-class mail matter.

## Special Notice.

Some over-zealous members of one of the Brotherhoods have recently made an attack on the character and reputation of one of the editors of this paper.

Many of our friends have expected us to take the matter up, and offered ammunition. LOCOMOTIVE ENGINEERING is a mechanical paper solely, and can not and will not descend to the level of vile, personal journalism. Our readers expect mechanics, and will get it.

The charges as made are false and malicious; that's all.

In a recent interview, Mr. P. M. Arthur, Grand Chief of the B. of L. E., exonerated the accused of all blame in the premises, and, further, asked us to refer those who would not be otherwise satisfied, to him. This we gladly do. The truth hurts no honest man.

## Triple-Expansion Locomotives.

As soon as the compound locomotive was an admitted success, it was inevitable that a triple-expansion form should next be tried. We have been watching for this kind of a locomotive to be offered to railroads by some of the American inventors who are going around with drawings of ridiculously designed compound locomotives in their pockets; but a man in Beloochistan has got his work in ahead. Beloochistan is not a town in Indiana, as one of our visitors with compound locomotive on the brain thought it was; it is a country in Asia, lying between the Persian Gulf and Afghanistan. Coal is said to be very dear there, and Mr. John Hickey, the locomotive superintendent of the Northwestern Railway, who is a Scotch marine engineer, has designed a triple-expansion locomotive with cylinders 14½, 20½ and 28 inches diameter and 26 inches stroke. The cylinders are set like those of the Webb locomotive, the largest one being in the middle.

The engineering details of the locomotive appear to be very well worked out, but we believe that the steam has to pass through too many cylinders before it reaches the atmosphere for an engine to work successfully that is dependent upon the exhaust steam to create draft. It is well-known that the ordinary compound locomotive uses more steam than a simple engine when running light. This prevents the compound from being such a good all-round locomotive as a simple single-expansion engine. The causes that operate to make a compound locomotive wasteful of steam when working light, would have increased force with a triple-expansion engine, and it would be likely to prove a most expensive motor unless worked under exceptional circumstances.

It would be difficult to imagine a form of mechanical god strange enough to prevent its having worshippers in this country, and we shall be greatly mistaken if many months pass before we hear that some railroad in America is going to try a triple-expansion locomotive. A great many men think in mechanical matters, as a New Jersey citizen of our acquaintance reasoned about medicine. His daughter had been taking a medicine in which there was ipecacuanha, a drug that is a strong emetic when taken in large doses. The father was suffering from gripes one day, and he reasoned that when small doses of the medicine helped his daughter's asthma, a large dose must settle his perturbed inwards. A big dose was taken, and the results were far from satisfactory. It will no doubt take equally drastic experience to convince some of our people that locomotives which effect saving by having the steam passed through two cylinders will not be improved by having still another cylinder added.

The exposed condition of locomotive cylinders will always be an obstacle to the successful use of triple-expansion; but the high boiler pressure that may be carried will tempt some engineers to see a medium of saving in the possible protracted expansion. There are certain duties that locomotives have to perform where the use of triple-expansion might be practical. In some places locomotives are employed constantly on heavy mountain service, and it is common for the simple engine to work with the steam following close to full stroke nearly all the time. This is service well fitted for compounds and triple-expansion might be used to advantage. But two or three departures from ordinary practice would be necessary to promote the success of triple-expansion locomotives. In the first place, the exhaust steam would have to be abandoned as a means of creating draft, and a direct method of forcing the fire resorted to. Were this done, a large exhaust opening could be used that would permit the steam to escape quickly at pressure little higher than the atmosphere. In the next place, it would be desirable to build the engine so that it would be possible to throw one or two of the cranks or crossheads out of gear when the engine was working light. This would be a rather difficult mechanical problem to solve, but it is quite within the possibilities of invention. The same arrangement might be applied with advantage to compound locomotives.

These are to some extent idle speculations, but we feel certain that American railroad men will soon begin to receive visits from the inventor, who is prepared to save the greater part of the fuel by means of a triple-expansion locomotive. Our remarks may offer suggestions for conditions to be imposed.

## Responsibility for Fires from Sparks.

A decision recently rendered by the Court of Session in Scotland on the liability of railroad companies for fires caused by sparks from locomotives has excited universal attention, because the highest court in Scotland affirms that a railroad company is not responsible for damage caused by sparks where ordinary precautions are taken to prevent spark-throwing. The parties who were plaintiffs, or pursuers, as Scottish law terms it, in the suit attempted to show that spark-arresting appliances had been employed on early locomotives which were not in use on the engine that caused the fire, and that consequently the railway company had not exercised proper care. In reply to this, evidence was given that special spark-arresting appliances interfered with the draft so much that they could not be used successfully on fast running locomotives, and the court held that this was a good reason why the spark-arrester should not be employed.

Decisions of a similar character to this one have been repeatedly rendered in American courts of late, with the difference that they require the locomotive to be equipped with the best-known appliances for preventing spark-throwing. It has been customary for American locomotives to be choked down with spark-arresting appliances, and the making of steam freely is a secondary consideration. The spark-arresters in use defeat the purpose of their introduction to a great extent, for the blast has to be made so sharp to overcome the obstruction that as many sparks are thrown out as would be thrown were a free passage left to the atmosphere and the nozzles enlarged to suit. It would be a great boon to railroad companies if American courts would decide that railroad companies were not compelled to decrease the efficiency of their locomotives to prevent spark-throwing.

Most railroad companies, however, are disposed to be satisfied with the decision that they are not liable for fires raised by sparks when they have in use the best-known appliances for preventing fire throwing. When this is generally understood to be the law, there will be more care exerted by those having property close to the right-of-way of railroads to prevent its taking fire. This will be a highly desirable change, for in the past it often looked as if fire raising was aided rather than obstructed by some owners of property. There have been numerous cases where people were able, by fires, to dispose of property to the generous buyers railroad companies are known to be under the threat of an Alliance jury.

## An Exhaust Injector.

One of the most alluring fields of improvement that ever inveigled inventors to disappointment and ruin is the perfecting means for saving fuel by using the exhaust steam from locomotive to heat the feed water. No engineer of experience and fairness will venture to deny that feed water heaters for stationary engine boilers are a success. Then why should the same principle not apply to locomotives? The difficulty of answering this question satisfactorily is at the root of the many efforts to do for locomotives what has been accomplished in stationary engine practice. The story from John Alexander in a recent issue of LOCOMOTIVE ENGINEERING explains in humorous fashion the real difficulty, yet few inventors can be convinced that the exhaust steam is all required for the generation of draft. If any part of it is taken away to heat feed water, smaller exhaust nozzles must be resorted to as a means of making the reduced volume of exhaust steam equal to the work required. Methods of taking heat from the smokebox meet with similar objections, the loss must be compensated for in some way that takes away all the profit.

Our attention has been directed to this old subject through an account that appeared in a British engineering paper, of the success achieved by the use of an exhaust injector for locomotives. Using a portion of the exhaust steam to operate an injector is merely an ingenious form of feed-water heater. It has been tried repeatedly and we are under the impression that patents of an English exhaust injector are controlled by a firm of injector makers in this country, but there are numerous serious objections to the device. In the first place, the saving promised or predicted is never forthcoming, and exhaust steam varies too much in pressure to be used successfully for operating a boiler-feeder. Calculations have been made that an exhaust injector saves about ten or fifteen per cent. of fuel on account of the heat put into the feed-water, but we have seen no figures to indicate the loss due through the exhaust being robbed of its energy.

## Going Back to Iron Fireboxes.

We have the authority of the *Railway Age* for the report that a prominent road in Chicago has specified Low Moor iron for fireboxes in a number of locomotives recently ordered from an Eastern builder. The superintendent of motive power believes he will have less trouble with Low Moor sheets giving out where impure water is used than with steel which is liable to pit and crack under such circumstances.

We will venture to express the opinion that the superintendent of motive power referred to is not well-posted concerning the literature of his business, and consequently he is ignorant of facts which he ought to know. To go from steel to Low Moor iron for firebox sheets is stepping backward twenty years. There has been nothing settled more definitely in the world of engineering than the fact that the best quality or iron ever produced is unreliable as compared with good steel for firebox sheets. Low Moor iron is superior to any other metal for many engineering purposes, but in firebox sheets it is out of place.

In our last issue we showed etchings of iron and steel axles where it could be plainly seen that the iron was a mass of fragments stuck more or less securely together, while the steel was homogeneous, or a single mass. Good Low Moor iron might appear more homogeneous than the specimen which we illustrated, but it would at best show different pieces welded together, with more or less foreign matter mixed in the welds. When a mass of this kind is rolled in a sheet, the welds become points of deficient adhesion. The sheet will stand physical tests satisfactorily, but when it goes into service the steady expanding and contracting caused by the extremes of temperature a firebox has to endure, work the sheet apart, and it fails from blistering or laminating.

It would just be as sensible for the chief engineer of the road that has gone back to the use of Low Moor iron for fireboxes to recommend his management to abandon Bessemer steel rails and adopt iron on the plea that it is less liable to crack. Iron fireboxes and iron rails fail in the same way; wear loosens the welds and the material comes apart.

## Inferior Steel.

Several cases have been reported lately of failures of steel firebox sheets from lamination and blistering, and there has been considerable discussion on the subject. We do not consider that there is any mystery about the causes of such failures. Steel has been used long enough for fireboxes to demonstrate beyond peradventure that good homogeneous metal, when rolled into sheets, gives no trouble from lamination or blistering. Trouble of that kind is absolutely unknown with proper steel. All the steel offered for firebox sheets is not however of first-class quality, and it is the inferior steel that laminates.

That failures of this character are becoming common enough to attract attention, is merely a sign that it is time the purchasers of steel were using vigilance in the inspection of the material received. There was a movement in the line of false economy by certain railroad companies a year or two ago to dispense with the laboratories, which were becoming a feature of all well-managed railroads. This helped to break down the pressure that was put upon manufacturers to produce goods of a high character, and we suspect that other material besides firebox steel has deteriorated in consequence. Railroad companies have this matter of inferior steel and inferior goods generally in their own hands, and they are to blame if material unfit for use is supplied. The steel sheets which laminate may not really be dangerous but they are made of material that will not be durable, and on that account sheets of that inferior quality ought to be rejected.

There is a committee of the Master Mechanics' Association investigating the subject of iron and steel and they are reported as doing valuable experimental work. We understand that the plan followed is to request manufacturers to supply specimens of the material to be tested. We should like to see that committee take specimens of the steel from the different makers as it has been sent out without selection and subject it to searching physical and chemical tests. The likelihood is that they would find the specimens to give different results from those specially selected or prepared for the use of the committee.

## Water Purifiers.

On another page of this paper will be found a statement of the performance of a locomotive on the Wabash Railway equipped with a Barnes water purifier. One cannot read the statement without being convinced that the purifier worked wonderfully well in eliminating from the feed-water the lime, salts and other impurities that so quickly fill up the locomotive boilers running in the calcareous regions of Illinois and other Western States. The engine ran with less than half the washings out of the boiler that would have been necessary had no purifier been in use. This in itself is no small matter on roads where engines have to be run night and day during the busy season. The cooling down of a boiler for washing out is an objectionable practice which is frequently followed because there is no time to permit natural cooling. Any device which obviates the necessity for doing this is certain to prolong the life of the firebox, besides preventing the leaving on the sheets of scale that takes place every time that a boiler is cooled down rapidly or is washed out without thorough cooling.

We did not receive a comparison to show how long a locomotive boiler that has no purifier would run without washing out, but we feel safe in saying that the tubes would have to be removed by the time the engine made 30,000 miles, or one-third of the mileage made with the engine having the Barnes purifier. If this does not prove the purifier to be a success, we would like to know what will.

In his letter accompanying the statement Mr. Lape gives full credit to the engineer for the care and attention he gave to the purifier, and attributes a share of the success to this care. This suggests the question, Why have so many water purifiers done well on railroads for a few months and then failed? The reason is that they acted satisfactorily while they were operated properly, and they failed when the necessary attention was withdrawn from them.

Bad water is one of the evils that will always be present with many of the railroads on the American continent. Any apparatus, compound or process that will rob the feed-water of its qualities that prove so destructive to boilers, and cause so much waste of fuel, will be worth attention and careful operation. The waste of money due to foul boilers is so great that the means of preventing the waste ought to receive the greatest attention from all concerned in the economical operation of railroads. There is too great a tendency to regard the putting on of a water purifier as the ending of the business. It is left to take care of itself, the same as a new form of safety-valve or a new stack. The same thing may be said of all the chemicals that have been tried to separate lime and magnesia from the feed-water. The compound would be supplied for a time, and no care taken to blow the sediment out of the boiler. Then it would be declared a failure, and, perhaps, a good thing condemned because it had not been treated properly. Our railroad history has repeated itself in this way very often.

In another part of this paper there is an interesting and valuable paper written by Mr. Eugene Chamberlin, master car builder of the New York Central, on "Car Repairs." This article comes with peculiarly good grace from Mr. Chamberlin, for he is in charge of yards and shops where an immense amount of repair work has to be done with expedition, and the plan he preaches is the plan he practices. There is no line of railroad work where a good system is likely to be productive of more profitable results than in car repairs, yet there is no line where good methods are more frequently neglected.

The railroad companies in this country that are illiberal in giving transportation to employés (and they are numerous) and their families, might with propriety take an example from the action lately of the directors of the Midland Railway of England. In the future tickets are to be issued without limit to the employés and their wives, allowing them to travel over the system at a quarter fare for the double journey. This is in addition to the free passes which they have previously enjoyed. These are to be continued without any alteration.

Southern papers are enthusiastic over a train of cars just built at Montgomery, Ala., for the Atlanta & West Point, and intended to be run on the Washington & Southwestern vestibuled express. The train consists of first class, second class, mail, baggage and combination cars. The cars are built of native woods, and are constructed and finished as well as any cars built in the best shops. Captain Tyler, the general manager of the road, decided to have the work done in his own shops to encourage local industries.

At the request of the World's Fair Department of Transportation Exhibits, George De Haven, General Western Agent of the Chicago and West Michigan and the Detroit and Lansing Railroads, has consented to undertake the work of making an historical collection of railroad tickets. To this end Mr. De Haven solicits the aid of general passenger and ticket agents of railway and steamship lines throughout the world, and of manufacturers of all kinds of transportation tickets.

The Baldwin Locomotive Works intend running a novel train from Philadelphia to Chicago this month. They are building twenty compound locomotives for the Chicago Elevated Railroad, and several large ones for the Chicago, Rock Island & Pacific. They intend making up a train of the twenty elevated engines and hauling it to Chicago with the Rock Island engine. It will be a very striking train and an exceedingly heavy load for one locomotive.

A present of 1,000 volumes of books on railroad subjects has been given to the Stamford University of California by Mr. Timothy Hopkins, lately Treasurer of the Southern Pacific. Mr. Hopkins has further agreed to pay for the purchase of copies of all books on railroad subjects in all languages, and a separate railroad library will be formed when the collection is complete. It promises to be the best collection of railroad books in the world.

Street car accidents are reported to be dreadfully common in the streets of Boston, where the electric cars are run. One day when the writer was in Boston an electric car ran over a boy, and it took half an hour to get the mangled remains out of the machinery. Next day the company supplied all their cars with Norton lifting-jacks.

John Russell Young, the widely-known newspaper man, has been elected fourth vice-president of the Philadelphia & Reading.

## PERSONAL.

We have learned with deep sorrow that our occasional correspondent, Mr. Walter F. Dixon, chief draughtsman of the Rogers Locomotive Works, lost his wife last month.

The many friends of Mr. A. J. Pitkin, superintendent of the Schenectady Locomotive Works, will hear with sorrow that he lost his wife last month. She died of typhoid fever after a short illness.

It is reported that Mr. E. E. Davis, master mechanic of the Boston & Maine, at Boston, has been offered the position of superintendent of the Portland Locomotive Works. Mr. Davis is undoubtedly the best shop manager in New England, so far as railroads are concerned.

Captain R. S. Hayes, President of the St. Paul & Duluth, is spoken of as President of the Union Pacific, to succeed Mr. Clark, who has decided to retire. Captain Hayes is known principally on account of his financial connections. He is said to be favored by both the foreign and the Gould interests in the Union Pacific.

Mr. Harry P. Robinson, editor of the *Railway Age*, has gone to Europe, accompanied by his wife. Mr. Robinson was anxious to take his wife on a visit to his fatherland, and his intention is to return home in time for the conventions in June, where the editing of the daily reports has become a recognized duty.

Mr. James E. Sague, who has been for some years mechanical superintendent of the Jamaica railways, has accepted the position of assistant superintendent of the Schenectady Locomotive Works. Mr. Sague has had considerable railway experience in this country, and his numerous friends are pleased to see him working under the Stars and Stripes again.

Mr. Charles S. Mellen has resigned as general traffic manager of the Union Pacific to become general manager of the New York & New England, succeeding Mr. Charles Howard, resigned. Before going to the Union Pacific, Mr. Mellen was general superintendent of the Boston & Lowell, at Boston. Mr. Mellen will have the sympathy of his many friends owing to the death of his wife, which occurred at St. Paul, Minn., March 28th.

We had a pleasant call during the month from Mr. Walsh, of the Falls Hollow Stay Bolt Company, who informs us that there is a very active demand among railroad companies for the hollow stay bolt iron made by his company. Among the companies that have recently sent in orders are: The Philadelphia & Reading, Atlantic & Pacific, Chicago & Alton, Illinois Central, Vandalia Line and the Toledo, St. Louis & Kansas City.

President Calvin Goddard, of the Chicago & South Side Rapid Transit Company, died on the 4th ultimo at San Francisco, Cal. Mr. Goddard was born at Norwich, Conn., and was about fifty-five years of age at the time of his death. He served throughout the Civil War and was a valuable aid upon the staff of General Rosecrans. He had been financially associated with several railroad companies before becoming president of the Chicago road.

Mr. J. J. Henry has resigned the position of general manager of the Universal Brake Beam Company, and is succeeded by Mr. L. G. Cannon. Mr. Henry came to this position from the Wabash Railway, where he was secretary to General Manager Hays. No one has gone into the railroad supply business who has made more friends in a short time than Mr. Henry. He achieved much success with the brake-beam, having placed it on upward of thirty railroads within a year.

Mr. David Preston, mechanical superintendent of the Canadian Pacific Railway, began railroad life on the first railway opened in Scotland. He was an engineer there for some years and about 1856, when there was a movement among Scotch railway men to come to the Grand Trunk he joined the exodus. He rose on the Grand Trunk to be assistant mechanical superintendent and from there went to his present position. We are sorry to say that he is mourning the loss of his wife who died a month ago.

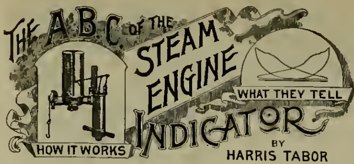
Mr. S. Higgins, who has been master mechanic of the Erie at Meadville for several years, has been promoted to the position of assistant superintendent of motive power of the same road in charge of the lines west of Salamanca and with office at Cleveland. Mr. Higgins had the reputation of knowing more about the engines under his charge than any master mechanic on the system, and for that reason he was selected for promotion. We heard a remark to that effect made in the Erie offices in this city months ago.

We find that Mr. P. H. Patriarch is associate editor of *Sparks from the Crescent Anvil*, a publication issued by the Crescent Steel Co., of Chicago. Mr. Patriarch is well known to a large circle of railroad friends, and many of them will remember that writing "sparks" is not his first effort in trade journalism. Mr. Patriarch was with the National Spring Co. when that firm started the *National Car Builder*, and he did a great deal of the work that first commended that paper to the favor of railroad men. We have no doubt that his *Sparks* will attract equal attention.

General satisfaction is expressed with the circulars issued by President King, of the Erie, and by Vice-President Thomas, of the Chicago & Erie, appointing Mr. A. E. Mitchell superintendent of motive power, *vice* Mr. Ross Kells deceased. Mr. Mitchell has been performing the duties of the position ever since Mr. Turreff died, and the work was done satisfactorily enough to prove that he was the right man for the office. He has been mechanical engineer of the road for several years, and came there with an unusually varied and valuable experience. Mr. Mitchell has experience as machinist, locomotive engineer, draughtsman and master mechanic. Few men go to the top better equipped with the varied stock of knowledge required.

Mr. A. Mitchell has been appointed superintendent of motive power and rolling equipment for the eastern and northern divisions of the Philadelphia & Reading, with office at Wilkesbarre, Pa. Mr. Mitchell is well worthy of advancement to the mechanical department of the road which he has worked for so ably these many years. He has been with the Lehigh Valley, as master mechanic, since 1864, and previous to that was in the best works in the country for acquiring a knowledge of locomotive engineering. No man of this generation has done more than Mr. Mitchell to improve the American locomotive. The first consolidation locomotive was designed by him, and numerous other minor improvements originated in his fertile brain.

At the April meeting of the American Railway Association the following officers and members of committees were elected: President, H. S. Haines, Vice-President of the Plant System; First Vice-President, Lucius Tuttle, Vice-President and General Manager New York, New Haven & Hartford, Second Vice-President, E. B. Thomas, First Vice-President New York, Lake Erie & Western Railway. The Executive Committee elected consisted of H. F. Royce, General Superintendent Chicago, Rock Island & Pacific, and Joseph Ramsey, Jr., General Manager Cleveland, Cincinnati, Chicago & St. Louis. The Committee on Train Rules consists of the New York, Lake Erie & Western, the Minneapolis & St. Louis, and the West Shore Railways.



The superintendent of a road said to the writer, a few years ago, that if it were possible to shoot passengers from New York to Chicago in two hours, with a certainty that only two in ten would arrive safely at destination, he believed the average American traveler would prefer that system. There is a fascination in passing mile-posts at intervals of sixty seconds or less for nearly all men who are not interested in keeping up rolling stock and roadbeds. This inclination cannot be said to come from a desire to save time. A reduction of two or three hours in time between New

York and Chicago would not affect the business interest of one man in one hundred, yet all who travel between these points insist upon the fastest trains. There seems to be an inborn love for fast riding that characterizes this country more than any other —a sort of Chicogoism which is becoming a national trait. This tendency on the part of the traveling public has been an important factor in railway management—in fact, it has compelled all roads to shorten schedules, and often against better judgment. Even that great system which bade the "public be damned" is now running the fastest train in the world. In reply to the question: "Who insists upon these fast trains?" a well-known superintendent of motive power said, "The Public."

Increase in speed has called for radical changes in the construction of locomotives. None but the designer can know how difficult many of these changes are. Passenger locomotives have always been run well-up to their limit. An increase in mileage of 25 per cent. in the same running time means larger drivers, larger cylinders, and more important still, larger ports. The increased horse-power calls for larger boiler. If the designer had plenty of room his task would be comparatively easy. But his road-gauge has not been broadened, and his bridges present the same narrow limits, which makes his task most difficult. At the risk of boring the reader, a comparison with stationary practice will again be made.

When it was announced that the great "Corliss engines" which furnished the motive power for the Centennial Exhibition of 1876, would have a piston speed of 720 feet per minute with a rotative speed of only 36 revolutions, the engineering world opened its eyes in amazement. At that time passenger locomotives were making regular runs with a greater piston speed. In that year the Buckeye Engine Co., of Salem, O., exhibited one of their earliest celebrated high-speed engines, with a piston speed of 500 feet, and a rotative speed of 125 revolutions, and lovers of good qualities in steam engines studied it with admiration. Since then the Buckeye people have increased their piston and rotative speeds, and other makers of high-speed engines have kept pace, until now, engines of the quick-running stationary type have a piston speed varying from 500 to 700 feet, with a rotative speed of 125 to 300 revolutions. Few builders of these engines care to go beyond these speeds. The modern passenger locomotive often has an average piston travel of 1,000 feet per minute, with a rotative speed of 250 revolutions. The piston speed in locomotives is often increased to 1,200 and 1,400 feet, with a corresponding increase in revolutions. In one case, a "Vauclain" freight compound made the remarkable piston speed of over 1,700 feet for a short run. If we consider that the stationary engine has all the natural advantages that go to make high speed possible, we may get an idea of the difficulties in the way of locomotive design, when speeds of from sixty to seventy miles per hour are contemplated.

The indicator illustrates, probably better than any other way, one of the serious difficulties in modern speeds, viz., steam distribution. It is a problem to supply a cylinder with steam when its piston is moving 1,000 feet per minute. An ordinary port counts for nothing in the case of admission and exhaust. Such speed calls for enormous openings, and these openings must be quickly opened and closed. Small ports and pipes would mean an amount of wire-drawing and back-pressure that would make high piston speed impossible, unless the engine were simply running itself. The greater part of the energy in the steam would be spent in overcoming its friction on the pipe and ports. Locomotive men understand this difficulty, hence we see larger driving-wheels and larger cylinders on modern engines designed for unusual speed. This increase in size would be carried still further if the limitations would permit.

The cards illustrated herewith show plainly the effect of piston speed on the steam line. They were selected on account of slow speed in miles per hour. If the steam lines in No. 1 are carefully studied, it will be seen that on one card this line keeps up throughout the stroke, while on the other card there is a perceptible falling away during the latter part of stroke. The card showing the straight steam line was taken when there was no slip to the wheel throughout the entire stroke. The card taken from the other end of the cylinder, which shows reduction in pressures, was made when the driver slipped, during the latter part of stroke, to the extent of giving the piston enough greater speed to cause the wire-drawing shown on card. Cut No. 2 shows this in a more marked degree. Here we see the wire-drawing extended through the entire stroke, showing that the wheels slipped during that period. The effect of speed on the various features of the card is well illustrated by Nos. 3 and 4, taken by students of Stevens Institute, from a Cen. N. J. passenger locomotive. These cards were taken under precisely the same conditions, except as to speed. The card at the slower speed shows clearly all the valve functions—cut-off, release, and exhaust closure, the card at the higher speed does not look as though it came from the same cylinder. The point of cut-off is not discernible, and there is nothing to indicate when the exhaust-valve opened; apparently the exhaust closed too early, but in fact did not close any earlier than in the card at slower speed. The high velocity of the piston rendered the ports insufficient to admit and exhaust the steam without excessive friction, which is shown by the difference in the appearance of the cards. The card taken at 33 miles per hour is most excellent—in fact, when the remarkable speed is taken into consideration, both are good.

*Harris Tabor*

## The Kom-kom Humbug.

In a statement recently made by the new president of the New York & New England, the following remarks were made about a mixture for doctoring poor coal:

"We have found out that Howard, entirely unknown to the company, had contracted with a Boston firm to have all the coal used by the company sprinkled with some patent stuff called 'kom-kom,' which was supposed to improve it in some way. The 'kom-kom' cost four cents a gallon and it took three gallons to sprinkle a ton of coal. Thus the company paid twelve cents on every ton of coal for stuff that was worthless. For this purpose alone Howard spent between $40,000 and $50,000. There is not a drop of 'kom-kom' used by the New York & New England road.

"An inspection of the coal in the bins showed that it was of the poorest quality and resulted in the rejection of several thousand tons that were ready for delivery. Yet the company was paying for good coal. The annual report showed that the cost of fuel had been twenty-six cents per train-mile, whereas the average for about fifty roads was only twenty cents. Between 'kom-kom' and poor coal, the New York & New England had a hard time of it."

## Three Men Asleep in the Cab.

When trainmen are overworked, it is very common for some of them to sleep considerable while running, but it is something unusual to find all the occupants of the cab asleep at once. This was what happened last month on a freight train on the Rome, Watertown & Ogdensburg, and the following is a dispatch describing the accident that resulted:

"A remarkable railroad wreck occurred at the Rome, Watertown & Ogdensburg junction, in this city, early Sunday morning. A freight train headed north stood on the main track. Another freight train came in from the south, running at the rate of twenty miles an hour. It smashed into the rear end of the standing freight, ploughing its way along with tremendous force, telescoping several cars and setting them on fire. There were three men in the cab of the moving locomotive, perfectly unconscious of what was going on about them. They were asleep, having been overcome by too many successive hours spent on the road. Two cars, one a caboose, were destroyed, the engine was badly injured and the bumpers on twenty-five cars were loosened."

We do not like the expression, "hard as fire and water can make it," used oftentimes in connection with the hardening of steel; it generally means that the steel is to be made coarse by overheating. It cannot be impressed upon the steelworker too often that his aim should be to refine the grain so that it will disappear when viewed by the unaided eye, the hardness will take care of itself. If it is not hard enough when refined by hardening at low heat, then the steel itself is too mild. Better take the steelmaker into your confidence and tell him what you want steel to do, then he will give you what will refine to a strong condition and harden just right for your purpose.—*Sparks.*

## Casting on Repairs—War Time Makeshifts.

*Editors:*

The question is asked by one of your correspondents if a piece can be successfully cast on a broken cylinder.

There is no difficulty about that if the metal is hot enough and enough allowed to run through the mold until the broken part of the cylinder is melted, which may be discovered by an iron rod run down through the cope so as to feel the surface of the broken part, noting the depth of the rod when run down to the broken cylinder before the metal is poured in, and the depth after the broken part is fused. I remember, when a boy in England, the oil cellar bolt-holes in brass driving-boxes on locomotive would wear out by the shake of the oil cellar, and the ends were recast on these boxes several times before the boxes were worn out; I also remember that during the war many cannon were brought to Richmond, Va., from the Norfolk Navy Yard that had their trunnions broke off before being abandoned by United States troops. At the Tredegar Iron Works new trunnions were cast on them—6x8-inch on 10-inch guns—and they did service to the end of the war.

I think Mr. Jas. E. Masters also cast teeth in large gear wheels at Richmond that had been broken out in service. These cannon were not rebored, only the trunnions turned up and mounted. I think electricity will play an important part in work of this kind before long.

I think I rifled some of the first cannon made in Richmond, Va., after the beginning of the war. The cannon were bolted on logs on the floor and a bar with tool in the end was attached to the bed of a planing machine, and by an inclined plane on which an arm slid up, the curve of rifle was given. This was one of the makeshifts of those troublous times. Jno. J. Bingley.

*Watertown, N. Y.*

## Bent Rods—"Burning on" a Patch—Lining Guides, etc.

*Editors*

Mr I. F. Wallace quotes his engine as bending right-side rod while pulling on a wreck; it is quite evident that the rod was sprung while passing the lower quarter. Possibly the engine was slipping and the back wheels took hold of the rail, which would have a tendency to allow the pins to close, the left side being at or near the center, and with a little lost motion there would be nothing to prevent the right pins from closing. If, as he says, the pins *were* in train (tram) and worked freely, I venture the assertion that the rods did not work free afterwards. The writer used to run an engine that had the same weakness.

A member of the Flat Wheel Club asks if a piece can be cast on a broken cylinder successfully. Of course it can, and a good job made of it. The days of putting a patch on a cylinder with top bolts have passed away on any well-regulated road. The process requires the handling of a large quantity of molten iron. A pattern of the broken piece is made and put in place, the sand rammed up, in and around the cylinder, the pattern taken out, and a stream of molten iron run through the mold and in contact with the fracture; of course, there must be an outlet to the iron it running through the mold heats and finally fuses the fractured edge, and when at the right heat the outlet is stopped up, when the mold fills up, and the job is complete. The above is about the substance of the operation. A molder could give a more detailed description of the process of *burning* in a piece, as it is called; but it is a cast-iron weld, and when well done, as they do it at the S. P. shops in Sacramento, Cal., it makes a good job, the joint being hard to detect after boring out.

About lining guides, Mr. Hitchcock and Mr. Dolbeer are both right. Mr. Hitchcock's methods are methodical and elaborate where plenty of time to do the work is at hand, but I don't see why they would give any better results than the method of Mr. Dolbeer. Mr. Hitchcock uses a line through the cylinders; now, to have this line represent the exact center of the cylinder as it should, depends a great deal on the man who puts the line through, as the same difficulty is met with as in culipering a piece of work; it is the sense of touch. We know the line exposes a minute surface and is hard to feel, more particularly in the back end of the cylinder, where as some do center from the back counterbore, the stuffing-box should be the point to work from when a line is used. I have found in practice that when the final adjustment of the line is made, a pine stick with an ordinary pin in it is better than inside calipers, as it is lighter and more sensitive.

A quick and good way to line guides when guides are planed or ground true, gland bushed, and rod turned, is to put in gland and bushing ring, put in piston and center it by liners in cylinder, hang lower guides so that the crosshead has a good bearing crosswise and in alignment with the engine across the frames; by moving the crosshead back and forth in the guides until the taper of the rod will enter crosshead without canting at either end of stroke; put on top guides and bolt them tight in their proper position. The crosshead must work free and not bind in the guides. The machinists can have their way in the shop, but the engine will have its way on the road. While we are speaking of guides, there is a painting hanging, or did hang, in the roundhouse timekeeper's office in Sacramento, that treats on hot guides. Will some of the S. P. boys tell us something about it, and what A. J. said?

There are a great many things in locomotive work in regard to close fitting of wearing parts that are giving better results by being a little loose in these days of push and hurry.

*Corry, Pa.* W. De Sanno.

## Where They "Burn on" Patches Successfully.

*Editors.*

In your April issue "A Member of Flat Wheel Club" asks if you have ever known of a patch being successfully cast in a cylinder which had been broken by some accident. Please inform the member or club that in the past fifteen years the Southern Pacific Railroad, at the Sacramento shops, have successfully cast, or more properly speaking, burned pieces in about seventy-five cylinders, some patches extending half the length of cylinder.

We have also drilled stud-holes in flange of cylinder through the seam of patch and there has not been a single failure up to the present time.

## Hot Brasses—Why They Heat.

*Editors:*

The above subject will interest every engineer and fireman, for I do not think there is anything about a locomotive that will cause an engineer more worry and trouble than to throw the babbitt.

Most machinists know that a brass after it has been in service a while will bind on the pin from A to B—Fig. 1. It has been my practice to take a light chipping from A to B and finish with a bastard file. Although I knew that it was increasing the pressure on the remaining area, yet if lubrication was all right it had the effect of stopping a tendency to heat. The only feasible explanation I have seen or heard is given in Joshua Rose's "Modern Machine Shop Practice" He states that the constant vibration and pressure causes the

*Fig. 1.*

*Fig. 2.*

surface C, Fig. 2, to condense and stretch, causing the bore of the brass at D to close upon the pin and bind with undue friction, causing heating. That I believe is the cause of nine-tenths of hot brasses. Many practical men refuse to believe that a brass will heat through pounding, but the above condition is brought about in many cases by pounding. Ebor

## A Good Suggestion.

*Editors*

In considering the various so-called railroad problems of the day, one, of great importance, seems to have been almost entirely negected.

The progressive roads have made great strides in improvements of a certain class; the time made is faster, the roadbed smoother and safer, the motive-power heavier and the capacity of the cars greater. There has been improvement in the method of running trains, in the manner of lighting and heating cars, and in every line that would tend to promote the safety and comfort of the traveling public and cheapen the rates for shippers; but one feature in the method of management remains the same to-day as it was years ago, despite the fact that there seems to be plenty of room for improvement.

Think a minute and tell if you can of any improvement that has been made in the method of disciplining the men for infraction of the rules. There may have been an increase in the amount of discipline administered, but the method remains the same. In years gone by what was the means employed for punishing a man for disobedience of orders? Simply suspension without pay for a certain length of time.

What does this suspension mean? Simply enforced idleness; or, in other words, an unlimited opportunity to brood over and magnify what almost always seems to the man himself an injustice. When a man has been at work regularly every day for years and then is suddenly taken from his occupation and permitted, nay, compelled to waste fifteen or thirty days in idleness, he is naturally at a loss to know what to do with himself and so spends his time in drinking, gambling, or what is worse for the road, going around amongst his fellow men and dilating on the injustice of his sentence. Thus a man who while at work may be sober and well disposed, when deprived of this safeguard succumbs to temptation and is led into states of dissipation and discontent. Such is human nature, and every railroad man of experience can call to mind cases to confirm these statements. What an inconsistent thing it is to force a man into idleness for misbehavior, and by that very act give him every opportunity to commit further indiscretion.

Discipline we must have, but why should it be idleness. Surely there is another way, and now we think of it a very simple one. When a man has been found guilty of carelessness or misdemeanor reduce him for a time to a lower rank, but *keep him at work*. Do not let him remain idle. Give him no opportunity to brood over fancied wrongs.

For example, if he be a passenger engineer let him pull freight for a time, or put him on a run that is less desirable, and pays less money. If he be a brakeman treat him likewise, but do not force him into idleness, nor for a time entirely take away his means of support, thus compelling him to go into debt, for this of itself is demoralizing. After a period of longer hours and less pay he will learn the desired lesson, and then he may be reinstated in his old position.

In this way *idleness* and its attendant evils are avoided, the younger men who are temporarily placed in an advanced position learn something of the work connected therewith, and are in consequence better prepared when the inevitable changes of time necessitate their permanent advancement. Paul Synnestvedt.

*Chicago, Ill.*

## Air-Brake Care—Kinks and Points.

*Editors:*

In your February issue I made some statements that were questioned. I waited to see what was said about them and find that I must once more take a hand in the discussion. On page 53, in regard to drilling hole in feed-valve No. 21, it seems to be taken that it would connect reservoir and train-pipe pressures. The reservoir pressure is against the end of feed-valve and train-pipe pressure against the side. A hole in the side of the feed-valve would open inside of feed-valve to train-pipe pressure, and if reservoir pressure should get in it would close it. If valve is loose enough, hole is not needed, but if a new feed-valve is put in there is likely to be trouble from an unbalanced valve, and on this road the valves that best maintain regular reserve pressure have holes in them, and if valve should gum hole will be open, showing that air is continually rushing back and forth in it. A glance at the parts in brake-valve and the position feed-valve occupies will make it clear.

As to opening throttle on a modern passenger engine with driver brakes set, unless an inexperienced man he would hurt nothing, at least not as much as when the brakes went on, as I have timed engineers in such cases and never saw one shut off steam until after brakes were dead on, for it generally takes them about ten seconds to realize their position. I would like to get others' experience on this matter.

While on brake-valves, would like to find whether leather or rubber gaskets No. 22, plate D 8, are most liked. I use rubber and warm them up with the sprinkler hose when I wish to get them apart. How about scraping rotary-valve No. 13 and seat, and how long does it take? What is used to set the grain on seats after scraping?

I still claim a passenger train should not be started until brakes have been applied after auxiliaries are charged, as I have often watched at the first stop after a test under pressure has been made, and

## PROGRESSIVE EXAMINATIONS OF LOCOMOTIVE ENGINEERS AND FIREMEN.

By JOHN A. HILL, editor of *Locomotive Engineering*, for ten years a fireman and engineer. Plan is the one proposed by Mr. H. to the American Railway Master Mechanics Association and so strongly recommended by their committee. Tells what should be required of a man when he goes firing. Examines him the first year on signals and the rudiments of firing, the second, on combustion, etc., and the third, on mishaps, breakdowns, and the engine Practical; nearly 300 questions and answers to 'em. Seventeen colored plates showing position and color of every signal carried on engine or train. Standard code. Adopted as official examination on several roads. Invaluable to engineers and firemen, and tells every young man with an ambition to run a locomotive, just what he ought to know to start with and what he must learn before promotion. Send 50 cents (U. S. stamps are good) for this neat book, pocket form, round covers, red and gold, to

## GALENA OIL WORKS,

LIMITED.

**Galena Engine, Coach and Car Oils, the Standard Lubricating Oils of America.**

SAFETY, SPEED and ECONOMY are the results of the use of Galena Oils. COLD TEST, 10 to 15 BELOW ZERO. These oils do not freeze in the coldest weather, while they are adaptable to the hottest climates.

In the use of Galena Oils there is an entire freedom from hot boxes, except when these are caused by mechanical defects.

The adoption of Galena Oils as standard railway lubricants by a large majority of the leading railways of this country is an evidence of their superiority, while the fact that the same roads use these oils to-day that used them more than 20 years ago, is an evidence of their uniformity from year to year and year in and out.

Galena Oils are in exclusive use upon three continuous lines from Boston and New York to the Pacific coast, and upon one continuous line from the City of Mexico to New York, thus demonstrating their adaptability to all temperatures and climates. Being entirely free from gum, these oils are not affected by dust and sand as other oils are.

We also furnish our customers SIBLEY'S PERFECTION VALVE OIL, which is also used exclusively upon a majority of the leading railways of America.

## BOSTON & ALBANY RAILROAD.

### "Springfield Line"

—BETWEEN—

*BOSTON and NEW YORK.*

Four magnificently appointed express trains leave either terminus at 9 and 11 A. M. and 4 and 11 P. M. daily, except Sundays, and on Sunday at 4 and 11 P. M. Palatial drawing-room cars on all day trains and luxurious sleeping cars on night trains. Dining car service on 4 P. M. trains all that can be desired.

A. S. HANSON,
Gen. Pass. Agt., Boston, Mass.

## THE "BROTHERHOOD SEAT."

**Perfectly Equalized, Adjustable to any weight, and Back can be quickly changed to any desired angle.**

We are both Brotherhood Men, and as to our reliability we would respectfully refer to B. L. E. No. 88, B. L. F. No. 28, or the Commercial National Bank of Appleton, Wis.

Satisfaction Guaranteed or Money Refunded.

Seats made in any size, from 12x15 to 18x22, with back 15x20; also, Drop Seats for engines where boilers extend through cab. Best Spring Cushions, stuffed with curled hair, both seat and back covered with best grained Horsehide Leather.

Everything Receives our Personal Attention.

SEND FOR CIRCULARS.

*No Engineer can afford to be without this Seat!*

It Improves Health and adds Comfort.

STANNARD & WHITE, APPLETON, Wis. Sole owners and manufacturers.

## FARMING IN THE SOUTH.

It is not astonishing that hundreds of Northern farmers have settled in the South at points on, or adjacent to, the southern division of the Illinois Central Railroad within the past five years, nor is it remarkable that instead of confining themselves to the cultivation of cotton exclusively, they are diversifying their crops with gratifying results. One of the important questions in the mind of any Northern farmer who contemplates locating in the South is: "What crops can be profitably grown in that latitude?" The passenger department of the Illinois Central Railroad will, on application to Mr. J. F. Merry, Assistant General Passenger Agent, Manchester, Iowa, mail free the following pamphlets: "Southern Home Seekers' Guide," "How to get Rich in the South," "Truck Farming," and "Farmers' and Fruit Growers' Guide to McComb City, Miss." These publications contain valuable information and should be read by every farmer looking for a Southern home.

## The Standard Tool Co., Cleveland, Ohio.

Manufacture Best Quality **Twist Drills** In All Sizes.

Also all styles of REAMERS and TAPS Can fill all orders promptly. Special Tools made to order. Send for Catalogue.

## THE WASHBURN Car-Wheel Company,

HARTFORD, CONN.,
MANUFACTURERS OF
CRUCIBLE STEEL-TIRED WHEELS

For Parlor and Sleeping Cars, Passenger Coaches, Locomotive and Tender Trucks.

## "Brunswick" STEEL TYRED Wheels.

WROUGHT IRON CENTERS.

Double or Single Oval Spokes.

"Brunswick,"
"Gibson,"
"Mansell Ring"
TYRE FASTENING.

PAGE, NEWELL & CO.,
139 Milk St., BOSTON.
NEW YORK. CHICAGO

## MOWRY CAR WHEEL WORKS,

CINCINNATI, O.

Manufacturers of CAR WHEELS of all descriptions. Wheels and Axles Chilled Tires; Engine, Car and Bridge Castings, of any pattern, furnished to order at short notice. Wheels of all sizes constantly on hand.

WORKS: Eastern Ave. and Lewis St.
OFFICE: 27½ W. Third St., Cincinnati O.

## THE BOIES STEEL WHEEL

For COACHES, LOCOMOTIVES and TENDER TRUCKS.

In use on 108 Roads.

Strongest, Lightest and Cheapest Wheel of its class made.

No Inflexible Connection between tire and axle.

Four (4) inches of bearing surface under tread.

Only four parts.

Centers Indestructible. Can be re-tired in any shop at nominal cost.

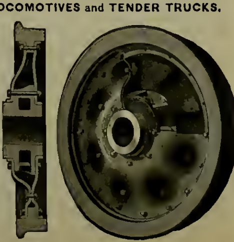
Severe and constant service for seven years demonstrates the truth of our claims.

MADE BY THE
BOIES STEEL WHEEL CO.
SCRANTON, PA.

COOLBAUGH & POMEROY, General Sales Agents, 20 Broadway, New York.

H. W. BOIES, Western Agent, 405 Phenix Building, Chicago.

*SEND FOR CATALOGUE.*



he required, even to the building of a consolidation locomotive with Krupp tires. Would it not be nice to be the M. M., or, better, the S. of M. P. and M. of a large and well regulated road, drawing say $8,000 or $10,000 per year, with such a talisman in your possession? If you needed, say, ten consolidators right away, you rub your old lamp, its slave makes his appearance, you say: "Afrite, ten consols, right away quick, and hark ye! let them be tired à la Herr Krupp, so that I may have them all trued up in eight or ten hours when necessary." Right here comes in quick work, again; men like Purves would want some one to rub the old lamp for them, and would want the necessary amount of friction generated in about one rub.

W. H. Wesley.

*Nashville, Tenn.*

[For the benefit of our correspondent we have investigated the process of wheel-turning at Mr. Purves' shop and find that they do turn a pair of tires on 44-inch centers, flanged, in three hours and a half, easily; they do not make a second cut, but go over them once, leaving the tool marks there. But one thing that helps them is the fact that this road does not allow tire to be worn down below 3/16 of an inch. The pay of the lathe men was also increased when the output was. This is better than the average "rusher" does.—Eds.]

## Mr. Purves Offers Proof.

*Editors:*

I understand that some of the readers of Locomotive Engineering in our neighborhood, have taken exceptions to, and even expressed a doubt as to the truthfulness of, that portion of my article on "New and Old Tools" in your March issue, where I state that two pairs of driving-wheel tires can be turned off in ten hours, and possibly three pairs in the same time. I mentioned the necessary speed, the amount of feed, etc., to accomplish this, and did not for a moment think the statement would be doubted, although I did expect that it would be criticised in the April issue, and was somewhat disappointed when I found that it had not been.

Here are some more facts and figures upon the same subject for the consideration of the craft.

We turned a pair of flange tires on 44-in. wheel centers belonging to engine No. 260 (Baldwin consolidation), in two (2) hours and forty-eight (48) minutes.

This is the actual time from when the wheels were lifted from the floor at 4.45 o'clock P. M., April 12th, until they were turned off and placed on the floor again at 8.33 o'clock A. M., April 13th, the power stopping at 6 P. M. and starting at 7 A. M. on the days in question. The tires are of Midvale steel, 2¾ in. thick and were reduced in size ½ in., taking a ¼ in. cut off.

The work was performed by W. H. Mooney, of Albany, and although it may sound like a "fairy story" to some, its veracity can be vouched for by many who witnessed it.

T. B. Purves, Jr.
B. & A. R. R.

## A Little Puzzle on the Air-brake.

*Editors:*

A few days ago one of our engineers was getting his engine out of the house and was a little late, so he ran the engine on the table before he started his pump; well, when his engine was turned, he tried to go, but could not; his brakes were set tight and would remain so as long as his pump was working and his valve on running or release position. This engine has the old-style triple and only one triple for driver and tank brake; this triple was cut in for automatic all right, but would release when pump was shut off.

Tink.

## An Engineer's Observations on Shallow Fireboxes.

*Editors:*

I am surprised to see some of the otherwise finest engines in the country turned out with shallow fireboxes. With this class of box the flues are only 10 or 12 inches above the grates, and the road men will tell you of stopped flues and bad fires all the time.

On the road I am running on the grates are only 9 inches below the flues, and we use a brick arch. The arch is 9 inches above the grates, and practically stops the two lower rows of flues up, and when the engine is at work on grades you often have to have 9 inches of fire on the grate, and the arch being so low at the front end of the firebox it does not give room for the fire to receive the proper amount of coal. Then there is not room for the gases escaping from the coal to flash into flame and burn.

When the flame strikes any substance as close as this arch is to the fire, it smothers it out, and the back end of the firebox has to do double duty; and when pulling in a siding with a heavy train the fire dies down, and when you pull out it takes some time to get the fire going. The cold air rushes in and the flues get to leaking.

To take the arch out the heat is so great, it soon burns the beads off and gets the flues loose in the sheet.

If the mud-ring should get to leaking, you have a bad job on your hands. This is all different with the deep firebox. I cannot see why railroad companies will purchase such engines when they can get a better engine with a deep firebox.

They say, "You will have to have a shallow firebox with a consolidated engine," which is all true enough, but I will take a mogul with a cylinder the same size, a deep firebox, and run her longer with less repairs and burn less coal, pull more cars, and the flues will last twelve to eighteen months longer. I have never seen a shallow firebox after twelve or fifteen months but what had to have the boiler-maker in them calking flues nearly every trip. On our road eighteen months is considered a long life for them, and the deep firebox is from twenty-four to thirty months or about the life of the engine until she goes into the back shops.

An Observer.

*Paducah, Ky.*

## Handling Train with Emergency Port Only.

*Editors:*

In your April number there is an article "Ingenious Remedy for Broken Air-pipe," which I do not agree with you about.

I think that if pipe from engineer's valve to small reservoir is broken or leaks bad, the union next to valve should be blanked and the service-exhaust from brake-pipe left open.

A valve in this condition does not require so much care in handling as one used with the service-exhaust plugged, especially with a long train.

One reason for this is that the emergency-valve in the quick-action triple-valve cannot be opened if all the air is instantly exhausted from above the piston-valve. Another reason is the brakes are liable to release on head-end of train when they should stay on. On the other hand, if the service-exhaust is plugged up and the air is exhausted out of emergency-port, and is allowed to escape a little too quickly, it will cause the emergency-valve on first car to open, and that will cause the brake to be applied in the emergency on the entire train. And if the valve is closed too abruptly it will cause the brakes on head cars to release when they should stay on.

I have handled thirty cars in a train with the small reservoir cut out and service-exhaust open, with good results.

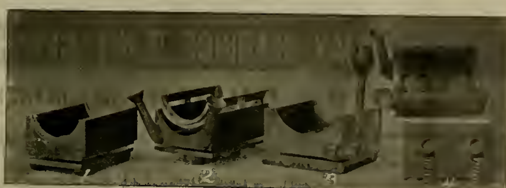
E. G. Desoe,
Air-brake Inspector.

*Springfield, Mass.*

## Dupont's Truck and Driving-Box Cellar.

The illustration on this page shows two forms of a journal cellar, the invention of B. E. Dupont, foreman of the L. & N. shops at East Louisville, Ky. As will be seen by looking at the plain cellar, the one to the left of the picture, No. 1, it will be seen that there is a plate under the cellar proper, between the plate and the cellar there are two coiled springs set in pockets that keep the cellar against the journal.

The top of the cellar has a fitting piece with an inward projecting flange that makes a tight fit on the ends and sides of the bearing.



Improved Journal-Box Cellar.

The oil for the box is carried by tubes to the cellar, and none is used on top of box except to oil the hub and wedges.

No. 2 shows the ordinary engine-truck cellar with fitting plate raised up and two oil tubes.

No. 3 shows a driving-box cellar with a single oil tube and strainer at the corner.

No. 4 shows the plate and the bottom of the box and spring pockets.

The cellar bolts go through the plate, leaving the cellar itself free to go up. Waste cannot get out of this cellar, and dirt and dust cannot get in. The inventor has had sets of them running for three or four years on different engines on the L. & N., the C. & O., the L. S. Ry. and others, and has a great many testimonials of its efficiency from officers in charge of motive power and engineers running locomotives equipped with it.

One engineer shows an engine-truck record of 3,600 miles with one oiling, and all of them show some 200 trips without oiling driving-boxes.

Mr. Dupont is desirous of putting his invention into the hands of some one able to push it, as he is too busy to handle an outside business. His address is East Louisville, Ky.

The Central Railroad Club has concluded to follow the example of the other railroad clubs and publish the proceedings in pamphlet form.

## Car Coupler Tests.

A committee of the Master Car Builders, consisting of John S. Lentz, J. M. Wallis and G. W. Rhodes, have issued a circular concerning the Master Car Builders' type of coupler. They direct attention to the necessity of using the contour line gauges made by the Pratt & Whitney Co., in order to maintain coupler standards.

They recommend the use of the pocket or "U" shape fastening in lieu of the tail-bolt.

It is proposed that drawbars, including knuckles and locking apparatus, should weigh 210 pounds or less, and that a greater weight than 220 be not allowed.

The drawbars should be tested for pulling strength and under a drop. When set solidly on end the bar should stand three blows of 1,640-pound weight dropped ten feet or two blows from the same weight dropped fifteen feet. In the pulling test the bar will be required to stand a strain of 100,000 pounds. It will only be considered a breakage when any part comes in two pieces.

Mr. Thomas Owens has been appointed superintendent of the Duluth & Iron Range, with office at Two Harbors.

The Rau Mfg. Co. will remove on May 1st from No. 66 West Monroe street, Chicago, to their new factory at Griffith, Ind. The increase of business made it necessary for them to have a larger factory. Their Chicago office and salesroom will be at No. 235 Lake street.

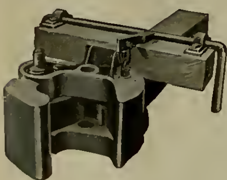
Mr Thomas L. McKeen, of the Thurmond Car Coupling Co., New York, has lately obtained several patents for improvements in car couplers. Mr. McKeen is an expert on car couplers.

Manning, Maxwell & Moore, of this city, have secured the contract for supplying one 80-ton and one 20-ton Shaw electric crane to the Midvale Steel Co. of Philadelphia. There are several advantageous features about an electric crane that are hard to meet in other forms.

Considerable interest is taken in economy of engine supplies by the men on the Chicago, St. Paul, Minneapolis & Omaha road. The amount they can use is in no way limited, and Galena oil is used, the engine oil being worth 29 cents per gallon and the cylinder oil 49 cents. There are 246 engines in service, and the following table for average work of November, December, January and February is in every way a creditable one to Master Mechanic J. J. Ellis and his men.

| Mileage. | Miles Run to pint, eng. | Miles run to pint, cyl. | Cost per mile, 1000 miles run |
|---|---|---|---|
| 678,017.... | 32.10 | 52.70 | 2.28 |
| 718,898.... | 32.10 | 58.43 | 2.18 |
| 625,474.... | 33.02 | 63.78 | 2.06 |
| 579,787 .. | 32.50 | 66.60 | 2.03 |

# THE STILGER & STROSLER AUTOMATIC CAR COUPLER



Is the Cheapest, Safest and Strongest Coupler, on account of its durability. The *only* Automatic Coupler that has a lateral swinging hook and couples with the link and pin proper, ***and pulls direct from the center at all times.***

This coupler has been in use on the Birmingham Division of the L. & N. R. R. seven months without a break. We take pleasure in referring to the Supt. Motive Power, L. & N. R. R., as to its merits.

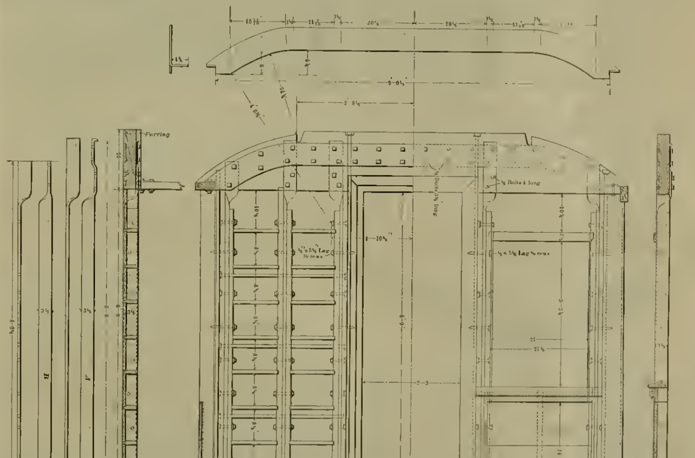
## A Very Strong Passenger Car.

The annexed engraving illustrates a method of composite construction adopted by the Lake Shore & Michigan Southern Railway for the purpose of strengthening passenger cars. The side-sills are reinforced on the inside by an 8 x ½-in. iron plate, extending 14 feet 10 inches back from end-sill, and being bent, forming an angle-iron, extending 8 inches onto end-sill, and having on the inside a piece of 2 x 7½-in. yellow or Norway pine, extending the full length of iron plate, flush with bottom of sill. The whole is securely bolted to side-sills by twenty-two ⅝ x 7¾-in. bolts, having heads let in flush in outside of end-sill, and secured by three bolts 9½ x ⅝-in. to end-sill, extending through end-sill, having head let in flush on outside of end-sill, with washers under both head and nuts, and ends of bolts riveted over on nuts. Between ends of iron plates, side-sills are reinforced by two ½ x 7½-in. yellow or Norway pine pieces, securely bolted to side-sill with twenty-eight ⅝ x 7¾-in. bolts, having washers under heads and nuts, and ends riveted over on nuts. These inside reinforcing pieces are mortised, gained and bored to receive bridging, bolsters and necessary tie-rods and bolts.

The end-sill consists of an inside and outside piece of white oak, with an 8 x ¾-in. wrought-iron plate between them. Outside pieces are of oak, and dressed on all sides to 4½ x 8¼ in., and mortised to receive platform sills, corner, door, and end-posts and end-studs; also gained out 3½ in. wide by ¼ in. deep at six places for receiving bottom of iron-end posts; and cut off at 45 deg. angle on each end, to receive bottom of corner post, and bored for necessary bolts and rods.

On the ends of the car six iron end-posts of ¾ x 3¼-in. iron are located, one close to door posts, one next to corner posts, and one half-way between the above. Posts to be put next to main end-posts, with an auxiliary post put on the other side, and the whole to be bolted together with five ⅝-inch bolts. Iron posts have ends twisted ¼ inch and extending to bottom of end-sill and to about 16 inches above bottom of end-plate, bottom end of post fitting into rabbet on inside of outside member of end-sill, and being secured by two ⅝-inch bolts, passing through entire end-sill in outer and intermediate posts, and by one ⅝-inch bolt through inner post, these bolts being also the ones which hold end-sill together. Top of posts lie flat on inside face of end-plate, and are offset to pass under and lip over a ¾ x 6-in. iron plate, extending from side-plate to side-plate. Outer posts secured by two ½-inch bolts through above tie-plate and end-plate, and intermediate and inside posts secured by two ½-inch bolts each through tie-plate and end-plate, and by two ½-inch bolts each, through end-plate alone. Cars built in this way have resisted tremendous blows without damaging the car. The plan adds so much to the safety of passengers in cases of accident that it deserves to be generally adopted in car construction.



Mr. William C. Baker, the well-known car-heater inventor, has lately patented an improvement on car heaters, consisting of an expansion vessel having a peculiar form of cock and funnel.

The Morris & Essex—long ago absorbed by the D., L. & W.—used to brand their stock M. E., and the car-hands promptly interpreted it "Methodist Episcopal."

Atchison, Topeka & Santa Fé R. R. have given the Hanrahan Refrigerator Car Co. an order for 250 cars. Barney & Smith, of Dayton, Ohio, are doing the building.

We are informed that the Long Island road have adopted the Smillie Coupler. The Lebanon Car Works are building 150 box cars for them, and the Middletown Works 250 gondolas.

## Car-Shop Management.

By Eugene Chamberlin.

Volumes might be written upon car-shop management, but, without entering into details, we will simply assert that, in a well-conducted shop, there should be "a place for everything, and everything in its place." Discipline should be perfect, and employés should be dealt with in a manner that they will readily understand that their advancement depends entirely upon their own exertions. Ability and strict impartiality should be the rule, and all promises made should be faithfully kept. The arrangement of machinery in every department should be such that, in the working of either metal or wood, it should approach completion by passing steadily in one direction, and, when finished, be as near as possible to the point required for use.

Men responsible for production of work should know what each machine can accomplish in a given period, when handled under the most favorable circumstances. The possession of such knowledge is valuable in arranging values for piece work, and for the prevention of trifling with a tool's capacity. The use of antediluvian machinery or tools is a serious draw-back. Templates of all work should be carefully made, properly lettered and classified, and kept in their respective pockets, that they may be readily obtained when required. All tools should be cared for in a room specially prepared for that purpose, so that in case of breakage or other mishap the work may continue without interruption, by the use of a duplicate tool, readily ob-

tained on the return of the one broken, which may be put in shape at convenience, and without the special attention and consequent delay to work upon which the party who breaks it is engaged. All manufactured stock should be classified and disposed of in a manner that will bring it readily at hand for use, and make it easy to inventory. Great care should be taken that an ample supply of manufactured stock, particularly standard parts, is always in readiness. The delay to work sometimes occasioned by men waiting for the preparation of material is very annoying, and becomes expensive as a labor item.

The economical handling, loading and unloading of heavy material, such as wheels, iron, coal, lumber, etc., in and about the shop, is an important factor. It will be found that a system of narrow-gauge surface tracks, with proper vehicles, and also the use of trolleys and other appliances, are valuable, and will result in a marked reduction of the cost of handling material. With regard to the work in repair and construction shops proper, satisfactory results have been obtained by assigning certain classes of work to groups of men specially qualified for each type of work, on the principle that in following one line of work they become in a measure expert, and are able to accomplish greater results. With this end in view, and that the work may arrive on the working tracks properly assembled, it will be found advantageous to locate a competent inspector at the head of shop yards, a part of his duties being to assign to designated tracks certain classes of work, such as roofs, sills, etc., etc. After these cars have passed through the shop finished, and before they leave the yard they may be again examined, with a view of determining if all work has been properly done. This, together with a system of accounting for the repairs done to each particular car, and by having entered upon such repair record the names of persons engaged in doing said work, precludes in a measure the possibility of any large amount of poor work leaving the shops, and, if defective work is discovered, certainly fastens the guilt upon the proper persons, and allows a remedy to be applied in the right direction.

It will be unnecessary at this time to enter into the merits or demerits of "piece work" on car repairs; much has been said upon this subject, and probably much more will be. In this age of progress, all things are possible, and if piece work is the true basis, why is it not possible to apply it to car repairs? To work such a system properly, a judicious compromise must be reached on the labor items for the renewal of parts on the multitude of cars of widely different construction, and the cost of inspection of such work will not counterbalance that which might reasonably be expected from day work.

In conclusion, the writer begs to say that he has not set forth in this article anything that invites criticism, and is fully aware that there is nothing new or startling in this method of conducting work on car repairs. It is only a plain matter-of-fact statement of how the business may be practically conducted with reasonably satisfactory results. This is written with a view that others engaged in the same occupation may see their way clear, to set forth the advantage occurring to them in handling the same class of work, but possibly in a very different manner, and probably with much better results in such case. We will be able to absorb information, if we cannot impart it, and the results might be beneficial to the service in which we are engaged.

---

An improvement in the under-trussing of cars has been patented by Frederick R. Canda, inventor of the Canda Cattle Car. It consists of a combination of projections on the queen posts and collars on the truss rods, the purpose being to hold the trusses steady. It is one of these small improvements that does a great deal to keep a car from getting out of shape.

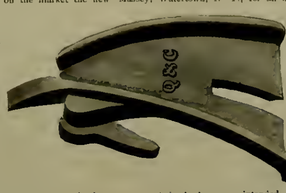
## Lehigh Valley Stock-Car.

The officers of the Lehigh Valley Railroad speak very favorably about the stock-car shown in the annexed engraving. The company have a great many of these cars in use. The special advantages claimed for this form of car are as follows: It is provided with a dead-air chamber in the top, which serves to retard the rays of the sun, and like a garret in a house make the car much cooler in warm weather, which is a very important factor in shipping cattle, sheep and hogs. Second, the stock is fed from the center of the car, the running-board consisting of a series of doors through which the food is let through the car and automatically distributes itself without further attention, and there is no liability of the food being wasted by running off from the sides of the car, like in other cars where the food is put up in its place close to the outer edge. Third, the convenience in watering is very great, as the tank on the end may be supplied with water from any convenient hydrant or hose and distributes itself all throughout the car, both upper and lower decks when used for hogs, and single decks for cattle. These troughs may be opened and closed by the attendant, who stands on the tank on end of car while operating the same. Fourth, the special advantage to be claimed over all other makes, is the fact, that the feeding and watering facilities in the car do not interfere in the least with the bracing of the car.

LEHIGH VALLEY STOCK-CAR.

## New Wrecking Frog.

The Q. & C. Company, of Chicago, have recently placed on the market the new form of wrecking frog shown herewith.

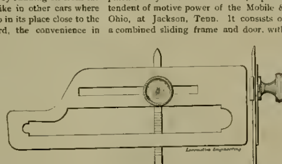


The same frog is used on either side of a derailed car; the slot in the frog fitting over the rail prevents any pushing away of the frog, crushing of ties, etc., and the heavy eccentric latch firmly grips the thin part of the rail to prevent the frog from slipping ahead, and is itself protected by the plate.

In this day of heavy equipment light, trappy wrecking frogs are of little or no use. These frogs weigh 350 a pair, and the makers guarantee them against injury by anything on wheels.

## Blackall's Tire Gauge.

The tool illustrated in the annexed engraving is the gauge used on the Delaware & Hudson for measuring the wear of tires. The device was gotten up by Mr. R. C. Blackall, the superintendent, and is simplicity personified. The recess at the end of the gauge goes over the flange and the straight surface rests on the face of the tire. The graduated slide is then slipped to the worn surface, and while in this position the thumb-screw is tightened. When the gauge is removed the graduated slide shows the amount the tire is worn beneath the original surface. The gauge is made of thin iron and can be carried conveniently in the pocket.



---

An improved car door has been patented by Mr. M. T. Carson, superintendent of motive power of the Mobile & Ohio, at Jackson, Tenn. It consists of a combined sliding frame and door, with provision for holding the frame securely in place, and special mechanism for holding the door tight in the door opening of the car. The object of the invention is evidently the making of a car door that will be easily operated and at the same time be perfectly weather-tight.

---

The Central Railroad & Banking Co. of Georgia are trying some of the Fox pressed steel trucks under tenders.

---

A patent has been granted to A. P. Massey, Watertown, N. Y., for an improvement in brake gear, intended to make the load of a car vary the leverage of the brake. This would be a very important improvement if it should work satisfactorily. The means employed in the arrangement designed by Mr. Massey appear to be very simple and therefore promising of practical utility.

## New B. & O. Cars.

The new passenger coaches built by the Pullman Company for the Baltimore & Ohio Railroad, and run between New York, Cincinnati and St. Louis, are models of the car builder's art, combining all known appliances devised to secure the comfort and absolute safety of passengers. While the train will be virtually made up in Baltimore it is really to be an extension of the 9 A. M. daily Royal Blue Line Express from New York. The entire train is vestibuled, including postal and baggage cars, and fitted with Pullman's latest anti-telescoping device. The standard Pullman color, an olive brown, is used. If the cars were blue they would, in every sense, be Royal Blues, for they are built upon the same model, and look just as pretty, stanch and shapely. There is the familiar coat-of-arms which decorates the Royal Blues, except that the Maryland insignia only appears. The interior bears even more striking resemblance, the upholstery being in old gold velvet plush and the woodwork being of mahogany. The only notable departure from the interior designs of the Royal Blues is the absence of the smoking compartments, which are rendered unnecessary by reason of the fact that the forward coach of the train is assigned to smokers. Each car has separate toilet rooms for ladies and gentlemen and a lavatory. A porter, in addition to the one in the Pullman sleeper, will accompany each train.

One of the most striking improvements is the substitution of easy-sliding damask curtains for the tight-fitting slatted wooden blinds, which are the accompaniment of a double window, the upper section being of frosted glass. For each window there are also dust screens and dust deflectors, which provide a delightful draught of fresh air free from dust. The cars are heated by steam drawn from the locomotive, and also are provided with Baker's patent heater, for use in case the car should be detached from the locomotive, or in case the supply of steam from the engine should for any reason fail. The cars are heavily carpeted, have reversible seats, and are provided with an automatic device by which the conductor can signal the engineer. In short, every provision known to the car builder is made for the safety and comfort of passengers, and the high standard of the entire equipment is in keeping with the aim of the present Baltimore & Ohio management—to place at the service of its patrons the best facilities for their accommodation obtainable, and to attain the highest speed for its trains that is compatible with absolute safety.

---

The poster pictures of "New and Old" locomotives recently sent out by us has attracted a great deal of attention, and the demand for them has been so great that another lot have been made. We will send one free to anyone who will put it up where railroad men can see it.

---

We have received a prospectus for proving and introducing the Loeber air car, which has evidently been sent expecting that it would receive a notice. It is well worthy of mention. There is a picture in the front of an immense vessel, like the hull of a ship upside down, with big projections on the sides that are supposed to represent wings. The thing is represented to be flying in the air, with a city far away beneath it. When we look at the picture of the Loeber air car in this position, the refrain of an absurd song keeps coming to our mind, which began "When hogs begin to fly." The projectors of the car say that it will be made of steel, and some beneficial scheme has been imagined for making the car overcome the laws of gravity. Old Nature is hard to cheat, and we do not expect to see the Loeber car rise into the air until the time when hogs begin to fly.

### Some Freaks of Fate.

By John Alexander.

I am just back from a visit to old scenes, old chums, and old memories of my interesting experience on the western fringe of Uncle Sam's great gray blanket — the plains.

If some of you fellows who know more about writing than about running engines would only go out there for a year and keep your eyes and ears and brains open, and your mouths shut, you could come home and write us some true stories that would make fiction-grinders exceedingly weary.

The frontier attracts strong characters, men with the pioneer spirit, men who are willing to sacrifice something to gain an end; men with loves and men with hates. Bad men there are there, some of them hunted from Eastern communities, perhaps, but you will find no fools and mighty few weak faces—there's character in every feature you look at.

Every one is there for a purpose, to accomplish something; to get ahead in the world, to make a new start; perhaps to live down something or to get out of the rut cut by ancestors; some may only want to drink, and shout, and shoot, but even these do it with a vim—they mean it.

Of the many men who ran engines at the front on the Santa Fé with me, I recall few whose lives were purposeless; almost every one had a life-story.

If there is anything that I enjoy it's to sit down to a pipe and a life-story—told by the subject itself. How many I have listened to out there, and every one of them worthy the pen of a Kipling.

The population of the frontier is never all made up of men, and the women all have strong features, too—self-sacrifice, devotion, degradation or *something* is written on every face. There's no blanks in that lottery—there's no material there for homes of feeble-minded.

It isn't strange, either, when you come to think of it, fools never go anywhere, they are just born and raised. If they move it's because they are "took"—you never heard of a pioneer fool.

One of the strongest characters I ever knew was a runner out there by the name of Gunderson—Oscar Gunderson. He was of Swedish parentage, very light-complexioned, very large, and a splendid mechanic, as Swedes are apt to be when they try. Gunderson's name was, I suppose, properly entered on the company's time-book, but it never was in the nomenclature of the road. With the railroaders' gift for abbreviation and nickname, Gunderson soon came down to "Gun," his size, head, hand or heart furnished the prefix of "Big," and "Big Gun" he remains to-day, Big Gun among his friends, but simple Gun to me. I think I called him Gun from the start.

Gun ran himself as he did his engine, exercised the same care of himself, and always talked engine about his own anatomy, clothes, food and drink

His hat was always referred to as his "dome casing," his Brotherhood pin was the "number plate," his coat was the "jacket," his legs the "drivers," his hands the "pins," arms were "side-rods," stomach "firebox," and his mouth the "pop".

He invariably referred to a missing suspender button as a "broken spring hanger," to a limp as a "flat-wheel," he "fired up" when eating; he "took water" the same as the engine; and "oiled 'round" when he tasted whisky.

Gun knew all the slang and shop-talk of the road and used it—was even accused of inventing much of it—but his engine-talk was unique and inimitable.

We roomed together a whole winter, and often, after I had gone to bed, Gun would come in, and as he peeled off his clothes, he would deliver himself something as follows

"Say, John, you don't know who I met on the up trip? Well, sir, Dock Taggert. I was sailin' along up the main line near Bob's an' who should I see but Dock backed in on the sidin'—seemed kinder dilapitated, like he was runnin' on one side. I jest slammed on the wind and went over and shook. Dock looks pretty tough, John—must have been out surfacing track, ain't been wiped in Lord-knows-when, oiled a good 'eal but narry a wipe, jacket rusted and streaked, tire double flanged, valves blowin', packing down, don't seem to steam, maybe's had poor coal, or is all limed up. He's got to get through the back shop 'fore the old man 'll ever let him into the roundhouse. I set his packin' out and put him in a stall at the grays' corrall, hope he'll brace up. Dock's a mighty good workin' scrap if you could only get him to carryin' his water right; if he'd come down to three gauges he'd be a dandy, but this tryin' to run first section with a flutter in the stack all the time is no good—he must 'a flagged in."

Which being translated into English, would convey the information that Gun had seen one of the old ex-engineers in Bob Slatterly's saloon, had stopped and greeted him. Dock looked like he had walked, had drank, was dirty, coat had holes, soles of his shoes badly worn, wheezing, seemed hungry and lifeless, been eating poor food, and was in a general run-down condition Gun had "set out his packing" by feeding him and put him in a bed at the Grand Central Hotel—nicknamed the graybacks' corrall. Gun thought he would have to reform before the M. M would put him into active service. He was a good engineer, but drank too much, and, lastly, he was in so bad a condition that he could not get himself into headquarters but some one helped him by "flagging for him."

Gun was a bachelor; he came to us from the Pacific side, and told me once that he first went West on account of a woman, but—begging Mr. Kipling's pardon—that's another story.

"I don't think I'd care to double-crew my mill," Gun would say when the conversation turned to matrimony. "I've been raised to keep your own engine and take care of it, and pull what you could. In double-heading there is always a row as to who ought to go ahead and enjoy the scenery or stay behind and eat cinders."

I knew from the first that Gun had a story to tell if he'd only give it up, and, I fear, I often led up to it with a hope that he would tell it to me—but he never did.

My big friend sent a sum of money away every month, I supposed to some relative, until one day I picked up from the floor a folded paper, dirty from having been carried long in Gun's pocket, and found a receipt. It read:

"Mission, San Antonio, Jan. 1, 1878.

"Received of O. Gunderson, for Mabel Rogers, $40.00. Sister Theresa."

Ah, a little girl in the story, I thought, it's a sad story then. There's nothing so pure and beautiful and sweet and joyous as a little girl, yet when a little girl has a story it's almost always a sad story.

I gave Gun the paper, he thanked me, said he must look out better for those receipts and added that he was educating a bit of a girl out on the coast.

"Yours, Gun?" I asked kindly.

"No, John, she ain't, I'd give $5,000 if she was."

He looked at me straight with that clear blue eye, and I knew he told me the truth.

"How old is she?" I asked.

"I don't know—'bout five or six."

"Ever seen her?"

"No."

"Where did you get her?"

"Ain't had her."

"Tell me about her?"

"She was willed to me, John, kinder put in extra, but I can't tell you her story now, partly because I don't know it all myself, and partly because I won't — I won't even tell her."

I did not again refer to Gun's little girl, and soon other experience and other autobiographies crowded the story out of my mind.

One evening in the spring I sat by the open window enjoying the cool night breeze from off the mountains, when I heard Gun's cheery voice on the porch below. He was lecturing his fireman in his own unique way

"Well, Jim, if I ain't ashamed of you there ain't no one; coming into general headquarters with a flutter in the stack, so full that you can't whistle, air pump a-squealing 'count of water, smeared from stack to man-hole, head-light smoked and glimmery, don't know your own rights, kind o' running wildcat, without proper signals, imagining your first one with a regardless order.

"You want to blow out, man, and trim up, get your packing set out and carry less juice. You're worse than one of their slippin', dancing, three-legged no-good Grants. The next time I catch you at high-tide I'll scrap you, that's what I'll do, fire you into the scrap-pile.

"Why can't you use some judgment in your runnin'? Why can't you say, 'Why, here's the town of Whisky, I'm going to stop there and oil around,' sail right into town, put the air on steady and fine, bring her right down to the proper gait, throw her into full release so as to just stop right, shut off your squirt, drop a little oil on the worst points, ring your bell and sail on.

"But you, why you come into town forty miles an hour, jam on the emergency and while the passengers pick 'emselves out of the ends of the cars you go into the supply house and leave the injector on, an' then when you go to move you're too full to move without opening your cylinder-cocks and givin' yourself dead away.

"Now I'm goin' to Californ. next month and if you get so as you can tell when you've got enough liquor without waiting for it to break your injectors, I'll ask the old man to let you finger the plug on the Esmeralda whilst I'm gone. But I'm dambed if I don't feel as if you was like that measly old 19—jest fit to be jacked up and saw wood."

While Gun was in California I was taken home on a requisition from Mrs. A. and Oscar Gunderson and his little girl became a memory—a page in a book that I had partly read and lost, but not entirely forgotten.

Last month I took the west-bound express at Topeka, and spreading my grip, hat, coat and umbrella, out on the seats, so as to resemble an experienced English tourist, I fished up a Wheeling stoga and a book and went into the smoking-pen of the sleeper, and had it all to myself for half an hour.

The train stopped to give the thirsty tender a drink and a man came in to wash his hands. He had been riding on the engine.

After washing he stepped to the door of the "smokery," struck a match on the leg of his pants, held both hands around the end of his cigar while he lighted it, then waving the match to put it out, he threw it down and came in.

While he was absorbed in all this I took a glance at him. Six-foot-four if an inch, high cheek bones, yellow beard, clear blue eyes, white skin, and a hand about the size of a Cincinnati ham. I knew that face despite twelve years of turkey-tracks about the eyes.

"Gunderson, old man, how are you?" I said, offering my fin.

"Well, John Alexander, how in the name o' thunder did you get away out here on the main stem without orders?"

"Inspection car," said I, "how'd you get here?"

"Deadheading home, been out on special, a gilt-edged special, took her clean through to New York."

"You did!" I exclaimed, "why, how was that?"

"Went up special to a weddin', don't you see? Went up to see a new compound start off—prettiest sight I ever see—working smooth as grease, but I'm kinder dubious about repairs and general running. I'm anxious to see how the performance sheet looks at the end of the year, John."

"Who's been double-heading, Gun?"

"Why—why, my little girl, trimmest, neatest, slickest little mill you ever saw. Lord, but she was painted red and white and gold leaf, three brass bands on her stack, solid nickel trimming, all the latest improvements, corrugated firebox, high pressure, smoke-consumer, and sand jet—jest made a purpose for specials and pay car. But if she ain't got herself coupled on to a long fireboxed ten-wheeler, with a big lap and a Joy gear, you can put me down for clinker. Yes, sir, the baby is a heart-breaker on dress parade, and the ten-wheeler is a whale on business, and if they don't jump the track, you watch out for some express speed that will make the canals sick, see if they don't"

Without giving me time to say a word he was off again.

"You ought to have seen 'em start out, nary a slip, cutting off square as a die, small one ahead speaking her little piece chipper and fast on account of her smaller wheels, and the ten-wheeler barking bass, steady as a clock, with 180 on the gauge, a full throttle, and half a pipe of sand. You couldn't tell to save you whether the little one was pulling the big one or the big one shoving the little—never saw a relief train start out in such shape in my life"

Gunderson was evidently enthusiastic over the marriage of his little girl.

We talked over old times and the changes, and followed each other up to date with a great deal of mutual enjoyment, until the porter demanded the "smokery" for his bunk.

As we started for bed Gun laid his hand on my shoulder and said

"John, a good many years ago you asked me to tell you the story of my little girl. I refused then, for her sake. I'll tell you in the morning"

After a hearty breakfast and a good cigar Gunderson squared himself for the story. He shut his eyes for a few minutes as if to recall something, and then, speaking as if to himself, he said

"Well, sir, there wasn't a simmer anywhere, dampers all shut; you wouldn't a-suspected they was up to popping point, but the minute they got their orders and the con. put up his hand, so, up went—"

"Say," I interrupted. "I thought I was to have the story. I believe you told me about the wedding last night. The young couple started out well."

"Oh, yes, old man, I forgot, the story, well get on the next pit here," motioning to a seat next him, "and I'll give you the history of an old hook-motion, name of Oscar Gunderson, and a trim "Class G" made of solid silver from pilot to draft gear.

"You think I'm a Swede, well I ain't, I don't know what I am, but I guess I come nearer to being a Chinaman than anything else. My father was a sea captain and my mother found me on the China Sea—but they were both Swedes just the same I had two sisters older than myself, and in order to better our chances father removed to New York when I was less than five years old

"He soon secured work as captain on a steamer in the Cuban trade and died at sea when I was ten.

"I had a bent for machinery and tried the old machine shops of the Central road, but soon found myself firing

"I went to California shortly after the war on account of a woman—mostly my fault.

"Well, after running around there for some years, I struck a job on the Virginia & Truckee in '73.

"Virginia City and Carson and all the Nevada towns were doing a full rush business, turning every wheel they had, with three crews to a mill. Why, if you'd go down town in any one of them at night, and see the crowds around the gamblers and molls, you'd think hell was a-coming

## SHOEN MANUFACTURING COMPANY,

MANUFACTURERS OF

## Articles in Pressed Steel for Railways and Car Construction.

Made to Interchange with any Standard.

**Office & Works, PITTSBURGH, Pa.**

Western Office, 814 Phenix Building, Chicago.

**Pressed Steel Drawbar Attachment.**

Our Pressed Steel Drawbar Attachment commends itself to all for its simplicity and strength.

**Pressed Steel Stake Pockets.**

*For Gondola, Flat and Coal Cars.*

No change whatever is necessary in substituting steel pockets for cast iron, as we make them to interchange in bolt-hole centers and inside dimensions.

**Pressed Steel Corner Bands.**

*For Gondola and Box Cars.*

Our Pressed Steel Corner Bands, as shown in cut, are heavily embossed. The inside corner bands are ribbed the opposite way so that they may lay flat against the timber. Besides being very strong, they add materially to the appearance of the car. At about the same cost as common wrought iron bands.

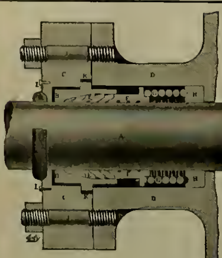
**Pressed Steel Center Plates.**

Made to interchange with present standard.

By the use of our articles the weight of your car will be decreased from 800 to 1,200 lbs. The cost of repairs reduced to a minimum. All without material increase in cost of construction. We will be pleased to give full information and quote prices upon application.

---

## JEROME METALLIC PACKING.



STANDARD.

This Packing is the Standard Metallic Packing all over the world and is now more generally adopted and in use on more Locomotives than any Metallic Packing in use. Give the JEROME a trial and be convinced. Put it in competition with any other Packing and be convinced of its superior merits.

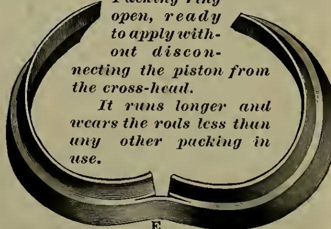
OFFICE AND WORKS:

**Nos. 35 & 37 South Canal St., Chicago, Ill.**

**C. C. JEROME,**

Inventor and Proprietor.

SEND FOR CATALOGUE



*Packing ring open, ready to apply without disconnecting the piston from the cross-head.*

*It runs longer and wears the rods less than any other packing in use.*

---

**GOULD & EBERHARDT, Newark, N. J.**

Builders of Machine Tools for Railroad Shops.

SHAPERS, PLANERS, DRILL PRESSES, LATHES.

12, 16, 20, 24, 26, 30-in. CUT REPRESENTS 16, 20, 24-in.

Notice the firm who will copy this first.

**FORREST SILVER BRONZE PACKING.**

Applied to any stuffing-box without disconnecting. Steam, air and water tight without the aid of soft packing under the highest steam pressure and piston velocity. Automatic, admits of excessive vibrations, lashing and crowding of rod, does not bind, economical, guaranteed to outlast all other packing. Used by the largest Iron Works, Steamships and Electric Light Companies for years all over the world.

Agents wanted everywhere.

[illegible]

115 Liberty St., N. Y.

A. CHIPMAN, Treas.

**GOULD'S STEAM and WATER PACKING**

(Patented June 1, 1880.)

Especially adapted for Locomotives. Never sticks the Throttle.

(The Original Ring Packing.)

In ordering give exact diameter of Stuffing Box and Valve Stem.

None genuine without this trade mark.

THE GOULD PACKING CO., East Cambridge, Mass.

**"TWENTY YEARS WITH THE INDICATOR,"**

By THOS. PRAY, Jr.

BRANCHES: New York, Chicago, and London, England.

forty-mile an hour, and that it wan't more than a car length away.

"Well, one morning I came into Virginia about breakfast time, and, with the rest of the crew, went up to the old California Chop-house for breakfast. This same chop-house was in a building about good enough for a stable these days, but it had a reputation then for steaks. All the gamblers eat there, and it's a safe rule to eat where the gamblers do in a frontier town if you want the best there is, regardless of price.

"It was early for the regular trade, and we had the dining-room mostly to ourselves for a few minutes, then there were four women folks came in and sat down at a table bearing a card, 'Reserved for Ladies.'

"Three of them were dressed loud, had signs out whereby any one could tell that they wouldn't be received into no Four Hundred, but one of them was a nice-looking, modestly dressed woman, had on half mourning if I remember. She had one of them sweet, strong faces, John, like the nun when I had my arm broke and was scalded, her sweet mouth kept mumblin' prayers but her fingers held an artery shut that was trying its damdest to pump Gun Gunderson's old heart dry—strong character, you bet.

"Well, that woman sat facing our table and kept looking at me; I couldn't see her without turning, but I knew she was looking. John, did you ever notice that you could *feel* the presence of some people; you knew they were near you without seeing them? Well, when that happens, don't forget to give that fellow due credit; for whoever it is, they have the strongest mind—the dominant one.

"I *had* to look around at that woman. I shall never forget how she looked; her hand was on the side of her face, her great, brown, tender eyes were staring right at me—she was reading my very soul. I let her read.

"I had been jacking up a gilly of a gafter who had referred to his mother as 'the old woman,' and I didn't let the four females disturb me. I meant to hold up a looking-glass for that young whelp to look into. I hate a man that don't love his mother.

"'Why,' says I, 'you miserable example of divine carelessness, do you know what that "old woman" mother has done for you, you drivellin' idiot, a thankin' God that you're alive and forgetting the very mother that raised you; if you could see the tears she has shed, if you could count the sleepless nights that she has put in, the heartaches, the pain, the privation that she has humbly, silently, even thankfully borne that you might simply live, you'd squander your last cent to make her life a joy from this day till her light goes out. A man that don't respect his mother is lost to all decency; a man who will hear her name belittled is a Judas, and a man that will call his mother "old woman" is a no-good, low-down, misbehaven whelp. Why, damn it, I'd fight a buzz-saw if it called my mother "old woman"—and she's been dead a long time; gone to that special, exalted, gilt-edged and glorious heaven for mothers. No one but mothers have a right to expect to go to a heaven, and the only question that'll be asked there is, "Have you been a mother?"

"Well, sir, them women clapped their hands; I looked around, and there were tears in the eyes of that one woman.

"She got up, came over to our table, laid a card by my plate, and said: 'I beg your pardon, but call on me, do.'

"I was completely knocked out, but told her I would, and she went out alone; the others finished their breakfast.

"She had no sooner gone than Cy Nash, my con., commenced to giggle—'Made a mash on the flyest woman in town,' he tittered, 'ain't a blood in town but what would give his head for your boots, old man, that's Mabel Verne—owns the Odeon dance hall and the Tontine in Carson.'

"I glanced at the card, and it did read, 'Miss Mabel Verne, 21 Flood avenue.'

"'Well, Flood avenue is no slouch of a street, the best folks live there,' I answered.

"'Yes, that's her private residence, and if you go there, and are let in, you'd be the first man ever seen around there. She's a curious critter, never rides or drives, or shows herself off at all; but you bet she sees that the rest of the stock show off. She's in it for money, I tell you.'

"I don't know how, but it made me kind o' heart-sick to think of the hell that woman must be in, for I knew by her looks that she had a heart and a brain, and that neither of them was in the Odeon or the Tontine dance-house.

"I thought the matter over, and didn't go to see her. The next trip, she sent a carriage for me.

"She met me at the door, and took my hat, and, as I dropped into an easy chair, I opened the ball to the effect that 'this here was a strange proceeding for a lady.'

"'Yes,' said she, sitting down square in front of me, 'it is; I felt as if I had found a true man when I first saw you, and I have asked you here to tell you a story, my story, and ask your help and advice. I am so earnest, so anxious to do thoroughly what I have undertaken, that I fear to overdo it; I need counsel, restraint; I can trust you. Won't you help me?'

"'If I can. What is it you want me to do, madam?'

"'First of all, keep a secret, and next, protect, or help protect, an innocent child.'

"'Suppose I help the child, and you don't tell me the secret?'

"'No, it concerns her, the child, sir; she is my child; I want her to grow up without knowing what her mother has done, or how she has lived and suffered, you wouldn't tell her that, would you?'

"'No, certainly not.'

"'Nor anyone else?'

"'No.'

"'You would judge her alone—forgetting her mother?'

"'Yes.'

"'Then I will tell you the story.'

"She got up and changed the window blinds, so that the light shone on my face, I guess she wanted to study the effect of her words.

"'I was born at Sacramento,' she began; 'my father was a well-to-do mechanic, and I his only child; I grew up pretty fair looking, and my parents spent about all they could make to complete my education, especially in music, of which I was fond. When I was eighteen years old I fell in love with a young man, the son of one of the rich merchants of San Francisco, where we had removed. Like many another foolish girl, I trusted too implicitly and believed too easily, and soon found myself in a humiliating position, but trusted to the honor of my lover to stand by me.

"'When I explained matters to him he seemed pleased, said he could fix that easy enough; we would get married at once and claim a secret marriage for some months past.

"'He arranged that I should meet him the next evening, and go to an old priest in an obscure parish and be married.

"'I stood long hours on a corner, half dead with fear, that night, for a lover that never came. He's dead now, got run over in Oakland yard, that very night, as he was running away from me, and as I waited and shivered under the stars and the fire of my own conscience.'

"'Did he stand on one track to get out of the way of another train and get struck?' I asked.

"'Yes,' looking at me close.

"'Did he have on a false moustache, and a good deal of money and securities in a satchel and everybody think at first he was a burglar?'

"'Yes, but how did you know that?'

"'Because I killed him.'

"'You!'

"'Yes. I ran an engine over him, couldn't make him hear or see me. He was the first man I ever killed; strange he should be *this* particular man.'

"'It's fate,' said the woman, rocking slowly back and forth, 'it's fate, but it seems I like you better now you were my avenger, that accident drove revenge out of my heart, caused me to let *him* be forgotten, and to live for my child. I have lived for her. I live to-day for her and I will continue to live for her.

"'My disgrace killed my mother and ruined my father. I swore I would be an honest woman, and I sought employment to earn a living for my babe and myself, but every avenue was closed to me. I washed and scrubbed while I was able to teach music splendidly, but I could get no chance. I made shirts for a pittance and daily refused, to me, fortunes, for dishonor. I have gone hungry and almost naked to pay for my baby's board, but I was hunted down at last.

"'One day, after many rebuffs in seeking employment, I went to the home of a sister of my child's father, and took the baby, told her who I was and asked her to help me to a chance to work. The good woman scarcely looked at me or the child; she said that had it not been for such as I poor Charles would have been alive, his blood was on my head, I ought to ask God to wash my blood-stained hands.

"'I went away from that house with my mind made up what to do. I would put my child in honest hands, and chain myself to the stake to suffer everlasting damnation for her sweet sake.

"'She is in the Mission San Antonio now, between three and four, a perfect little princess, she looks like me, and grows, oh, so lovely. If you could see her you'd love her.

"'I can't go to see her any more; she is old enough to remember. The last time I was there she demanded a papa.

"'I am making a great deal of money. Many of the rich men, whose Puritan wives and daughters refused me honest work, are squandering lots of their wealth in my houses. I am saving money, too, and propose as soon as I get a neat fortune together to go away to the ends of the earth, and have my little girl with me. I will raise her to know herself and to know mankind.'

"'And what do you want me to do, madam?'

"'I want you to be that child's guardian, the honest man through whom she will reach the outside of San Antonio and the world. Who will go between me and her until a happier time.'

"'I am only a rough engineer; the child will be raised to consider herself well off, perhaps rich.'

"'Adopt her. I will stay in the background, make her expenditures and her education what you like. I will trust you.'

"'I can't do that.'

"'You are single, your life is hard, I have money enough for us all. Let us go to the Sandwich Islands, anywhere, and commence life anew. The little one will know no other father, and all inquiry will be stopped.'

"'I couldn't think of it, my dear madam, it's too easy; it's like pulling jerkwater passenger—I like through freight.'

"Well, John, to make a long story short, the interview ended about here, and several more get to about the same place. There were a thousand things I could not help but admire in that woman, and I liked her better the more I knew her. But it wan't love, it was sort of an admiration for her love of the child and the nerve she displayed in its behalf. But I shrank from becoming her husband or companion, although I think she loved me, in the end, better than she ever did anybody.

"However, I finally agreed to look after the little one in case anything happened to her, the mother, and commenced then to send the money for her board and tuition, and the mother dropped out of all connection with the child or those having her in charge.

"The mother made her pile and got out of the business, and at my suggestion went down near Los Angeles and bought a nice country place, to start respectable before she took the little one home. She left money in Carson, subject to my check, for the little girl, and things slid along for a year or so all smooth enough.

"I was out on a snow bucking expedition one time the next winter, sleeping in cars, shanties or the engine, and I soon found myself all buggered up with the worse dose of rheumatiz you ever see. I had to get down to a lower altitude, and made for Sacramento in the spring. I paid the mission a year in advance, and with less than a hundred dollars of my own, struck out, hoping to dodge the twists that were in my bones.

"A hundred blind gaskets don't go far when you're sick, and the first thing I knew I was dead broke, couldn't pay my board, couldn't buy medicine, couldn't walk—nothing but think and suffer. I finally had to go to a hospital. Not one of the old gang ever came to see me. Old Gun was a dandy when he was making—and spending—a couple hundred a month; the rest of the time he was supposed to be dead.

"I might have died in the hospital, if fate hadn't decreed to send me relief. It suddenly dawned upon me that I was getting far better treatment than usual, had a special nurse, the best of food, flowers, etc., all labeled "From the boys."

"I found out, after I was well enough to take a sun bath on the porch, that a woman had sent all my luxuries, and that her purse had been opened for my relief. I knew who it was at once, and was anxious to get well and at work, so as not to live on one who was only too glad to do everything for me.

"A six months' wrastle with the twisters leaves a fellow stiff-jointed and oldish, and laying in bed takes the strength out of him. I took a notion to get out and go to work one day, and walked down to the shops—I was carried back, chuck full of 'em again.

"The doctor said I must go to Ojo Caliente, away down south, if I was to get well. John, if the Santa Fé road had a-been for sale for a cent then I couldn't a-bought a spike.

"At about the height of my ill-luck I got a letter from Mabel Verne—she had another name, but that don't matter—and she asked me again to come to her, to have a home, and care and devotion. It wasn't a love-sick letter, but it was one of them strong, tender, *fetching* letters. It was unselfish, it asked very little of me and offered a good deal.

"I thought over it all night, and decided at last to go. What better was I than this woman? Surely she was better educated, better bred. She had made one mistake, I had made many. She had no friends on earth, I didn't seem to have any either. I hadn't had a letter from either of my married sisters for six or eight years then. We could trust one another and have an object in life in the education of the child. I'd be no worse off than I was, anyway.

"The next morning I felt better. I got ready to leave, bid all my fellow flat-wheels good bye, and had a gig ordered to take me to the train—the doctor had given me two hundred dollars a short time before, 'from a lady friend.'

"As I sat waiting for the hack, they brought me a letter from home—a big one with a picture in it. It was from my youngest sister, and the picture was of her six-year boy, named for me—such a happy, sunny little Swede face you never see. 'He always talks of Uncle Oscar as a great and good man,' wrote Carrie, 'and says every day that he's going to do just like you. He will do nothing that we tell him Uncle Oscar would not like, and anything that he would. If you are as good as he thinks you are you are sure of heaven.'

"And I was even then going off to live with a woman who made a fortune out of Virginia City dance houses. I had a sort of a remorseful chill, and before I really knew just where I was I had got to Arizona, and from there went to the Santa Fé where you knew me.

"I wrote my benefactress an honest letter, and told her why I had not come, and in a

short time sent her the money she had put up for me; but it was returned again, and I sent it to the mission for my little girl.

"Well, while I was with you there I got a fare-thee-well letter, saying that when I got that Mabel Verne would be no more—same as dead—and that she had deposited forty thousand dollars in the Phœnix Bank for *your* little girl — *yours*, mind ye — and asked me to adopt her legally and tell her her mother was dead.

"John, I ain't heard of that woman from then till now. I thought she had got tired of waiting on me and got married, but I believe she is dead.

"I went to California, adopted the baby —a daisy too—and I've honestly tried to be a father to her.

"I got to making money in outside speculations, and had plenty, so I let her money accumulate at the Phœnix and paid her way myself.

"About four years ago I left the road for good, bought me a nice place just out of Oakland, and settled down to take a little comfort.

"Mabel, my daughter Mabel, for she called me papa, went to Germany nearly three years ago in charge of her music teacher, Sister Florence, to finish herself off. Ah, John, you o'rt to see her claw ivory. Before she went she called me into the mission parlor one day and almost got me into a snap; she wanted me to tell her all about her parents right then, and asked me if there wasn't some mystery about her birth, and the way she happened to be left in the mission all her life, her mother disappearing, and my adoption of her."

"What did you tell her, Gun?" I asked.

"Why, lied to her, of course, as any honorable man would have done. I told her that her father was an engineer, and a friend of mine, and that he was killed in an accident before she was born—that was all plausible enough.

"Then I told her that her mother was in poor health and had died just before I had adopted her, and had left a will giving her to me, and beside had left forty thousand dollars in the bank for her when she married or became of age.

"Well, John, cutting down short, she met a fellow over there, a New Yorker, that jest seemed to think she was made a-purpose for him, and about a year ago he wrote and asked me for my daughter—think of it. His petition was seconded by the baby herself, and recommended by Sister Florence.

"They came home six months ago, and the baby got ready for dress parade, and Sister Florence and I went down to New York and seen 'em off; but here's where old Fate gets in his work again. That rascal of an O. B. Sanderson—I didn't notice the name before — was my own nephew, the very young cuss whose picture kept me from marryin' the baby's mother. I never tumbled till I ran across his mother, she was my sister Carrie.

"John, I don't care a Continental cuss how good he was, the baby was good enough for him—too good—I just said nothing and watched the signals. You or't to a seen me a-givin' the bride away. Then, when it was all over and I was childless, I give the bride a check for forty-seven thousand and a fraction, kissed her, and lit out for home—and here I am.

"But I ain't satisfied now, and just as quick as I get back, I'm a going running again, then, when I get so old I can't see more'n a car length, I'm going to ask for a steam-pump to run. I'm a going to die a railroading."

"Have you ever made any inquiries about the mother, Gun?" I asked.

"No, not much, it's so long now 'taint no use, I guess that her light's gone out."

"What would you do if she was to turn up?"

"Well, I don't know; I guess I'd keep still and see what she done."

"Suppose, Gun, that she showed up now, loved you more than ever for what you have done, and renewed her old proposal? You know it's leap year."

"Well, old man, if an angel flew down out of the sky and give me a second-hand pair of wings, and ordered me to put 'em on and follow her, I guess I wouldn't refuse to go out. Time was, though, when I'd a held out for new, gold-mounted ones or nothing; but that won't come, John; but you just or't to a been to the consolidation, it was just simply—well, pulling the president's special would be just like hauling gravel train to it."

The train stopped suddenly here, and Gun said he was going ahead to get acquainted with the water-boiler, and I took out my note-book and jotted down a few points.

After the train got into motion again, I was reading over my notes, when, without looking, I thought Gunderson had come back, and I moved along in the seat to give him room, but a black dress sat down beside me.

We had been sitting with our backs to a curtain between the first berth and a state-room. The lady came from the state-room.

"Pardon me, sir," she said; "I want to finish that story. I have heard it all; I am Sister Florence, music teacher to Mr. Gunderson's daughter; he does not know that I am on this train.

"Mr. Gunderson did not tell you that the Phœnix Bank failed some months ago, and that the fortune of his adopted child was lost. He never told her, and she does not know it to-day ——"

"He said he paid her the full amount," I interrupted.

"Very true. He did. But he paid it out of his own pocket. Sold his farm, put up all his securities, and borrowed seven hundred dollars to make the sum complete. That is the reason he is going to run an engine again. He does not know that I am aware of this, so don't mention it to him."

"Gun is a man," said I, "a great, big-hearted, true man!"

"He is a nobleman!" said the nun, arising and going back into the state-room.

Half an hour later Gunderson came back, took a seat beside me, and commenced to talk.

"Say, John, that's the hardest riding old pelter I ever see, about three inches of slack between engine and tank, pounding like a stamp-mill and ——," looking over his shoulder, then at me, "John, I could a swore there was some one standing right there, I *felt* 'em."

"It seems to me they or't to keep up their engines here in pretty good shape. They've got bad water, and so much boiler-work that they have to have new flues before the machinery gets worn much. But, Lord, they don't seem ——" he looked over his shoulder again, quickly, then settled in his seat to resume, when the door of the state-room opened softly and a pair of hands covered Gun's eyes—the nun's hands.

"Guess who it is Gun?" said I, and noticed that he was very pale.

"It's Mabel," said he, putting up his hands and taking both of hers, "no one but her ever made me feel like that."

---

Mr. Charles M. Raymond, a young man who had the good sense to learn the details of iron-rolling right at the rolls, after coming out of college, has been placed in charge of the Cambria Iron Company's new 26-in. billet mill, at Johnstown, Pa. Few young men of twenty-two get a chance like this.

---

At a point in New Brunswick we lately examined a locomotive built by a firm in Manchester which is almost an exact copy of the old form of Baldwin straight-boiler eight-wheel engines. English builders seldom make cast iron wheels of any kind, but this engine has cast iron driving wheel centers and chilled wheels in truck and tender. The boiler is of steel, and is evidently too hard, for one of the sheets blew out, and the metal is said to be so hard that it could be tempered. The fire-box sheets are also said to be very hard and given to cracking, although the water used makes no incrustation to cause overheating.

## When Does it Pay to Destroy a Locomotive.

By A. Doibeer.

The question of what is the profitable age that a locomotive can be maintained to, is one over which opinions differ. There are railroads that are prominent and profitable that have locomotives in service that are twenty-five years old. There are other roads that have destroyed engines that were less than twelve years old.

We must bear in mind that the condition of a locomotive rather than its age should be the pivot upon which rests the proposition of whether it is policy to consign it to the scrap pile, or by repairs continue it in service.

We must bear in mind that the capacity of rolling stock has increased two-fold within the past fifteen or twenty years. Twenty years ago we stood in the yard of a prominent railroad, and saw a train of new cars, each loaded with fifteen tons of coal. There have for several years past been many cars with double that load passing over the road. Many car builders claimed and still claim that this load is excessive, but still the capacity is increasing.

So with locomotives. We remember when a locomotive of 60,000 lbs weight, with cylinders 16x24, was considered large. To-day few freight engines are built of less than 100,000 lbs. weight and with cylinders less than 19x24, while many are in use of 120,000 lbs. weight and 20x24 cylinders.

We speak of this simply to illustrate that the advancement and changes of railroads and their equipment will to a great extent enter into the question of economy of maintaining engines that were built fifteen or twenty years ago. The Pennsylvania Railroad fifteen years ago began the process of destruction of its old power, yet, last year, we saw upon this road an engine that was over twenty years old. We recognized it at once as an old-time acquaintance. This engine, while not so heavy as one of the modern type, was equipped with 20x24 cylinders. This road, which, we believe, was the pioneer in the destruction of old power, was using engines older than many newer ones which had years before been destroyed.

You cannot consider this question from a motive-power standpoint exclusively, but let us see how it stands as far as that department is concerned.

Let us take an engine that has been in active service hauling freight for twelve years past. This engine comes to shop and you look it over, and find the engine will have to receive new firebox and one flue-sheet, new cab, cylinders, tender-cistern, and tires. At same time you will apply air-pump and driver-brakes, and very likely apply some new driving-axles. This engine will cost for these repairs $3,000. While these repairs are going on you watch things carefully. The boiler is swung out of frames, and after flues are out and inside of boiler is cleaned, you find things you do not like. Your boiler-maker calls your attention to the fact that one sheet in the boiler looks bad, thin in some places, and in another, narrow, longitudinal grooves worn in sheet. However, you feel that the boiler is safe after it stands the hydraulic pressure. Your firebox is put in, and you look with some pride upon the work that has been done, but that boiler-maker of yours will probably spoil your good feeling, which is enough to commend him for doing a good job, by remarking. "Yes, it's a good job, but that throat-sheet—" Then he will wag his head. "Well, what's the matter with that—isn't that all right?" "Yes, it is all right for a while," is his answer, "but it is only going to be a short time before that will have to be renewed." You leave the boiler and go over into the blacksmith-shop, where one of the frames is being straightened, and you find them interviewing a crack that had developed by getting the frame hot. You have this remedied by welding, and instruct them to bring in the other frame and examine that. And so you go. Whichever way you turn the engine is showing weakness that was never dreamed of while in service, and you wonder whether your $3,000 estimate is going to hold out. Time goes on and the engine goes into service. We will say that it is satisfactory, and you are getting good service, and it runs without mishap for a year, or perhaps eighteen months, when the engine comes to shop for repairs. About the time this engine was turned out of shop a new engine was bought and put on the road. This engine comes into shop for repairs at same time. You look over the expenses during the past year, and you will find the engine which you had repaired so thoroughly, has cost a great deal more than the new one for running repairs. You give both engines the repairs they need, and find the cost of the new one $250, while upon the other engine you are lucky if it does not reach $1,000 or $1,200.

Now, let me ask my mechanical friends if we have stretched that little fable any? It don't happen to be a fable, it is a fact based upon actual experience. The next year when your engines come to the shop you will find that the one engine will cost about $600, the other will cost you at least $1,200.

We have been asked to prepare a table with estimated cost of repairs for eight (8) years to an engine that is twelve (12) years old and to one that is new. Below is the estimate. We invite criticism of it, fairly, fully and freely.

| | Eng. No. 1 (Old). | Interest. | Eng. No. 2 (New) | Interest |
|---|---|---|---|---|
| Value as scrap. | $800 | | | |
| Cost of repairs | 3,000 | | | |
| | $3,800 | | $9,000 | |
| First year | 1,000 | $100 | 250 | $450 00 |
| Second year | 1,200 | 240 | 600 | 462 50 |
| Third year | 1,500 | 300 | 1,000 | 492 50 |
| Fourth year | 3,000 | 375 | 1,400 | 542 50 |
| Fifth year | 2,000 | 525 | 1,500 | 642 50 |
| Sixth year | 2,000 | 625 | 1,600 | 707 50 |
| Seventh year | 2,500 | 725 | 1,800 | 787 50 |
| Eighth year | 2,500 | 850 | 2,000 | 877 50 |
| Total | $19,500 | $3,830 | $19,550 | $4,952 50 |

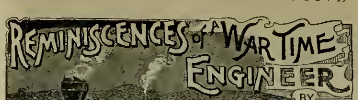
You find by this estimate that you have now one locomotive on your hands at the end of eight years that has, including its price, cost you $19,550. The older engine has cost you $18,700 for repairs alone. Had you sold the older engine eight years before you would have realized at least $800 for it, so that practically you have one engine eight years old and one twenty years old that, as far as your department is concerned, have cost you about the same. We have not lost sight of the fact that at the outset the company have invested $9,000, and that the interest of this amount during the eight years would amount to considerable, say $4,952 50, as against $3,830, the interest on cost of repairs to the old engine. Neither have we lost sight of the fact that your new engine has been hauling upon an average four more cars per train than the older engine. We are not prepared to say what the value of this additional service would amount to, but it would certainly be far in excess of amount of interest on the money invested.

It would be folly to say that an engine should run a certain number of years and then be destroyed, for some engines at fifteen years of age are worth more than others at eight. The condition and worth of the individual engines must decide that, but we do believe that many roads are maintaining engines that it would be economy to destroy. At the same time we wonder whether some engines are not destroyed that it would be economy to repair.

*Rochester, N. Y.*

---

Mr. Daniel Kiley, 12 Cooper street, Brooklyn, N. Y., has recently patented an improvement on balance valves. He provides a check-valve in the top of the slide-valve cavity, and another on the balance plate, these to relieve the engine of the pumping action when running down hill, and to prevent excessive wear on the strips and seat.



## Wrecking Under Difficulties.

Some time during the summer of 1864, while employed as engineer of the government wrecking train, and while laying over at Kingston, Ga., Colonel W. W. Wright, the military superintendent, came to me and wanted to know how many soldiers I would want, as guard, to go with me on the engine to find engine 44, John Maloney, engineer. This engine had been started from Kingston with a commissary train of supplies for Resaca. After leaving Kingston and passing Adairsville and Calhoun, nothing had been heard from her for several hours; so long that the superintendent had become anxious about the fate of the train.

I said to Colonel Wright that I was ready to go after the train, but did not want any guard of soldiers. That if, as he feared, there were guerrillas in the vicinity, they would be more likely to fire into a guard of soldiers than to fire on civilians. The Colonel was anxious to go with us, and I furnished him a civilian's suit, and we started, with orders to run to Resaca, regardless of all south-bound trains.

Arriving at Adairsville, we found Captain Dan Callahan with a company of the Third Indiana Cavalry, who informed us that he was almost sure there was a company of Carter's Bushwackers somewhere in the neighborhood, and that he feared they had captured the train. Between Adairsville and Calhoun the county road and the W. & A. R. R. runs parallel for some distance. Here we were jogging along about ten or twelve miles an hour, when I saw a squad of horseman approaching us. I slowed down, expecting to see them unsling their carbines or draw their revolvers and fire on us. Colonel Wright was sitting on the fireman's seat, the fireman standing in the tank, his arms resting on the tank-box; I was sitting on my seat and leaning out of the cab window; none of us made any move to duck or dodge so long as they let their carbines and revolvers remain as they were.

When close enough to be heard, the officer at the head of the squad hailed me with the remark that we could jog along, as what we were looking for was in the ditch near Doctor ——'s barn, but they were afraid to tackle the train, as it had too strong a guard for them, but that they would get some of us yet.

After leaving them, we ran along, keeping a good look-out for the track ahead. We passed Calhoun without stopping, and soon came upon a flagman who informed us that the engine had been blown off the track with a torpedo. This was made of cast iron, something like a jug, about ten inches in diameter by twelve inches high; the top had a plug screwed in it; through the plug there was a quarter-inch hole, for the purpose of putting a steel rod, on the end of which they placed a percussion cap, which rested on a nipple cast on the bottom of the bomb. This machine held about six or eight pounds of powder, and for the purpose for which it was invented was a success.

To place one in position for business, a hole was dug under the rails of the track, and the machine buried. The top of the steel rod touched the bottom of the rail, so that as soon as the weight of the engine struck it the pressure on the rod exploded the cap.

In the case of the "44," Maloney stated that the front of the engine was lifted into the air so high that she almost stood straight up. When we arrived at the wreck, we found the engine laying on her side down the bank, in Doctor ——'s barnyard, as the Guerrilla Captain had informed us. On the left of the road, going north, stood a large two-story white frame house belonging to Doctor ——.

I often wondered why it had not shared the fate of most such houses—been burned, being as it was directly in the track of our army, but I afterward learned that the old Doctor was a strong Union man.

After messages had been sent both ways we did what we could to clear the track, and the dispatcher started some trains North. The first to arrive was loaded with the Eleventh Indiana Infantry, going home on veteran furlough. Soon after their arrival some one told the soldiers that the train had been wrecked by the inmates of the house, and that the house ought to be burned. The inmates consisted of two little girls and their mother, none of whom were capable of wrecking the train. In those days soldiers did not need much urging to take vengeance on anything they thought would cripple the "Johnnies." So it was but a short time until the dwelling was in flames, in spite of the earnest protest of Colonel Wright and myself. Much of the furniture was saved, as were all the out-buildings. The government has since paid for the house, it being proven that the owner was loyal to the government. Captain Callahan and the squad of Carter's men had a lively brush the same day near Adairsville, the "Yank" getting the best of the "Johnnie."

Captain Callahan was before and after the war an engineer on the O. & M. R. R., running out of Seymour, Indiana. The trainmen of the railroads, especially the engineers and conductors, were well represented, and made good officers in the army. I could name a long list of them who did good service during the disturbance.

### The Old Timers.

I think the "General," of which Mr. Wesley writes, was not brought down to the main line. If she had been I would remember her. Until the government began sending engines from the North the principal make of engines in the service was Rogers, Moore & Richardson, a very few Danforth & Cooke and one or two Tredgar engines. The first engines sent south by the government were the Hercules and Jupiter, from the L. M. C. & X., eight-wheelers; there were two Niles ten-wheelers, from the three C.'s, the Bellefontaine, from the B. Line. They also sent several Memphis and Charleston engines to Chattanooga.

Nearly every builder in the country at that time had a government contract, Baldwin, Rogers, Cooke, Hinkley, Mason, Norris and the Fairbanks, Taunton. The Norris had defective boilers, and the Hinkleys would not make steam. I have seen a corporal's guard escorting engineers and firemen from their quarters to a Hinkley or a Norris engine, and in two instances knew engineers preferring imprisonment in the stockade to running Norris engines, the boilers of which had no stays in their domes.

The cut of the old Nashville depot and surroundings looks very natural. The piles of wood, the crossing-watchman's shanty and the old boiler, the row of engines and tenders appear like old friends. The U. S. on the rear of the tanks looks very natural, also the balloon stacks of the engines. About the time that picture was taken, John C. Maginis was general engine dispatcher, Harry Elliott was master mechanic, and the present master mechanic, James Cullen, of the N. C. & St. L., was foreman of the government shops at Nashville; at Stephenson, Ala., Asa Daniels, and at Chattanooga, Steve Hobbs, were the engine dispatchers for the N. C. & St. Louis; Ford was at Knoxville. Mr. Ford, previous to his being employed by the government, was master mechanic of the Michigan Central. He was suspended by A. S. Sweet, who was the party who placed the "Last Straw" on the back of the camel, the breaking of which hurried the organization of the old brotherhood of the footboard, of which W. D. Robinson was the founder.

James H Hevey

## McAdam Junction.

There are a good many towns in different parts of this country that have been created by railroads, and not a few others that depend principally on railroad men for existence, but we have never seen or heard of a place created and so thoroughly dependent upon railroads as McAdam Junction, N. B. When a traveler going from Boston to the maritime provinces of Canada has made up his mind from the scene outside the car window that he is not ambitious to be a land owner in northeastern Maine he enters New Brunswick and finds out that the poverty of the land keeps increasing. The climax appears to be reached about six miles across the line, where we find McAdam Junction.

A native brakeman whose acquaintance I made, indicated the condition of things without attempting a description.

"There appears to be a good crop of stones in this country," remarked the writer.

"Yes," said the brakeman, rather proudly. "I have fifty acres of land near here, and you can go over the whole of it without stepping off a stone."

It was in this region that a young man from New Jersey got married and was trying to make a living by farming. "Why, George," exclaimed his father, who had gone on a visit, "I never expected that a son of mine would ever settle in a place like this."

"I am not so bad off as you think," answered the son, "I don't own the land."

McAdam Junction, the Petrea of New Brunswick, is known to the world as the headquarters of the mechanical department of the New Brunswick Railway, now a part of the Canadian Pacific. No carriage road or even pathway goes to the town, and there is not a human habitation within twenty miles of the place on one side and six miles on the other. All the men in the place are engaged in railroad work except two storekeepers.

The shops at this point are required to do the work on all the rolling stock employed on about 700 miles of track. The shops are not well provided with appliances or conveniences for doing work, but "how to make the best of it" is the prevailing motto, and its influence effects wonders. Mr. George A. Haggerty, the master mechanic in charge here, is well known to many of our readers, for he has been on several roads in the United States. Mr. Haggerty holds a peculiar position in McAdam Junction, for he appears to be chief magistrate as well as master mechanic. We know of no other potentate so powerful in his domain. When he went to McAdam Junction there were eight saloons in the place. There are not any drinking places there now. There is no crime in the place, because, as George puts it, when any fellow comes in who does not want to obey the law we send him away.

The greater part of the locomotives that have headquarters at McAdam Junction are of odd makes, shapes and dimensions, owing to the New Brunswick Railway having absorbed numerous small roads. This makes repairs expensive, but good management keeps down the cost remarkably well. The machine tools are nearly all of English make, and are not nearly so powerful to take cuts as modern American tools. A fire destroyed the shops some years ago and all the tools had to be rebuilt by Mr. Haggerty. The work was done in excellent shape, and the repairs of engines and cars kept going at the same time. Only those who have gone through an experience of this kind can understand the difficulties to be encountered.

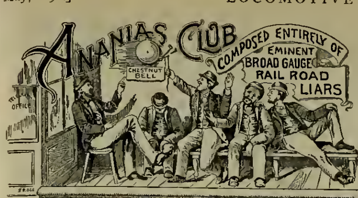
A very large volume of work is turned out of these shops, and it is due in a great measure to the orderly and systematic way in which everything is done. Many of the shops in Canada lead a visitor to think that an article of faith among those in charge is that no scrap heap is necessary so long as a shop is not full of litter. The shops at McAdam Junction are a notable contrast to the results of this policy. There appears to be a place for everything and everything in its place, while the scrap heap is the place for parts that are on the way to cupola or forge. His surroundings and the way that his business is conducted leads a visitor to the conclusion that, in spite of his being king of his city, Mr. Haggerty is greater than the place he fills.

## Cost of Cheap Cast Iron Wheels.

A correspondent lately asked us how it was possible to sell cast iron wheels for $8 each. In searching for the information we found in our note-book a communication, several years old, from a company making wheels, which says: "The average cost of charcoal pig iron used in casting car wheels is $26.50 a ton, from which four wheels can be cast. Old car wheels to the extent of 25 per cent. can be used, which proportion at $19 a ton, the present price, would bring the cost of the metal, unmelted—three-quarters charcoal pig iron, one-quarter old car wheels—to $24.62½ per ton. The item of labor in this amount is 90 per cent. of the whole. The labor, therefore, on the metal for one wheel, unmelted, would be one-quarter of 90 per cent. this cost of $24.62½, or $6.16, and this the wheel manufacturer pays out before the materials come to his mills. Then the items are as follows for one wheel Cost for melting, core drying, etc., 20 cents; sand, molds and cores, flour and facing, 15 cents; foundry labor of molding and casting, 85 cents; outside work, unloading pig iron, coal, etc., 10 cents; repairs, wear and tear, taxes, insurance, motive power and delivery charges consume 40 cents more, and the cost is $7.86, leaving the company just 14 cents profit on each wheel."

This does not indicate that there is much temptation for capitalists to embark in the business of making cast iron wheels.

George E. Bell, West Somerville, Mass., has received a patent for what is called a "smoke conveyer" for locomotives. The smoke conveyer is an arrangement of pipes that extends the smokestack to the back end of the train. This is one of the most persistent inventions of our acquaintance, and has kept bobbing up periodically ever since people began to complain of annoyance from smoke and cinders.



## After the Wrong Crew.

"I heered a good one on old Kernal Ricker," said the old timer, as the Boies wheel-man stopped at the end of a "whopper." "It's a good 'un," smiled the old timer, "just like the Kernal.

"You know how he will stop and talk to a feller on a train, or on the grade; he's always huntin' for p'ints about the road from the ground up.

"Well, jest after he went to the Iron Mountain, they say he took a ride over one of the Southern branches on the regular train—sorter half *incog.*, you know.

"Well, things was not runnin' the smoothest, delays were grevious, and fact o' the matter was it wan't much like railroadin'; real railroadin'.

"The longer the Kernal set in that car the madder he got—you know that when he turns loose a kussin', old Cappen Kidd ain't nowheres.

"Well, they was a long wait and a lot of poundin' of couplers, and slakkin' ahead an' slakkin' back, an' hollerin' and swinging lamps before a start was made.

"Jest as the train started a feller in blue clothes and cap come in, shut the stove door, sort o' authority-like, and set down behind the door—the Kernal riz up and went and set down by him.

"'What'en the blue-blazes is the matter out there?' he ast.

"'Cuddent find a small pin for one of them pattent shakkle-bars,' sais the man.

"'Whyinthe h——l don't you keep pins in the baggage car?' ast the Kernal, sassy-like.

"'Because, tain't my bizziness to——'

"'That's it, that's it tain't your bizziness, hey. You fellers are gettin' so all-fired dam partickler about what you do that there's no gittin' along with ye. Look at that lamp,' sais the Kernal, pointin' to a smoky lantern by the stove. 'Jest take an' look at it; when did you clean that lamp?'

"'That ain't my lamp, sir,' sais the man, kinder scared like, 'that belongs to the conductor.'

"'Well, dam a hind man that can't keep *both* lamps clean, you ain't cut out for this kinder work, you'd better go back farmin',' sais the Kernal, gettin' madder. 'No, no, don't commence to tell me who you air or how long ye've bin here. When you git in you'd better quit, and that dodrotted, lazy, no good, blunderin' jackass with a conductor's sign on him, wants to do better train runnin' than this, or by the bald-headed, jumped-up——'

"'Ah, my friend,' said the man, 'how about your soul?'

"The Kernal riz up to get a good full breath to scorch that feller up, when he noticed a red band on the man's cap which said 'Salvation Army.'"

## A Windy Division.

"Yes, it blows sometimes on the Mohawk division," acquiesced Nat Sawyer, on hearing one of the engineers in the New York Central roundhouse tell that trainmen in that part of the country frequently had their beards carried away by the wind.

"I'll admit," continued Nat, "that the wind is often fresh up that way, but if you want to meet with wind that is out of the common you must go up the Harlem division. Since the timber grew up in the more exposed parts it is not so bad as it used to be, but I tell you the wind screams there at times. Why, it used to be common for the wind to blow the packing out of the engines' stuffing-boxes."

"That's true," said Pete Gibson, "I've often seen the engines come in that way."

"Do you remember, Nat, about Tom Blank burning the old 93 owing to the wind?" asked Pete.

"Yes, of course I do."

"Let's hear the story," called out half a dozen voices.

"It was this way," said Pete, "Tom was out with the 93 hauling a heavy freight train and a terrible storm came on. Something like a cyclone or some of these Western storms. Well, Tom came out of it with the crown sheet of 93 down. I don't know just how the thing happened, but I heard Tom's explanation to the old man.

"Tom was ordered up to the office, and the old man said sharp like 'Blank, what have you got to say for yourself about burning that engine?'

"'Well, sir,' said Blank, 'it was the wind.'

"'The wind? How could the wind burn an engine?'

"'If you did not see that storm, Mr. Buchanan, you don't know what wind can do. Why, sir, that wind blew the water off my crown sheet!'

"'Blew the water off your crown sheet, and went through a thick lagging and a ⅜ iron sheet?'

"'No, sir; you don't understand. Just where the thing happened we were in a deep cut, and the wind blew so all-fired hard down my stack that it just forced its way down the nozzles through the steam-pipes and right on to the crown sheet like a blast. I could not make out why the engine stopped, but I happened to try the water at that time, and a puff of pure air came out of the gauge-cock. I shut the throttle quick, but it was too late.'

"'That was a most extraordinary experience you had, Blank,' remarked the old man. 'I am glad you showed so much presence of mind. You deserve promotion for that. You can begin running a wheelbarrow to-morrow.'"

## A Double-Headed Joke.

"A long time ago,' said the conductor, "a long time ago, back in the early seventies, I was running a train on the St. Paul. I had in my crew a loud-mouthed young fellow named Ed. Peterson, he had more gall than a book-agent, a little given to bragging, but a good brakeman—and would fight if you said there was another better.

"Some of the boys got their heads together and put up a job on Ed. I knew it but said nothing—the other brakemen and a couple of operators did the work. The plan was to send Ed. a dispatch, on the West trip Saturday, ordering him to come to Milwaukee to run an extra stock-train—Ed. was dead anxious to run a train, but there were a dozen older men. When he got to a certain station, part way over the division, deadheading on passenger toward Milwaukee—and a train—another message was to be delivered to him telling him to stop there and take Bill Westbury's crew West. When he got into the caboose the other brakemen proposed to have fun with him.

"The scheme worked fine, Ed. got the message all O.K. and immediately swelled up two sizes; he came to me and said, 'Old man, I thought you was lying when you said you put in a good word for me ahead of these wax figgers. Put her there,' then he handed me a message that read

"'Come to Milwaukee on No. 2 prepared to run a special stock-train through to Prairie du Chien. J. C. G.'

"J. C. Gault was superintendent there.

"Ed. telegraphed to his father, who lived at a small place about half over the road, to get him to watch and bring his best suit down to No. 2, and took the passenger train East, the proudest man in seven States.

"For some reason or other Ed. could not be found at the station where the stop-message was to be given him, and once by it the operator dare not use the wire to head him off, so he just held his breath, got his resignation ready and waited developments; and old Ed. got to Milwaukee none the wiser for the joke.

"When J. C. G. got to his office he found an impatient brakeman awaiting him.

"'What can I do for you, sir?' asked the official.

"'I'm here on your order, sir; Collins (our trainmaster), don't know what your arrangements are.'

"'My order, said Gault. 'My order, let's see. What's your name?'

"'Peterson.'

"'Peterson, Peterson, lets see the order.'

"The old man read the message over two or three times.

"'Bill Westbury, hey. I see. Mr. Peterson, I guess that the boys have put up a job on you and me, and I guess it wouldn't be very hard to find out who it was and fire 'em. But two can play at the same game. Now *we* will put up a job and see where the laugh comes in. You *can* take a stock-train out to-night just as this message says, and you can keep it all fall; as long as the rush lasts.'

"'There are a dozen men ahead of you and they are at the bottom of this joke—they won't feel so funny. Then I will have Collins send a message to all operators asking them to find out, privately, who forged my signature to certain orders. They will surely tell the trainman and none of 'em will dare say 'boo'—and, mind you, you keep still and we will watch the fun.'

"Ed. got a new blue suit and a nickel-plated lantern and put on style till about holidays. The boys were awful broke up over it, but nary a one of us dared to 'peep.' It was the best job I ever seen put up—for the victim."

## A Dangerous Curve.

"It is sometimes amusing to hear the excuses invented by engineers," remarked F. A. Casey, turning to draw the attention of Lauder.

"You remember old Dick Brown who used to run the boat train on your road?"

"No, that was before my time," said Lauder.

"Well it does not matter. Dick was an ingenious man—a sort of natural mechanic, and he was always tinkering with some new attachment for his engine. His inventions never amounted to anything, and his only success was in explaining why he was not a rich man through the value of his inventions. He was also very fertile in explaining away things that ought not to have happened.

"One day he invented an improved style of pump-packing, and put it into the stuffing-box of his left-hand pump. He watched it a little after starting and it seemed to be going all right. It did not keep going all right, however, for when he got to Providence he found the bushing cut to pieces and the plunger broken.

"On getting back to Boston he was ordered by the master mechanic to explain the cause of the accident.

"'It was the Providence curve that did it,' Dick calmly explained.

"'How could a curve cut out the bushing and break the pump plunger?' queried the master mechanic.

"'That's easily explained,' said Dick, 'and being a practical as well as a scientific man you will readily see it.

"'You know that sharp curve at Providence. Well, I was a little late, and was trying to save some time and took the curve rather rapid. The twist she gave on that curve just bent that pump plunger like a dog's leg and before we got in all the damage was done. It seems to me that something ought to be done to ease that curve.'

"The explanation was accepted as satisfactory."

## Not a Protectionist.

One of the great Western roads recently got out a new form of agreement for tie contractors, that provides that "All ties shall be of sound oak, not less than twelve inches in diameter, free from sap, have two sides flattened by edge tools to present an eight inch face and be taken out of the wind"—meaning the twist.

One old country merchant, who had always been depended upon to furnish some thousands of ties each winter, wrote to the tie inspector, as follows.

"Your contract received and returned herewith unsigned, I want you to understand that I ain't no millionaire and don't propose to build sheds to take your dam ties in out of the wind—the wind never hurt 'em before. I think this provision has been made to freeze me out of the contract, but I want you to understand that I'll go to the president with it. You ain't the St. Paul road, young feller. I suppose you will want 'em painted and varnished yet."

## An Australian Spark Arrester.

Charles Cooper, of Guilford, Western Australia, has recently patented in the United States, a spark-arrester for locomotives. It consists essentially of the old balloon-top stack so well-known in this country, with a spark-chamber between the lining and outside of the stack. He adds pipes leading from the spark-chamber to two tanks of water carried at the sides of the smoke-box, where the sparks are deposited and quenched, as in several spark-arresters patented in this country where the quenching-water is carried in a tank in the bottom of the smoke-box.

The Australian patentee appears to think that he has got something valuable, for the spark-arrester is patented in South Australia, Victoria, New South Wales, New Zealand, Queensland, England and the United States.

Railroad companies are objects of many curious suits for damages, but one of the most far-fetched suits that we have heard about lately is one presented by David Jacobs, of Seymour, Ind. He has sued the Pennsylvania Railway Company for $10,000 for being sunstruck while waiting for a load of brick, on a hot day of August last, while a freight train cleared a local crossing.

Our British friends pay a rather high price for the exclusion which they say travelers enjoy in a compartment-car. The small compartment, excluded from intercourse with the rest of the train, offers an opportunity for outrage, robbery and murder, which ruffians and thieves avail themselves of. Last month an outrage was attempted on a young lady in a compartment-carriage on an English railway, which has roused the press to demand the abolition of the compartment system. Several railways are running trains with cars built on the American plan, and every outrage committed in a compartment-car helps to drive in the wedge that will force the old-style carriage out of service.

## Railway Supply Men's Dinner.

A number of well-known gentlemen in New York connected with the railway machinery and supply trade arranged to have a dinner together, and it was held at Delmonico's, New York, on the evening of April 22d. Mr. William Toothe, of the Nathan Manufacturing Co., and Mr. C. A. Moore, of Manning, Maxwell & Moore, did the principal part of the work in getting the supply men together.

About 150 gentlemen were present at the dinner. General Greeley had been chosen chairman. He welcomed the guests with a few well-chosen remarks, in which he spoke of the pleasure and profit to be derived from men in similar business meeting at the festive board.

In the course of the evening there were numerous toasts responded to, some of the speeches being very humorous and amusing. Among the toasts brought in for response were "The Press as a Promoter of Business Enterprise," replied to by Mr. Joseph Eccleseine, of the *Railway World*; "Sympathy and Goodfellowship in Competitive Business," replied to by Mr. C. A. Moore, of Manning, Maxwell & Moore; "Steam Power, the Developer of Civilization," by Capt. H. G. Tarr, Worthington Co.; "The Press as an Exponent of Inventive Genius," by Angus Sinclair, *Locomotive Engineering*; "The Electrical Age of Machinery," by David Dodd, National Lock Washer Co.

During the evening Mr. C. S. Bushnell, who is a splendid singer, favored the company with a number of songs. Great enthusiasm was aroused by Mr. C. A. Moore telling that to the liberality and public spirit of Mr. Bushnell's father was due the building of Ericsson's Monitor, as he had from his own means supplied the necessary funds, after the plans were rejected by the Naval Department.

General Green, of Brooklyn, amused the company with several recitations and humorous stories. Mrs. Shaw, the famous whistler, entertained the meeting with several selections. Before the close Mr. C. A. Moore proposed that a permanent organization of the railway machinery and supply trade be formed, and the motion was carried amid great enthusiasm. General Greeley was elected President for the first year.

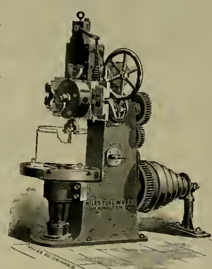
## Meeting of American Railway Association.

The annual meeting of the American Railway Association was held in New York last month. This association is composed of railroad managers, or representatives sent by the managers. They discuss all topics that are of general interest to railroad companies. President Haines, in his inaugural address, took the subject of car-couplers and gave a very exhaustive history of the car-coupler for freight cars. The work done by railroad companies through the Master Car Builders' Association was described and commended. The efforts of State Legislatures to force safety couplers into use was also related with great minuteness, and it was shown that all these efforts were in the direction of confusion. He considered that railroad companies are making satisfactory progress in the introduction of automatic safety couplers and he argued against legislative interference. Compulsory legislation would be unjust to railroad companies and might lead to new complications that would delay the good work of applying safe couplers upon all cars. No one was more anxious than himself to stop the accidents due to the coupling of cars, but he wanted the business to be managed by practical men who understood all the requirements.

Among the subjects under consideration by this association were the advisability of adopting the 24-o'clock system, freight car changes and safety appliances. No action of any consequence was taken on either of these subjects.

## Combined Turret Boring and Turning Machine.

The illustration represents a turret machine recently brought out by the Niles Tool Works, of Hamilton, O., for general boring and turning of small work, and for the special duty of turning piston rings for locomotives or other steam engines, the turret principle being employed



to bring into successive action the different tools necessary to complete such rings.

The turret saddle is mounted upon a substantial cross-rail fixed to a vertical slide in the column. The table is supported on a heavy spindle with large bearings, and receives motion through bevel gearing from a cone having five steps for a 4-inch belt. Cone is strongly backgeared, thus affording ten changes of speed for the table.

Four feeds by power are provided, the change from roughing to finishing cut being made instantly by means of a small lever projecting from side of column. Quick hand adjustments to facilitate setting are also provided.

In the illustration a casting for piston rings is shown in outline secured to the table, while the turret carries three special tools for finishing the rings without stopping.

It will be seen that the machine has remarkable advantages for performing such work in duplication. When once set, the different tools can be made to perform their respective duties again and again cutting up casting after casting into rings, and the work when done will be characterized by a degree of uniformity altogether beyond the reach of lathe or other ordinary methods.

By means of a taper dowel, the turret is secured over center of table for boring with double-ended cutters and for general chucking work.

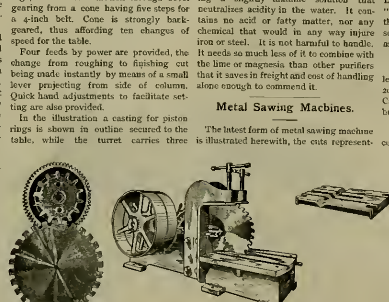
The machine will swing 31 inches in diameter, the table being 30 inches, and has a clearance under overhang of column of 18 inches, this height always being available for work, as the vertical slide allows an adjustment of the cutting tool to suit.

## A New Water Purifier.

The American Fluoride Co., New York, are hearing of very satisfactory results from the use of fluoride, which they are supplying as a feed-water purifier. It has long been known that a preparation could be made from fluorine which would precipitate lime and magnesia, but the cost of the material was so great that it could not be used. Prof. C. A. Doremus, of New York, a well-known chemist, lately succeeded in preparing a compound of fluorine which can be produced cheap, and this is the water purifier now handled by the company named. It is a white crystalline powder, dry, free from water, which means that the purchaser does not pay for water at a dollar or more the gallon when buying a scale preventer, but gets full weight of chemical for every pound. It can be kept in wood or paper indefinitely without deterioration or melting. It dissolves readily in cold or hot water, forming a slightly alkaline solution that neutralizes acidity in the water. It contains no acid or fatty matter, nor any chemical that would in any way injure iron or steel. It is not harmful to handle. It needs so much less of it to combine with the lime or magnesia than other purifiers that it saves in freight and cost of handling alone enough to commend it.

## Metal Sawing Machines.

The latest form of metal sawing machine is illustrated herewith, the cuts representing the Bryant system of metal saws, both in the portable and power form, together with specimens of work and detail of method of driving the saws.



The portable machine is especially designed for cutting of rails, being operated by two men, a sixty-pound rail has been cut off in three minutes with it.

The power machine is designed for machine shop work, cutting heavy pieces. Metal sawing is not practiced so extensively in American shops as in those in Europe, the main trouble being in general want of confidence in the process, brought about by extensive experiments with rotary saws driven from the arbor, like wood saws.

The Bryant saw is driven by a gear meshing into the teeth of the saw itself, and is therefore driven in direct line with the cutting point.

The teeth are really small planer tools in form, and each one takes out a chip as if driven alone, the speed of the saws being limited to seven turns per minute—20 to 25 feet.

The portable machines have been in use for some time on the Lehigh Valley road. They are being introduced by the Q. & C. Company, of Chicago.

---

One of our most valued correspondents recently witnessed a number of tests of the Smith fire-kindling device for locomotives, in the shops of the C. R. I. & P., at Chicago, and reports that in each instance a full fire of coal was ignited in from 10 to 14 minutes and the engine put in steam, from cold water, in from 45 to 55 minutes. This invention is an oil-burning device with an inexpensive plant, it entirely prevents smoking-up of cabs and brass fittings; has enough air blast of its own to create a good draft: does away with the use of wood and the danger of fires from it; insures the absence of spikes and nails to stick and burn off grates and reduces the number of men required to fire-up and care of engines. The neat, cleanly and efficient service gotten out of this improvement will commend it to any man in charge of motive power.

---

The Boston & Albany Car Department are covering a number of milk cars, also several passenger coaches with the Lee Composite Manufacturing Company's "Permanence Brand" of roofing, which they claim effects a saving over tin of some fourteen dollars per car in first cost and will not require painting.

---

President Haskell of the Mahoning Valley Railroad, has just let the contract for 200 coal gondolas to be built by the Erie Car Co., under Buffalo, Rochester & Pittsburgh specifications.

---

The D. & R. G. has advanced the pay of conductors and brakemen. These men now receive the largest pay for the service performed of any in this country.

---

The New York Railway Club, under the efficient presidency of Robt. C. Blackall, is rapidly growing in popularity, meetings being well attended and discussions full and interesting. It is the purpose of the club to raise for the Grant Monument Fund five hundred to one thousand dollars. This is to be done by voluntary contributions. The treasurer reports fifteen hundred dollars in the treasury as a club fund.

---

The Lukens Iron & Steel Co., Coatesville, Pa., have added to their list of customers the following roads: The Chicago & Northwestern, Central Vermont, Illinois Central, Ohio & Mississippi. This steel has long occupied an enviable position in the marine field and bids fair to become as well known in the railroad field.

---

Mr. John Fagin, master mechanic of the Atchison, Topeka & Santa Fé at Atchison, has resigned. He has been with the company for twenty years.

---

The Roberts spring dummy hose coupler is gaining some ground, and the makers report some orders and many inquiries.

---

The New York, Ontario & Western will be placing orders soon for considerable additional equipment.

Master Car Builder E. D. Bronner, of the Michigan Central, has during the month turned out of the shops at West Detroit, six handsome passenger cars, elegantly finished and very substantially built. A notable feature of these cars is the end framing which is constructed on a plan similar to the Lake Shore passenger car illustrated in this issue of LOCOMOTIVE ENGINEERING. The Michigan Central was the first railroad company to adopt this strong style of composite end framing, and it was worked out by Mr. Robert Miller, now general superintendent. The private car of President Ledyard, framed in this way, once took the shock of a very bad tail collision with very little damage.

A new engine has just been turned out of the Lackawanna shops in Utica, and is of the class known as culm burners. One of its principal features is a combustion chamber in the firebox, which, it is figured, will protect the flues to a great extent. The cylinders are 18 x 24 inches, and the drive wheels 5 feet 4 inches in diameter. The cab is finished in black walnut and mahogany, and the entire engine is fitted with all the modern and most approved conveniences. It is equipped with air-brakes, air-whistle to be used instead of the bell cord, and the bell will be rung by air pressure.—*Buffalo Courier*.

The Chicago, Burlington & Quincy are adding very rapidly to their freight-car equipment, for they have now given out new orders for 2,000 cars, just as the last cars of a big order have been delivered. The new cars are all furnished with the latest improvements in car construction, including Westinghouse air-brakes, steel brake-beams and M. C. B. couplers. All cars for this road now have the trucks made with rigid centers. Swing center trucks were formerly standard, but the great expense of repairs led to the change.

The Ohio Falls Car Co., Jefferson, Ind., are building two combination and baggage cars for the Minneapolis & St. Louis, and four passenger cars for the Evansville & Terre Haute. They have lately delivered ten suburban coaches for the Chicago & Grand Trunk. They are building fifty Jenkins patent poultry cars and a train of cars for a show company.

The Rogers Locomotive Works have received an order from the Chicago, Burlington & Quincy for fifty locomotives. Of this number twenty-five are 10-wheelers, twenty-five moguls, class "H," with 60-inch boilers and standard Burlington dimensions, and with Westinghouse air-pump and brake arrangement.

The St. Charles Car Co. are building some passenger cars for the Des Moines & Northwestern. They have just finished some unusually handsome coaches for the St. Louis & San Francisco. They are finished in mahogany and have all the best appliances for promoting comfort and safety.

The Rhode Island Locomotive Works are building some engines for the Saltair Railroad of Salt Lake City. The Wabash recently placed with these works an order for twenty-five, including twelve 8-wheel passenger, eight 10-wheel freight and five 6-wheel switching engines.

The Schenectady Locomotive Works are unusually busy. They have not yet begun to deliver the engines of the New York Central order of 100, and they now have orders from the Chicago & Alton, the Cleveland, Cincinnati, Chicago & St. Louis.

The Lafayette Car Works, which have been in the hands of a receiver for some months, were sold lately to a local syndicate for $39,500.

An order has been given to the Pennsylvania car shops at Port Wayne, Ind., to build 100 of the large furniture cars used by the company.

The Pennsylvania gave out contracts last month for 1,500 standard gondola cars.

(45) K. C., Kansas City, asks:

How is the connection made between the dry-pipe and the front-head? *A.*—By a ground joint held against the sheet by the flange of the T-pipe.

(46) Geo. E. Rhoads, Westtown, Pa., writes:

1. Did the knuckle of the Hien coupler open to the left? *A.*—Yes. 2. Are the Hien coupler interests consolidated with the Janney? *A.*—Yes. 3. Who was the inventor of the Belpaire firebox? *A.*—An engineer of that name in Belgium.

(47) G. W. P., Kansas City, writes:

I am making a model locomotive, and want to know how the firebox is put in a locomotive. If they rivet it together outside, I don't see how they get it in, and if riveted inside, how do they hold the rivets? *A.*—When the firebox has straight sides it is usually put in from the bottom; but where the crown sheet is wider than the mud-ring the box is put in through the end and the back-head put in afterward.

(48) R. Chase, Alleghany, Pa., writes.

Your article on "Electric Motors against Locomotives," has caused much discussion. Several of your readers would like to know what relation the expense for coal bears to the total cost of operating an electric railway? *A.*—In an address delivered by President Huntley, of the National Electric Light Association, he made a statement saying that the cost of coal was only about 10 per cent. of operating expenses of an electric railway.

(49) J. F., Selma, Ala., asks:

1. Will not shortening the eccentric blades on an indirect engine increase the lead, and on a direct decrease the lead? *A.*—No; shortening the blade will only make the valve travel out of the center of the seat; if it increased the lead opening on one end, it would decrease it on the other. Advancing the eccentric will increase the lead. 2. What is meant by the linear advance of the eccentric? *A.*—Linear means "in line with" or "in the same line," and linear advance of an eccentric means moving the eccentric ahead on the axle, *toward* the eccentric-rod connection. 3. If, on passing the forward center, the piston should strike the front cylinder-head, would it not be proper to insert a liner in the back end of the main straps? *A.*—It would do no good to put a liner behind the brass unless it made the rod shorter; take out one in front of brass and put it behind—anything that will shorten the rod.

(50) G. W. P., Little Rock, Ark., writes.

I often see the expression "co-efficient of friction," used in mechanical papers, and I am not sure what it means. I have tried to pump several of our learned engineers, foreman, etc., to get some light on the subject, but they are all like one who said that he knew but lacked the power of language to explain it. Do you possess the necessary gift of the gab? *A.*—The co-efficient of friction is the proportion of the weight of a body that is necessary to overcome the resistance to movement. Thus, if you put a block of iron weighing, say, 5 pounds, on a flat surface, and attach a string to it, the amount of the pull required to move the block will give the co-efficient of friction. If a pull of 1 pound moves the block, the co-efficient of friction is $\frac{1}{5}$. A similar expression, very familiar to railroad men, is the "co-efficient of adhesion." This is the proportion of the weight on driving-wheels required to make them slip. This depends upon the condition of the rails, and it varies from $\frac{1}{4}$ to $\frac{1}{10}$ of the weight resting on the wheels. An engine having 80,000 pounds on the drivers may have a turning power of 20,000 pounds applied to the driving-wheels without slipping. When the rails are in bad shape, a turning power of 8,000 pounds may slip the wheels.

(51) R. J. Ross, Boston, Mass., writes:

I have heard it said that "A Modern Samson," the monster locomotive seen on the front page of your February paper, is equal to a simple engine with $24 \times 28$ in. cylinders. Several of your readers would like to know what pull an engine of that sort can make on the drawbar and the horse-power that could be exerted when running at twenty miles an hour. *A.*—The tractive power, as the force that a locomotive can exert on the drawbar is called, is figured by a very easy rule which is found in all engineering hand-books. Those wanting to learn how to figure the power of a locomotive should not be frightened at the rule because it is expressed by letters or algebraically, thus

$$T = \frac{d^2 \; L \; p}{D}$$

meaning, T traction equal to $d^2$, the square of the diameter of one cylinder in inches, multiplied by L, length of stroke in inches, and multiplied by $p$, the average pressure on the piston, in pounds per square inch. These are divided by D, the diameter of the driving-wheels in inches, and the answer shows the number of pounds that the engine can exert on the drawbar. When applied to the Erie engine referred to in the question, we have $d^2$ equal to $24 \times 24 = 576$. This multiplied by 28, the length of the stroke, makes 16,128. Next multiplier is $p$, which represents the average pressure per square inch of piston. As the boiler pressure is 200 pounds, we can take 90 per cent. as the cylinder pressure, which gives 180 pounds. We have now $16{,}128 \times 180 = 2{,}903{,}040$. This is divided by 50, the diameter of the driving-wheels, and we have 58,060 pounds as the pulling force the engine can exert. To find the horse-power developed at twenty miles an hour, we have first to find the average cylinder pressure. From indicator diagrams taken from the other engines, we are safe to assume that this one will give an average in the cylinders of half the boiler pressure when making 136 revolutions per minute and cutting off at half stroke. This is 100 pounds. We now find the area of the piston, which is 452.39. The two pistons make 904.78 square inches, which is multiplied by 100, the steam pressure in pounds, and gives 90,478 pounds of force exerted on the crank-pins. This is exerted through twice the stroke during each revolution and is $28 \times 2 = 56$ in. or $4\frac{2}{3}$ ft. The speed is 136 revolutions per minute, so we have 90,478 lbs. $\times 4\frac{2}{3}$ ft. $\times 136$, equal to 57,423,369. This is divided by 33,000, the number of foot-pounds in a horse-power, and gives 1,740 as the horse-power exerted.

The time-honored adage that "It's an ill wind that blows nobody good" finds another illustration in a use for boiler scale, which has heretofore been regarded as an unmitigated evil. Mr. John Player, superintendent of machinery of the Atchison, Topeka & Santa Fé Railway at Topeka, Kan., has found a way of using this scale to good advantage in making floors for the shops. It is spread over the floor and then hammered down solid, and then thoroughly soaked with water. On becoming thoroughly dry it forms a floor as solid as could be obtained by a good grade of cement floor. It can be very cheaply made and readily repaired, and affords a means of usefully disposing of a material supposed to be utterly worthless.—*Railway Review*.

The Pittsburgh Locomotive Works are building for the Pittsburgh & Lake Erie five locomotives, two of which will be for fast passenger service. Mr. Wightman, superintendent of these works, is said to be working on the plans of a compound locomotive of a tandem design. He thinks that a tandem arrangement of cylinders will give the most compact means of developing the great power likely to be called for in the near future.

The order given out during last month of fifty locomotives for the Cleveland, Cincinnati, Chicago & St. Louis, excited much pleasant anticipation among leading builders. It carried comfort to three establishments, Richmond getting thirty engines, Schenectady ten and Brooks ten. There is a tendency among people to congratulate the Richmond people, as the plums that fall in that direction are not generally very large.

The Green Bay, Winona & St. Paul Railroad shows a performance sheet for the locomotives that reflects credit on Master Mechanic Fenwick. That region is hard on locomotives in winter, yet, the engines in March were operated at a cost of 16.86 cents per mile. Of this about half went for fuel. Repairs cost only 2.82 cents per mile.

An announcement has been made that the *Railway Age* and *Northwestern Railroader* will publish daily reports of the Master Car Builders' and Master Mechanics' Conventions at Saratoga, in June next. This has been done for several years by the *Northwestern Railroader*, and the reports have been very popular.

On March 28th, the Empire Line Express ran from Oneida to De Witt, 21.37 miles, in 17 minutes and 40 seconds, the average speed having been 73.69 miles per hour. The engine that made the run was one of Mr. Buchanan's 8-wheel 19 x 24-inch engines, with driving-wheels 78 inches diameter.

The Lima Iron Works, says the *Age of Steel*, are now completing one of the smallest locomotives ever built for practical purposes. It will be used by a fruit company in the orange groves of Florida. The total weight of the engine complete, including the cab, is about 6,000 lbs.

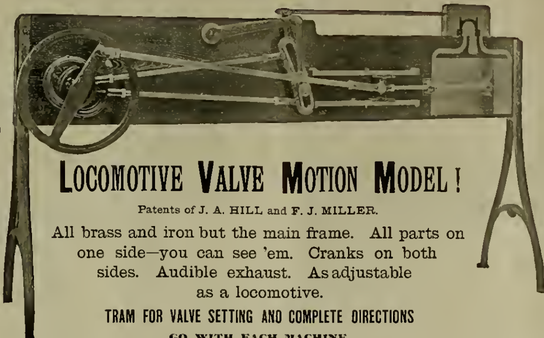
The Midvale Steel Company have contracted with Manning, Maxwell & Moore, New York, for a 20-ton Shaw electric crane of the kind illustrated in LOCOMOTIVE ENGINEERING last month.

Contracts have been given out for the building of the New York Central shops at Depew, which we illustrated two months ago, and the work is being pushed vigorously.

The C. & W. M. have ordered four new ten-wheelers from the Rhode Island Works.

The B., R. & P. have ordered four compounds from Baldwin's.

# FOR YOUR LODGE ROOM!



PRICE REDUCED TO **$60.00**

IMPROVED FOR 1892.

## LOCOMOTIVE VALVE MOTION MODEL!

Patents of J. A. HILL and F. J. MILLER.

All brass and iron but the main frame. All parts on one side—you can see 'em. Cranks on both sides. Audible exhaust. As adjustable as a locomotive.

**TRAM FOR VALVE SETTING AND COMPLETE DIRECTIONS GO WITH EACH MACHINE.**

**Half size of 17 x 24 Engine.—A Machine, not a Toy.**

ESPECIALLY USEFUL IN M. M.'S OFFICE WHEN EXAMINING FIREMEN FOR PROMOTION.

**PEDRICK & AYER, MAKERS, PHILADELPHIA, PA.**

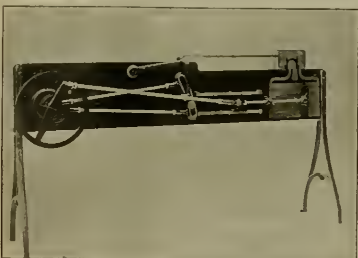
# PREMIUM LIST.

## Useful Things for Enginemen and Machinists that can be had for a Little Overtime.

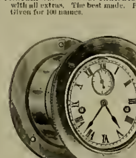
THESE are no job lots that we have got cheap, but every identical thing in the list is new and the latest and best, *and will be shipped direct to you from the maker*—just as though you had sent *them* the cash. Every subscription must be accompanied by $2. When a club is received and the premium mentioned that is wanted, we will order it sent direct to you from the maker—and we will always pay the mail or express, no premium shall cost you an extra cent on any pretext. We want you to work. In sending your club write each name, town, box and street plainly, and state when paper should commence. Send the money with the list, and give the name and number of the premium you want. Renewals just as good as new names.



**Premium No. 1. Valve Motion Model.**

Built by Pedrick & Ayer. *Improved for 1892.* Half the actual size of a 17 x 24 locomotive. Just as adjustable as a locomotive. Tram for setting valve furnished, and complete directions for setting valves, eccentrics, finding exact dead centers, etc., go with each machine. No wood but the main frame—a machine not a toy! Everything visible from one side. Just the thing for lodge rooms. Crank on back as well as front. Patented audible exhaust, you can watch something else and hear the exhaust. More can be learned from this practical machine than from anything else. *No lodge room complete without it.* It is worth $60. We will give it for 85 subscribers for 1 year. In case you can't fill out the complete club of 85, we will accept 70 names and $18.00 cash extra, 60 names and $23.00 extra; 50 names and $25.00 extra, 40 names and $30.00 extra; or, 30 names and $39.50 extra.

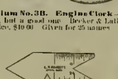
**Premium No. 2. Tabor Indicator.**—In case, with all extras. The best made. Price, $85.00. Given for 100 names.



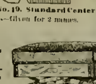
**Premium No. 3B. Engine Clock.**—Not Jeweled, but a good one. Becker & Lathrop make. Price, $10.00. Given for 25 names.

**Premium No. 3. Howard Jeweled Chronometer.** Price, $40. Given for 60 names.

**Premium No. 3 A. Seth Thomas Jeweled Engine Clock.** The best they make. Price, $37.50. Given for 50 names.

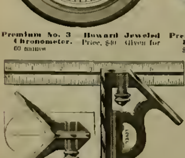


**Premium No. 19. Standard Center Gauge.**—Given for 2 names.

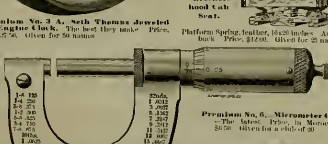


**Premium No. 33. Brotherhood Cab Seat.**

Platform Spring, leather, 16x20 inches. Adjustable back. Price, $12.00. Given for 25 names.



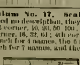
**Premium No. 7. Combination Square, Level and Center Square.**—With 6-inch scale. Given for 8 names. With 12-inch scale for 12 names.



**Premium No. 6. Micrometer Caliper.**—The latest. Price, in Morocco case, $6.50. Given for a club of 20.

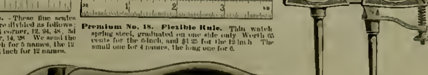
**Premium No. 17. Scales.**—These fine scales need no description, they are divided as follows: 1st corner, 10, 20, 50, 100; 2d corner, 12, 24, 48; 3d corner, 16, 32, 64; 4th corner, 14, 28. We send the 3-inch for 4 names, the 6 inch for 5 names, the 12 inch for 7 names, and the 24 inch for 12 names.

**Premium No. 18. Flexible Rule.** Thin watch spring steel, graduated on one side only. Worth 65 cents for the 6-inch, and $1.25 for the 12-inch. The small one for 4 names, the long one for 6.



**Premium No. 8.**

**Small, Fine Square.** 2 blades. Fine tool. Given for 10 names.



**Premium No. 5.—Combination Tool.**—Handiest tool in your box. Black are worth $1.25. Given for 6 names. Nickel, $1.50. Given for 7 names.

**Premium No. 20. Trammel Points.** Adjustable, with extra Pencil holder. Given for 13 names.

## BOOKS.

**We offer the following Books, which we consider good and well worth the money. They are grouped according to price.**

**Ten Dollar Books.—For 40 names each.**

MODERN LOCOMOTIVE CONSTRUCTION. By J. G. A. Meyer. This is the latest exhaustive book on the locomotive, every piece being shown by drawings and rules given for determining strains and designing the machine to meet them. About 1,000 engravings.

**Five Dollar Books.—For 20 names.**

TRAUTWINE'S ENGINEERS' POCKET-BOOK. This is a high-class reference book for engineers and mechanics. Contains facts and figures on many subjects, mostly civil engineering. Bound in morocco, flap, gilt edge. More than 40,000 have been sold.

HASWELL'S. A standard work much like Trautwine's, same size and style. One of the best authorities on strength of materials, etc. Contains many useful tables. Same price.

BOUND VOLUMES OF "THE LOCOMOTIVE ENGINEER." Four years in one handsome volume—1888, '89, '90, and '91. There is more useful and interesting matter gathered in this volume, that will be prized by the locomotive men, than in any book extant. Complete index. Nearly 2,000 engravings.

**Three and a half Dollar Books.—For 15 names.**

FORNEY'S CATECHISM OF THE LOCOMOTIVE. The new and enlarged edition. This work needs no explanation—there have been some 30,000 sold. Every engineman and shopman needs it.

**Two and a half Dollar Books.—Given for 13 names.**

HEAT—A MODE OF MOTION. By John Tyndall. This is the best and most interesting work on the mechanics of heat ever written. It reads like a story, is full of illustrations and experiments. No mechanic's library is complete without it. A large handsome work.

A TREATISE ON STEAM BOILERS—Their Strength, Construction and Economical Working. By Robert Wilson, C. E. Enlarged and illustrated from the fifth English edition by J. J. Flather, Ph. B., Lehigh University. 108 fine illustrations, tables, etc.

TWENTY YEARS WITH THE INDICATOR. By Thos. Pray. A well known work; no deep formulæ. Many useful rules and tables.

**Two Dollar Books.—For 10 names.**

SINCLAIR'S LOCOMOTIVE ENGINE RUNNING AND MANAGEMENT. This is a book dear to the hearts of all enginemen—it's about running and firing by a man who has done both. The last edition is improved very much and the number of engravings has been increased. You can't afford to be without it.

HEMENWAY'S INDICATOR PRACTICE AND STEAM ENGINE ECONOMY. This is the best thing ever written on the indicator and what can be done with it. It has been adopted as a text-book in the Stevens Institute of Technology. Illustrated.

WOOD'S COMPOUND LOCOMOTIVES. Illustrating and describing the different forms and makes of compound locomotives. 1891.

BOUND VOLUMES OF "THE LOCOMOTIVE ENGINEER" for any one year—1888, '89, '90, or '91. Neatly bound and indexed.

**Dollar and a half Books.—For 7 names.**

ALEXANDER'S READY REFERENCE. This is one of the deservedly popular little books. It contains plain directions for the many distresses of a locomotive: what to do to man and to engine in case of accident. Illustrated by plates.

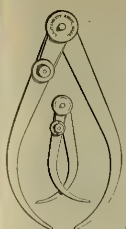
**One Dollar Books. For 5 names.**

PHELAN'S AIR BRAKE PRACTICE. A plain talk on air brakes from an engineer used to handling them. Bound in pocket form, with two large plates showing the air brake in every detail. Has rules for figuring leverages and directions for operating under all conditions. The Westinghouse Company bought one thousand of these books as instructors. The best thing on the subject.

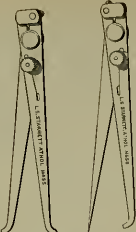
BOILER MAKING FOR BOILER MAKERS. A practical treatise on work in the shop, showing the best methods of riveting, bracing and staying, punching, drilling, smithing, etc., and the most economical manner of obtaining the best quality of output at the least expense. By W. H. Ford, M. E.

**Fifty Cent Books.—For 2 names.**

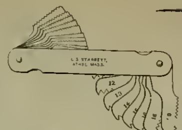
PROGRESSIVE EXAMINATIONS OF LOCOMOTIVE ENGINEERS AND FIREMEN. By John A. Hill. Between five and six hundred questions and answers on practical questions on locomotive firing and running, proposing a new plan of examination of enginemen. Adopted by several roads as standard. Has 17 colored plates, showing color and position of all signals carried by trains or engines. 1891.



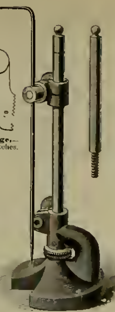
**Premium No. 21.—Lock-Joint Calipers.**—The 4-inch size we give for 4 names, the 8-inch for 6, the 12-inch for 8, and the 18-inch for 13 names. You can have either inside or outside.



**Premium No. 22.—Hermaphrodite Calipers.**—6-inch, patent lock nut. We send it for 5 names.

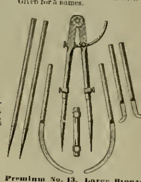


**Premium No. 16.—Screw Pitch Gauge.**—Will fit a nut as well as a bolt. 20 pitches. Given for 5 names.



**Premium No. 12. Starrett's Surface Gauge.** A good one 8 inch size sent for 10 names, the 12-inch for 18

**Premium No. 15.—Double Plumb and Level.**—18-inch. Given for 8 names



**Premium No. 13. Large Bronze Dividers and Calipers.**—The best one there is. Given for 15 names

**Premium No. 28.—Ideal Outside Calipers.** Heavy spring, patent nut and washer. The 2½ and 3-inch will be sent for 5 names, the 4 and 5-inch sizes for 6 names, and the 6-inch for 7

**Premium No. 29.—Ideal Inside Calipers.** Same style as the 28 The 3-inch given for 5 names, the 4 and 5 for 6, and the 6-inch for 7.

**Premium No. 40. Drawing Set.**—K. & E. Price, $4 50. Given for 12 names.

**Premium No. 41.—Drawing Set.**—K & E. Price, $8 50 Given for 20 names

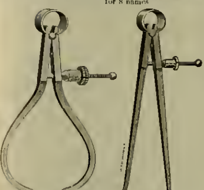
**Premium No. 42.—Drawing Set.** K & E Price, $12 75. Given for 24 names.

**Premium No. 43.—Drawing Set.**—K & E Price, $20.25. Given for 38 names.

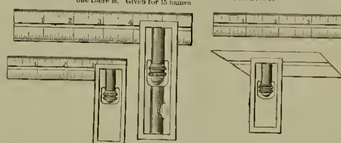
**Premium No. 100. Westinghouse Engineer's Brake and Equalizing Discharge Valve.**—Full size, with case cut away so as to expose all valves Indispensable in a lodge-room Not a model—an actual valve. Given for 40 names.

**Premium No. 101. Westinghouse Quick Action Triple Valve.**—Full size, case cut away so as to show movement of every piece The actual valve Your lodge-room ought to have one Given for 20 names.

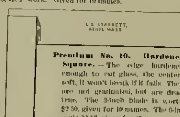
**Premium No. 102.—A Fine Gauge Lamp.** Solid stand, heavy globe, plain or painted Brass cap and base Neatest lamp out Cost $30 a dozen at wholesale. We will send you one for a club of 10.



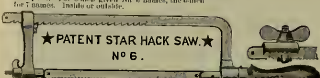
**Premium No. 23.—Fay's Patent Spring Nut Calipers.**—4 or 5-inch given for 6 names, the 6-inch for 7 names. Inside or outside.



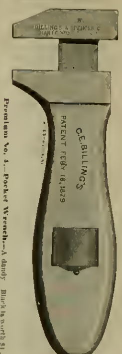
**Premium No. 9. Double, Sliding Head Square.**—With 2 blades, one for finishing Hex work. Given for 10 names.



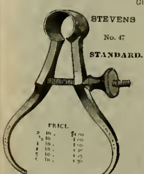
**Premium No. 10. Hardened Square.**—The edge hardened enough to cut glass, the centers soft, it won't break if it falls They are not graduated, but are dead true. The 3-inch blade is worth $2 50, given for 10 names. The 6-in costs $4 50, given for 15 names



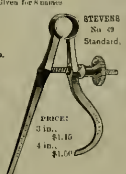
**Premium No. 21. Hack Saw Frame,** and a dozen Saws —Nickel-plated. Given for 8 names



**Premium No. 4.—Pocket Wrench.**—A dandy Black is worth $1. Nickel, $1 25; given for 5 names given for 6 names



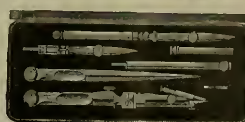
**Premium No. 25** is furnished in 6 sizes, prices as above The 2, 2½ and 3-inch will be given for 5 yearly subscriptions each The 4 and 5-inch for 6 each, and the 6-inch for 7



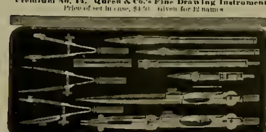
**Premium No. 26. Key-hole Calipers.** The 3 inch for 6 yearly subscribers, and the 4-inch for 7

**Premium No. 27. Inside Calipers.** 5-inch, given for 6 names for a year

**Premium No. 31. Spring Dividers with Thumb Attachment and Patent Washer.** The 2 or 3½ inch for 6 subscriptions, the 4 or 5 for 7, the 6 for 8

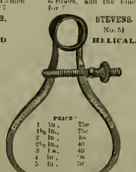


**Premium No. 14. Queen & Co.'s Fine Drawing Instruments.** Price of set in case, $4 50 Given for 12 names



**Premium No. 45. Queen & Co.'s Case of Instruments.** Price $14 50 Given for 25 names

**Premium No. 30. Standard Spring Dividers.** The 2 and 3½-inch for 5 subscriptions, the 4 and 5-inch for 6, and the 6-inch for 7



**Premium No. 32. Helical Coil Calipers.** Something extra nice The two smallest sizes are gold plated, and are used as watch charms We will send either of them for 4 yearly subscriptions We will give any size of the larger plain steel for 3 yearly subscriptions

**Premium No. 11.—Inclinometer.** A very fine tool, worth $5 Given for 20 names

**Premium No. 14. Level and Plumb.** 6-inch Given for 7 names

**Premium No. 16.—Q. & Co.'s Extra Fine Set Drawing Instruments.** Price $30. Given for 35 names.

# LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

VOL. V, No. 6. NEW YORK, JUNE, 1892. PRICE, 20 Cts. Monthly. $2 00 per Year.

## Compound Locomotive for Grade of 575 Per Mile.

The peculiar looking locomotive shown herewith was designed for logging service on the Sinnemahoning Valley Railroad of Pennsylvania, which has grades of 575 feet per mile, with curvature of 40 degrees. The engine is to be used on stringer track, the cross-ties being placed 20 feet apart, and the rails laid upon log stringers between the cross-ties. The maximum weight allowable upon each pair of stringers is 35 to 40 tons. A locomotive exceeding that weight must therefore have a wheelbase exceeding 20 feet to avoid overloading the stringers. With so long a wheelbase, a locomotive of the ordinary type would be too rigid to work upon the sharp curves.

The "Edward T. Johnson" has 12 driving wheels, arranged in two six-wheeled swiveling trucks, the firebox being between the trucks. Each truck is driven by Vauclain compound cylinders, the two trucks, of course, working simultaneously. Live steam is communicated to the cylinders by means of a thoroughly jacketed steam-pipe on the engineer's side of the locomotive, and the exhaust steam is conveyed to the stack through a similarly jacketed exhaust-pipe on the fireman's side of the locomotive. The steam connections from the fixed steam-pipes to the swivelling truck are made by means of Moran patent flexible joints. The principal dimensions are as follows:

Gauge, 4 feet 8½ inches.

Fuel, soft coal.

Cylinders, H. P., 9½x18; L. P., 16x18.

Driving wheels, 40 inches diameter on the tread.

Wheelbase of each truck, 7 feet 6 inches; total wheelbase, 27 feet 6 inches.

Boiler, 50 inches diameter, wagon-top form of ½-inch and $\frac{9}{16}$-inch steel, with butt joints and double welt strips.

Fire-box 66 inches long, 47½ inches wide, 59½ inches deep at front, 40 inches deep at back.

Crown sheet supported by radial staybolts 1⅛ inch diameter.

The water is carried in a rear tank, similar to an ordinary tender tank (capacity, 900 gallons) and in two side tanks holding 1,600 gallons; aggregate, 2,500 gallons.

Coal capacity, 4 tons.

Weight in working order about 150,000 pounds, equally divided between two trucks.

Steam and exhaust-pipes covered with magnesia sectional lagging and jacketed.

Piston-rods and valve-stems fitted with U. S. metallic packing.

Steam-brake on all wheels, LeChatelier pressure brake to act upon both sets of cylinders.

Water supplied by two No. 8 Monitor injectors.

The locomotive is said to be doing satisfactory work upon the Sinnemahoning Valley Railroad, but no special tests of its capacity have been made up to this time. This engine does the same work as that performed by some geared engines employed on the same line.

Eight-Cylinder Tree-Climber.

---

On the St. Louis & San Francisco road they use the regulation bulletin notice of engine performance. Following the engineer's name there is a blank space left large enough to contain the letters A. B. C. D.; these represent waste, coal, engine oil and cylinder oil respectively, and are only placed after the name when that engine and engineer have used more than the average amount of the stores designated. Below the sheet these words stand out boldly: "Letters A. B. C. D. denote poor record of engineer and engine." Just as quick as a man finds his name he sees at a glance just how he stands with the average runner of his own road—he isn't compared with the best. Some of the men have all the titles, others have none.

---

In the Boston & Maine shops, at Boston, they have in use a simple arrangement which materially increases the capacity of the driving wheel lathes. It is well known that when a heavy cut is attempted on most wheel lathes there is a tendency to chatter. This is due in some measure to the small bearing work set in centers has on the lathe. To prevent chattering they have an arrangement of two pillars, one of which goes beneath each of the axle journals, bearing part of the weight. A strong clasp encircles the journal and makes the work so unyielding that any cut a tool is capable of making can be done without causing the least disturbance.

---

The Jersey Central's compound 385, recently swung a Royal Blue train over a mile in 39¼ seconds—this is the fastest time on record, that we know of. If this speed could be maintained between New York and Washington it would reduce the time, without stops, to two hours and a half. The fastest regular time is five hours.

## A Novel Engine Board.

Superintendent of Motive Power James R. Groves, of the St. L. & S. F., has in his office at Springfield, Mo., an engine record board out of the usual run.

Instead of the engine numbers being arranged in rows they are arranged on lines representing the road itself, with all branches, shops and roundhouses.

These lines are arranged like a map of the road, the mileage of divisions is marked on it, the principal towns located, etc.

There are three lines on the map, the upper one is a blue line, the center one a heavy line in gold leaf and the lower one a white line. On each of these lines there are many little brads on which to hang small brass tags which show the engine number and a symbol for its class.

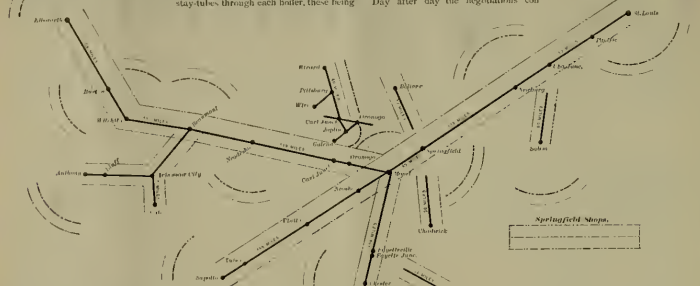
Engines in first-class condition are always represented on the blue line, those in good working condition, not more than two-thirds worn out, on the gold line, and those in bad condition on the white line.

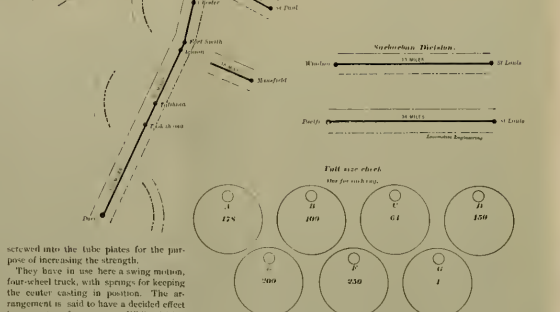
At each place where there is a roundhouse it is shown by an arc of a circle and there are three rows of pegs for every stall in the shops.

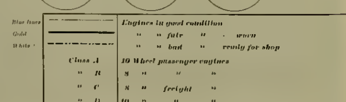
Traveling Engineer M. Savage takes care of the board and changes the number tags whenever changes are made.

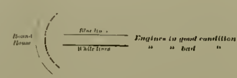
Our engraving gives a pretty fair idea of the arrangement of the board, which is about three feet square, and locked under a glass door, and the details show checks and symbol system.

The arrangement of the engine numbers in this way shows at a glance the distribution of power on the road, and is the neatest thing of the kind we have seen.









## Canadian Pacific Shops.

During a recent visit to the Canadian Pacific shops at Montreal, I found them unusually busy with repair work of locomotives. They are making several permanent improvements in the shops, one being the putting in of an air compressor to supply pressure all over the establishment for power purposes.

They are working 550 men in the locomotive works alone. Last year they built twenty-five new locomotives in the Montreal shops, rebuilt ten others, and effected heavy repairs upon about eighty engines. Their method of building is very good, and the work is carried on nearly as systematically as it is done in regular building shops. The railroad companies in Canada follow the English practice of building their own motive power. In the Canadian Pacific shops they are at present building some ten-wheel express engines with cylinders 18 x 24 inches, driving wheels 62 inches outside diameter, and a boiler with 1,290 square feet of heating surface. The boiler is straight, and has the firebox secured by radial stays. They are using stay-bolts one inch thick round the fireboxes and find that there is very little trouble with broken stay-bolts since this size was adopted. The boilers are particularly well braced, and every care is evidently rendered to secure safety. They use eight stay-tubes through each boiler, these being screwed into the tube plates for the purpose of increasing the strength.

They have in use here a swing motion, four-wheel truck, with springs for keeping the center casting in position. The arrangement is said to have a decided effect in preventing flange wear. While visiting here I failed to meet Mr. Preston, superintendent of motive power, but was shown everything by Mr. R. Atkinson, the general foreman, who deserves great credit for the condition of the shops and the way the work is carried on. A. S.

## The Great Northern Order for Locomotives.

Great excitement prevailed in New York for a few days last month among the leading locomotive builders of the country. Mr. Jas. J. Hill, president of the Great Northern, intimated that he would contract for a large number of locomotives and rumor gave it out that the order might reach into the hundreds. There is an exciting uncertainty in bargaining with Mr. Hill, for on more than one occasion he is said to have raised high hopes of an immense order and negotiated half the night to pull down prices to the lowest notch, then finished up by ordering one or two engines.

The builder representatives duly met Mr. Hill in New York, and at once he opened an onslaught to break prices. The builders have got tired of making locomotives for glory, and on this occasion they stood firm. Mr. Hill threatened to buy his locomotives in Scotland, and no doubt would have done it if the plan would have saved a dollar. But our builders knew that owing to their superior methods of manufacture, they could construct locomotives cheaper than the builders in Glasgow, and the 35 per cent. *ad valorem* duty on the importation of locomotives into this country was certain to render the bringing of locomotives from Scotland an expensive luxury.

Day after day the negotiations continued. All sorts of rumors were in the air. One hour it was reported that the deal was off and that no locomotives would be ordered at this time, then the wise men of Gotham were ready to tell all about a general break in prices and a spreading round of an order for 200 locomotives. The facts were, however, that the road could no longer get along without the engines, and the builders had grown wise by experience and were determined to obtain a living profit on the work, or build no locomotives. The outcome was that fifty-six locomotives were ordered, fifty of them going to Brooks and six to Baldwin's. The fifty engines are consolidations, with cylinders 19x26 inches and a working weight of about 130,000 pounds.

---

Among the many inventions patented monthly we look in vain for a good flue cleaner for locomotives. The flues of a locomotive are so difficult to reach with the ordinary rod and brush that a better means of removing the soot and cinders is badly needed. Would not a sectional flue cleaner, to be operated by power from a flexible shaft, or a steam cleaner, be a good thing?

## "The Moon Extension."

The Denver & Rio Grande has a branch eight miles long, from Hecla, Col., to the Calumet iron mines, with a maximum grade of 407 feet per mile.

This track runs through the rugged Box Cañon, is very crooked, and often clings to the side of the gorge away above the stream below. The men on the road long ago nicknamed it "The Moon Extension."

It is, we believe, the heaviest grade in the country operated by an ordinary road locomotive

The track is 3-foot gauge, laid with 52-pound steel, and the engine is a consolidation pattern, with 16 x 22 cylinders and 36-inch wheels, the boiler is 52 inches in diameter; total weight of engine, 60,000 pounds, with tender, 100,000 pounds, and having a total length of 44 ft. 11½ inches—considerable engine for a 36-inch track.

Three empty gondola cars and a "pasteboard" caboose are sufficient load on this grade, but the engine brings down all the loads that are ready, seldom more than twelve, however.

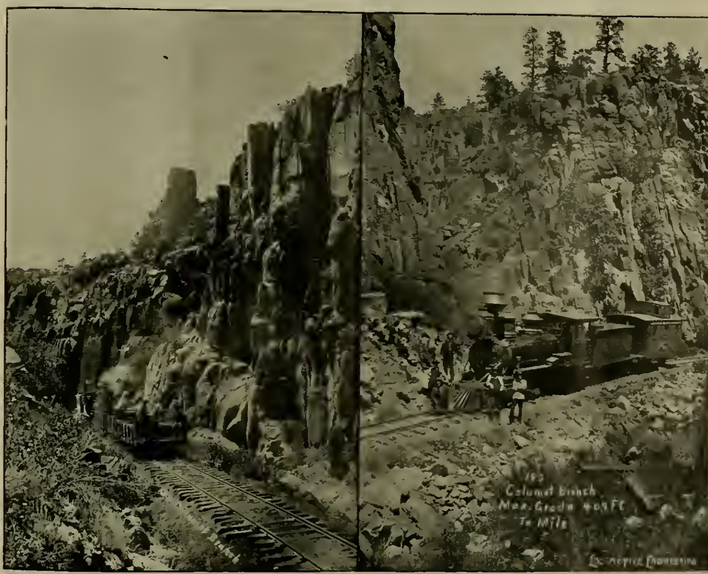
Every wheel on this road has an air-brake hold of it, and on this grade they don't let go to recharge; straight air is used, and the water-brake on the engine is in constant operation.

The artist insisted on looking down the grade at the engine in each instance here, which makes the incline appear less than it really is.

The writer has himself run a locomotive over this track, but not for a regular diet. A. W Leonardson was the runner in charge of engine "408" when these pictures were taken.

Perhaps there has been more sensational articles written about the wonderful feat of ascending and descending this mountain ladder than about any other piece of track in America. Some ten years ago the company forbid the carrying of passengers on this line under any pretext whatever, but that don't keep the imaginative reporter from telling how "the engineer stood like a statue holding the throttle reversed, with the steam and water oozing out of the chests from over-pressure, and the water-brakes throwing a stream of sparks from every wheel, while the train rushed from the mines, perched like an eyrie ont he mountain crest, to the main line along the torrent-dashed waters of the Arkansas below." The "rush" is about six miles per hour.

The operation of this branch shows nerve and skill all the way through, from the civil engineer who picked out the path to the locomotive engineer who daily (excuse the road expression) "keeps his eye on the gun."



"The Moon Extension," Denver & Rio Grande Railway. Grade, 407 Feet.

The Atchison, Topeka & Santa Fé are increasing the capacity of the repair shops at Argentine, Kan. The intention is to put in a plant there that will do the work that is beyond the capacity of the over-crowded shops at Topeka. The latter shops are badly adapted for carrying on work on a large scale, and it is the intention of the management to relieve them of the work that cannot be done to good advantage.

We are in receipt of a large number of letters telling about engines that slipped without steam. All of them explain the apparent paradox as being caused by bent axles.

## Locomotive-Running Among the Bush-whackers.

By Old Soldier.

In 1862 I went to Nashville, Tenn., with General Buell's army. At that time, the only railroad in the Army of the Cumberland that was opened was the L. & N. R. R.

At that time I was wagon-master of the post of Nashville, and the Army of the Cumberland had a good number of worked-down horses and mules. Captain Stevens, of California, was acting quarter-master, he had a civilian by the name of Henry Little as an assistant, with the title of Superintendent, who had charge of all wagon-masters and all mechanics of the post. He had ordered me to go out in the country and rent all the pasture land I could get, so as to pasture crippled and overworked horses and mules to recruit them up. I think, in all, I rented about 6,000 acres; we had about 3,000 head; so Mr. Little put me in charge of the pastures. About that time Captain Stevens took sick and died. I do not remember how long he lay sick, but as things did not go to suit me I quit.

Being a machinist and engineer, I went down to the Nashville & Chattanooga shops T. W. Smith was master mechanic, he gave me work in the shops on some old scrap heaps to get them ready for the road. The track at that time was the old English U rail. Mr. John Mackenzie, now superintendent of motive power of the Nickel Plate road was an apprentice in the shop, and his father was working journeyman-work as a machinist.

The Confederates had torn up the rails as they retreated south and had bent some of them.

I think the Ninth Michigan Regiment of sappers and miners built up the road. When they got out to Mill Creek bridge we had just finished up a little old Harkness engine called the "J. Edgar Thompson." The M. M sent me out with her with a load of bridge timber. I think we finished the bridge, or nearly did so, in one week. I wanted to lay off one trip, and I got an engineer by the name of Mart Quinn to make a trip for me. Mart was a Nashville man, and had been running for the Confederates Well, Mart made the trip out with the "J. Edgar Thompson," but she never came back.

Mart came back in about two months the hardest looking citizen you ever saw. He had pretty hard work to get away from the Johnnies, but they did parole him and let him come to Nashville That parole meant for him never to run again or to go into the Yankee army, for any man caught the second time with a parole would be put to death, so Mart was stricken from the ranks of the engineers at his special request.

His engine had been captured right opposite Capt. Richard McCann's property Dick at this time was captain of a Confederate company. Before the war he was a passenger conductor on the Nashville & Chattanooga road, but you can see, dear reader, what a grand mistake he made in capturing a locomotive and burning her up with his own fence rails. That same locomotive belonged to his enemies, who were twice as strong as he was. Revenge is sweet to the Yank, and we had it.

Before 12 o'clock that night one regiment was ordered out to burn Richard McCann's house down I think it was the Nineteenth Illinois Infantry.

I was the engineer ordered to haul them out. I had an old inside-connected called "Slatter." I think she was got for the Pittsburgh & Fort Wayne road, anyhow she was an old-time Mason engine. My fireman's name was, I think, on that particular night Pat Crosby

The colonel got on the engine with the fireman and myself. The night was very dark, and when we got to within about two miles of Dick's residence we could see his camp-fire about one and a half miles on the right side of the road. I do not think he had more than 50 or 75 men, while we had about 700 or 800, but of course we did not know how many men he did have, and our colonel was expecting them to attack us while on the train.

I think he as well as myself became a little nervous I am sure that at one time he thought we were right into a trap, as he could see Richard's men on the move. He caught me by the shoulder, and asked me in loud tones

"Can you not stop that d—d noise the engine is making?"

"What noise?" I asked.

"That noise coming out of the stack"

I was pulling up a pretty good grade, and going around a curve into Antioch. I told him

"Yes, sir, I can stop that noise if you want it stopped"

"Well, stop it at once"

Well, you know all I had to do to stop was simply to shut off and it stopped.

Immediately the colonel stepped from the gangway to my foot-board and laid his hand on my shoulder and said

"Why, the train has stopped."

"Well, the noise is stopped," I answered

"D—n it, can't the train move without that noise?"

"No!"

"Well," he says, "put out that headlight and let her go"

Say, boys, we did not need any fancy cushions to sit on, we just stood up on our little foot-board ready to dodge bullets—and, I assure you, we had many a one to dodge Well, we arrived and stopped in front of Dick McCann's house. I asked the colonel to let me go with him, so he did I asked him what his orders were, and he told me they were to get the folks out of the house and burn up the house and contents, not even allowing Mrs McCann to take her wardrobe out.

I says, "Colonel, that is pretty hard."

He surrounded the house with his men, and he and I went up on the gallery at the front door and rapped. It was then about 11 P. M. Mrs. McCann came to the door herself As soon as she saw who it was she said in a very pleasant voice

"Good evening, Colonel." The colonel says

"Good evening, Mrs. McCann."

He then pulled out a large government envelope and says, "Mrs McCann, I have called on you on very unpleasant business"

She says, "I expected you, and I told and begged Richard not to capture that engine and burn it up, for the Yankees would have revenge soon, but I did not expect it so soon," but like a brave woman she says

"Colonel, do your duty as a soldier should, but let me save my wardrobe, as it is not much, but I never expect to get any more."

I looked at the colonel, and saw big tears standing in his eyes.

I said, "Colonel, please let me have some of your men, and give us five or ten minutes before you apply the torch" The men in front could hear all we said, and responded just as soon as the colonel gave his consent, which was five minutes.

I told Mrs. McCann to tell us quick what she wanted to save, and we hustled it out lively. Inside of six minutes that house was one solid mass of flame

As soon as the colonel was satisfied, we all boarded the train and started back to Nashville

Poor Dick had to stand on the hill and see his hard-earned money go up in flames and smoke. Perhaps you will laugh at the idea of a passenger conductor having hard-earned money in the good old days before the war, but everybody said that Dick was honest

Well, we will drop Dick for a while. Colonel McCullom, the colonel of the Ninth Michigan, was an indefatigable worker. He pushed the road through to Murfreesboro, thirty miles from Nashville.

Of course, if your refer to the history of the war you will see that we fought for every inch of the ground, and we fought one of the hardest battles ever fought before we got to Murfreesboro—that was the battle of Stone River The Yanks got there, then we got to running regular trains to that point Brice Custer (a brother of General Custer), Hi. Keys, George Richardson, Bill Russell, Daniel McGee and myself ran them We kept this run about three or four months General Rosecrans was in command of the Army of the Cumberland. I believe General Sherman relieved him before we left Murfreesboro. Well do I remember when we left A little incident happened to Hi. Keys before we left.

I was lying at Murfreesboro one night, when Hi. Keys came in on extra and had orders to come right back to Nashville. He commenced joking me about getting out ahead of me I tell you, boys, I never felt sad about anybody getting ahead of me going out, for in those days it was safer to stay inside of the lines.

Well, he got out in about one hour's time About two hours afterwards I was called to get ready and go. Well, I started out. My fireman's name was Mike Campbell. When Mike got aboard, I asked him how he felt. He said he felt just as if something was about to happen I laughed at him and away we went.

We got within nineteen miles of Nashville, on the Knowland pike, when I saw Hi.'s red lights. I called Mike's attention to them. "Didn't I tell you, we had better look out, for that train is captured," says he At that time we carried with us forty or fifty soldiers as a guard on each train

I pulled up to the red lights, and halloed —but got no answer. I got off my engine and went up to the caboose and found it empty. I heard Hi.'s engine blowing off steam through the safety-valve. I called the captain of the guard and told him something was wrong in front of the train. It had been raining hard and the ground was very muddy. I asked the captain to take half his men and go one side and I would go up the other side.

He said "No," very quickly. I said, "All right, you stay and guard this train, and I and my fireman will go." So Mike and I started up each on a side—of course we were unarmed, and I thought if we were captured they would parole us and let us go—but it would not have been so, for Dick McCann and Gen. Forrest sent me word the very next day that if ever they caught me they would kill me, for hauling the troops out that burnt Dick's house.

Now you see what a generous railroad man he was after what I had done for him. I guess if I had heard this one day sooner I would not have gone up to that train.

Well, as it was I did go, and Mike also. We did not find, nor see, nor hear of any rebels, nor did we see old Hi. nor his fireman, nor any Yanks, all were gone, and the poor old engine was laid over on her side, trucks badly damaged and one cylinder broken. This engine was an old Roger engine, called after the M. M., "T. W. Smith"

On looking around, we could see where old Hi. and his fireman had made tracks through the mud and ran to Lavene, about two miles away. It was a telegraph station.

Hi telegraphed to Nashville, and said that the Rebs had a battery planted on the Knoxville pike, and had fired into him and knocked the engine off the track. Well, poor old Hi thought this was so, but it was not, Mr. Editor, the Rebs had a better thing than the trouble of placing a battery to knock an engine off the track. It was simply a bomb-shell, as we found out afterwards. It was placed there by one man. He slipped out a tie and dug a hole, then placed in the bomb, and laid the end of the rail on the cap. As soon as the engine struck it, it exploded and knocked her off the track The bomb was made like a jug I think it would hold about a peck of powder and slugs.

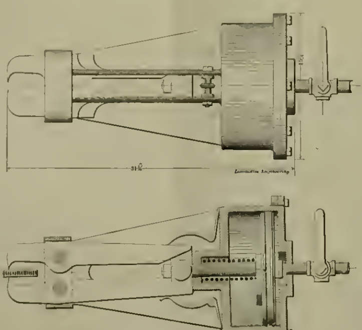
*[To be continued.]*

The B. & O. are getting ready for the World's Fair business, and are fast adding new engines to the passenger equipment. They have put into service some forty engines within two months. There are now employed out of Chicago some of the big 19x24 American engines with $6\frac{1}{2}$-foot drivers. Engines of this class are those that do the dizzy act in hauling the Royal Blue trains between Philadelphia and Washington.

## Baird's Stay-Bolt Cutter.

We hereby illustrate a novel form of stay-bolt cutter in use in the shops of the Atchison, Topeka and Santa Fé, and invented by the boiler shop foreman, Mr. Archie Baird. Those interested will readily understand the machine by examining the engravings. It is a set of beveled shears operated by a piston and having sufficient power to cut a stay-bolt. It does the work very expeditiously. The medium of power may be air, steam or water, but the former is best suited for ordinary shops. The device takes very little room, being 32 inches long and 15 inches diameter, and is suspended by a clevis at the center of gravity so that it can easily be handled by one man. The piston is connected to a V-shaped crosshead, which operates the shears. The leverage is three to one and the piston receiving a pressure of nine tons imparts a shearing power of 27 tons. The cutting edges of the shears are so made that in operating the machine for cutting stay-bolts all that the operator has to do is to simply let the shears come up as close to the boiler as the shears will allow it, and after the bolt is cut off it leaves just enough protruding to make a good head of a bolt after it has been hammered up. There is attached to the piston a rubber washer and coil spring, which render the machine noiseless, prevents any pound, and acts as a cushion while returning the piston to its normal position. There are also plate springs at each side which return the blades to the normal position when the bolt has been cut off.

This machine can cut off an average of 1,000 bolts, $1\frac{1}{4}$-inch diameter, per hour. It makes a neat, clean, shear cut, allowing an equal amount of each head to be riveted over afterwards, and does this without the injury to bolt and thread, so common with the hand process. After cutting over 50,000 stay-bolts the cutting edges of the shears are as sharp as when they were first applied.



BAIRD'S STAY-BOLT CUTTER.

## The Memphis Bridge.

One of the greatest bridges in the world was last month opened across the Mississippi by the Kansas City & Memphis Railway, at Memphis, Tenn, being the only bridge across this river below St. Louis. It is the largest truss bridge in this country and is the third largest in the world. The eastern end of the bridge is located on a high bluff near the point from which De Soto is said to have first viewed the Mississippi. The first span is a cantilever anchor arm, 226 feet high. Then there is the main span of $794\frac{1}{2}$ feet, and then two more large spans aggregating 2,597 feet and terminating in 2,300 feet of plate girder viaduct, making a total length of nearly a mile and a half. The bridge weighs 9,500 tons The main posts are 80 feet high and weigh 30 tons each. It is entirely of steel and some of the plates used are said to have been the largest ever rolled in the United States. We have condensed these facts from an illustrated article in the *Engineering Record*.

It is surprising to witness the hopefulness there is among inventors relating to bumper-brakes. That was the first of continuous brake tried for controlling railroad trains, and it has been brought out in a variety of forms that follow closely on the number of car-couplers. No form of bumper-brake ever worked satisfactorily, and every inventor of bumper-brakes appears to have wasted his time; yet others keep coming up like sheep to the slaughter. A month ago a patent was granted to William B. Guernsey, Norwich, N. Y., for an automatic compression-brake, for which no less than thirty-five separate claims are made. The principal novelty of the brake is that it has more mechanism than most of those that went before it

## Some Tests of Hollow Stay-Bolts.

The Falls Hollow Stay-Bolt Company recently submitted some of their bolts to severe tests in order to demonstrate the fact that there were no welds of any kind in them.

That they are made of good material is shown in the picture below, which was reproduced direct from the photograph; in each case where the bolt is partly broken it was first "nicked" deeply to insure a break.

The central piece is one of many that we saw drifted until they split. In each case there was a distinct tear of the metal and no appearance of a weld.

There are makes of hollow bolts that are welded up of half round stock or of two common gas-pipes one placed within the other and welded there; this last is a dangerous thing when a bad weld occurs as the outer tube has the thread and is fast to the sheet while the inner one has nothing to hold it; when the outer skin breaks the inside tube pulls out like a telescope.

With high pressures, hollow stays or drilled stays are an insurance of notice in case of rupture, the drilled stay will tell of the bolt broken next to the outer sheet—where most of them do break—but the bolt with a hole clear through it will inform on a case of treason anywhere from the fire-box to the shell.

About the most fertile of car-coupler inventors is Mr. Lucien Barnes, of Syracuse, N. Y. He was the inventor of several couplers that are now in the market under other names, notably the Gould. Last month patents were granted him for still another coupler of the M. C. B. standard type.

On the railroads of Jamaica the train men get about the smallest wages paid for similar service. The conductors get from six to ten dollars a week, and the engineers from ten to fifteen. One of the curious who ran a 10-wheel Rogers engine there on a 176-foot grade, while building the division, got the magnificent salary of fifteen dollars per week; when the road was completed he was promoted to running a regular passenger train and his pay was fixed at ten dollars and fifty cents per week. Jamaica is an English colony and the management of the road is English. It is too bad that this road can't be forced to pay its responsible men, the engineers, decent living wages.

A "Circumstance"—Forty Head of Cattle Killed.

The Toledo, St. Louis & Kansas City, of which Mr. John Orton is master mechanic, have lately erected very good shops at Frankfort, Ind., for locomotive and car repairs. The shops are substantially built of brick, and are arranged on the parallel plan. The equipment of tools is very good, and the tools are said to be admirably arranged for doing work with least possible movement of material.

We have lately heard numerous highly favorable reports from master mechanics about the Leach sanding device for locomotives. Those who are using the invention appear to be finding new virtues in it all the time. Several of those who have the sander in service say that it saves enough tires in six months to more than pay for the outlay of applying it. The saving of sand is also no small item. It appears to fulfill the double purpose of providing sand at the right time and place, and at the same time using less than half the quantity distributed by the common sand-box.

## An Old Hay-burning Locomotive.

The above heading does not mean that the curious old locomotive shown attained eminence by setting fire to the hay on the right of way. She obtained in early days her energy for train-pulling by burning hay in the firebox. She is to be seen in the Canadian Pacific yard at McAdam Junction, N. B. The engine was built by the Portland Locomotive Works, in 1856, for the Portland, Saco & Portsmouth road, and was one of the first outside-connected engines built at Portland. The cylinders are 13x20 inches, and driving-wheels 60 inches diameter. The steam-chest is horizontal and the cylinders inclined and riveted to the smokebox, which is wrought iron. The throttle-valve is in the smokebox and is of the old D pattern.

The engine came into the possession of the New Brunswick Railway by consolidation of the road for which she was built. She is fitted up for sawing wood and is still used for that purpose. The mate of this engine was thoroughly overhauled three years ago and sold to the Chigneto Ship Railway Co. for construction purposes.

A Laboring Man.

A cylinder-casing formed of one piece of pressed steel has been patented by E. W. Mackenzie Hughes, of Chicago. The intention is to make the casing by the Fox process.

## Indicating the Engine on the Fastest Train in the World.

By Angus Sinclair.

DESIRE FOR HIGH SPEED.

The desire that people have to transfer themselves from one place to another with the least possible loss of time will always keep up a keen popular interest in rapid means of transportation. The mind flies round the world fast as the electric flash and the means of making the body keep pace with the mind at that kind of speed is what would satisfy the extremist demand for rapid transit. Something very much less than this will have to suffice even with electricity as a means of propulsion, but meanwhile the people want to know to what extent their progress through space is likely to be accelerated in the near future. It was for the purpose of being able to obtain some accurate information on this subject that the writer lately made a power test of a locomotive pulling the fastest train in the world.

The resistances to movement encountered by railroad trains at the higher speeds and the amount of power required to move trains at high velocities have excited great diversity of opinion among the men who ought to be best capable of settling these problems. The subject is certainly not well understood, or there would be less uncertainty about how fast it is possible to run trains. For years a mile a minute has been regarded as the outside limit at which a railroad train could be run, but performances have lately demonstrated that the locomotives coming into use on our first-class lines are capable of exceeding by one-half the old accepted limit of forced velocity. There are probably as many locomotives in the country to-day that could be urged, under favorable circumstances, to attain a speed of ninety miles an hour as there were engines fifteen years ago capable of maintaining on a level track a speed of sixty miles an hour.

THE EMPIRE STATE EXPRESS.

There is at present in this country a popular demand for faster trains between the principal cities. This demand was inevitable with the improvement in railroad structures that rendered fast traveling safe, but it has been very much stimulated by the remarkable success of the Empire State Express run by the New York Central Railroad Company. This train is the fastest in the world. The running time between New York and Buffalo, a distance of 439½ miles, is 8 hours and 40 minutes, calling for an average speed of 52½ miles an hour. A peculiarity about this train is, that it is the most punctual in arriving at its destination of any long-distance train in the country. If any delays occur they are nearly always made up, and on one occasion lately 31 minutes were made up on one division

Through the courtesy of Mr. William Buchanan, superintendent of motive power of the New York Central, the designer of the locomotives that run these fast trains so successfully, the writer was privileged to make a test of one of the engines The work consisted in making a record of the water and coal used in two runs from New York to Albany, and the taking of indicator diagrams to show the working of the steam in the cylinders and supply data for estimating the horse-power developed.

LOCOMOTIVE 870

The engine tested was No 870, with cylinders 19 x 24 inches diameter, driving wheels 78 inches diameter, and having a boiler with 1,821⅝ square feet of heating surface and carrying steam at 170 pounds pressure The engine which is of the eight wheel type, was illustrated in the February number of LOCOMOTIVE ENGINEERING, and was built at the Schenectady Locomotive Works There is nothing peculiar about the engine except that she has an exceptionally large boiler and has steam passages sufficiently large to permit the steam to get in and out with little wire-drawing or obstruction The engine is equipped in excellent style for convenience in operating She has Richardson balanced valves, Jerome metallic packing, Nathan light-feed lubricators, and piped lubricators to the principal bearing

ATTACHING THE INDICATOR

As a connection for the indicator openings were drilled into the counter bores at the ends of the cylinders, and connecting pipes led to the top of the steam chest where the indicator was set Motion from the cross-head was taken by a Brumbo pulley secured to a swinging bar fulcrumed on the running-board This is a fairly good method of reducing the cross-head motion for ordinary locomotive speeds, but it is not adapted for the shocks that are inevitable when a train is running faster than sixty miles an hour. The indications were taken with a Tabor indicator, having a five-inch drum and a spring with a scale of 100 pounds to the inch. The indicator is all that could be desired for high speed purposes A Crosby revolution counter was used which gave an accurate record at the highest speeds

THE RECORD.

The mechanical department of the New York Central have devoted a great deal of attention lately to keeping close water and fuel records, which enabled me to obtain the benefit of men accustomed to taking records and appliances that had been found satisfactory. The speed counter was operated by Mr P T Lonergen, chief draughtsman of the mechanical department and he also noted the steam pressure and position of levers. The water and coal record was taken by Mr. Wm J McDonald, an engineer who has much experience of that special work.

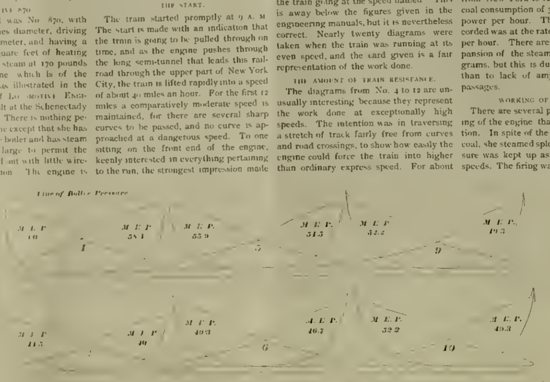
THE TRAIN

The train consisted as usual of four coaches weighing, with estimated load, 340,000 pounds The engine and tender in working order weigh 200,000 pounds, so that a total weight of 270 tons had to be kept in motion

In watching the preparations for the start to make a run of 143 miles without stopping, there was nothing unusual to be noted. Engineer Buchanan appeared to devote anxious attention to having all the bearings carefully oiled, and the fireman had the long 8-foot firebox well loaded with a clear-burning fire The coal on the tender had a very unpromising look, for most of it would have passed through a 1-inch mesh, but it proved better than it looked.

THE START.

The train started promptly at 9 A. M The start is made with an indication that the train is going to be pulled through on time, and as the engine pushes through the long semi-tunnel that leads this railroad through the upper part of New York City, the train is lifted rapidly into a speed of about 40 miles an hour. For the first 12 miles a comparatively moderate speed is maintained, for there are several sharp curves to be passed, and no curve is approached at a dangerous speed. To one sitting on the front end of the engine, keenly interested in everything pertaining to the run, the strongest impression made was the careful manner in which the train was handled.



*Tabor Indicator, Scale 100*

THE ROUTE.

This route offers exceptional opportunities for fast running, because the railroad follows the bank of the Hudson River and there are no track crossings at grade and few road crossings. The streets of the numerous villages are well protected and the track is almost a true level A speed of a mile a minute could probably be maintained safely all along the route after leaving the Grand Central Station, but they do not operate the train in this way. At a few sharp curves the engineer reduces the speed sufficiently to permit the train to go round without shock and then the few seconds of time lost are made up by faster running on the straight track

THE POWER REQUIRED TO PULL THE TRAIN.

During the time that the engine was first lifting the train into speed diagram No 1 was taken. It shows a mean cylinder pressure of 59 pounds. According to this the power exerted on the rails to move the train is 6,553 pounds, or 24 pounds per ton The speed is 37 miles an hour, which could be maintained on about half the expenditure of power represented by the diagram. The balance, of course, is expended in accelerating the speed. When a speed of nearly 60 miles an hour was reached, the engine settled down to steady running, neither accelerating the velocity or letting it decrease. Card No. 2 represents the work done in this way and measures the power required to keep this weight of train running at a mile a minute. The average cylinder pressure is 40.7 pounds, representing a total traction force of 4,520 pounds without making deductions for interval friction. If we deduct 10 per cent. for friction, it leaves 15 pounds per ton to keep the train going at the speed named This is away below the figures given in the engineering manuals, but it is nevertheless correct. Nearly twenty diagrams were taken when the train was running at its even speed, and the card given is a fair representation of the work done.

THE AMOUNT OF TRAIN RESISTANCE.

The diagrams from No. 4 to 12 are unusually interesting because they represent the work done at exceptionally high speeds. The intention was in traversing a stretch of track fairly free from curves and road crossings, to show how easily the engine could force the train into higher than ordinary express speed. For about 20 miles the speed was maintained at about 70 miles an hour, and it probably ran up to 80 miles, for diagram No 11 was taken when the engine was making 340 revolutions per minute, which is within a few feet of 79 miles an hour. Cards 4 and 5 were taken shortly after water had been scooped up and when the engine was working into speed Cards 6, 7 and 8 represent the work of keeping the train running 70 miles an hour. They were taken three miles apart when the speed was almost uniform. The average cylinder pressure for the three cards is 47.6 pounds Deducting 10 per cent. again for friction, this leaves 17 6 pounds per ton as the power exerted in keeping the train up to a velocity of 70 miles per hour. Cards 9 and 10 show an increase of area due to the opening of the throttle, and by the aid of a slight descending grade it worked up the speed to about 79 miles an hour, when diagram No. 11 was taken. This is a phenomenally good diagram for the number of revolutions and a piston speed of 1 360 feet per minute. The back pressure is unusually small for this speed, and the compression is not beyond what is necessary to insure smooth running. This result is due in a great measure to the large steam ports.

THE DIAGRAMS.

The diagrams represent the steam distribution as it goes on in the ordinary working of the locomotive. Some of them show bad reduction in initial pressure due to throttling. The evil of this can be appreciated from a study of diagrams 2 and 11. In the former, 31.4 pounds of water are exhausted for each horse-power developed, and in the latter the water consumption per horse-power is 21 pounds. Throughout the trip 7 pounds of water were evaporated per pound of coal As near as I can estimate, the work of pulling the train from New York to Albany was done on a coal consumption of 3½ pounds per horse-power per hour. The highest power recorded was at the rate of 1,120 horse-power per hour. There are traces of initial expansion of the steam in most of the diagrams, but this is due to throttling rather than to lack of ample steam pipes and passages.

WORKING OF THE ENGINE.

There are several points about the working of the engine that are worthy of mention. In spite of the slack character of the coal, she steamed splendidly, and the pressure was kept up as easily at the higher speeds. The firing was very skillfully done. There was very little jar to the engine, and she rode like a coach, and passed the sharpest curves very smoothly. When running close on 80 miles an hour the machinery worked as smoothly as at the lower speeds, and no trace was to be perceived of hammer-blow or other disturbance due to the heavy weights swinging round at a great velocity.

Annexed are a few leading dimensions of the engine

Size of cylinders, 19 x 24 inches

Driving-wheels, 78 inches diameter.

Steam ports, 18 x 1¼ inches.

Exhaust port, 18 x 2¾ inches.

Bridges, 1⅛ inch thick.

Eccentric throw, 5¼ inches

Valve travel, 5½ inches.

Outside lap, 1 in.

Inside lap, $\frac{1}{64}$ inch each side.

Driving-axle journals, 8½ x 10½ inches.

Engine truck journals, 6 x 10 inches

Tender journals, 4½ x 8 inches.

Crank pins, 5½ x 5½ inches.

Side rods, channeled, 4½ x 3½ inches.

Boiler material, steel, $\frac{9}{16}$ inch thick

Firebox, 96 inches long, 40⅞ inches wide.

Tubes, 268, 2 inches outside diameter, 12 feet long

Heating surface of tubes, 1,670.7 sq feet.

Heating surface of firebox, 150 8 sq feet.

Grate area, 27 3 sq. feet.

PARTICULARS OF INDICATOR DIAGRAM.

| No. of Diagram | Throttle opening | Reverse lever notch | Point of cut off | Boiler pressure | Revolutions per minute | Speed in miles per hour | Indicated horse-power |
|---|---|---|---|---|---|---|---|
| 1 | ¼ | 18 | 8½ | 160 | 160 | 37.1 | 648 3 |
| 2 | ¼ | 18 | 8½ | 165 | 260 | 60.8 | 728 |
| 3 | ⅛ | 18 | 8½ | 170 | 190 | 44 | 551 |
| 4 | ⅛ | 18 | 8½ | 170 | 250 | 58 | 891 |
| 5 | ¼ | 18 | 8½ | 160 | 260 | 60 | 900 |

## How to Fix Up a Headlight.

By C. B. Conger.

Some of the young men who have fired a good engine with a headlight in first-class order, which was looked after by an engineer that was an expert in the business, get a great shock when they are promoted and get an engine ready to fall to pieces. The headlight on her in generally in bad shape, wick burned short, a leaky oil tank, air passages around the burner and wick-tube full of dirt and pieces of crust off the wick, reflector smoked up and top of case filled with soot.

It is quite a trick to put it in good shape to give you good service.

In the first place empty the oil tank, rinse it out with a little clean oil, see that the oil-pipe between wick-tube and oil-tank is open and clean of sediment; if it leaks around the shaft of the little cog-wheel that turns the wick up, put some candle-wick packing in the nut and don't screw it up too tight. If the oil-tank leaks, now is the time to get it soldered, the pipe to let air in the top of the oil-tank should be high enough so oil won't splash out; an air hole as large as a small needle is large enough if kept open, a large air hole lets the oil slop up around a loose wick.

A knit or felt wick is the handiest to put in as they are made the right size, if you have to make one of cotton flannel, get some one to show you if you don't know how, as it is something that can not be well described. Put it in smooth and even, tie it at the bottom around the wick-holder with fine linen thread with a small knot so it will not crowd the wick against the other side of the wick-tube. After getting the wick in so it can be raised or lowered easily, run it clear down and burn off the top even with the top of the wick-tube, with a small flat piece of red-hot iron; then fill the tank with oil. See that *all* the holes and air spaces about the burner and the air hole up inside the wick are wide open and perfectly clean; the supply of air inside and outside the flame must be adjusted or it will smoke. If the flame strikes the chimney, too much air comes up inside the flame around the button, if it runs up straight and close to the button, there is not enough inside. A new headlight has a slide at the bottom of the inside tube to shut off the supply of air when necessary; if this slide is gone, get a cork large enough to fill the hole and cut big notches in its edge to let a sufficient supply of air past it.

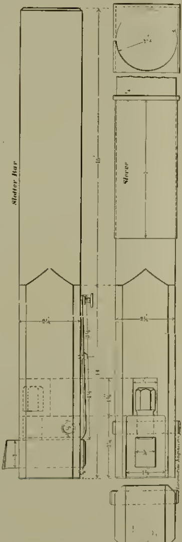
See that the springs on top of the reflector are bent so as to hold the chimney square with the burner, and keep it from striking the edge of the hole in the reflector when running. Then use oil and fresh lampblack to clean the reflector. Old lampblack often has dirt and grit in it on account of the package being open on the engine for months, and it will scratch your reflector. Do not use any tripoli, whiting, or patent polish, the silver coating is thin enough without scouring it off. If you use alcohol to mix the lampblack with, it is better than oil, as it evaporates and leaves the silver clean. When the reflector is done, clean out the case, get all the soot out of the opening in the top, so the draught will not be interfered with; wipe the case out clean, get some quick-drying white paint, with which paint the inside of the projecting ring the glass is set in. The reason for this is, pure white is a good reflector of light. If the headlight has the number of the engine in the sides of the case, paint the outside of the reflector, sides, and back of the case also. It is an advantage to tip the top of the headlight away from the stack a little and put a wedge under the bottom, so it will throw more of the light on the track, where you want it, and not up in the air. When the flame is the right height and burning properly, the middle of the flame should come level with the little prick punch mark that is exactly in the middle of the back end of the reflector, then the light is in the focus of the reflector. If you suspect the oil you use is poor or has water in it, empty the oil-tank once in a while, as the water all settles in the oil pipe at the bottom of the wick and keeps the oil out.

It will take half a day to do all this work, and do it right the first time you try it, *but it pays to do it well*. A good headlight may save your job for you the first time you head into a siding with a full train and show you cars, when the siding was said to be "all clear." This is a long item on this subject, there is some more of it on page 5, March number, 1889, Locomotive Engineer.

## Improved Slotter Bar.

Illustration is made herewith of a very handy slotter bar designed by W. E. Ormond, a machinist in the E. T. V. & G. shops at Atlanta, Ga.

The writer recently saw one of these



Slotter Bar.

bars at work there, and was much impressed with the handiness of the tool. This particular bar was 29 inches long, 15 inches of the upper end being turned round and fitted into a split box that clamped it in any position, the lower part being of 2-inch square steel stock, the bottom is slotted out and a tool holder hinged into it, the sizes being given on the plate. Behind the tool block there is an adjustable spring that holds the tool firmly against the set screw bearing, yet allows it to swing clear on the up or return stroke.

The bar saves a great deal of setting, and requires only the cheapest and easiest made tools.

On another page, in Mr. Tabor's article, will be found an indicator card taken from a Baldwin compound locomotive running 91.7 miles per hour—the fastest on record.

## A Texan Narrow Gauge.

The Houston, East & West Texas system of narrow gauge line reaches from Houston, Tex., northwest to Shreveport, La., and taps a large lumber and agricultural district.

This road is one of the few old-fashioned narrow gauges. It has pretty good sized cars and they carry a standard gauge load all right, but their largest locomotive has only a 13-inch cylinder, and the majority of them are 12x16-inch.

There are in operation some 232 miles of the yard-wide track, and their passenger trains make over one hundred stops in this distance.

Our old friend E. A. Campbell has charge of the motive power, and seems to be wringing a good deal out of it without putting much in. It is almost useless to ask for anything on a narrow gauge—"Wait till after we widen out," is the usual form of delay.

One thing they have got, the best I saw in the South, and that is a diamond stack for wood-burners. It is smaller than the usual balloon affair, and seems to be especially efficient in a cotton-carrying country, and the fire claims of the road are practically *nil*.

The shops are mere sheds, not worth mentioning, and while all the new machinery is first-class there is not much of it, and a whole lot of old stuff.

Campbell is one of the happiest of men, however, has more friends than the Governor, and knows how to show a railroader all the shops in the city as well as his own.

This little road was built by a shrewd old Frenchman, Paul Bremond, who also built the H. & T. C. road. Bremond was an eccentric old fellow, a confirmed spiritualist; he claimed that a spirit appeared to him once and said "Paul, arise, go thou and build railroads—but don't try to manage any of them."

Paul arose and built the H & T. C. and sold out at a large profit, and the road prospered. Then Paul arose again and built the narrow gauge, and tried to run it—and that appears to be the matter with it now.

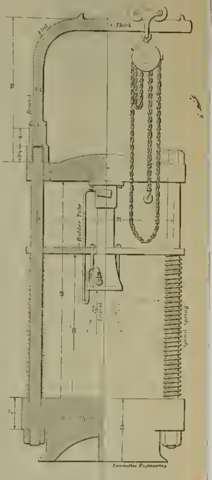
J. A. H.

We have heard reports lately that several railroad companies having large shops are contemplating the adding to their establishments a foundry for making malleable iron castings. Malleable iron is coming so much into use for railroad rolling stock purposes that it seems natural for railroad managers to conclude that they ought to make the castings themselves, just as they make their other castings. We have reason to believe that establishing plant for making malleable iron castings is likely to prove an expensive way of obtaining the desired product. The running of a malleable iron foundry requires not only special skill in management and workmen, but it requires special selections of iron. It might be well for those intending to go into this business to inquire into the experience of others who have added malleable iron foundries to manufacturing establishment. The makers of agricultural implements have in some instances started malleable iron foundries in connection with their works, and we understand that in every case the cost of castings is greater and less satisfactory then it was to purchase from those who make malleable iron casting a specialty.

A praiseworthy arrangement has been arrived at between all the French railway companies. In future every employé, of no matter what line, will be entitled to a return free pass once a year to any station in France, and his family living with him to passes at one-quarter the usual passenger rates. This understanding will, therefore, allow railway employés to spend their yearly holiday in their own home, or wherever else they may choose, at little or no expense.

## Cheap Hydraulic Press.

The press shown was designed by Mr. E. E. Davis, master mechanic of the Boston & Maine shops, at Boston, and is used for pressing in driving box brasses and for the numerous other jobs about a machine



Handy Press.

shop where steady pressure is much preferable to blows. As will be seen the apparatus consists essentially of a hydraulic jack set in a frame and special springs to return the head to the normal position.

An improvement in car heaters has lately been patented by William C. Baker of Baker Heater fame. The improvement is designed to use steam from the locomotive as the heating medium for a perfected system of hot-water circulation. He has also patented an improved form of safety vent for steam apparatus, which appears to overcome the shortcomings that have usually been found in giving relief to the Baker heater.

Concerning the question of long locomotive mileage which has been exciting some of our readers, a correspondent in New Orleans makes a plea for an engine on the Louisville & Nashville, which he considers deserving of the confectionery. The engine doubles a run of 180 miles every day of the year, making over 120,000 miles annually.

To be ready for the variety of cars that will be running all over the country during the World's Fair, the Chesapeake & Ohio people have prepared a drawing, showing the maximum dimensions of cars that will pass through their tunnels. Blue prints will be furnished to all connecting lines or others desiring them.

The New York, Providence & Boston are in the market for six locomotives. The chances are that the Rhode Island Locomotive Works will secure the contract. These works have lately secured an order from the Ohio & Mississippi for fifteen ten-wheel engines with cylinders 20x24 inches, and five six-wheel switchers.

LOCOMOTIVE ENGINEERING.

## Steel vs Iron for Fireboxes.

The following letter, written by the American agents of the Low Moor Co., appeared in a recent issue of the *Railway Age*:

"An article in the May number of LOCOMOTIVE ENGINEERING, concerning an order recently given for Low Moor fireboxes opens up an interesting question for discussion. The writer of that article seems to have overlooked some important considerations. Twenty years ago Low Moor iron was almost invariably used for this purpose, and there are engines in service to-day that have Low Moor fireboxes and boilers that have been in use twenty years or more and are still in good order.

"Steel superseded Low Moor iron because it was cheaper and ... service. This ... filled ...

... on roads ... pits and corrodes ... Low Moor iron does not crack, and it withstands the effects of the bad water in a way that steel never has and never will.

"As to failures of iron plates caused by blisters and laminations, that is entirely a question of proper welding. Low Moor iron is a clean, sound metal, and being properly welded, very seldom shows either of these failures. The possibility of such defects is more than offset by the tendency of steel plates to crack and blister.

"If the writer of the article referred to will read Dr. Dudley's report read at the meeting of the American Institute of Mining Engineers in regard to the tests made by him at Altoona on steel plates, he will see that the conclusion which the Pennsylvania people have come to is, that the trouble with steel plates, aside from their tendency to crack, is blisters caused by slag and gas bubbles which it is impossible to prevent.

"The master mechanics who used Low Moor plates twenty years ago and have gone through the steel age are the ones who are coming back to this material to get them out of the troubles which the use of steel has brought them into. The superintendent of motive power referred to in the article is one of these men, and one who stands among the very highest in his profession. So far from being twenty years behind the times, he is in line with the movement which bids fair to replace steel with Low Moor iron almost universally on the roads which are obliged to use bad water."

It is rather a late day to revive the discussion of the causes that led to the general substitution of steel for the iron plates formerly used in fireboxes, but the memory of persons interested may be refreshed by a review of the facts. It is natural that the agents for Low Moor iron should consider that the change to steel was a mistake, and that their interests and aspirations should magnify the prospects of a return to iron, but there are few disinterested persons likely to see the question in the light that favors employing iron again. The experience with the different kinds of material for fireboxes has been too conclusive in favor of steel.

No question relating to railroad machinery received more investigation from the Railway Master Mechanics' Association than the "material best suited for boilers and fireboxes." A convention seldom passed during the first ten years after the association was formed without this question being reported on or discussed. For years iron as a material for fireboxes had many friends, but they gradually grew less until their voices ceased to be heard. They were all compelled to yield to the inevitable and adopt the use of steel, because iron was notoriously given to failure through laminations and blisters. One of the latest reports on material for boilers and fireboxes says:

"As steel of a low grade has so firmly established itself in favor, and is almost universally used for the firebox sheets of coal-burning locomotives, we do not consider it necessary to prevent the relative merits of steel, iron and copper, but we may safely conclude that steel is the best. Steel of a low grade seems to meet all the requirements, if we except its tendency to crack in the side sheets of the firebox. This tendency is not confined to steel, but reports show that iron has the same tendency in an equal if not greater degree, besides its liability to blister from imperfect welding in the process of manufacture, or in other words, from its not being homogeneous."

As the manufacturers of steel plates obtained year by year increased experience in their business, an article was produced which was much more reliable for fireboxes than the steel used in the first few years after it was introduced. The best quality of sheets were, however, given to cracking round the stay-bolts when the inside became incrusted with scale, and this character of failure has continued to be a source of complaint against steel. Some men are very ready ... magnitude of ... ii ...

... ted to abide ... of experience, especially ... owners, and this class of men have flown at sundry times from the evils of cracking steel sheets and bought new experience with iron sheets that cracked and blistered and laminated. Six or seven years ago the troubles with iron had become so dim that the master mechanics of several roads began using iron, and the movement was heralded far and wide by the iron sheet interests. The movement was of remarkably short duration. While investigating at that time the experience of various roads with iron and steel for fireboxes, the writer received a great many letters from master mechanics which were practically unanimous in favor of steel.

The following is an extract from a letter received from Mr. William Buchanan, superintendent of motive power of the New York Central: "My experience thus far has been entirely satisfactory in the use of steel, and I consider it in every way superior to iron for both boiler and firebox. Very frequently while using iron we would lose about one out of every three plates in flanging, resulting from the looseness of the metal, and the boiler would need patching; and a so-called new boiler would be patched after completion. Another objection to iron for fireboxes was that the sheets would become blistered, and after not more than three months' service would have to be patched. Since using steel there has only been one or two instances where the metal blistered. Another advantage of steel over iron is that the metal does not draw in working, but retains about its original thickness. It is also less given to the dangerous practice of grooving inside."

The criticism Dr. Dudley made on steel plate in his report to the Institute of Mining Engineers is no doubt true. Steel is far from being perfect, especially the cheaper brands that some roads are short-sighted enough to purchase. But the Pennsylvania Railroad Company, which Dr. Dudley represents, do not propose going back to iron because steel is defective. There are sufficient records belonging to that company to keep them informed of what they would experience if they were to fly from the lesser evil into the vortex of the greater. If we could hear of any material likely to give better results than steel for fireboxes, we should be glad to advocate its use. Iron gives no such promise. It has been weighed and found wanting. Iron is superior to steel for stay-bolts and many other purposes, but for firebox sheets it is not a success. If any master mechanic is inclined to coquet with iron for fireboxes, we would advise him, "Don't!"

## Good Joint Inspection System.

A number of the railroads running into Buffalo, Cleveland and other interchange points are delivering and receiving cars under a joint inspection agreement prepared by Mr. A. M. Waitt, assistant general master car builder of the Lake Shore.

A joint foreman is engaged, whose duty it is to see that all cars are carefully and impartially inspected. The foreman has the authority to decide all disputes, but appeals may be made to an executive committee appointed by the roads interested. The decision of this committee is final.

All cars are received if safe to run, and defect cards given by the joint foreman.

When trains are delivered on receiving tracks, no loaded cars are sent back. If they require repairs, they are attended to by the receiving road and a defect card given. If a loaded car cannot be put in safe condition, the load is transferred at the expense of the delivering company and the car returned. All action ... cars must be ... d ...

... the ... responsible for ... connected with the inspection, oiling and light repairs of all cars.

The joint foreman is governed by the M.C.B. rules, and special interpretations of them or special rules issued by the executive committee.

Each road accepts its own cars with certain old defects without defect card, provided the defects have not been caused by derailment, wreck, or unusually rough handling. The acceptable old defects are: running boards defective; roof boards loose or missing; end or side finish loose or missing; end or side sheathing loose; ends or sides bulged (not broken); corner plates cracked; truck or body bolster broken; spring planks broken, truck springs broken; draft springs broken, brake-shoes worn out; journal bearings worn out (in accordance with M. C. B. rules); center plates broken; center plate bolts broken; truck truss-rods broken or missing; body truss-rods broken or missing; center pins broken or missing; oil-box covers broken or missing; spread trucks; loose dead blocks; cars low on trucks, where wheels come in contact with intermediate timbers; side bearings and bolts broken.

## Train Resistances.

There ought to be no great difficulty in ascertaining with some degree of accuracy the measure of the resistances encountered by railroad trains at various speeds, yet there is no measurable quantity in engineering about which there is so much uncertainty. The article published on another page, giving particulars of tests made on the New York Central's famous Empire State Express, gives figures of the train resistance that are greatly at variance with the results that would be obtained by calculating the resistance according to the rules laid down in engineering manuals. Many years ago D. K. Clark proposed a formula for calculating train resistances, which was accepted without question and is still used. According to this rule there is a resistance of eight pounds per ton to movement, and then that the resistance increases with speed at the rate of the square of the velocity in miles per hour divided by 171. American engineers modified this to read six pounds per ton for the constant resistance and accepting the remainder of the rule; so that in our engineering text-books we find the rule for finding the train resistance on a level, straight track to be

$$\frac{V^2}{171}+6=R$$

That is, V representing miles per hour and R resistance per ton. The rule plainly stated is: Square the velocity in miles per hour, divide this by 171, add 6 to the quotient, the result being the resistance at the rails in pounds per ton.

In the run referred to a speed of seventy miles an hour was maintained for some miles and several diagrams were taken when the locomotive was doing the work of maintaining the speed without loss or gain. The power developed showed that the entire resistance of the train and locomotive at that speed was 17.6 pounds per ton. In the discussions that come up periodically about what the ultimate speed of railroad trains will be, arguments are advanced that after a speed of sixty miles an hour is passed a point is soon reached where the locomotive will absorb the whole power developed in moving itself. Figures to prove this are always given, based on the text-book rule. According to this rule the resistance per ton at 70 miles an hour is over 34 pounds. If this were true there is not a locomotive in the country that would keep three cars running at 70 miles an hour.

The fact is that the ... ity does ...

... used to ... trying to find ac... ... data to calculate from. Its existence was evidently due to the desire of mathematicians to establish formulæ for everything. In this case the formula was established without the necessary data upon which to build correctly.

A number of American railroad companies have used dynamometer cars for years in which excellent provision was made for keeping an accurate record of train resistances. These go to prove, not only that the resistance does not increase in proportion to the square of the speed, but that the resistance varies greatly according to the load per axle. On a Western railroad a great many records were made some years ago on the resistance of different kinds of freight trains, with the view of finding out how many cars certain locomotives ought to haul. A train of loaded freight cars weighing 940 tons gave an average resistance of $5\frac{1}{2}$ when running twenty miles an hour on the level. A train of empty freight cars weighing 340 tons showed a resistance of 12 pounds per ton when running twenty miles on level track. A passenger train weighing 363 tons gave $7\frac{1}{2}$ pounds per ton resistance at a speed of thirty miles an hour. The records respecting train resistance of the roads having dynamometer cars agree substantially with those which we publish in our article on the Empire State Express.

## The Mechanical Conventions.

The railroad mechanical conventions which meet at Saratoga this month promise to be as interesting and as profitable as any meetings of the kind ever held. Both the Master Car Builders' and the Master Mechanics' Associations have programmes of business that will keep the members in close session if each association is to get done in the three days usually devoted to each convention. The arrangement of bringing the meetings closer together, which goes first into effect at the approaching meetings, promises to have a good effect upon both conventions. Persons who wish to attend both meetings may do so by spending about one week at Saratoga. From the talk that was heard when the proposal to reduce the time between the conventions was under consideration, we should believe that the greatest part of the superintendents of motive power who have been in the habit of attending the Master Car Builders' Convention only will remain over and give their counsel to the master mechanics. We understand that the managers of several of our largest railroad systems are encouraging their mechanical men to attend these conventions. This is a move in the direction of encouraging enlightenment, and we doubt not that the companies following this policy will be the gainers.

There are eleven subjects to be reported upon by Committees of the Master Car Builders' Association and nine by Committees of the Master Mechanics. This means a great deal of work. If the conventions take vigorous hold at once and deal with the most important questions, letting minor ones pass, there may be time for the reading of all the reports and full discussions of points where members are in the position to add valuable information. But there will be no time to waste on trifling talk. Much depends upon the presiding officer for pushing the business along fast enough to insure dispatch and not too fast to stifle the discussion of important subjects. Both the associations are fortunate in having good presiding officers, and we have no doubt that both will perform their duties so that the conventions will be the best ever held.

## Big Driving-Wheels.

The railroad companies that have most experience with the running of fast trains are inclining toward unusually large driving-wheels for the high-speed locomotives. The Pennsylvania Company are building at Altoona a two-cylinder compound locomotive that will have driving-wheels seven feet in diameter, and the New York Central people are putting wheels of the same size under one of their engines in the West Albany shops. This is not the first time that this size of driving-wheel has been used on American locomotives. Nearly half a century ago there was a tendency on American railroads to use locomotives with very large driving-wheels, but the fashion was short-lived. Several railroads in New England had engines with driving-wheels six feet diameter and upwards. Some of the lines now constituting the New York Central tried the same practice, and the Camden & Amboy was noted for the large wheels of its "flyers."

There were several causes which made large-wheeled locomotives unpopular in those days. The track was not adapted for particularly high speed, there were no means of controlling trains so that they could be stopped quickly, and no signal system to insure notice when stations were not clear of trains. These circumstances made the running of particularly fast trains unsafe. Besides that, the engines were by no means efficient, for there was not sufficient boiler or cylinder capacity behind the wheels to produce the power required. Consequently the engines were slow in starting and of little use on a hill. That made them unpopular. The modern big-wheel engines are different. They have very large boilers that supply steam freely and cylinder capacity to turn the wheels rapidly on moderate grades. The prospects are that the big wheels have now come to stay and that they will soon appear in increasing numbers.

We lately examined a steel casting in the Cambria Iron and Steel Works that weighed fifteen tons.

We understand that the Committee of the Railway Master Mechanics' Association investigating the subject of exhaust pipes, nozzles and steam passages have not been able to finish experiments they expected to carry out, and that in consequence an unfinished report will be presented. This Committee has already done a great deal of original investigation that is calculated to be highly valuable to railroad companies, and we look with interest to the discoveries they have made during the year. Strangely enough, most of the members of the Committee have been on roads where single nozzles are almost exclusively used and their recommendations refer mostly to this kind of nozzle. The single nozzle is in a small minority, and it is highly desirable to obtain accurate information upon double nozzles and the best way to place them for an open stack. It would also be interesting to see some accurate comparisons of the steaming and coal-consuming properties of single and double nozzles tried on the same engines. A great deal has been spoken and written upon the subject of nozzles, but it is one that will still profitably bear investigation. There is nothing about the engine that affects the coal consumption so intimately and nothing in which a trifling change produces such important effects.

## NEW BOOKS.

RECORD OF SCIENTIFIC PROGRESS. By Robert Grimshaw, M. E. Cassell Publishing Co., New York.

This book gives in convenient form a brief outline of the scientific progress of the past year. The improvements on railroads and in all departments of the mechanic arts appear to be fairly complete and concise. The book will be convenient for persons having to refer to the material progress of the past year.

VALVE-GEARS FOR STEAM ENGINES. By Cecil H. Peabody. John Wiley & Sons, New York. Price, $2.50.

This book has been written by a professor of the Massachusetts Institute of Technology for the use of engineering students. We imagine that the students who profit by this work will need to be well advanced in mathematics, for the author appears to talk in algebraic formulæ. The subjects treated are plain slide-valves, shifting eccentrics, link motions, radial valve-gears, double valve-gears, and drop cut-off valve-gears. The book is about as interesting as a chapter of Euclid and is prepared much in the same style.

LIABILITY OF RAILROADS FOR PERSONAL INJURY TO EMPLOYÉS. By Addison J. Penn. Published by Geo. H. Smith & Co., Cedar Rapids, Ia.

This is a small hand-book written by a member of the Iowa bar, giving a plain condensation of the laws and decisions in every State of the Union on the liability of railroad companies for personal injury to employés. It gives in convenient form a great deal of information that railroad men ought to know. Incidentally it gives evidence of the miserable diversity of laws in the different States respecting liability for injury and the necessity for radical reforms.

ELEMENTARY LESSONS IN HEAT. By S. E. Tillman, Professor of Chemistry, United States Military Academy. John Wiley & Sons, New York. Price, $1.50.

This book was written for the use of students of the Military Academy, and it is best adapted for a text-book on the subject treated. It contains, however, the information in very concise form, which will be found valuable for anyone studying the various phenomena of heat. The subjects treated are thermometry, dilation of bodies, calorometry, production and condensation of vapor, change of state, hygrometry, conduction, radiation, thermo-dynamics, terrestrial temperatures, aerial motors, and aqueous motors. Engineers will find the chapter on thermo-dynamics of much value and interest.

## PERSONALS.

Mr. E. O. Hill, who was for years superintendent of motive power of the Erie, died last month at Port Jervis, N. Y.

Mr. Herbert Wallis, mechanical superintendent of the Grand Trunk Railway, has gone to Europe for a two months' visit.

Mr. W. R. Morris has been appointed foreman in charge of cars and locomotives of the Chesapeake & Ohio at Ashland, Ky.

Mr. W. T. Smith, master mechanic of the Chesapeake & Ohio at Lexington, has had his jurisdiction extended over the Big Sandy division.

Mr. Edward Gibbs has been promoted to be general engine dispatcher and road foreman of engines of the Manhattan Elevated Railroad.

Mr. John G. Thomas has been appointed assistant superintendent of motive power and rolling stock of the Port Reading Railroad.

Mr. H. M. Curry has been appointed assistant road foreman of engines of the Northern Pacific. He has been for several years an engineer on the road.

Mr. James Nute has been promoted to be engine dispatcher of the Boston & Maine at Northampton, Mass. Mr. Nute has been for years an engineer on the road.

Mr. J. T. Lord, for some time general foreman of the Northern Pacific shops at Mandan, N. D., has been promoted to the position of master mechanic at the same place.

Mr. James P. Ring, engine dispatcher for the Boston & Maine at Concord, has resigned. Mr. Ring had been with the company forty years as engineer and engine dispatcher.

Geo. Royal, Sr., represented the Sunday Closing Association of Chicago, at the Engineers' Convention in Atlanta last month, and secured their indorsement for Sunday closing of the Exposition of 1893.

The Nathan Manufacturing Co., New York, have recently issued a revised catalogue of all their goods. Every mechanic who has charge of the repairs of injectors, lubricators or oil-cups should send for it.

Mr. John Howard, for some years general foreman of the West Shore shops at Frankfort, N. Y., has been appointed master mechanic of the Weehawken division in place of Mr. Aldcorn, resigned.

Mr. E. R. Beatty, formerly a Pan Handle engineer, and late assistant road foreman of engines, is now R. F. of E. of the Richmond division of the P., C., C. & St. L. Ry., with headquarters at Richmond, Ind.

Mr. Chas. B. McCormick has been promoted from engineer on Division B of the Pittsburgh division of the Pan Handle to assistant road foreman of engines in charge of Division A; office at Pittsburgh, Pa.

Mr. George Foster, an engineer on the Newport News & Mississippi Valley, has been promoted to be trainmaster. Mr. Foster had been less than a year on this road, and came from the Chicago & West Michigan.

Mr. C. H. Wiggin, master mechanic of the Boston & Maine's Concord division, is said to be the youngest master mechanic in the country. His youth is not found to be any drawback, as he has no end of vim and energy.

Mr. George E. Merchant, president of the Rochester & Pittsburgh Coal and Iron Company, has also been appointed assistant to the president of the Buffalo, Rochester & Pittsburgh Railroad, and becomes general manager.

Mr. Thomas Aldcorn has resigned his position as division master mechanic of the West Shore Railroad to accept the position of mechanical superintendent of the Empire Car Coupler Co., with office at No. 15 Warren street, New York.

Mr. H. H. Warner has been appointed master mechanic of the Seattle, Lake Shore & Eastern, with headquarters at Tacoma, Wash. Mr. Warner has long been master mechanic in charge of the Northern Pacific at Tacoma.

Mr. George S. Branch has been appointed master mechanic of the Wilmington, Onslow & Eastern Carolina. He was formerly roundhouse foreman of the Norfolk Southern, and went there from the Port Jervis shops of the Erie.

Mr. M. Patterson has been appointed division master mechanic of the Union Pacific at Salt Lake City, Utah, to succeed Mr. A. C. Hinckley, resigned. He has been general foreman of the shops at Omaha, Neb., for a number of years.

The many friends of Mr. Morris Sellers among our readers will be gratified to know that the beautiful young lady shown in "A Revery," in the *Cosmopolitan Magazine* for April, is Miss Blanche Sellers, daughter of the old-time master mechanic.

H. K. Porter & Co., of Pittsburgh, Pa., have closed a contract with Colonel Pedro Villar, chief engineer of the Army of the United States of Colombia, for five middle-gauge locomotives, which are to be used on railroads in the mountainous regions of Colombia.

We made a slight error last month in saying that Mr. James E. Sague had been appointed assistant superintendent of the Schenectady Locomotive Works. Mr. Sague was made mechanical engineer, and Mr. White continues to be assistant superintendent.

Mr. E. P. Jones, lately promoted to the position of road foreman of engines of the Norfolk & Western, has been with the company for thirteen years. If intelligence and knowledge of the business commend men for promotion, Mr. Jones truly earned his rise.

Mr. O. F. Nichols, chief engineer of the Brooklyn Elevated Road, has been appointed general manager in place of Mr. Frederick Martin, resigned. Mr. Nichols is the practical railroad man who has been supplying the knowledge on which the road was operated. He is now coming to his own.

Theodore L. Woodruff, inventor of the Woodruff sleeping-car and formerly president of the Central Transportation Company, was run over and killed by a railway train at Gloucester, N. J., May 2. He was eighty-one years old. It will be remembered that Mr. Wagner, inventor of the sleeping-car which bears his name, was killed in a collision.

Mr. William Mahl, who has long been private secretary for President Huntington of the Southern Pacific system, has been appointed assistant to the president. Mr. Mahl is a particularly able railroad man, and has enjoyed a great range of experience. He is a mechanical engineer, and is exceptionally well posted about rolling-stock matters.

Mr. A. C. Hinckley has been appointed master mechanic of the St. Joseph & Grand Island. Mr. Hinckley was for years an engineer on the C. B. & Q., and was made road foreman of engines of the Union Pacific by Mr. G. W. Cushing. From that he went to be master mechanic of the Salt Lake division, which he left to accept the position he now holds.

Mr. Lewis Gleason, who went to Brazil two months ago to be resident engineer and representative of the Brooks Locomotive Works, is reported to have had a slight attack of yellow fever. We have received a letter from Mr. Gleason, written shortly after his arrival, and he was in excellent health then, but he must have been seized with the disease a few days afterwards. We are pleased to learn that the attack was slight and that Mr. Gleason is recovering.

Mr. Charles A. Thompson has been appointed superintendent of motive power and rolling equipment of the Port Reading Railroad, which takes in all the lines of the Central Railroad of New Jersey. Mr. Thompson has long been with the Long Island Railroad, and has enjoyed a long and varied railroad experience. There is no man in the country more faithful to his employers or more zealous for their interests than Mr. Thompson. He has charge of all the master mechanics and car builders on the road.

Mr. Lewis W. Towne, late general superintendent of the Kansas City, Fort Scott & Gulf, died last month. Mr. Towne was one of a family of railroad men who all rose from humble positions to important offices. The best known of these brothers is A. N. Towne, now general manager of the Southern Pacific system. Mr. Lewis W. Towne was successively fireman, locomotive engineer, shop foreman, master mechanic, assistant superintendent, and general superintendent. The latter position he filled with honor and success on several important railroads.

People who are in the habit of going to Dunkirk, N. Y., on business, will be pleased to learn that a first-class hotel has been opened in the town. From what we have heard the Hotel Gratiot will compare favorably in all respects with any of the first-class hotels in other cities. We note in an illustrated pamphlet, sent out about the hotel and other attractions of Dunkirk, that Mr. R. J. Gross, of the Brooks Locomotive Works, is president of the company that owns the hotel and that Mr. H. C. Hequembourg is secretary and treasurer. With such names in the management, travelers will have the assurance of everything being first-class.

Railroad men and others interested in obtaining accurate information respecting the real value of compound locomotives have reason to be thankful to Mr. Geo. Gibbs and the other members of the Railway Master Mechanics Association Committee investigating the subject for the extensive work done to obtain facts relating to the working of this type engine. The Chicago, Milwaukee & St. Paul Railroad Company permitted no expense to stand in the way of thorough tests being made. The amount of work involved in getting the data obtained into shape for a report was enormous. About sixty runs were made and all the information obtained had to be digested for the report. At one time Mr. Gibbs had eight men working on the figuring required to get the data into comprehensive form. Ever since the committee was appointed we have felt assured that a report of the very greatest value to the engineering world would be prepared, and appearances now indicate that we are not going to be disappointed.

## The Cambria Iron and Steel Works.

A large party of railroad men went with Coolbaugh & Pomeroy, New York, in an excursion party to visit the Cambria Iron and Steel Works at Johnstown, Pa., and the Lukens Iron and Steel Works at Coatesville, Pa. Incidentally the party took in Altoona, and visited the Pennsylvania Railroad shops there.

Arrived at Johnstown they were taken around the outskirts of the immense Cambria Iron and Steel Works by a locomotive. The magnitude of the place could well be judged from the views obtained on the heights above the establishment. They were then taken from building to building for the purpose of following the product in all the varying processes, from the time when it left the cars in the form of crude ore until it came out as shining steel. The leading officers of the works accompanied the party round, and they seldom receive visits from a more appreciative company.

The departments in which the visitors were most strongly interested were those that produced the open-hearth steel products. The genesis of this part is in a row of Pernot revolving furnaces. This furnace is a novelty to most men who are familiar with the plain open-hearth furnace. The Pernot furnace has a circular bed which rests on a central spindle, and wheels like a turn-table. The bed is set at an angle of about six degrees. As it revolves the charge keeps moving, so that the whole is exposed to the heat of the gas flame. The claim is made that the product of this kind of furnace is much more uniform than that of the common furnace, where mixing of the metals depends on the boiling action.

After seeing this metal poured into ingots, we follow them to the rolls, where, after much skillful manipulation, they emerge in the shape of axles and blanks for crank-pins, the two products that our party are most interested in following. This material is about to go through the Coffin process of toughening steel, and we follow the details with keen interest. The process is based on the discovery that a small bar of steel if suddenly reduced to a certain temperature by dipping in water and then permitted to cool slowly will be toughened. It is said that the effect of this process is to produce a double internal action on the molecules of the metal that changes the texture from crystalline to what is called the amorphous form—that is, a form where the fracture shows neither crystals, grains or fibers.

After coming through the rolls, the axles and blanks are cooled slowly to put the carbon in a non-hardening state. They are then taken to a heating furnace of peculiar shape with a charging-door on one side and a drawing-door on the other. Here the axle is heated to the temperature at which carbon changes to the hardening state, the effect being to break up the crystallization. It is then drawn by an ingenious apparatus and dipped in a trough of water and kept revolving. In a few seconds it is raised out of the water and rolled on to a cooling-bed. When it first passes on to the bed the axle is black, but the internal heat soon makes itself manifest and the metal becomes red again. The axle is now permitted to cool in the air, after which it is ready for the lathe. This company rough-turns all the axles and crank-pins made.

The party could not follow a single axle from the furnace, but the various processes were traced. From the cooling bed we followed an axle taken at random to the drop test. The axle was put on the usual supports and a weight of 1,600 pounds permitted to fall upon it from a height of 25 feet. Each time the blow was struck the axle was turned round. Some of the party stood watching till it received about thirty blows, with no sign of fracture, then most of them left, one of the wits telling them to keep on and he would return in a week. The axle broke after receiving 49 blows. All material intended for crank-pins is treated by the Coffin process.

These works turn out an enormous quantity of iron and steel, their Bessemer plant being one of the finest in America. Space does not permit us to go into details. After visiting most of the leading rolling mills in the world, the conclusion arrived at here was that the Cambria Works are far ahead of all others in the mechanical appliances employed in the various operations. Nothing is done by hand where machinery can be employed, and the most perfect appliances known are the kinds used. The extent of the works may be judged from the fact that about 5,000 men are engaged in keeping the machinery in good order. Another suggestion as to the amount of work done is the fact that fifteen small and twenty-five large locomotives are in use daily handling the material.

DELEGATES TO ATLANTA CONVENTION B. OF L. E., MAY 11, 1892. GRAND OFFICERS IN FIRST ROW.

*Photographed by Edwards & Son, Atlanta.*

# The A. B. C. of the Steam Engine Indicator

BY HARRIS TABOR

The recent designs of locomotives for fast passenger service show that the lesson of the indicator has been heeded by the designers. The great reduction in initial pressure at high-piston speed and the consequent increase in back-pressure indicate that the limit of piston speed, with present port openings, has been reached, if it has not been exceeded. In new passenger engines, especially the "record breakers," there is a tendency to larger drivers, which means an increased speed in miles without increase in piston travel. The "Vauclain" compound, 385, on the Central of New Jersey, has driving-wheels 78 inches in diameter, and the engines drawing the Empire State Express on the New York Central have wheels the same size. Both these engines are famous; the former has made the quickest recorded mile, and the latter have the reputation of making the fastest long-distance runs. The cylinder capacity of these engines is about the same. The compound has two high-pressure cylinders 13 inches in diameter, and two low-pressure cylinders 22 inches in diameter, with a stroke of 24 inches. The New York Central engines have simple cylinders 19 inches in diameter by 24-inch stroke. The compound would probably start a heavier train because steam is admitted from the boiler to the low-pressure cylinders in starting, and a comparison, at that time, would be between 19-inch and 22-inch cylinders. But at these very high speeds it is not the starting that makes the problem difficult. The real question is to make the time, and, in this respect, the cylinder capacities of the two engines, assuming equal ports and pipes, would be about the same.

Attempts at higher speeds will probably result in larger cylinders and drivers. The Pennsylvania road is building a fast passenger compound with drivers 84 inches in diameter, and the New York Central have under way a simple engine with drivers the same size. If these engines have the boiler and cylinder capacity, they can easily add 10 per cent. to the speed of the wonderful Empire State Express. We may look for fast riding when the compound, with 90-in drivers, said to be under consideration by a prominent builder of locomotives, is on the rails. This locomotive may not inaugurate the 100-mile gait that so many seem to be looking for, but the chances are that she will demonstrate the fact that a limited train of three cars may be pulled at that speed over good roads, if enough people are willing to pay for the luxury of riding that fast, and are willing to take chances of the train being controlled by the system of brakes now in use

Wire-drawing and abnormally high back-pressure are not the only evils incident to fast running. The strain on side-rods, due to centrifugal force, when an engine is running 300 revolutions per minute, is enormous This fact is occasionally attested by a broken rod. The English designers of locomotives for fast runs have so great a fear of this danger that they avoid it by using one pair of drivers only. With their light trains this may be done without fear of putting too much weight on bearings or track. American trains are much too heavy to be handled by uncoupled drivers, notwithstanding our friend Le Van insists that the side-rod is the great bar to high economy in American locomotives. If one would ride between Jersey City and Philadelphia on a "slippery rail" behind the "Webb" compound, he will readily understand how weak the English system would be on our roads There is, undoubtedly, an evil in coupled drivers for fast trains; but the heavy passenger trains in this country cannot be handled by uncoupled wheels. The tendency to slower piston speed, and consequently less number of revolutions per mile, due to larger drivers and larger cylinders, will correct the evils that follow the unnatural rotative speed that many American locomotives have to make to meet the requirements of their schedules.

In the preceding paper attention was called to indicator diagrams from a simple engine, taken at widely different speeds, which illustrated the tendency of steam to wire-draw or reduce in pressure when compelled to flow too rapidly through pipes and ports. The accompanying cards were taken from a "Vauclain" compound (No 385) running in fast passenger service on the Central R. R. of N. J., and will serve to show how great an influence reduced flow of steam through pipes and passages has in its cylinder distribution. In considering these remarkable diagrams we must keep in mind the fact that some of them were taken at the fastest speeds ever indicated or authentically recorded. The record was not made by an attempt to count the revolutions by touch or sound, but was carefully timed, by the aid of a stop-watch, from mile post to mile post.

In the compound engine the function of the steam-pipe is to supply the high-pressure cylinder with steam from the boiler. When the ratio between the high and low-pressure cylinders is three to one, as is the case of the compound in question, the high-pressure cylinder is much smaller than the cylinders on a simple engine The high-pressure cylinder of 385 is 13 inches in diameter, and the low-pressure is 22 inches The cylinder equivalent in a simple engine would be about 19 inches in diameter. The area of a 13-in. cylinder is 132.7, and of a 19-in. cylinder it is 283.5, more than twice as large. In the compound engine this smaller cylinder is fed with a larger pipe than is generally used on a simple engine of this class, and the steam ports in the piston-valve are much more liberal, hence we expect much less wire-drawing of steam, at fast speeds, in this type of engine. The diagrams fully confirm our expectations.

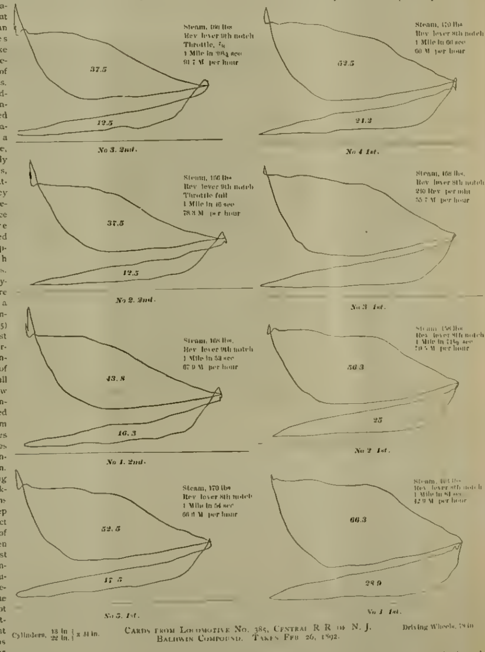
Two sets of cards are submitted. The first, at slower speeds, with reverse lever in the eighth notch, and the second, with reverse lever in ninth notch, the latter showing an earlier cut-off. The scale of pressure in both sets is 100 lbs. to the inch.

If the reader will take the series of five cards, with reverse lever in the eighth notch, he will notice that, beginning with No. 1, at a speed of about 43 miles per hour, all the valve functions are discernable on the card. The point of cut-off is very distinct, and there is little of what is called initial expansion, that is, the expansion of steam before cut-off takes place, due to wire-drawing. As he follows up this series he will find that, as the speed is increased, the valve functions are less distinct; but in no case are they difficult to locate. No. 5 shows the effect of speed more clearly than the others, and here the steam line is well kept up and point of cut-off well developed at a speed of 66.6 miles per hour.

The second series is more remarkable than the first, if the great speed at which they were taken is considered. The piston speeds are, respectively, 1,170 feet, 1,348 feet and 1,581 feet per minute. With ordinary steam-pipes and passages the least of these speeds would render an indicator card almost unintelligible, so far as defining the steam and expansion line is concerned; these lines would run together so that they could not be separated by the most practiced expert. It may be suggested that larger pipes and ports in the standard engine would reduce the evils of wire-drawing. If the steam pipe be too large, another serious trouble appears, viz., a tendency to draw water from the boiler when the engine is working hard. The free admission in the compound does not come from larger pipes, but from a reduction in the cylinder which takes the steam from the boiler. The effect of this reduction in the "Vauclain" compound is to double the size of the steam-pipe and passages without enlarging the opening to the boiler

If speed above sixty miles per hour is to be sought economically, larger wheels and cylinders will follow. The lesson of the cards published in this number insist upon the piston speed being kept below 1,000 feet per minute, even when cylinders are compounded, if the best duty be expected from the motive power.

Harris Tabor



Cylinders, 13 in. / 22 in. x 24 in.   CARDS FROM LOCOMOTIVE NO. 385, CENTRAL R R OF N. J. BALDWIN COMPOUND. TAKEN FEB 26, 1892.   Driving Wheels, 78 in

Mr William A Baldwin has resigned the vice-presidency of the Buffalo, Rochester & Pittsburgh Railroad.

## Some More Points on Combustion.

By M. E. Weil.

In my article in the March number it was shown that the hydrogen of the hydrocarbons was the first to burn, and that the union or combustion of hydrogen with oxygen produced water, $H_2O$. Before proceeding to the chemical changes that take place in the combustion of carbon with oxygen, I wish to give some idea of the intense heat given off when hydrogen is burned in the locomotive firebox by the oxygen, from the air. The reason for the hydrogen burning first is on account of the strong chemical attraction of oxygen for it. In fact, oxygen has a stronger affinity for hydrogen than for any other combustible.

You have learned that it is the clashing together of these atoms that produces the heat. Now since the attraction of oxygen for hydrogen is so great, the clashing will be more severe and therefore the heat more intense. In the complete combustion of one pound of carbon there are given off 14,500 heat units, while in the complete combustion of one pound of hydrogen there are given off 62,000 heat units.

The intense heat produced by the burning of hydrogen in oxygen is shown by the oxyhydrogen blow-pipe. This is an arrangement by which oxygen and hydrogen are brought together into one gas jet from two separate gas-holders. The heat produced by this blow-pipe flame far exceeds in intensity of temperature that produced by our most powerful furnaces. It is employed to melt platinum, which requires a temperature estimated at 2,000 degrees centigrade or 3,632 degrees Fahrenheit. This, of course, is pure hydrogen burning in pure oxygen. No such intense heat can be obtained by burning hydrogen in the air, for four-fifths of the atmosphere is nitrogen and only one-fifth oxygen. Neither is the hydrogen pure as consumed in the locomotive firebox being more or less mixed with other gases.

*One pound of hydrogen burned with its proper equivalent of oxygen gives off the same amount of heat, whether the combustion takes place in the locomotive firebox or in the oxyhydrogen blow-pipe.*

From the above, the importance of burning all the gases (hydro-carbon), and especially the hydrogen, is readily seen.

From the fact that only one-fifth of the air passing through the firebox is oxygen, the necessity of a free admission and good draft is very apparent. So much has been said about light fires and free admission, that I fancy I hear some of you saying "Chestnuts." Perhaps they are "chestnuts" to some of you, but they are truths, nevertheless, and will stand repeating. This matter of light fires can be overdone, however. I have in mind a young and energetic fireman who was so zealous in his desire to get the best possible results from the coal he put in the firebox, that he overdid the matter of shaking grates and cleaning fires.

While it is important to have a clean and light fire, you must not lose sight of the fact that enough fire must be on the grate to heat the oxygen to the igniting point as it passes through. What is needed in firing, as in all other things, is the "happy medium." This same "happy medium" is what Dame Nature hit upon when she diluted the oxygen of the air with four-fifths nitrogen. Did you ever think what would happen to the locomotive firebox if the atmosphere was pure oxygen? I have seen the time, before now, as the pointer lingered at 90 and 100, when I have wished for an atmosphere of pure oxygen.

Firemen often say of a good steamer, "I can burn her up." This they certainly could do if they had pure oxygen to work with. The effect of pure oxygen on combustion is shown by the following experiments.

A lighted match blown out so as to leave a coal of fire on the end—this inserted into pure oxygen, immediately bursts into bright flame. A piece of watch-spring with burning sulphur attached, plunged into pure oxygen, burns with greater brilliancy, and kindles and burns the watch-spring as if it were a shaving from the carpenter's bench. The combustion that takes place in our own bodies is identical with that in a locomotive firebox. It is the union of carbon and oxygen that produces animal heat.

With an atmosphere of pure oxygen this combustion would be accelerated, the blood would leap through our arteries and veins with increased velocity, our bodies would be practically burned up, and our light would finally go out. This odorless, colorless, tasteless nitrogen can be compared to the governor on an air-pump, in that it controls action, which, if allowed to go on unchecked, would lead to death and destruction.

I have asked you thus far to keep in mind but four chemical terms. Have you got them and can you tell where each one is found?

For the convenience of those to whom this appears difficult, I will repeat each chemical name I have used, giving its symbol. Carbon (C), hydrogen (H), oxygen (O), nitrogen (N). From now on, in using above terms, I will only use the chemical symbols C, H, O and N. You have not forgotten that H has a chemical affinity of one and that O has a chemical affinity of two. This was shown in the formation a molecule of water ($\begin{smallmatrix}H-\\H-\end{smallmatrix}O$ or $H_2O$). Now comes C with a chemical affinity of four. It naturally follows that one atom of C is capable of taking on four atoms of H, thus.

$C\begin{smallmatrix}-H\\-H\\-H\\-H\end{smallmatrix}$ or $CH_4$, which is the chemical formula of one of the hydrocarbons given off from bituminous coal. In nature this gas is called marsh gas. This same gas collects in mines and is called fire-damp. It is very explosive, and is much dreaded by the miners. In the complete combustion of C, one atom of C unites with two atoms of O, thus. ($C\begin{smallmatrix}=O\\=O\end{smallmatrix}$ or $CO_2$ *carbonic acid* gas. If, from any cause, the flow of O through the grate is retarded or checked, C will be content with taking on but one atom of O, thus. ($C\begin{smallmatrix}=\\=\end{smallmatrix}O$ or CO *carbonic oxide*. I say the atom of C will be content with but one atom of O. I might better say that it is content with but one, because it could not get two, on account of the scarcity.

In looking back, you will see that C, burning to CO, has two affinities unsatisfied. The atom of C passing up through the fire unites with one atom of O, and has two hands left feeling around for another atom, but it could not get in. The carbon is not to blame for this; it is more apt to be the fireman, who has not cleaned his ash-pan or who has allowed a foot or two of dead ashes and cinders to collect on the grate. Perhaps the blame may be on the engineer, who thought they could "get in," and would not stop to have ash-pan or fire cleaned.

A pound of C, burning to carbonic oxide, CO, as just described, gives off but 4,452 heat units; whereas, if sufficient oxygen had been present for it to burn to carbonic acid gas, $CO_2$, the same pound of C would have given off 14,500 heat units.

If from a dirty fire or other cause the C on the grate cannot get sufficient O for perfect combustion, what can the hydrocarbons, and especially the H, the king of heat producers, do but pass out of the stack unconsumed? You may say, admit O above the fire. This is not the difficult part. The admission above the fire must be regulated and under the control of the fireman. The O thus admitted must also be heated to the igniting point—here is the sticker. The man who by some *simple* means accomplishes this end for locomotives will have solved the smoke problem and immortalized himself to future generations. I have an "idee," but as none of my family have ever immortalized themselves I don't wish to break the record, and I propose to give every reader of Locomotive Engineering a chance for this honor.

A Flounced Petticoat.

## Cheap Passenger Cars.

The Pennsylvania Company is building an experimental excursion car at the Columbus shops which, if it turns out as expected, will solve an important problem. The company expects to handle a great many more people at the world's fair at Chicago than its ordinary passenger equipment will accommodate. To provide for the emergency it is proposed to construct a large number of cheap excursion cars which can be disposed of with as little loss to the company after the fair as possible. To this end it has been proposed to build a car body on an ordinary gondola. The idea is to make a sightly and comfortable car, but plain. An experimental car is now being constructed, and if it is satisfactory a large number will be built. The car will be about thirteen feet shorter than the standard passenger car and will seat about forty-five people. The cost would be about $850 to $1,000 against $5,000 or $6,000 for an ordinary passenger coach. The idea appears to be a practical one and is being worked out with great care. After the fair the gondolas can of course be utilized for freight traffic. In 1876 the Pennsylvania Railroad made a mistake in building a large number of cheap passenger coaches which could only be utilized on the branch lines and were of no practical value.—*Ohio State Journal.*

## A Flounced Petticoat Pipe.

In the engraving shown we see a form of a petticoat pipe very popular with some engineers, as it appears when the smoke-box front is taken down. It does not seem as if the contrivance would lead the gases in a straight line to the stack, yet the engine steams well. The view is from an old Portland locomotive, built in 1856, and still in use switching at McAdam Junction, N. B.

## Group of Master Car Builders and Master Mechanics.

When we decided to publish a group of the older officers and older members of the Master Car Builders' and Master Mechanics' Associations, we requested those whose portraits were to appear to supply us with some particulars of their professional career. Our intention was to publish as good a biographical account of each man as we could procure, but we have found it necessary to modify this design. A few of those who sent in notes of their career appeared afraid to let their light shine, and made the particulars as brief as possible. Others, however, wrote at considerable length about their experience, and we find on our hands a series of extremely interesting and valuable biographies of men who have performed a highly important part in the development of American railroad rolling stock. The biographies are too valuable to be condensed, and we cannot give them in full this month because they would entirely fill up the paper. So we have decided to give merely a plain outline of each man's professional career, and we will follow this up with detailed biographies as our space permits.

There are several old and prominent members conspicuous by their absence from our group. This happens in most cases from the excess of modesty that led to the refusal of a photograph. We have pleasure in presenting to our readers

JOHN KIRBY, President of the Master Car Builders' Association and General Master Car Builder of the Lake Shore & Michigan Southern Railway. Mr. Kirby learned the business in England and entered railway service in this country in 1848. He has been on the Lake Shore nearly 40 years and has risen from a workman to his present position. The Master Car Builders' Association was formed in his office at Adrian, Mich., in 1866. He acted as chairman of the meeting and was always one of the hardest working members.

JOHN MACKENZIE, President of the American Railway Master Mechanics' Association and Superintendent of Motive Power of the New York, Chicago & St. Louis Railway. Mr. MacKenzie rose to his present position through the course of training that has made a large proportion of our master mechanics. The outline is machinist apprentice, fireman, locomotive engineer, shop foreman and master mechanic. He was a foreman in the Rogers Locomotive Works for two years, and from there went to be superintendent of motive power of the Hannibal & St. Joseph. Was afterwards on the Kansas Pacific and the Union Pacific. In 1883 he went to the position he now holds. He joined the Master Mechanics' Association in 1876.

G. W. DEMAREST, Treasurer Master Car Builders' Association, and Master Car Builder of the Northern Central part of the Pennsylvania Railroad. Mr. Demarest learned the carriage building business in Rahway, N. J. Began car building with Cummings & James in Jersey City in 1852. Shortly afterwards he entered the shops of the Camden & Amboy Railroad and remained there till 1856. That year he went to take charge as foreman of the car shops of the Trenton Locomotive Works, remaining there till 1859. He went from there to be assistant foreman of the Pittsburgh, Ft. Wayne & Chicago shops at Ft. Wayne, Ind. In 1862 was appointed general foreman of the car department of the Northern Central and has remained there ever since.

O. STEWART, Treasurer Master Mechanics' Association and Superintendent of Motive Power of the Fitchburg Railroad. We have received no information respecting Mr. Stewart's professional career. He joined the Master Mechanics' Association in 1885, and has been an industrious member, taking an active part in many of the discussions.

JOHN W. CLOUD, Secretary Master Car Builders' Association and Western agent for the Westinghouse Air-Brake Co. Mr. Cloud was for several years mechanical engineer, and subsequently engineer of tests for the Pennsylvania Railroad at Altoona, Pa. He left there in 1887 to become superintendent of motive power for the New York, Lake Erie & Western, where he remained for about two years. He was for several years representative member for the Pennsylvania Railroad to the Master Car Builders' Conventions, and took a very active part in the proceedings.

ANGUS SINCLAIR, Secretary Master Mechanics' Association and one of the editors and proprietors of LOCOMOTIVE ENGINEERING. Mr. Sinclair received a mechanical training on a part of the Caledonian Railway, in Scotland, and subsequently had some experience in marine work. Began work in this country on the Erie; worked in Brooks' Locomotive Works and was engaged on engineering work on several Western railroads. Went to Chicago, Clinton & Western as assistant engineer, and subsequently was locomotive engineer. Then locomotive engineer and roundhouse foreman on the Burlington, Cedar Rapids & Northern. Joined the editorial staff of the *American Machinist* in 1883, and since then has been engaged on editorial work. Joined the Master Mechanics' Association in 1883.

Our artist has arranged the remaining names by numbers and placed them so as to give the best effect according to the tone of the photographs.

1. JOHN BLACK, an honorary member of the Master Mechanics' Association, and one of the first members. Mr. Black received the first part of his mechanical training in Scotland, and on coming to this country entered railroad service in the West and rapidly rose to the position of master mechanic of the Dayton & Michigan Railroad. When that road was absorbed by the Cincinnati, Hamilton & Dayton, Mr. Black became superintendent of motive power of the whole system, and remained there till a few years ago, when he retired from service. He has been a very regular attendant at the conventions.

2. WILLIAM GARSTANG, Second Vice-President of the Master Mechanics' Association and Superintendent of Motive Power of the Chesapeake & Ohio Railroad. Mr. Garstang received the greater part of his mechanical training on the Cleveland, Columbus, Cincinnati & Indianapolis Railroad under the late W. F. Turreff, and rose on that system through various grades to be master mechanic, with charge of the shops at Brightwood, Ind. In 1888 he was appointed to the position he now holds on the Chesapeake & Ohio. He joined the Master Mechanics' Association in 1887, and was elected vice-president two years ago.

3. JACOB LOSEY, now an honorary member, was one of twenty men who met at Cleveland, O., on September 20, 1868, and organized the American Railway Master Mechanics' Association. There are only four others of these men alive to-day. He was then master mechanic of the Louisville, New Albany & Chicago Railroad. He is now superintendent of the Louisville Steam Forge Co. Mr. Losey is a New Jersey man, and learned the machinist trade with the famous Seth Boyden at Newark, N. J. In 1853 he went West and went to work fitting valve and link motions by contract in the Menominee Locomotive Works at Milwaukee, Wis. From there he went to be foreman of the Detroit Locomotive Works. After remaining there four years he left to be foreman of the Detroit shops of the Michigan Central. Shortly afterwards he was made master mechanic of the Western division and held the position three years, leaving to take mechanical charge of the New Albany road.

4. H. A. TOWNE, an honorary member of the Master Mechanics' Association, is one of a family of railroad men who have all risen to prominence in the business. He is one of the oldest members of the Association, and was for years one of its most active and hard-working members. He rose by the foot-board, having been fireman, machinist and locomotive engineer on the Chicago, Burlington & Quincy. Next he was shop foreman on the Illinois Central, and then master mechanic of the Hannibal & St. Joseph. Here he devoted a great deal of study to boiler incrustation and water purification, and was for years an authority on the subject before the railroad world generally. Among prominent positions which he afterwards held were those of superintendent of motive power of the Northern Pacific and superintendent of the road.

5. CHARLES R. PEDDLE, an honorary member of the Master Mechanics' Association and purchasing agent of the Vandalia Line. Mr. Peddle learned the machinist trade in William Norris's Locomotive Works, Philadelphia, beginning in 1836. From there he went and worked in the Reading Railroad shops under Lewis Kirk. Among his associates there were Andrew and James Vauclain, David Clark, J. O. D. Lilly, George Peterman and others who have made their mark on railroad machinery. After working in the shops for a time he went upon the road as a locomotive engineer. From there he went to New England and worked in the different locomotive building shops there. In 1848 he went West and ran an engine for a time on the Madison & Indianapolis. Three years later he accepted the position of master mechanic of the Terre Haute & Richmond Railroad, which grew and swallowed others until it became the Vandalia Line. He joined the Master Mechanics' Association in 1872, and for years took an active part in the proceedings.

6. J. H. SETCHEL, Past President and Past Secretary of the Master Mechanics' Association and now agent for the Pittsburgh Locomotive Works. Mr. Setchel has doubtless done more to advance the interests of the Master Mechanics' Association than any other man. He joined the association at the second meeting, and at the fourth convention was made secretary, an office which he held till the close of the twentieth convention, when he was elected president. He has been present at every meeting of the association since he joined, and no man has taken a more active part in the proceedings. When he joined the association Mr. Setchel was master mechanic of the Little Miami Railroad and he remained there till 1882. From there he went to be superintendent of motive power of the Ohio & Mississippi, holding the position for three years, when he was induced by the late Mr. Brooks to accept the position of superintendent of the Brooks Locomotive Works. He left there three years afterwards and entered his present position.

7. W. H. DAY, Member of the Executive Committee of the Master Car Builders' Association and Master Car Builder of the Atlantic Coast Line. Mr. Day entered railroad life on the Chesapeake & Ohio at Richmond, Va., in 1866. Three years later he left to go with the Wilmington, Charlotte & Augusta, and has remained in the same place ever since. Mr. Day has been Mayor of Florence, S. C., for the last five years. He joined the Master Car Builders' Association in 1885, and is renowned as one of the most eloquent speakers in the association.

8. T. A. BISSELL, Third Vice-President of the Master Car Builders' Association and General Manager of the Wagner Car Shops at Buffalo. Mr. Bissell is one of the most celebrated car builders in the country and has held the most important positions in the business. He was for years superintendent of the Barney & Smith Manufacturing Company's works, and before that was in charge of the Pullman shops at Detroit. He was elected a member of the Executive Committee of the Master Car Builders' Association in 1883, and was elected vice-president at the 1890 convention.

9. JACOB JOHANN, an honorary member and Past President of the Master Mechanics' Association and Western Agent for the Safety Car Heating and Lighting Co. Mr. Johann has passed through an unusually varied experience as a railroad mechanical officer. He was born in Germany, but learned the machinist trade in the Norris Locomotive Works at Philadelphia. He worked in various Eastern shops for a few years and went West about 1855. His first prominent promotion was to the position of assistant master mechanic of the Missouri Pacific. He held this position for three years, when, in 1861, he was made master mechanic of the southwest division of the same road. The railroad position which he held longest was that of superintendent of motive power of the Wabash. He was there for eleven years. Mr. Johann has been a leader in the Master Mechanics' Association and a hard worker. A pet scheme of his was the converting of the Boston Fund into college scholarships, a thing that was consummated last year.

10. F. D. CASANAVE, Member of the Executive Committee of the Master Car Builders' Association and Superintendent of Motive Power of the Pennsylvania Company's lines west of Pittsburgh. Mr. Casanave received the regular mechanical training accorded to apprentices in the Pennsylvania shops at Altoona, and afterwards worked there in various capacities. From there he was appointed assistant superintendent of motive power at Fort Wayne, and on the promotion of Mr. Wood was advanced to the chief position. He is considered one of the ablest mechanical officers in the employ of a company that has been famous for developing men of ability.

11. JOHN HICKEY, First Vice-President of the Master Mechanics' Association and Superintendent of Motive Power of the Northern Pacific Railroad. Mr. Hickey was for about ten years master mechanic of the Milwaukee, Lake Shore & Western, and while there made his mark as one of the most progressive men in the business. Two years ago he was appointed to the position he now fills. He joined the Master Mechanics' Association in 1883, and was elected Vice-President in 1890. We have received no particulars of Mr. Hickey's experience.

12. WILSON EDDY, honorary member of the Master Mechanics' Association, is one of the few men remaining who had reached a working age when the first locomotive turned a wheel in America. Mr. Eddy was born in Vermont, in 1813. His first experience with locomotives was acquired in the shops of the Locks & Canal Co., Lowell, Mass. Here, in 1831, he helped to build the first locomotive built in New England, for the Boston & Lowell Railroad. The engines were made after the style of the Stephenson locomotives and weighed about 17,000 pounds. In 1840, Mr. Eddy went to superintend the repairs of the locomotives on what is now the western part of the Boston & Albany. In 1850 he was made master mechanic of the road. In that year he built the locomotive "Addison Gilmore," which was the first with outside connections and horizontal cylinders. On this locomotive he put the first pipes applied for oiling the cylinders from the cab, and the engine had the first spliced frame generally known as the Mason splice, although not used by Mason for two years after it was made by Mr. Eddy. This engine, the "Addison Gilmore," in a public trial at Lowell took the first prize for speed—a gold medal. Mr. Eddy remained on the Boston & Albany till 1880. While in charge of the Boston & Albany machinery, Mr. Eddy built 135 locomotives of his own design, making the drawings himself.

13. WILLIAM MCWOOD, Past President of the Master Car Builders' Association and master car builder of the Grand Trunk Railway. We have little information about Mr. McWood's professional career. He joined the Master Car Builders' Association in 1875, and has been an earnest worker and ready speaker. He was president several years.

14. BENJAMIN WELSH, one of the oldest

members of the Master Car Builders' Association and master car builder of the Central Pacific. We have no information respecting the experience of Mr. Welsh.

15. JOHN THOMPSON, honorary member of the Master Mechanics' Association. In 1848, Mr. Thompson began railroad work in the locomotive repair shops of the Eastern Railway of Massachusetts. After working there for four years he went to Cuba to superintend the erection of sugar machinery. Returned after a year to the Eastern as shop foreman. In 1855 was elected by the board of directors master mechanic and held the position till 1877. Mr. Thompson was the inventor and patentee of the extension smokebox, and he was the first to introduce other improvements on locomotives that are now universally used. We shall give more particulars in a future issue. Mr. Thompson joined the Master Mechanics' Association at the second meeting.

16 W. A. ROBINSON, honorary member and Past Vice-President of the Master Mechanics' Association. Mr. Robinson began railway work by serving a seven years' apprenticeship in the locomotive department of the London & Northwestern Railway of England. In 1862 he was appointed assistant mechanical superintendent of the Great Western of Canada and shortly afterwards became chief. He joined the Master Mechanics' Association in 1871, and for years took a very active part in the proceedings. He was several times elected vice-president. In 1875 he retired from railway life and entered into a manufacturing business at Hamilton, Ont.

17. JOHN W. PHILBRICK, honorary member of the Master Mechanics' Association, and long known to railroad men as Master Mechanic of the Maine Central. Mr. Philbrick was born at Waterville, Me., in 1821, and began mechanical work on the steamers on the upper Kennebec. In the fall of 1849, with a fellow engineer from a river boat as fireman, he ran a construction engine on the Androscoggin & Kennebec Railroad. The following season he set up the engine and tools for a repair shop for the road at Waterville. After working as a machinist there for two years, he was made master mechanic of the road. When the consolidation of roads forming the Maine Central was effected, Mr. Philbrick was appointed general master mechanic and held the position until 1883. In 1868, he built at Waterville the first locomotive ever built in Maine. He joined the Master Mechanics' Association at the first meeting and previous to that was a member of the New England Master Mechanics' Association. Since 1883 Mr. Philbrick has been in retirement from active service. At the age of 71 years he is still well and retains all his faculties.

18. MORRIS SELLERS, honorary member of the Master Mechanics' Association and one of the most active of the early members. Mr. Sellers belongs to the well-known family of engineers of that name. He received a first-class mechanical education, and in the Master Mechanics' Association was looked upon as authority on all scientific lines of engineering. A paper on "Combustion," which he read before the Association attracted the attention of the scientific world, and was translated into several languages. Some time in the early sixties, Mr. Sellers was made foreman of the Michigan Southern shops at Michigan City, a position he left to run a locomotive on the same road. After varied experience as engineer, machinist, draughtsman and foreman on different Western roads he was appointed master mechanic of the Des Moines Valley. He left that position about 1873 to become agent for the Westinghouse Air Brake Co. He introduced this brake upon a great many roads. After working at this line for three years he went into the business of rolling railroad splice bars and has been exceedingly successful.

19. JAMES M. FOSS, honorary member of the Master Mechanics' Association and Assistant President of the Vermont Central Railroad. Mr. Foss has been in railroad service all his working life. He learned the machinist trade in the Concord Railroad shops, and went upward on that road through the course of machinist, engineer and shop foreman. In 1861 he was appointed master mechanic of the New York Air Line, and remained in that employ four years. In 1865 he returned to the Concord Railroad as master mechanic. Three years afterward he changed to become master mechanic of the Vermont Central. Here he rose through recurring grades of superintendent of motive power, assistant superintendent, superintendent, and general superintendent. He was made assistant president last year.

20. CHARLES GRAHAM, one of the oldest members of the Master Mechanics' Association, and well known to railroad men for his long connection as master mechanic of the Delaware, Lackawanna & Western. Mr. Graham was born in Scotland, in the same town where Andrew Carnegie first saw the light. He learned the machinist trade there, and came to America in 1853. His first work was done with the Rogers Locomotive Works. Being an exceptionally fine mechanic, he had no difficulty in getting a choice position even in the dullest times. His first railroad work was done in the Piermont shops of the Erie. From there he went to the D., L. & W., at Scranton, as machinist and extra engineer. After a year's work here he was made general foreman. In 1864 he was appointed master mechanic of the Lackawanna & Bloomsburg road, which was controlled by the D., L. & W., and when the latter road was extended to Buffalo, his authority was extended to that point. In 1886 Mr. Graham took charge of the Scranton shops and the engines running on the main line. Few men have received more tempting offers to leave railroad work than Mr. Graham, but he clung persistently to his old road. He joined the Master Mechanics' Association at the second meeting, and has been a useful member of committees and a regular attendant at the conventions.

21. JAMES M. BOON, one of the oldest members of the Master Mechanics' Association and Superintendent of Motive Power of the West Shore Railroad. We have no notes of Mr. Boon's professional career, but we know that he has been one of the leaders in imparting progressive ideas into the designing, running and repairing of railroad rolling stock. He was one of the first to introduce standard parts, and his advocacy has greatly helped to advance the cause of uniformity and interchangeability in car and locomotive work. He was long master mechanic of the Pittsburgh, Fort Wayne & Chicago, and while there performed a highly valuable work to the company in reducing a chaos of oddities into convenient standards. Mr. Boon joined the Master Mechanics' Association at the third convention, and at once took his natural place as a leader in all the business transacted. He was ever active in the discussions and in committees and always had valuable information to impart.

22. WILLIAM SWANSTON. On June 10, 1868, six master mechanics met by appointment at Dayton, O., and talked over the advisability of forming an association of men having charge of railroad motive power. This resulted in an invitation being sent out to all master mechanics to meet at Cleveland three months later, when the Master Mechanics' Association was organized. One of the six men who met at Dayton was William Swanston, master mechanic of the Cincinnati, Sandusky & Cleveland Railroad. There is only one of the others alive, viz., Reuben Wells. Mr. Swanston learned the machinist trade in Scotland. He went to work in the shops of the Little Miami in 1850, and rose through the ranks of machinist, gang foreman, and general foreman. In 1866 he was appointed master mechanic of the Cincinnati, Sandusky & Cleveland road. Subsequently, after several changes, he settled as master mechanic of the Jeffersonville, Madison & Indianapolis. He is still on the same road, although it is now a part of the Pennsylvania system. Mr. Swanston is not only a first-class mechanic, but he is well informed on engineering science. There are few men in the business better fitted for the higher positions.

23. H. ELLIOTT, honorary member of the Master Mechanics' Association and one of its oldest members. Mr. Elliott learned his business in the Stephenson Locomotive Works, in England, and came to this country in 1849. Like many other mechanical men who have risen to be master mechanics, he began work in the shops of the Little Miami. He worked for the company successively as machinist, locomotive engineer, and assistant master mechanic. In 1857 he was appointed master mechanic of the Ohio & Mississippi. In 1863 he left this road and went into the Government service as master mechanic on the military roads of Tennessee, with charge of the shops at Nashville. Here he remained till the close of the war. Then he returned to the Ohio & Mississippi, but left it in 1874 to enter business for himself in the manufacture of railroad track supplies, and is now president of the Elliott Frog & Switch Co.

24. R. C. BLACKALL, a member of the Executive Committee of the Master Car Builders' Association and Superintendent of Motive Power of the Delaware & Hudson. Mr. Blackall entered railroad service in 1850 as machinist on the Saratoga & Washington Railroad, and rose through the usual course to be master mechanic on a road afterwards absorbed by the Delaware & Hudson, where he is now the chief mechanical officer. He has always taken a deep interest in the affairs of the Master Car Builders' Association and has been for many years a member of the Executive Committee. He is also a member of the Master Mechanics' Association and president of the New York Railroad Club.

25. E. W. GRIEVES, First Vice-President of the Master Car Builders' Association and Master Car Builder of the Baltimore & Ohio. We have received no particulars about Mr. Grieves' experience in his business. He joined the M. C. B. Association in 1885 and has always been a particularly active member.

26. J. MULLIGAN, honorary member of the Master Mechanics' Association and President of the Connecticut River Railroad. Mr. Mulligan was one of the charter members of the M. M. Association. About the time he joined he was made general superintendent, but he has continued to take a warm interest in the association, although unable to attend the conventions. He rose through the grades of machinist, locomotive engineer and foreman to the position of master mechanic. He held this position sixteen years, and then was made general superintendent. Later, he became general manager, and last year was elected president. His success is a fair gauge of Mr. Mulligan's ability. He is one of the most genial men in the business, and his pleasant face betokens his character.

27. J. W. MARDEN, a prominent member of the Master Car Builders' Association and Superintendent of the Car Department of the Fitchburg Railroad. Mr Marden entered railroad service in 1861 as apprentice in the car shops of the Concord Railroad. From there he went to the Norwich & Worcester and rose to be general foreman, and subsequently master car builder He went to the Fitchburg in 1881. He has been one of the hardest working members of the Master Car Builders' Association and has been repeatedly a member of the Executive Committee.

28. JOHN F. DIVINE, General Superintendent of the Wilmington & Weldon and other lines and honorary member of the Master Mechanics' Association. We have received no information respecting the professional career of Mr. Divine, but we know that he has always been a leading member of the Master Mechanics' Association. He joined at the second convention, and he appeared to exert a good influence in bringing Southern master mechanics into the organization.

29. J. T. CHAMBERLAIN, Master Car Builder of the Boston & Maine and a member of the Executive Committee of the Master Car Builders' Association. We have no notes of Mr. Chamberlain's life. He joined the M. C. B. Association in 1883, and has always been a hard worker.

30. ROBERT MCKENNA, one of the oldest members of the Master Car Builders' Association and Master Car Builder of the Delaware, Lackawanna & Western. We have no information about Mr. McKenna's life.

31. DR. E. H. WILLIAMS, honorary member of the Master Mechanics' Association and a member of the firm of Burnham, Williams & Co., proprietors of the Baldwin Locomotive Works. Dr. Williams is universally known wherever railroads are operated. The first railroad experience of Dr. Williams was in Canada in 1851, on a line which was being constructed between Rouses Point and Montreal; then on another line as resident engineer and afterwards as superintendent from Montreal by way of Lachine and Caughnawaga to the Province line, both since absorbed by the Grand Trunk. Then in 1854, division superintendent and division engineer on the Michigan Southern & Northern Indiana Railroad, first on the Eastern Division, then on the Western, with headquarters at Laporte, Ind. Leaving there in 1858, he assumed the position of assistant superintendent of what was then the Milwaukee & Mississippi Railroad, extending from Milwaukee to Prairie du Chien, now a part of the St. Paul system. Next as assistant superintendent of the Galena & Chicago Railway, now in the Northwestern system, where he remained until he became connected with the Pennsylvania Railroad in the winter of 1864 and '65, as assistant general superintendent and general superintendent until 1870. In that year he connected himself with the Baldwin Works, where he has remained up to the present. Besides being the most genial of men, Dr. Williams is a famous organizer and is said to have been the author of the organization under which the Pennsylvania Railroad is now operated. He is blessed with a phenomenal memory, and can tell details of events and names extending back forty years ago as exactly as if they were before his eyes yesterday.

32. R. H. BRIGGS, Past-President of the Master Mechanics' Association and Master Mechanic of the Kansas City, Fort Scott & Birmingham. We have no information about Mr. Briggs' career. He has been a prominent figure in the M. M. Association, and was successively elected vice-president and president.

33. M. N. FORNEY scarcely requires mention. Those who are not familiar with Mr. Forney's career are not likely to see this paper. He is the most celebrated railroad journalist in the world, and besides that has long been an industrious worker in the various organizations for advancing the interests of railroad appliances and increasing the knowledge of railroad men. Mr. Forney received an engineering training in the Baltimore & Ohio shops at Mount Clare, Baltimore, and was for some time chief draughtsman of the Illinois Central. He was then considered the most expert draughtsman in the country. He left railroad life to become editor of the *Railroad Gazette*. He is now proprietor of the *Railroad and Engineering Journal*. Mr. Forney joined the Master Car Builders' Association in 1873, and at once became one of its most valuable members. Principally through his efforts the association was reorganized in 1882, and he became secretary, holding that position till 1889. He is also a member and active worker in the Master Mechanics' Association.

34. J. N. LAUDER, Past-President of the Master Mechanics' Association and Superintendent of Rolling Stock of the Old Colony Railroad. Mr. Lauder is recog-

nized as one of the ablest and most progressive mechanical officers in the country. The Master Mechanics' Association has been his pride, and no one has worked more faithfully and zealously to advance its interests. We have received no notes of Mr. Lauder's career, but we know that he learned the machinist trade in New England and for a time worked in various shops, among them the Pennsylvania shops at Altoona, where his uncle, Mr. Laird, was superintendent of motive power. He rose to be master mechanic of the Northern Railroad of New Hampshire till 1882, when he accepted the position of superintendent of motive power of the Mexican Central. A year later he returned to New England to the position he now holds. Mr. Lauder is a ready speaker, and he is exceptionally well informed on all matters relating to railway machinery, and seldom talks on a subject without throwing new light upon it. He joined the M. M. Association at the second meeting; in 1877 was elected vice-president, and held the office till 1880, when he was elected president and held the office two years.

35. JOHN S. LENTZ, Vice-President of the Master Car Builders' Association and Superintendent of the Car Department of the Lehigh Valley Railroad. We have failed to obtain any information about the railroad career of Mr. Lentz. He has been for years one of the leaders in the Master Car Builders' Association, which he joined in 1879. He is considered one of the ablest car builders in the country.

36 E. T. JEFFERY, honorary member of the Master Mechanics' Association and President of the Denver & Rio Grande. Mr. Jeffery was born in Liverpool, England, in 1843. He entered railway service October, 1856, as office boy in the machinery department of the Illinois Central Railroad, served his apprenticeship as machinist on that road, and from 1863 until 1871 he was mechanical draughtsman and secretary to the superintendent of machinery; from February, 1871, to May 4, 1877, he was assistant superintendent of machinery of same road, when he was advanced to general superintendent, and on December 15, 1885, to general manager, which position he resigned on September 1, 1889. After having made a trip to Europe in the interest of the World's Fair at Chicago, in the latter part of 1889, he returned to Chicago, taking the management (as president) of the Grant Locomotive Works, which had just been organized, and under his direction the plant just completed at Cicero, near Chicago, was designed and erected. On October 1, 1891, Mr. Jeffery assumed the position of president and general manager of the Denver & Rio Grande Railroad, where he now is. He took an active part in the World's Columbian Exposition of 1893 for Chicago, and his earnest efforts in the interest of Chicago contributed to the selection of that city for the Exposition. After the organization of the Exposition Company, he was elected a director and made chairman of the Grounds and Buildings Committee, which arduous and unremunerative office he held until his change of location from Chicago to Denver. Mr. Jeffery is generally considered to be one of the ablest railroad managers in the country, and he has pushed his way to the top of the tree by sheer merit and energy. He joined the Master Mechanics' Association in 1874.

## Southern Pacific Shops at New Orleans.

Strictly speaking the S. P. shops are not at New Orleans, but just across the Mississippi river at Algiers, La.

Of all the shops in the South anywhere, those of the old Morgan line—now all S. P.—are the best. The management do not invest in poor equipment. Their shop buildings are excellent, the tools new and modern, the motive power in excellent condition, and their freight ships the finest in the world.

During my visit to New Orleans Master Mechanic Connell was in Cuba removing the machinery from one of their ships that had been lost.

The shops are under the care of General Foreman John P. Nolan, a mechanic who served his term right there.

Patrick J. McGuire is a master builder. I can't hardly see what his position really is. He is a ship carpenter and has charge of the repairs to the fleet, is over the M. C. B. at the car shops and superintends the erection of buildings.

The buildings are of brick, well kept up, and are quite extensive. The motive power of the shops is furnished by a compound Westinghouse engine set in the center of the shop, supplied with steam from a locomotive pattern of boiler, also located in the shop. There is one advantage about this plan, and that is that it insures cleanliness and care of both boiler

Fig. 1.

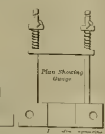


Fig. 2.

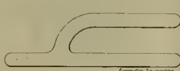

Fig. 3.

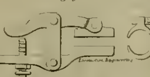

Fig. 4.

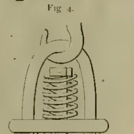

Fig. 5.

and engine. This boiler is covered with galvanized iron fitted up in sections, braced with angle iron, the edges fitted down to the boiler, leaving an air space of about one inch, no other lagging being used.

In the shop there are one or two old tools used for rough work, one of these being an old Confederate gun lathe with the face-plate solid with the spindle.

This shop does all the steamship work, some of which is very heavy. They have some ships with steeple compound engines, using a single crank with a pin about 12 inches in diameter.

Instead of red lead they use ¼-inch asbestos gaskets around boiler fronts, under stack saddles, etc. This requires little work to get ready, and makes a tight joint, but one that "lets go" when the work is taken down.

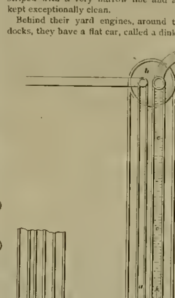
This road is level all over this part of the country, and there is very little use for heavy engines, so that a very nice class of 16 and 17-inch cylinder eight-wheelers are used, and these have a good sized boiler, and are just right for solid comfort for enginemen.

They have a nice little trick here that I should think would pay to imitate in any country, and that is in setting the water tank upon inch and a quarter strips running across the tender deck. Around the inside of the coal pit they fasten a molding that prevents coal from getting under the tank proper, yet all the water can run out.

This plan gets the tank up off the wet deck, prevents its rubbing on the sharp coal dust and prevents its rusting out. They say that it is often possible to find a leak and insert a copper rivet without lifting the tank off the deck at all. This practice is followed on several Southern roads more or less, but seems to be the standard practice here.

The engines are very nicely painted and striped with a very narrow line and are kept exceptionally clean.

Behind their yard engines, around the docks, they have a flat car, called a dinky



DEEPWELL PUMP.

These cars are painted and striped the same as the engines, have side and end steps, a headlight, and carry tool-boxes, wrecking frogs and switch ropes.

Cars and engines are fast being equipped with air, most of the engines being ready, and cars receiving their fittings by the dozen daily.

In the shop, they have recently fitted up a power hose-cutter that is very efficient, and are at work on a device for putting hose-heads on.

On their wheel press, they have fitted up a neat little kink. Of course, there is no test gauge around to compare their press gauge with, it registers too high—tons instead of pounds—and they became suspicious that it wasn't exactly honest. They tapped into the cylinder and made a safety-valve of the lever pattern that was graduated the same as the gauge, and then put a stop-cock under the gauge itself. When doing common work, like freight car wheels, the safety-valve is set to the maximum pressure wanted, and it will instantly let up and relieve the press when this pressure is reached, and the gauge can be shut off and saved from constant strains.

No railroad mechanic can go through these shops without admiring the many handy kinks to be found in the blacksmith shop, which is under the care of James Lusted. He does a great deal of work on his steam hammers that is usually done on a press or shear. I have made a rough sketch of a device he uses to cut bar iron up into lengths, a great deal of this having recently been done in getting out brake rigging for cars.

Fig. 1 shows the cutters as arranged. A pair of coil springs lift the knife to allow of handling the work. Fig. 2 is a plan of the same tool, showing the gauge extending back of the cutter. This gauge is held against stops by springs, so that when the hammer cuts off a piece, it is pushed through and the gauge returns to its correct position. Fig. 3 shows a form of draw-bar they make for engine-tenders. It is capable of being used in six different positions. Fig. 4 represents the business end of a quarter-bar for handling axles, or other heavy work. As will be seen, this bar insures a fair grip on the axle no matter what its shape or size—the hold is a solid one.

In forging frames or heavy work of any kind they use the arrangement shown in Fig. 5 between the crane and the work; the heavy spring prevents damage being done by a foul blow.

In punching heavy work they use loose punches that are driven entirely through the stock. The latter is then straightened, and a drift driven through the hole to get it true and to the exact size. In a fork-ended piece, where the holes must be in line with one another, this plan is a surety.

Between the engine and tender they use here a draw-bar with a knuckle in it. This admits of heavier fastenings in the engine and tender frames.

While at New Orleans I had the pleasure of visiting this company's steamers, *El Monte*, Capt. Quick, and Chief Engineer Geo. Uhler, and the *El Mar*, Capt. Morgan, and Chief Engineer Miller. These are exceptionally fine steamers, the former being driven by a steeple compound engine, and the latter by the latest triple expansion style of engines. The engine-rooms are full of machinery and the quarters close, while the fire-rooms are dark and close. But it was comical to listen to one of the assistant engineers tell of a ride he had on a locomotive, how mean it all seemed to him, and how much he had rather be under deck with the engine and let the captain steer. All the time I was thinking how much I would rather run a "hog" than be cooped up between a condenser and a grease extractor with the best engine in the line, and four thousand feet of water between me and the bottom. But these sea-going engineers are jolly good fellows, just the same, and there is no accounting for tastes. One of these ships has carried 288 car loads of cotton, so the captain told me, and to save my life I couldn't think of ever hearing an engineer claim to haul more than 280 with a locomotive, so I kept still. I hate to be beaten that way, however.

J. A. H.

Apparatus for leading the smoke-stack of a locomotive to the back end of a passenger train has again been patented. This sort of a device has been patented so often that it is difficult to see where the opportunity is given to accept Patent Office fees, but the feat has been accomplished, which is greatly to the credit of the patent lawyer employed. There is one good opportunity for novelty about this invention, and that is the prevailing on some railroad company to try it.

## The Empire Car Coupler.

The latest candidate in the coupler field for consideration by railroad mechanics is the Empire, illustrated herewith.

This coupler has a locking device of very strong construction, and a knuckle-opening arrangement that is simple and entirely closed within the draw-head.

It can be unlocked against considerable pull, which is an advantage in yard work.

The knuckle is thrown open by the continuation of the unlocking movement.

Provision is made for unlocking if the

coupler or draft-gear breaks, thus preventing the head from falling on the track.

The knuckle is heavier and stronger than the average, and a smaller pin is used, thus leaving extra metal in the angle of the knuckle, where most needed.

This coupler has recently gone through some very severe trials on the West Shore road, where it is being used.

The Empire Car Coupling Co., of 15 Warren street, this city, are introducing the invention.

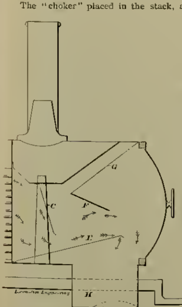
## New Arrangement of Extension Front.

The sketch shown herewith makes plain the internal arrangement of an extension front designed and used by Master Mechanic J. W. Addis, of the Texas & Pacific, at Algiers, La.

There is a hopper under the arch proper, and an opening in the partition sheets through which the cinders are thrown, and are then prevented from being picked up by the force of the blast.

The netting is higher and there is not quite as much of it as usual.

The "choker" placed in the stack, as



shown, was found to help the engine's steaming wonderfully.

The T. & P. have in use a great many Brown spark arresters. These are large diamond stacks with a 6-inch pipe running from the lower part of diamond back to the ash-pan. They are very heavy and troublesome. Sometimes the netting becomes clogged and then the gases going back through the pipe take fire at the ash-pan, and several men have been burned severely by them.

The company are cutting off some of these pipes and turning them directly into the smoke-arch, just back of the stack saddle.

## Lukens Iron and Steel Works.

A party of railroad men, at the invitation of Messrs. Coolbaugh & Pomeroy, New York, last month visited the Lukens Iron and Steel Works, at Coatesville, Pa. They made the tour of the establishment and very great interest was manifested in the various processes to be seen. Beginning at the fine new open-hearth furnaces, lately put in operation, the party watched the charging of one furnace, and others interested themselves in looking through colored glasses at the boiling mass inside the furnaces nearly ready for pouring. The manner of selecting the pig and iron to produce the desired mixture was carefully noted, as well as the means employed in making preliminary tests of the charge.

Next they witnessed the pouring of a charge and saw the working of the wonderfully ingenious machinery for doing the work. The furnaces are built and operated by the most approved methods, and the latest kind of appliances are employed in handling the product. The rolling-mill received great attention, and the systematic fashion in which all operations go on excited great admiration. One of the most observant of the party remarked that he had never before seen such a place where there appeared to be so little lost labor. There was no hurry or tumult, but every man appeared to have a certain thing to do and was doing it.

General surprise was expressed at the great capacity of this rolling-mill, which is devoted entirely to plate work. The first boiler plate rolled in America was made in these works, and that was away early in the century. Although the owners of the place are proud of its history and the work done here by crude appliances, they possess none of the spirit that clings to the old methods. Nothing of the most approved and advanced character is too good or too new for them. They want the best of everything in the line of their business, and take care to have it. They have the largest rolls in the country and the best machinery for handling the material in its way to and from the rolls. The party had the opportunity of examining boiler sheets $1\frac{1}{4}$ inches thick and other sheets as thin as $\frac{3}{16}$-inch. They roll sheets 120 inches wide, and have quite a demand for that size.

The Chicago Rock Island & Pacific Railway people have entered to the Illinois Supreme Court a bill for injunction to restrain the City of Chicago from causing the arrest of engineers for whistling at certain places in violation of a city ordinance. Whistling is necessary at the crossings, which are protected by interlocking signals, but the city authorities make this necessity a crime. Several engineers have already been arrested and fined for whistling. If they did not whistle they would be discharged by their employers. This condition of things is exceedingly hard on the men. If the court does not give relief there is likely to be a hot kind of quarrel with the city authorities.

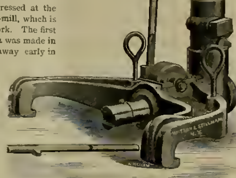
The Delaware, Lackawanna & Western have been lately introducing the extension front on the locomotives on the Eastern divisions. In connection with this Mr. W. H. Lewis, master mechanic, has been experimenting with single-nozzle and high exhaust-pipe. He tried several forms of pipe before he got the engines to work satisfactorily. One he is now using with excellent results has a bridge that extends up far enough to contract the opening a little below the area of the nozzle.

The New England Railroad Club has got up an illustrated pamphlet with the constitution of the club and a list of the members. It also contains engraved portraits of President Twombley, Vice-President Chamberlain and Secretary Curtis.

## Hydraulic Rail Bender.

The well known hydraulic engineers, Watson & Stillman of this city, have recently placed on the market a rail bender of some use. The rails are getting too heavy for screw benders, the latter are slow, clumsy and require a gang of men to work them, while a couple of years' wear ends their usefulness.

This tool, while it weighs a little more, is not so clumsy to handle, and can be quickly applied and worked much easier by *one operator*. Experiments have shown that it was not the method of bending, but the long spacing which sprang the rail up, so that a very heavy hook to catch the web was not necessary. In this tool the ram may be run in and out without pumping for a distance of $3\frac{1}{2}$ inches. This allows the tool to be placed over the rail and the ram brought up to its work on the rail head, when a few strokes will bend the rail to the desired curvature; it may then be slid along easily and another pressure given. The ram is graduated to show the spring of rail, and has a loose steel head which fits the rail head which is being bent. In a recent test in service two men bent forty 30-ft. 90-lbs. steel rails in



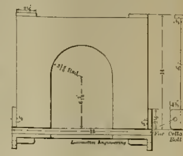
one day, where previously twenty had been the best work of six men with best of screw benders, and one rail was bent perfectly flat on 45 feet radius in $1\frac{1}{2}$ *minutes*, on 16-inch centers of application. The tool weighs 275 pounds.

A test was lately made by Professor Johnson, Washington University, St. Louis, of hollow stay-bolts taken from the ordinary stock of the Falls Hollow Stay-bolt Co. The breaking strength was 49,200 pounds per square inch of area, the limit of elasticity, 28,300 pounds; percentage of elongation, 34, area of reduced section, .30; percentage of reduction, 50. Professor Johnson remarks about the material "This is a remarkably fine specimen of wrought-iron for stay-bolt purposes. Its elongation, 34 per cent., is the greatest I have ever found for wrought-iron, and this is of the utmost importance in stay-bolt iron. The fracture shows a pure, fibrous, unlaminated and uncrystalline structure."

## Wearing Plates for Taking Up Lateral Motion.

The accompanying engraving shows a simple little device used upon the S. C. road for taking up lateral play between driving-boxes and hubs and also on engine trucks.

The brass plate, as shown, is dropped in between the hub and box and secured by



putting the cellar bolt through the lugs cast on bottom of plate.

They keep on hand plates of ⅛-inch and ¼-inch for driving-boxes, and ⅛-inch, ⅜-inch, and ¼-inch for trucks. They are not planed up, but the sand is cleaned off them.

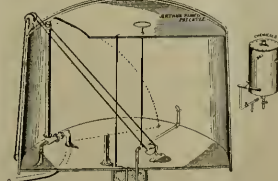
These are very useful where engine is "running to one side," as it admits of taking up all the slack on either side. When worn out they are nearly as valuable as scrap as when new.

The Wood Extensible Air Step Co. have sent out a graphic illustration of the advantages of having their extensible air step on cars. Two trains are shown side by side. From one a lady is descending by the ordinary steps and the stool on the ground tips over with mortifying results. From the other train which has the Wood step a lady trips down with dignity and comfort. A step of this kind is convenient for all trains, but for suburban trains it is an absolute necessity. We daily receive in the neighborhood of New York exhibitions of the inconvenience and annoyance of getting on and off trains with high steps that make us indignant at the railroad company which forces people to engage in acrobatic performances.

## Feed Water Purifier.

Mr. Arthur Pennell, of Kansas City, Mo., has been investigating the feed-water question for some years, and has recently perfected a system that seems to have decided merits of its own.

Instead of burdening each locomotive with a device which must of necessity be small and through which a large quantity of water must be passed, he goes directly to the station water-tank.



The process consists in treating the water with chemicals that precipitate the foreign matter, an arrangement for drawing off the deposit from the bottom, and a tank spout so constructed as to draw water from the top of the tank instead of the bottom.

The cut shows how this is accomplished. A jointed stand-pipe inside the tank is so arranged as to be drawn down to any incline that will allow it to fill with water.

Where mud is the trouble, it would seem as though Mr Pennell's plan was a good one.

Most railroad companies accept rails from the makers without requiring tests. The Louisville & Nashville is an exception in this respect.

## FARMING IN THE SOUTH.

It is not astonishing that hundreds of Northern farmers have settled in the South at points on, or adjacent to, the southern division of the Illinois Central Railroad within the past five years, nor is it remarkable that instead of confining themselves to the cultivation of cotton exclusively, they are diversifying their crops with gratifying results. One of the important questions in the mind of any Northern farmer who contemplates locating in the South is: "What crops can be profitably grown in that latitude?" The passenger department of the Illinois Central Railroad will, on application to Mr. J. F. Merry, Assistant General Passenger Agent, Manchester, Iowa, mail free the following pamphlets: "Southern Home Seekers' Guide," "How to get Rich in the South," "Truck Farming," and "Farmers' and Fruit Growers' Guide to McComb City, Miss." These publications contain valuable information and should be read by every farmer looking for a Southern home.

## Jim Skeevers Illustrates a Point.

Skeevers was "acting master mechanic" once while the real article went "down East," got married, and honeymooned around a while for all the world like a common engineer or a human being.

Skeevers didn't make any startling changes, but while he sat in the office he was boss, all the same, and he put the knife into every sore caused by friction between engineers and firemen.

They couldn't any of 'em shut Skinny Skeever's eye with a five-act story—Skinny knew all the stories by heart, and the men, too.

Skeevers went over the road with the officials on a tour of inspection once, and saw, for the first time, a middle-aged scrap heap on the Coalville branch, and Skeevers made a note in his book that the "38 was the dirtiest engine he ever saw."

When he got back home he wrote a letter to the engineer, saying that he was ashamed of the engine and of him, that whoever the fireman was, he, the engineer, was responsible for him, and that if the engine wasn't at once put into decent condition the engineer would hear something drop.

In a couple of days a reply came in couched in very dignified language; there was no excuse for the dirt, no promise to remove it, no word about the fireman, but a protest against the summary way that Skeevers wrote.

"I want you, sir, to distinctly understand that I am a gentleman and shall insist on being treated as such," concluded the epistle of the offended "plug-puller" of the branch run.

Skeevers sent him a pass by the first train,—and also sent a man to relieve him.

The next day he climbed the stairs to Skeevers' office with three gauges of indignation on—Skeevers knew he was coming and was busy writing.

"Is Mr. Skeevers here?" he asked, as he leaned his arm on the railing.

"What do you want to see him about?" asked a fresh young clerk.

"I want to see the master mechanic of this here road," said the gentleman from Coalville.

"I am that person," said Skeevers, quiet like. "May I ask who you are?"

"I'm the engineer of the 38."

"Oh, yes, let's see, how long have you been running an engine here, sir?"

"Six years, and I—"

"Never mind, now, but don't you draw pay from this company for another position?"

"No, sir!"

"Just hired for an engineer and paid for that and nothing else?"

"Yes, sir."

"I'm glad to know that; I got the impression from a letter you wrote me that you were down on the pay rolls as a gentleman. They may need some of them in other departments, but I want engineers, firemen and mechanics; I wouldn't give the best gentleman in America $20 a month for my part of the work.

"I understand, sir, that you are connected with some of the first families here, but that cuts no figure with me. After working-hours you may lead the German at the Governor's ball if you want to, for all me, but while on duty here you are in charge of a locomotive and are responsible for it to me, and I to the management. I don't care a Continental cuss whether you were born in the White House or the gutter, who you married or what church you belong to. It cuts no figure here, as I remarked before.

"I do care what kind of an engineer you are, though, and you can't be any better engineer because you belong to the Masons, the Episcopal church, the Greenback party or the Holy Rollers. Marrying into the first families won't help you, and being born in a hovel won't hurt you,—as an engineer.

"It's an engineer's duty to see that his engine is kept reasonably tidy; the fireman should do most of this work under your direction, but you are as responsible for that as you are for the packing of the valve-stems.

"Now, sir, this road wants good engineers, and gentlemen would be a drug on the market. If you want to try running the 38—as an engineer, mind you—I am willing. You go right ahead and marry a wench or a Pawnee squaw, if you want to, and tell 'em all it's none of my business, but if you don't clean up that engine before Saturday night I will fire you off the face of the earth and hire an engineer.

"Give Mr. Pangborn a pass to Coalville, James. Good-day, sir."

"Good-day, Mr. Skeevers."

"That's what I call a dry roast," said the chief clerk, as the gentleman runner shut the hall door at the foot of the stairs.

"That's what my old fireman calls an object lesson, illustrated," said Skeevers, "and, whatever it is, I know that Pangboro sees something in a different light than he did, and he won't forget it, *eyether*."

## An Improved Pilot.

Making and keeping in repair the ordinary wooden pilot is rather expensive, and the iron pilot has this serious disadvantage when it gets a crimp in it—you can't get rid of it.

The most expensive part of a wood pilot is the cross-framing, and this framing picks up cinders and often gets on fire. The method of fastening the drawhead is also liable to many ills; and to support the nose of the pilot heavy heel-braces or supporting-rods are necessary.

The accompanying diagrams taken from the working drawings of the S. C. roads show a cheap and strong pilot that is fast becoming popular in the South. The triangular sill-frame is of hard wood, and instead of angle-braces framed into it, the bracing is a single casting, as show in Fig. 2; this is of angle-iron section and securely braces the three sill-pieces, will not burn, and is lighter and stronger than wood braces.

From the nose of the pilot to the center of the buffer-beam two wrought-iron forgings, as shown in Fig. 1, are used, the upper end, which carries the drawhead, being thicker than the lower end that merely supports the nose. When a pair of these braces are bolted from the buffer to the nose of pilot they form a strong frame; the pilot slats are merely dropped into place and held at each end with a lag-screw; they are not even beveled off, but the corners are rounded.

The drawhead swings on a heavy bolt

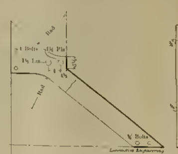


Fig. 1.

across the wrought-iron backbone, and another pin holds it in position for work or when thrown back out of the way. No long drawbar is needed.

This pilot is as strong as an iron one, has all the advantages of a wooden pilot, and is cheaper to make and keep in repair than either.

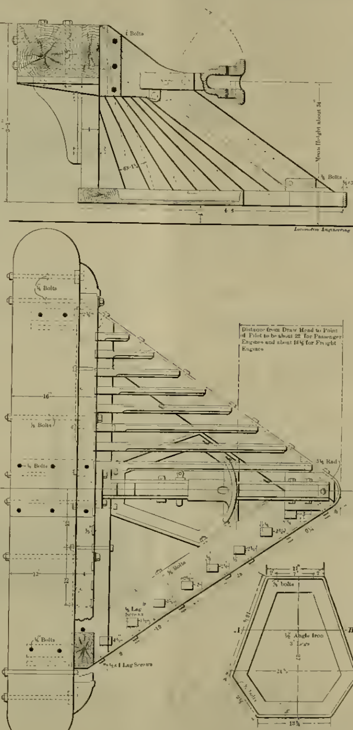

Fig. 2.

## Combustion Chamber Boilers.

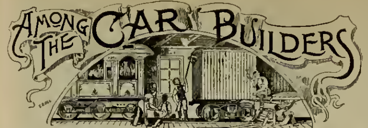
There is a tendency among some of the most enterprising locomotive men in this country and in Europe to revive the form of boiler that has a double set of flues and a combustion chamber between the two internal flue sheets. That kind of boiler has been tried years ago in various forms with all the influence of patent rights behind it, but nothing could make it a success. Talking on this subject lately, an old superintendent of a leading railroad said, that when coal burning was first introduced they tried nearly every thing invented that promised to improve combustion and increase the amount of the heat absorbed by the steam-making medium. Among other devices the combustion chamber was tried in numerous forms. It was tried from 1 to 5 feet long, tried next the fire-box and in the middle of the boiler. Large flues and flues as small as 1½ inches were tried with it. Brick arches were applied in various forms to protect the chamber, and different methods were tried to help the mixing of the air with the fuel gases in the combustion chamber. It was all of no avail. When the combustion chamber was removed and the space filled with tubes the boilers invariably steamed better.

---

Railroad men visiting the ancient city of Quebec would do well to make the acquaintance of Mr. W. R. Russell, superintendent and master mechanic of the Quebec, Montmorency & Charlevoix Railway. The railroad he operates is small but it has some unique features. The principal business done is the carrying of pilgrims to the holy shrine of Ste. Ann, where a great pyramid of crutches may be seen that have been thrown away by holy cripples that went to the shrine and were cured. Scarcely less wonderful than the pyramid is the means that Mr. Russell employs to carry people there. He carries 135 passengers in a 16-ton car, which is something unparalled in railroad operating. And the people are carried safely and comfortably

---

Mr. Arthur Pennell, of Kansas City, who has devoted a great deal of study and experiment to the subject of feed-water purification, has lately obtained a patent on a water purifier for boilers.



The Ohio Southern is said to be in the market for 1,500 cars.

The Buffalo, Rochester & Pittsburgh are in the market for 500 cars.

The Delaware & Lackawanna have placed an order for ten coaches.

The New York, Ontario & Western have ordered 500 cars from the Peninsular people.

The Southern Pacific have awarded a contract for the building of 500 cars to the Ensign Co.

An improvement on the quick-action triple-valve has lately been patented by H. H. Westinghouse.

Within the last month over 2,500 cars have been specified to be equipped with the Butler draw-bar attachment.

A contract for the construction of twelve tank water cars has been awarded to the Madison Car Company by the Mexican Central Railroad.

The Southern Pacific have placed an order with the Pullman Palace Car Co. for twelve new improved parlor cars. They will be longer than the other cars belonging to the road, and will have two drawing-rooms.

The Staten Island Rapid Transit Co. have contracted with Baldwin's for three Forney and one eight-wheel engine. They have also ordered sixteen coaches. Engines and cars will have Boise wheels and Cambria steel axles.

An improved form of car bolster to be made of pressed steel has been patented by Charles T. Schoen, Philadelphia. The invention seems to produce a bolster that will combine the greatest strength with the least weight of material.

All new cars belonging to the Atlanta Coast Line are being equipped with air-brakes and M. C. B. couplers. They have marked in bold letters "Westinghouse Air-brake." About twenty new cars a month are being built in the company's shops.

The Staten Island Rapid Transit Co. have placed an order for twenty-four new cars. Twelve of them will be the ordinary suburban car, eight excursion cars and four combinations. The cars will have Boies steel wheels and Cambria axles made by the Coffin process.

A rather ingenious slack-adjuster for car-brake gear has been invented and patented by Howard Hinckley, Trenton, N. J. By a very simple arrangement a ratchet is made to turn an extended nut on the brake-rod, which lengthens it as the wear of shoes imparts lost motion to the gear. The invention seems practicable and likely to work well.

As a precaution against the dangers that result from broken stay-bolts, the New York Central are now using a great many of the hollow stay-bolts made by the Falls Hollow Stay-Bolt Co. This kind of stay-bolt has been specified for the one hundred new locomotives under construction for the company by the Schenectady Locomotive Works.

The Franklin Institute at Philadelphia has recommended the award of the Elliott Cressen medal to Mr. C. H. Batchellor, chief draughtsman of the Rhode Island Locomotive Works, for his improvement on compound locomotives. The improvement consists mostly of an intercepting valve which was illustrated in the January number of LOCOMOTIVE ENGINEERING.

The Chicago, Milwaukee & St. Paul Railroad Company has just completed at its West Milwaukee shops fifty Wickes refrigerator cars. These cars are especially designed for business in the California fruit trade, which the C., M. & St. P. is preparing to take care of during the coming season. The cars are equipped with air-brakes and are modern in every respect.

The shops belonging to the Wagner Car Company at Buffalo are very active with car building at present. About 1,600 men are at work in the shops, and this force will soon be increased. They have under way more then one hundred new sleeping cars, and they are also building part of the new passenger car equipment for the Adirondacks & St. Lawrence Railroad. The first instalment of this work consists of ten day cars and two observation cars. They are also building a car for the transportation of horses, having 15 stalls. The A. & St. L. people are also getting some smoking cars built at Troy, N. Y.

At a convention of railroad commissioners held lately at Washington, D. C., Hon. John R. Wheeler, of Illinois, read a paper on "Private Freight Cars" in which strong grounds were taken against the use of live stock, refrigerator and other cars owned by shippers. He held that the practice of operating such cars was a serious loss to railroad companies and injurious to the interests of shippers who did not own or control cars. The profits made by the owners of certain lines of private cars was said to be enormous, while the railroad companies doing the work receive less than a fair share on business that is carried away from the legitimate channels.

An improved vestibule connection for passenger cars has been designed by Messrs. A. M. Kitteridge, of the Barney & Smith Mfg. Co., and John Kirby, general master car builder of the Lake Shore & Michigan Southern. The patent on the invention covers a vestibule upon the platform of a car composed of an inherently elastic extension always projecting beyond the outer end of the vestibule and forming a practically tight connection under all conditions of train operating. The elastic element appears to be formed of a tubular cushion strengthened by webs to give it stiffness. This tubular cushion forms the closing part between connecting vestibules.

In a discussion on draw-bar attachments of cars that took place at the May meeting of the New York Railroad Club, a curious objection was raised to some of the appliances for strengthening the draw-gear. The first aim of a maker of these things is to prevent breakage of the draft timbers. The objection was made that this practice was carried so far that the draft timbers were made so strong that in case of a collision they held intact and the longitudinal stringers broke. Mr. George McGuire, who was present, made the point that the Butler draw-bar attachment was so proportioned that it resisted ordinary shocks, but when a blow was given that was bound to fracture something, the Butler attachment broke, although strong enough to resist anything short of a collision.

The orders which General Superintendent Brown of the Fall Brook Railroad issues are noted for being pointed. Here is a specimen from the order board called out by some delay in getting a wreck cleared away "In case of a wreck, all trains occupying the main track must be side tracked at once and get the engines to work at both sides of it as soon as possible. It will not be necessary for the men to go and look at the wreck and talk matters over until their trains are side-tracked and engines return ready to go to work, and then go to work in earnest to clear the track as soon as possible. Do not wait for Corning office to tell you every move to make. Wake up and do something yourselves. You are on the ground and know better what is necessary to be done than we do at Corning."

The New York City & Northern is one of the most crooked roads we know of. The greater part of it is single track, yet there has never been a serious collision on the road during the ten years it has been in operation. This is highly creditable to the superintendents who have had charge of the operating of the road. The first superintendent to put the operation of the road in first-class order was Mr. Frank S. Gannon, now in charge of the Staten Island Rapid Transit Road, and he was succeeded by Mr. H. H. Vreeland, the present incumbent. Both these men are noted for being popular with the employes under them, yet they maintain rigid adherence to rules. Accidents are not prevented by severely punishing all and sundry after something has happened, but by the keeping of all hands vigilant at all times. The careless and neglectful practices that lead to accidents are checked before they lead to their natural effect. We do not know of two men in charge of comparatively small roads who are more deserving of advancement than Messrs. Gannon and Vreeland. Both are practical railroad men with experience in different branches of the business, and both are good organizers with the talent for seeing that their plans are carried out.

## Old and New Defects in Car Interchange.

Those familiar with the disputes and heart-burnings that arise in the interchange of freight cars in the endeavor to make every road act justly in carrying its own share of the expense of repairs will be likely to sympathize with remarks made by Mr. C. A. Schroyer at a recent meeting of the Western Railway Club. He said most emphatically that there are defects which should not be carded. "We are getting," he continued, "into such a state of affairs in interchange that if a nut doesn't stand square you have got to card it."

This strong expression of dissatisfaction was brought out in a discussion on carding cars for old defects. Many railroad men, especially in the West, are opposed to carding for old defects, but we cannot see where the line can be drawn between old and new defects. The annoyance caused by excessive demand for carding is due to certain roads holding to the final letter of the rules of interchange, and getting the better of their neighbors by strictly legal means, carried beyond the line of justice. This lack of fairness is the real cause of the trouble. The only way for all the roads to get justice is to hold to the letter of the rules as closely as possible. It is impracticable to establish rules that will indicate exactly when a defect card is due if the spirit of fairness is absent.

Those who are opposed to the carding for old defects have good practical reasons to give in support of their position. Old defects are generally of a character that result from ordinary wear and tear, and the owners are the parties who should bear the expense of doing the work. For that reason old defects ought not justly to call for carding. On the other hand, it frequently happens that a car is a long time away from home, and defects due to hard usage become old while it is dancing to and fro on a foreign road. It is rather hard that this car should be returned in a half-wrecked condition to the owners to repair when all the damage was done while the car was earning money for parties who held it away from home as long as it could be used with safety. Another objection to the non-carding of old defects is that the man inclined to act unfairly will insist on making many defects, old or new, just as the decision will favor his own interests. We have listened to both sides debating this question with much earnestness, and we are inclined to believe that the only practical solution of the question is in holding to the rule that a card may be demanded for a certain defect, no matter when the defect appeared.

## The Unreliable Tail-Bolt.

The increasing capacity of cars is constantly developing new weaknesses in the cars of old dimensions that demand increase of sizes. A part that has been greatly under fire lately is the tail-bolt of the draw-bar. This was long the popular means of connecting the draw-bar to the draft attachments. Straps are now on the ascendant. In proposing an amendment to the M. C. B. rules of interchange requiring the strengthening of the tail-bolt, Mr. William Forsyth lately said:

"We have recently taken out of foreign cars some tail-bolts which were 1½ or 1⅝ inches in diameter, secured by a key, and pulled them in our testing-machine. We have broken such keys at as low as 40,000 pounds, and broken the bolt at 50,000 or 60,000 pounds. A 1¾-inch bolt with a key will not stand much over 70,000, and you would be surprised to see how small a section of iron there is in a tail-bolt which has a key. The area is not as large as that of a common link, and I think it is essential, with our large engines and heavy capacity cars, that the strength of the whole train should not be impaired by the introduction of the old cars having small tail-bolts. The accompanying figures are full-sized sections through the key-ways of 1½, 1¾ and 2-inch tail-bolts, and underneath is given the results of tests made upon them. In view of these results, I think it is important that in this section of Rule 3, there should be added, 'tail-bolts for cars of 40,000 capacity and under, not less than 1¾ inches diameter; tail-bolts for cars of 50,000 pounds and over, not less than 2 inches diameter.' I move that the clause be inserted in that part."

In the treatment of fine steel after it leaves the maker's hands it is often forged, annealed reannealed, hardened and tempered, each operation requiring an application of heat. In these processes the steel is subjected to more or less sudden and extreme changes of temperature, being sometimes improperly plunged into ice-cold baths from white heat. If the steel does not remain perfectly sound under all forms of torture, it is very likely to be condemned as bad. Thus steel is many times unjustly blamed, not for fault of its own, but because the steelworker is either not careful to observe, or does not fully comprehend, the laws of its treatment.—*Sparks.*

Several new patents have lately been granted to Mr. James F. McElroy, of Albony, N. Y., and assigned to the Consolidated Car Heating Co. There is a novel system of charging car-heating apparatus with the heating medium, a temperature regulator, and a coupler for electric wires. They are all designed as improvements, to be applied to the company's system of car heating.

## A Correction.

*Editors:*

In the rule which I gave you for counterbalancing driving wheels, by some unaccountable and unfortunate circumstance a very serious error was made in the figures used as an example, and which I, through carelessness, overlooked before sending to you.

I will give you a corrected example as taken from actual practice, as follows

| | | |
|---|---|---|
| Weight back end main rod, | 117 | lbs. |
| Weight front end side rod, | 97 | " |
| One-third weight crosshead piston, front end main rod, | 108 | " |
| Total . . . . . . . . . . | 322 | " |
| One-half stroke . . . . . . | 12 | " |
| | 3,864 | |

Point of suspension, 30) 3864 (128⅘

I am very sorry that this error occurred and appeared in the May issue, but I hope that it will not lead any one wrong before the correction reaches them.

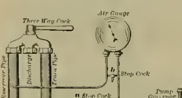
E. M. Roberts.

*Charleston, S. C.*

## Why is this Stop-Cock Used?

*Editors:*

A class of engines running on a road out of this city are equipped with the regular Westinghouse air appliances and deviating from the standard only in having a three-



way cock instead of brake-valve and the two air-gauge pipes connected with a pipe fitted with a stop-cock as shown below.

Will some air-brake man tell why those gauge-pipes are connected?

Will W. Wood.

*Terre Haute, Ind.*

## Not an Explosion.

*Editors,*

Last month Engine 206 on our road, the Illinois Central, dropped her crown-sheet, and engineer and fireman were hurt. It was claimed the engineer was blown two hundred feet, may lose his eyesight, and the fireman suffered a broken leg.

Now, the crown-sheet pulled off 16 of the crown stays and only sank two and a half inches, the force of the explosion (?) did not displace the brick of the arch or crack a glass in the cab.

There are two parties here. One says it was a *bona fide* explosion, the others claim it was simply a case of low water or other cause for crown pulling off the stays, and that the crew were scalded by steam from the open fire-door and jumped off, the engine running 200 feet, and that they were not *blown* anywhere. An explosion that does not break windows is tame, isn't it?

A. D. Prentz.

*Chicago, Ill.*

## A Cinder Lasso.

*Editors.*

What a painful thing it is to get a cinder in your eye, and have to wait until you find some one with experience and a steady hand to remove it for you. Even then the "experienced hand" will take a match, whittle a point on it, and "prod" your eye with it until the eye becomes inflamed,

and after all his "monkeying" the cinder, or whatever it may be, still remains. Never use a match to take anything out of the eye.

Up to date I have taken three car loads of cinders out of men's eyes and have never found anything equal to the little "Lasso," made of horse hair, as per sketch herewith. I hope you will show it up to the boys. It will be found especially handy while running along the road, because if you get anything in your eye, all you have to do is to take hold of the eye-lash, pull the lid away from the eye-ball, and put the "Lasso" up under the lid, drop the lid, roll up the eye, pull out the "Lasso" and the cinder is yours—provided, however, it has not been in long enough to imbed itself in the eye—in that case we use a lead pencil or knitting needle with a sharp, flat point. Don't *pick* but *scrape* off the particle.

W. F. Relyea.

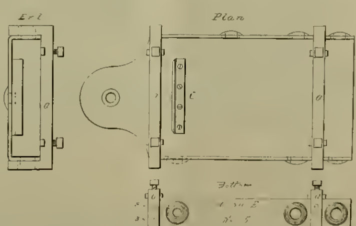
*Syracuse, N. Y.*

## Template for Rod Straps.

*Editors:*

At the B. & A. shops here we use a template for drilling rod straps that saves a great deal of time and insures uniform work.

It is made of ⅜-inch flange iron, flanged and planed on inside the width of the strap. The yokes *A A* are 1 inch square, fitted



snugly down over flanges and riveted at *B B*. Stop *C* is 1¼-inch angle iron and fastened with screws, *D*. After strap is placed in template it is secured with set-screws and gibs, as shown. This, you will notice, is for strap without key-way, but where wedge and screw are used instead of key.

T. B. Purves, Jr.

*East Albany, N. Y.*

## Effect of Large Equalizing Drum.

*Editors:*

The criticisms published in the last number of your paper, on the engineer's brake-valve that had a broken pipe connection to the equalizing drum, make very interesting reading for air-brake men, and show clearly a very largely increased knowledge of the engineer's equalizing brake-valve, and this in turn indicates a better knowledge of the air-brake in general, as this valve is about the hardest to master of any in the system, and cannot be well understood without at least a fair knowledge of the action of the other parts. Cases such as that cited by Mr. Hooker, in which a stop-cock in the train-pipe exhaust became accidentally closed, preventing any application of the brakes in the service stop position, were not infrequent when the valve was first put into service, for at that time Westinghouse sent them out with a stop-cock in that place instead of the small threaded elbow now used, purposely to provide a convenient means of meeting just such contingencies as that described by Mr. Bishop, or any difficulty encountered from leakage by the train pipe exhaust-valve.

Occurrences such as Mr. Hooker mentions (accidental closing of this stop-cock) finally brought about the change to the threaded elbow, which may be plugged up with either wood or a ⅜-inch pipe plug in any case where it is necessary to cut out the automatic action of the valve. If there is an exhaust-pipe in the elbow a blind gasket may be put in the union.

While running an instruction car on one of the railroads, I frequently, for purposes of illustration, had occasion to put a blind gasket in the connection to the equalizing drum, and when the valve was so "fixed," found great difficulty in controlling the brake without plugging up the train-pipe exhaust and making reductions by a slight opening of the emergency port. Cutting off the drum so greatly reduces the size of the cavity above the piston that the moment the handle of the valve is brought around to service stop position the pressure on the gauge disappears like a flash, and there is then no way to prevent all the air from escaping from the train-pipe except to release the brake.

Of course, with great care and very quick movement of the handle back to the lap some of the air may be retained in the valve cavity, but if Mr. Desoe got *satisfactory* results in this manner on an engine in motion he is much more skillful than the great majority of "us experts."

A very amusing experience in connection with the size of this drum came under my notice up in the northwestern part of the country a number of months ago. The brake equipment for an engine had been sent without the equalizing drum, and when the foreman had it set up he substituted a passenger car auxiliary, not thinking at the moment of the effect this would have on the action of the valve. The engine was on a passenger run and the slow action of this valve became famous. A number of the men thought the trouble might be in the size of the drum, but did not like to stand against the action of the foreman, so for some time the engineer had to make the best of it, though it was rather hard on him, as he had to begin applying his brake a long distance from the station to make a service stop at all.

While riding with him he tried to get me to make some of the stops, but as I felt sure I could not handle the thing half as well as he was doing I declined with thanks.

Paul Synnestvedt.

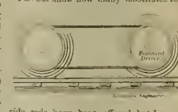
*Chicago, Ill.*

## Proposed Substitute for Side Rods.

*Editors:*

Everyone who has put in any time on a railroad has seen evidence of the damage done by broken side rods, to say nothing of the loss of life and limb.

I do not know how many substitutes for



side rods have been offered, but I never heard of belting the drivers of an eight-wheeler together.

What stands in the way of the use of a steel wire cable, say two inches in diameter, running on sheaves on the outside of wheels?

Why is it not practically possible to use it? It would certainly be far cheaper than side rods, be almost noiseless, require no counter-balance or crank pin boss cast in rear pair of wheels and less counter-weight in the forward pair and would certainly reduce the hammer blow.

Rope transmission of power is very common now-a-days. Who says it won't work?

H. K. Bates.

*Fort Scott, Kan.*

## Tink's Puzzles on Air.

*Editors.*

Permit me to hazard a guess at the answers to Mr. Tink's two problems

In the case of the engine which could not be moved from the table because the brake stuck when the pump was started, one thing is plain, air must have reached the cylinders or the brake would not have stuck. From the description given, the only way this air could get into the cylinder-pipes was through the triple-valve under the tender. It is possible that the handle of the four-way cock was on wrong, and stood in a horizontal position, when the straight air port was open from the train-pipe to the cylinder. There might have been a leak from the train-pipe to the cylinder connection, either around the plug of the four-way cock, or by the slide-valve in the triple, but in either such case the air should have blown out of the exhaust instead of accumulating pressure in the cylinders, and Mr Tink does not mention such a symptom. If there was no blow from the exhaust, either the four-way cock could not have been in "automatic" position, or the triple-valve piston must have been stuck down uncommonly hard with some leak, for the accumulation of pressure above it, or possibly the exhaust might have been stopped up, which in conjunction with a small leak through the valve would stick the brake.

Now let us proceed in a similar manner with the other problem. This triple-valve worked satisfactorily until the emergency was set, after which, on endeavoring to release there was a continual blow through the exhaust, the brake remaining set. The opening of the exhaust shows that the main piston and slide returned to release

position, but as the brake remained set, the air must have been entering the cylinder as fast as it was escaping. This blow could only have been supplied from the train-pipe, and as there is no other passage where it could get through except by the emergency-valve, this valve could not have been properly seated. It might have been held away from its seat in any one of a number of ways Dirt or cinder on the seat, or scale above the emergency-valve piston, preventing it from going back to its proper position; but as in either such case the valve should have blown before the emergency application was made, as well as after, the indications are that either the spring under the valve was too weak to return it to its seat, or else it had been left out altogether, or put in on the wrong side of the valve, as happened in a case that came under my notice a couple of years ago. Evidently the spring did not seat the emergency-valve after it was once opened, either because the spring itself was too weak or the resistance was greater than is ordinarily the case.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

## Tink's Puzzle.

*Editors:*

In answer to Tink's "Little Puzzle on Air-brakes," page 161, May issue, will say, the trouble was caused by air-hose not being properly coupled between engine and tender. SINK.

*Durham, N. C.*

## Answer to Puzzle on Page 159.

*Editors:*

In answer to the little puzzle on the air-brake This engine had but one triple-valve for the tank and driver-brake, so it is necessary to have two hose between tank and engine; this engine had been disconnected the day before in order to do some work on her, and in connecting her again they connected the hose wrong, so that when the pump was working, she was pumping air direct into brake-cylinder instead of into the train-line, and the driver-brake was connected to the train-line; this is something that may happen a great many times, as the hose look to be all right connected either way.

TINK.

## Answer to Puzzle on Page 161.

*Editors:*

The trouble with this little triple-valve was that the bore of the check-valve No. 15 was out of line $\frac{1}{16}$ inch with the bore of the emergency-valve, seat No. 9 in the case, so that after an emergency application the valves would bind and remain open, and after recharging the train-line it opened exhaust from brake-cylinder and the air blew continually through triple exhaust, and the brakes would remain set as long as there was any pressure in the train-line; then, by tapping the case, the valves would drop to their places again; then it would work all right again in service-braking. This emergency-case was a new one that had been put on. TINK.

*South Kaukauna, Wis.*

## Care of Side-Rods.

*Editors:*

The side-rods of engines to run with success, when put up standing on the center, should bear on the inside of the pins; then this will allow for the lengthening of the wheel-center, which is necessary on account of the driving-box playing "up and down" in the pedestal jaws. If rods are put up in this manner and receive the proper care from the engineer, and he keeps his wedges adjusted, there will be very few bent rods and sprung pins. If they are stub ends with straps, they should be put up without keys, for the key has not enough bearing; the brass to run well should have full bearing of the stub end. When they need adjusting, have the machinist slip in a thin liner, giving the bolt a small draw; this will give better service than the key. There are many engineers who will not keep the rods properly keyed, letting the straps and brasses wear out of shape. I have seen engineers who would run with their wedges down, in this way letting all the work come on their side-rods; the brass would gap open on every revolution of the engine. These men are always complaining "that their rods are always giving them trouble." A great many are prejudiced against the solid rod. They claim they pound worse than the strap. This is not according to my experience. The straps not being solid give a little, which kills the pounding and knocking, and it not being so perceptible as with the solid rod, but the lost motion being there it must be the same with both.

Some claim they cannot keep oil cups on solid rods. If they will use a leather or pasteboard washer underneath the cups it will soften the shock, and they will have no trouble with their cups, no matter how bad the rods get.

AN OBSERVER.

## Completed History of the Rebel General.

*Editors:*

Let me tell the rest of the "Rebel General's" story, commenced by Mr. W. H. Wesley in a recent issue of your paper.

I took charge of the motive power of the Tenn. Coal & R. R. Co. in 1880, and found this old engine—then named the "Sewanee"—out back of the shop, where she had been furnishing steam for the shop.

She was re-built and did switching service up to 1887, when she went into the scrap.

They had at that time another engine, the "A. S. Colyar," that was just like the "General" in war times and before her re-build.

Mr. W. W. Knight, of Memphis, Tenn., has photographs of these old timers that might be used in your paper as examples of "before and after." W. A. KNIGHT.

*Birmingham, Ala.*

[We are indebted to Mr. W W. Knight for use of photos from which our engravings were made.]

"ENDURIN' DE WAH."

A PEACEABLE CITIZEN.

## Tbat Overworked Wheel Lathe.

*Editors:*

I notice in your issue for May, a criticism on the statement made by Mr. Purves of the time it took him to turn driving wheels in his shop. This does not take up the question of time, but is a criticism of Mr. Purves for making a tool work too hard—that is, in the writer's opinion.

To be a critic, a person must be, or should be, an expert in the work he criticizes.

Now, I am afraid that, while the article mentioned shows the writer to be a person of intelligence and one who would, by personal attention to his abilities, shine in another field, and his article would lead us to suppose him to be just the kind of a man that railways are looking for to fill positions at the present time. For all that, he is a poor critic.

I would judge, by the article, that he is a machinist and that his interpretation of a machinist's duty is to do work good and in as long a time as possible, and, unfortunately, this seems to be the opinion of many machinists of the present day, while the idea of a few years ago was, for a man to be competent to do the work, and in doing it he was to, and did, devise mechanical means to do it expeditiously and well.

Such a man was proud of what he had done, and there is no doubt that the man who run the planer with four heads—a very common tool that seems to be unknown in Nashville—was one of the kind who found

a means of clamping the driving-boxes down to the planer *between* the boxes. A machinist devised the four heads when he was employed as a *machinist* and not as a *tool*, and took rank above a laborer for the reason that he used his brain.

But, now, let us take up Mr. Purves on the wheel question, and see if it was an extraordinary thing to turn a driving wheel in the time mentioned.

I suppose Mr. Purves has a lathe designed by a machinist who knew the nature of the work it was to do; then it was the duty of Mr. Purves to see that it did it, and let me say that the tool did the work and not the machinist—he controlled the machine, and more by mental than physical effort. Let us turn to the lathe which wants our sympathy, and see if it is suffering from overwork.

The diameter of the driving-wheel was 44 inches. Now, you say that these wheels had only $\frac{3}{8}$-inch to come off—let us say $\frac{1}{4}$-inch, that leaves $\frac{1}{8}$-inch cut and that is a very light one; now let us also make a light feed, say $\frac{1}{16}$-inch, and we must confess that these conditions are all light in view of the fact that a modern wheel lathe will take a $\frac{1}{2}$-inch cut and $\frac{1}{4}$-inch feed without suffering to the tool or lathe. Let us allow a cut of 10 ft. per minute (now this is light, as a good tire steel will permit 11 ft.), and see if Mr. Purves is guilt of cruelty to his lathes. The wheels were 44 inches. There would be a face on a tread of about $4\frac{3}{4}$-inches; this would give 76 feeds of $\frac{1}{16}$-inch. The circumference of the wheel would be 11.55 ft. and the time it takes to turn that wheel on a tread equals $\frac{11.55 \times 76}{10} = 87.7$ minutes.

Let us again be liberal, and allow 60 minutes for flanging, and there will be left 33 minutes in which to change the wheels and do the work in 3 hours.

Perhaps the wicked Mr. Purves used a hydraulic lift with which to remove his wheels; if he did, it was wrong. Water should not be used in that way, and it is not intended that it should be; he should first boil and convert it into steam before attempting to use it, or by absorption in the body of a laborer, and utilize it in that form of energy usually called "man power;" or, perhaps he has diverted electricity from the use for which nature intended it—which is to—well, I will let Sir Wm. Thompson tell what that is—and is removing wheels by that means. If so, this is decidedly wrong, and when Mr. Purves is older (I see he is a junior), he will know better and curb his ambition, which now seems to be great, and I would not be surprised to hear that he has apprentices in his shop.

Now, when we get to an investigation of the work this lathe has to do, I have no sympathy for it, while I have for the man who is compelled to sit on a hard bench, or perhaps the bottom of a nail keg, for four or five hours of the day, and, like Helen's babies, "Zee the wheels go wound."

*New York.* ROUNDHOUSE.

## Recharging in Quick Time.

*Editors:*

In your April issue, Mr. W. C. Parsons is quoted as saying, "We must bear in mind that the air has to pass into the auxiliary reservoir through a very small opening, and it takes some time to recharge them;" and again, "The attempt to apply them at once after release often results in running past the water tank, and the blame is laid on the equalizing discharge-valves, when it should be laid to the fact that sufficient time was not given for the auxiliary reservoir to be recharged with air." What he says is quite true, but he neglects to inform us how we are to recharge a reservoir through these small openings in the usually very limited time between release and an attempt at reapplication. In fact, at such times it is impossible to recharge reservoir and brakes are released and a second application is required when, or even before, brakes are fully off. Under these conditions it is apparent that reservoirs cannot be recharged, and to cause brakes to respond to a second attempt at application we must have an equalized pressure both sides of triple piston, not by recharging reservoir, but by regulating flow of air from main drum to train-line sufficiently to move triple to release position and no more. This can readily be done by moving brake-valve handle to release position and immediately back to lap. If brake-valve is moved to full release position and left there till the second application is required, a considerably higher pressure results in train-pipes above that in reservoir, and it is obvious that brakes will not reset till this train-line pressure is reduced below auxiliary pressure. If a half minute or more elapse between release and second application, or when descending grades, then it is proper to move brake-valve to full release and leave it there, thus taking advantage of the time to recharge the reservoir.

## A Break-Down.

*Editors:*

I beg space to give the readers of your most valuable paper a nut to crack. I am running a standard 18-inch engine on a five-car local passenger train. On a very hilly part of the division I broke down. The engine in question had her eccentrics put on in halves. These were bolted together securely with two bolts. One of these bolts is what broke, letting the cam slip loosely around shaft. In trying to set set-screws up so as to hold cam, I found it bound tightly in strap. I did not put washers in strap to open it more, as I consider this a very poor method. Neither did I disconnect, but came in working both sides and without any fear of stopping on dead center. I was just twenty-five minutes from time of break-down until I was ready to go, and most of this time was waiting for flagman to return. I will add still further that I made better than schedule time over remainder of division. How did I have engine fixed?

*Wymore, Neb.* OIL-CAN.

## Long Mileage.

*Editors:*

I noticed in the April number of LOCOMOTIVE ENGINEERING an article from an engineer on the C., H. & D., saying they have engines that double a division of 131 miles every day, making a mileage of 7,860 per month. I am ready to admit that engines are capable of making such mileage. But the brother of the oil-can forgets to add whether one or a dozen men were running them. Until he does, I shall claim the longest mileage ever made by one man in one month. I am running passenger engine No. 103, B. & M. R. R., and during the month of April made 7,363 miles, with L. Dean as fireman, who never missed a trip. The most mileage I made in one day was 504. Our division is 125 miles long and we have been doubling this for the past three months. As a rule we miss several days in the month for repairs.

*Wymore, Neb.* LIN MOLER.

## A Test with Three Engines Supplying Air.

*Editors:*

In your May edition, page 159, our E. T. friend recommended a cock in place of exhaust-pipe fitting No. 25, plate D 8, in order to use piston No. 17 in service stop, when $\frac{3}{4}$-inch union-nut No. 23 has blind gasket. I do not, for my part, believe that it would be needed often enough to pay for its cost, and the dangerous predicament in which a man might be placed by this cock being closed, accidentally or otherwise, more than over-balances, in my opinion, any benefit that may be derived from its use. I was once on an engine where this cock had been closed by wiping the brake-valve after the brakes were tried, and we came so near hitting another train that I shall fight against their use whenever I come in contact with them.

Once more in regard to Brother Ellis and his problem. On reading the S. D. criticism I went to the roundhouse and coupled three engines together, first setting their governors with a test-gauge. Two of these engines had American brakes, the other a pull-up cam brake. One of the American brakes was practically air-tight, the others leaked a very little. On reducing 10 pounds on one engine, all pumps would start promptly, but everything except pumps worked slower than with single engine, and brake-valve that applied brakes would blow at service exhaust hard enough to raise train-pipe pressure about two or three pounds, but no brakes would pump off while on; the driving brakes that leaked the air would hardly take hold, and would then leak off. The tender brakes being push-out cylinders and practically air-tight, would not leak off at all (would say they had 12x33-inch reservoirs and 8-inch cylinders, and so had more power). At the end having the engine with tight driving-brakes, when air was applied from the other end these brakes would stay on for ten minutes, and then we released them, as that seemed proof that it would not pump off. We made several trials at different pressures, and repeated our tests from each engine, and our conclusions were that with three engines with pumps in first-class order, coupled together, and all pumps running and supplying train-pipe, two of these pumps could not make air fast enough to choke exhaust in brake-valve on third engine, when brakes were applied by it and handle then placed on lap. On one engine the packing-ring No. 18, plate D 8, leaked a little, and in ten minutes the black hand came up five pounds, and if left long enough would have let the brakes off.

The brakes all worked slower and more in the style they used to before packing ring No. 24, plate D 9, was put in, and after brakes were released each pump had to make up the air in its main reservoir before it could help the lead engine, as their reservoir pressures were but a few pounds more than the air in space above piston No. 17, plate D 8, on braking engine, as that space was a governor or pop-valve spring in respect to the engines whose brake handles were in release positions. There is a lot to think about right there.

I also believe this to be a very dangerous practice, as the rear pumps were forcing all sparks and sediment lodged in air-pipes ahead of their brake-valves into space under piston No. 17, and it would be but a question of time when the packing-ring would be so dry and this space so full of dirt that the piston could not seat itself, or, something might be deposited in service exhaust when brakes would be released, and in this go-as-you-please style would probably lead to serious consequences.

*Roanoke, Va.* GEORGE HOLMES.

## A Point on Firing.

*Editors:*

There is a difference of opinion in regard to a point on firing which we would like you to settle through your valuable paper. I am firing a passenger. We have a Baldwin engine which carries 160 pounds of steam. Forty-six miles of the division is up-grade; between that point and the terminus, a distance of eighty-seven miles, it is up and down hill. The point in dispute is, as to the best method to save coal. Some claim that by firing an engine at from 120 to 140 pounds and regulate your fire so that the needle will not advance beyond that point is the best. I claim that you lose coal by so doing. They are free steaming engines, and you have to let your fire burn so low that when you pick her up and you throw in green coal which will not ignite right away, down goes your steam, and consequently you have to work under great disadvantages; but by keeping a good fire to work on, and carrying from 140 to 155 pounds of steam you can save coal, yet not allowing your engine to blow off.

A FIREMAN.

*Marquette, Mich.*

[We should say that your method was best by long odds.]

## Repeating Emergency Stops.

*Editors:*

It is often asserted that an emergency action of the quick-acting triple-valve can not be obtained after a ten-pound service reduction, and in a recent number of the *Engineer's Journal* a correspondent of their technical department expresses the same opinion, giving as reasons that the pressures in brake cylinders and train-pipe are sufficient to resist the movement of emergency-piston.

Each successive application of the brake will increase the resistance against emergency-piston, by increasing the pressure in brake cylinder until the emergency-valve is inoperative, and in order to determine the pressures in brake cylinder, an expert in the service of the Westinghouse Air Brake Co. gauged auxiliary reservoir and brake cylinder of one car in a thirty-car train and from 70 pounds pressure made the following reductions with accompanying results

| | Reduction from train-pipe. | Pressure in brake cylinder | Pressure in auxiliary reservoir. |
|---|---|---|---|
| Service application, | 10 lbs. | 20 lbs. | 60 lbs. |
| " " | 14 " | 29 " | 55 " |
| " " | 18 " | 43 " | 52 " |
| " " | 20 " | 50 " | 50 " |
| Emergency " | 10 " | 58 " | 58 " |
| " " | 35 " | 58 " | 58 " |

Now with a 10-pound service reduction we have 60 pounds left in the auxiliary reservoir; the pressure on the slide-valve, which is the only retardation to the movement of triple-piston, is considerably lessened, and another quick reduction of eight pounds will compress graduating spring and uncover emergency port; the auxiliary pressure at 60 pounds per square inch bearing on the $1\frac{1}{2}$-in. emergency-piston with a total force of 294.5 pounds. The service reduction of 10 pounds gives a pressure in brake cylinder of twenty pounds per square inch, which amounts to a resistance of 98.17 pounds against emergency-piston. The other point of resistance is the train-pipe pressure, which, we will say, remains at 70 pounds per square inch between the emergency check-valves, giving a pressure against the upper one—which has $1\frac{1}{4}$-in. seat—85.9 pounds, but from which must be subtracted the brake cylinder pressure against its upper side, which through the 1-in. port amounts to 15.7 pounds, leaving a total check or train-pipe resistance of 70.2 pounds, and adding it to the brake cylinder pressure under emergency-piston we find the full power of resistance to the operation of emergency-valve to be 168.35 pounds against an actuating force of 294.5 pounds.

It is plain that a pressure of 126 pounds in excess of all resistance, will very easily force down the emergency-piston and open communication between train-pipe and brake cylinder. There is 52 pounds in train-pipe and but 20 pounds in brake cylinder, and when the emergency-valve is opened, unless figures lie, it is quite possible to get a certain amount of benefit from an emergency application, following a 10-pound service reduction.

The trouble with Tink's quick-acting triple-valve was caused by the emergency-piston "sticking" when forced down; the other case was the result of a leaky four-way-cock opening communication directly from train-pipe to brake-cylinder, as with the old straight-air system, the air press-

ure was low, as the pump was not started until engine was on the table, and after stopping the pump the brakes released from leakage. WILL W. WOOD.

*Terre Haute, Ind.*

## Boiler-Making and Boiler-Makers.

*Editors:*

Your article on one cause of leaky flues is very timely and to the point on the leaky flue question. Now any one that is a practical boiler-maker knows that the results of allowing your men to run the shop to the extent of being able to have the holes made to suit their convenience is bound to make grief for some one that may have the care of their work. I am a foreman boiler-maker who happens to have this to oversee, and I can say that one thing I look after very sharp is the flue holes and the setting of the flues. You well know that is the most important thing about the engine. Now, the first point is, make your men as intelligent as you are by giving them some pointers on this work, and you will get a better quality of work than can be had by telling them that anything will do so that they get the flues in and set.

I make a practice of giving the workmen a few lessons on the length of the flues. They should be the proper length, say about ⅛ for beading over, as the rolls will expand them some, and that makes a solid bead and as much as the iron or steel, as it may be, will stand, and saves blows that are more injury to the flues than all the expanding they may get. In using the Prosser segment expander the number of blows should be determined, so that they may be of uniform number, then you get a first-class job in flue-setting, reflecting credit on all concerned. This is my rule for flue-setting, and one that I exact from the men doing the job.

We all know that boiler-making is making rapid strides from the old thumb and finger rule of the years gone by, and a more intelligent set of men has grown up, and now have the trade down to some system. It is one of the best trades, if the men willing to learn it will only study a little, first the metal, then the most practical way of getting at results in working it to the best advantage. I always have flue fit holes tight, rolling the copper by a gauge furnished the men then the flues will be a fit every time and results in a good job. Work done in this way will last some four years or more without any great amount of labor on them after being put in.

Now a few remarks about boiler-makers. There is quite a large percentage of them that had better be called boiler butchers, as I have seen some wretched work done with the drift-pin. This is one source of trouble in bad work and poor boilers. We have quite a number of a well-known maker's engines on the road, and we find evidence of want of intelligence in boiler-work; the front shell sheets are cracked at the point spoken of by your correspondent, Mr. Heron, in his "How to Lay Out a Boiler," and which ought to make it plain to any intelligent man who cares anything about his reputation as a first-class boiler-maker. Several roads make the same complaints of these engines, while the other makes of engines give no trouble in that line. Now, to my mind, the only way out of the slough is by creating a better class of men that will produce boiler-makers, not boiler butchers; men who will give a little time to educate themselves up to their trade and less running around gin mills. I am glad that Mr. Heron has taken the true way to make a good boiler-maker, if they will only give application to the work in hand. I have never been afraid of giving the men all the information on any point, and always like to have men quite as well informed as myself on the true and best way of doing things as they ought to be done. This practice gives best results, and the best interest of my employers are thereby served.

CHARLES E. BETTS.

*Marshall, Mich.*

## Lining Guides.

*Editors:*

On page 112 of April, 1892, issue of LOCOMOTIVE ENGINEERING, Mr. A. Dolbeer, of Rochester, N. Y., explains a lightning method of lining guides. I am glad to have him explain this method, for if it is a quicker and better way to do this work than that explained by myself in the February issue, his method is just what we wish to get before the readers of LOCOMOTIVE ENGINEERING. While I have never seen this method tried, nor heard of it previous to reading Mr D.'s description of it, there are several questions which came to my mind in regard to whether it is always best to follow his advice when he says "Do not fool with a line or take measurements when you can avoid it" I have seen guides lined where a mandrel or the piston-rod was used in lieu of a line, and the work, when completed, certainly looked as though the operator had taken no measurements and had been fooling with something other than a line, and the length of time taken to do the work should have been productive of far better results.

By the way, it appears to me, that the plan of taking correct measurements and working closely to them is a good one, allowing that it is a little old.

Now, relative to planing the crosshead while keyed to piston-rod, and the rod placed in V blocks. Any person having planed a head in this position knows that the back end of the head will settle unless blocked up from the planer-bed, and the correct distance it should be raised is simply a matter of guess-work. Whereas, if the head is bolted solidily to planer-bed and the short mandrel perfectly in line with same, no guess-work is necessary and you *know* that the planer work will be in line with the rod when the head is bolted to it. Now, Mr. D. says, "Have gland ready to slip on the piston. This gland should fit the stuffing-box at back cylinder-head."

Just so, and it strikes me that it should fit both rod and stuffing-box very closely, as a slight amount of lost motion at this point would throw the crosshead out considerably. This, then, necessitates making a special gland to fit each rod after it is trued up in the lathe. For, when turning them, the best way is to let each go as large as it will true up, and where this is done no two rods will be exactly the same size, and if any kind of metallic rod packing is to be used (and this style of packing in some form, I believe, is pretty generally used) the glands used while lining the guides must be replaced by another style of gland when the engine goes into service. Another thing in Mr. D.'s method is that from the fact of the spider being wedged to the center of the cylinder, the guides are lined to the wearing part of the cylinder in front, and to the center of counter-bore in the back, and I think that the better way is to line to the center of the counter-bore in each end of the cylinder and let the packing adjust itself to the wearing surface of the cylinder.

Then, too, it appears to me that if the guides fit closely between the cylinder head flange and guide-yoke (as they should do) it must be a difficult and tedious matter to clamp them firmly to the crosshead and not throw it and the spider out of proper position, the replacing of which would of course take time. Now, I do not wish to be understood as insinuating that the method, as previously explained by me, is the best way, for in it I have only related my experience in lining guides, and I am not prepared to speak from experience upon the merits or demerits of Mr. D.'s method, but have simply expressed the thoughts which occurred to me while reading his article, and have given them expression for the sole object of drawing out others and obtaining through the medium of our good LOCOMOTIVE ENGINEERING, their ideas upon the subject, which will, I am sure, be beneficial to us all. So stand up, boys, and speak right out, and I am sure that by so doing you will receive (as has Brother Dolbeer) the thanks of us all. L. C. HITCHCOCK.

*Minneapolis, Minn.*

## Protecting the Rear of Trains.

*Editors:*

Cannot the frequency of railroad disasters be diminished? is a question discussed perhaps as often as their occurrence. I shall not here discuss this subject at large, but I do want to say a word about the kind of accident here referred to—"rear collisions." I do not hesitate to assert, that the fatality resulting from this kind of collision could certainly be lessened in extent, and that by a very simple expedient.

The remedy which I am about to suggest is not "carefulness" in running trains. I concede this is first in importance, and I am willing to assume that railroad men generally try to do their duty; but it seems useless to expect human efficiency beyond a certain degree, and therefore, collisions are likely to occur in the future about as they have in the past, and unless something else can be devised to supplement human efficiency, lives must be sacrificed. My plan, then, is that trains should be "made up" with the baggage car last. An examination into the results of "rear" collisions will show, I think, that it is the last car of the train run into that suffers almost exclusively. It gets the full force of the blow, as well as the dreadful effects of escaping steam and devouring flame; 'tis here that life is sacrificed and bodies mangled. The car immediately ahead usually suffers little in proportion, and the colliding train still less.

Now, with this fact so repeatedly demonstrated, it is clear that were the baggage-car placed last, it, and not a passenger or sleeping coach containing many invaluable human lives, would, in event of such collision, be the object to take the brunt of the shock. Perhaps if passengers should insist upon being more level-headed than the "officials" and refuse to take berths in an end sleeper, the railroad companies might realize the necessity of running trains in such a manner as to insure all possible protection to the traveling public.

I do not overlook the slight added inconvenience to the railroad men of placing the baggage-car last, but it is practicable and possible, and if only one human life would thereby be saved it becomes a moral responsibility. G. B. PRICE.

*New York, N. Y.*

## Lining up Guides—Which Way is the Best?

*Editors:*

In the February number of LOCOMOTIVE ENGINEERING, I read the article on guides, by L. C. Hitchcock, with a great deal of interest and pleasure, thinking to myself, after reading it carefully, that it was one of the best articles I had ever read on the subject of guides. It was so clear, concise and to the point, full of practical information in all its details in regard to putting up guides, and so impressed me, as an article that should be read by every progressive machinist apprentice (and machinist also) that I spoke to several machinists in regard to it, telling them that in this age of mechanical progress and improvement, it was the right kind of instruction desired by our young men, as I fully believed that a young apprentice of progressive ideas and ordinary intelligence could put up a set of guides by carefully following Mr. Hitchcock's instructions.

In reading April number of LOCOMOTIVE ENGINEERING I was very much surprised at A. Dolbeer's criticisms and remarks on Mr. Hitchcock's method.

Elaborate methods, as he calls it. He says it is all right, but decidedly slow. I think that is where he is mistaken. I should say, Mr. Dolbeer's plan is radically wrong; is harder work, and a great deal slower than Mr. Hitchcock's method.

By his own explanation he cannot put up his guides until crosshead, piston-rod, spider and gland are completely finished. Does he call that the proper way to expedite his work, waiting for all that work to be finished before guides can be put up.

Suppose an engine breaks down, comes in shop or roundhouse with back cylinder head, piston-rod, spider and crosshead broken, to be repaired as soon as possible. With Mr. Dolbeer's plan, we could not line up guides until we had spider, rod, crosshead and gland finished.

With Mr. Hitchcock's method, all we want is the back cylinder head, we get that laid out and drilled, put in position, and we are ready for our guides.

Our plan is to fool with a line, notwithstanding Mr. Dolbeer's objection. It is a great deal easier than lifting a heavy piston in position, putting crosshead on, clamping guides to same, and then lining up spider to suit and running a chance of multiplying errors at every step of your work, for, if your gland is loose in back head as it should be, and a free fit on piston-rod, we will have to block up crosshead end to make allowance for same. We make a very simple calculation, measure from bottom bearing of crosshead to center of piston-rod, and we are all ready for our bottom guides (it is not the complicated calculation Mr Dolbeer would have us believe), decidedly easier, and a great deal more accurate than lifting all the heavy work he does to find out the same result. If crosshead is not finished we can line and level bottom guides to our measurement, and if ordinary care is taken I guarantee they will be correct if Mr. Hitchcock's method is followed. If crosshead is ready we can put up top guides and we are ready as far as guides are concerned. If eccentric cams were disabled at same time we can square valves and put valve motion in proper shape while waiting for piston work to be finished.

By Mr. Dolbeer's method we have not commenced doing anything to our guides, as we are waiting for our piston-rod, spider and gland.

Taking both methods into consideration and judging them on their merits, I think the advantage is decidedly in favor of the line and measurement system of Mr. Hitchcock, both in regard to quality of work, and time and labor saved, and you are confident that your work is correct and true every way.

When I worked in the erecting shops part of my work for several years was hanging cylinders and putting up guides on new locomotives. And my method was precisely the same as Mr. Hitchcock's method. In all that time I never had a set of guides to cut or piston-rod to run hot, though engines were put to service after a trial trip of ten miles each way. I never felt cheap about the looks of guides when finished. I lined as close as possible. All I required was the crosshead to be perfectly free in guides.

ONE WHO HAS LINED UP GUIDES.

*South Easton, Pa.*

## Use of Graphite for Front Ends.

*Editors:*

Replying to yours of May 9th. We use for our stacks and fronts—S. L. & S. F. Railway—genuine Ceylon plumbago.

When prepared for use in the shop we mix it with varnish, making a paste, this is thinned with equal parts of raw oil and turpentine so that it can be applied with a brush. Where we do not have a polished surface this application is sufficient, but where we desire to polish it we apply this mixture and before it is dry sprinkle over it the dry plumbago, this is allowed to dry and is polished with a brush or a piece of waste.

Many of our firemen mix the plumbago with water, others with vinegar, and others with lard oil. We think, however, that our shop formula is best because it does not wash off so readily when exposed to the rain.

I have no knowledge of graphite having been used for the purpose of polishing head-light reflectors.

## Good Flavor For Water.

A party of New England railroad officials and others interested in the new Reading combination were lately making a tour over the main line, and, of course, were very much interested in all that was to be seen.

"What river is that?" inquired one of the party, addressing the colored porter.

"Dat, sah, dat am de celembrated Schuylkill riber."

"The Schuylkill; isn't that the river where the city of Philadelphia gets the water supply from?"

"Yis, sah; dat am where dey get da watta."

"It's very nasty-looking stuff. Where do they take out the supply?"

"Jes dar, sah, under de bluff."

"Take the water there with that grave-yard on the bank draining into the river?"

"Yis, sah. But dat am all right. Why, sah, none but de bes people in Philadelphia am buried in dat dere grave-yard."

## A Moral Certainty.

He was a stout, elderly German farmer, who traveled twice weekly over a short one-train road in the West. He persistently avoided buying a ticket, and a good deal of quiet banter occurred between him and Conductor George Flensen on the subject.

One day last week the cars were pretty full and as Conductor Flensen collected the farmer's fare he asked, in a voice loud enough for all around to hear:

"How is it, Mr. Schlappenhausen, that you never purchased a ticket at the depot? You must have some reason for it."

"Yah! I for mein gonduct a goot reason haf," answered the German in a sort of confidential voice, "but berhabs it vas bedder dot I it should not dell. Howefer, if you vould like to know, I dond mind delling you all aboudt it in der sdrictest gonfidence."

"All right, old Sauer Kraut, toot out your strictest confidence," said some one.

"Vell, you see," he began, looking around benignantly, "aboudt dree years ago I haf a cow on dis railroad killed, and whent to der gombany for gombensation. I abblies, dey answer no. But I abblies a segond dime, und den dey answer dot dey gondemblate putting in a glaim againsdt me for injury done to deir enchine. Den I gedts mad, und I a vow svears dot not von odder cent of mein shall dot gombany efer bocket, und—(looking up pleasantly at Flensen) as long as you vas gonductor on der drain, Sheorge, *I don't believe dey efer shall*."

## A Powerful Machine.

A party of master mechanics and other railroad men were visiting the Cambria Iron and Steel Works, and every few minutes their steps were arrested to witness the enormous power exerted by machines in kneading great masses of steel with as much ease as the plastic clay is shaped in the hands of the potter. One machine excited great attention. It was beside a puddling furnace and its duty was to grasp the puddled roll and squeeze the cinders and slag away from the iron. It grasped the roll between serrated revolving cones and squeezed and twisted it till the metal seemed turned outside in several times.

The party stood in awe and watched several operations of the ponderous machine. Exclamations of wonder and admiration were whispered. "Tremendous," "Immense," "Wonderful," "Terrible," were heard in heartful echoes above the din. And then E. N. Lewis gratified the desire for expression by exclaiming, "Wouldn't that give a fellow's girl all the hugging she wanted!"

## The Coroner's Opportunity.

Nearly a dozen years ago, when the Rio Grande road got to the wild and woolly western town of Durango, in Southern Colorado, the cow-boy gamblers were running the town and proposed to show off some of their "dead cinch" on the railroaders. As an introduction, one of them shot the fireman on the first engine that came into town, and it was given out cold that if the car-hands wanted to live they hadn't better come up town.

That night the boys "got together," went up town in a body and hung the revolver artist to a telegraph pole. Then they interviewed the coroner and intimated, in an unmistakable way, that railroad men were the proper people to sit on a coroner's jury. The verdict was *suicide*.

A more recent case is reported from Texas, by the San Francisco *Examiner*, in which the coroner looks out for his State in a patriotic way:

Down in Texas, near the little town of Langtry, a laborer fell off a big viaduct that is being built for the railroad across the Pecos River canyon and was killed.

An inquest was held shortly afterward by Coroner Roy Bean, and when he arrived at the scene of the accident with a number of people from the town and a score or more of the bridge workmen, he found on the body a Colt's revolver and $40 in money.

Mr. Banzano, of the Phœnix Bridge Company, who is building the viaduct for the road, was present at the inquest, and in a letter to W. G. Curtis tells about it.

According to Mr Banzano's letter Coroner Bean's verdict was as follows.

"'Gentlemen,' said his honor to the by-standers, 'there is nothing to find out how that man came to his death. He fell from the bridge; that's all there is about it. But there is one thing which is not so plain, and that is, what was he doing with that gun? Of course he is dead and can't explain, but that ain't the fault of the law; it's his own misfortune. Justice is justice, and law is law, and as he can't offer no satisfactory explanation of the matter I shall be obliged to fine him $40 for carrying on or about his person that pistol. Because a man chooses to don his wings and skim off to the skies is no reason why the great State of Texas should not have what is coming to her all the same.'"

An hour later the body was buried by the bridgemen.

## Anecdotes of Alick Gordon.

At the last Master Mechanics' Convention a number of veterans had ensconsed themselves on the shady side of the hotel veranda, and were exchanging experiences for mutual delectation and instruction. This practice of comparing notes is a very valuable feature of these conventions and many a man carries away information that saves thousands of dollars to his employers in the course of a year.

From business talk they dropped into social and personal reminiscences. Meehan had been telling anecdotes of workmen with his inimitable style, and Swanston began stroking his beard as an aid to memory.

"My men," he remarked, "have not been so funny as Meehan's, but I have at times heard things from some of them that struck me as amusing. I once had a blacksmith, named Alick Gordon, who was an excellent hand and a pious man as becometh my countrymen, but he liked a drink of whisky and at long intervals he would forget his professions enough to get fuller than he could comfortably hold. We had a Burns Birthday anniversary one year, and Alick got comfortably drunk before the meeting broke up, and several others were in a poor condition to sing with him, "We're nae sae fou." Alick lived outside the town, and at a very late hour he started for home. On his way he found one of the crowd lying by the wayside suffering from leg prostration.

"Give me your hand and help me up, Alick," exclaimed the inebriate sufferer, as he saw my blacksmith stagger within sight.

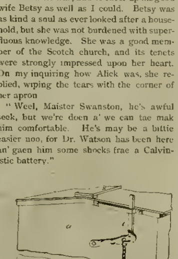
Alick stopped and with drunken gravity studied the situation. Then he answered.

"No, ma freen'. I winna try tae help ye up, but I'll just lie doon a-side ye." And he did.

Some years after that Alick received a paralytic stroke, and it eventually finished him. Dr. Watson was called, and did all in his power to relieve the sufferer, among other things giving him treatment with a galvanic battery.

The day after he was prostrated, I called to see how he was, and to cheer up his good wife Betsy as well as I could. Betsy was as kind a soul as ever looked after a household, but she was not burdened with superfluous knowledge. She was a good member of the Scotch church, and its tenets were strongly impressed upon her heart. On my inquiring how Alick was, she replied, wiping the tears with the corner of her apron

"Weel, Maister Swanston, he's awful seek, but we're doen a' we can tae mak him comfortable. He's may be a bittie easier noo, for Dr. Watson has been here an' gaen him some shocks frae a Calvinistic battery."



CAR COUPLER, WITH CAR ATTACHMENT.—A STORY WITHOUT WORDS.

Those who have the designing of driving-brake apparatus are aware that there is often difficulty in getting the gear conveniently and securely fastened to the engine frames. Mr. Charles C. Higham, St. Louis, Mo., has attacked this difficulty at the foundation by inventing and patenting a locomotive frame with integral attachments for the driver-brake. The patent has been assigned to the Westinghouse Air Brake Co., and we understand that they intend putting the improved frame on the market.

## Romance in Railroad Life.

Considering the great magnitude of railroad interests in this country and the vast number of people who are directly and indirectly dependent on railroads for a livelihood, it is surprising the small figure that railroad life cuts in the literature of our time. Many of the most stirring romances that belong to the literature of the world relate to seafaring life and experiences on shipboard. The fundamental romance of the sea is the danger of the calling. Much of the romance of war has its sole origin in the dangers surrounding those engaged. If danger and the opportunities to display acts of bravery and heroism are real bases of romance, railroad life ought to be better represented in song and story than any other calling. It is the heroic calling of to-day, but its chroniclers have not yet appeared. Most of those who have tried to employ railroad life as the woof on which to weave a web of romance have been peculiarly unfortunate in their work. They have not been true artists, and used their imagination where they ought to have made use of their eyes and ears. The result has been inartistic productions that repelled those who readily perceived that the pictures were caricatures and daubs instead of likenesses. The work of the sensationalist and the ignoramus has brought railroad life into disrepute as a field for romance and poetry.

A light which suddenly faded came up for a few brief months and promised to redeem the railroad field and show therein in living shape the joys and the sorrows, the victories and the failures that are seen so attractively amidst the men and women who make up our railroad world. Wolcott Balestier, whose name first became familiar to readers of general literature through his associating with Rudyard Kipling a few months ago to write the American part of an Indo-American story, was familiar with railroad life, and there was the likelihood that he would favor the world with works of true art having a railroad background. This hope has been cut off, for he died in Germany about the time his name was becoming familiar to his countrymen.

Since Balestier's death the *Century Magazine* has published two railroad stories from his pen, which are greatly superior to the American part of the "Naulahka." When we read the first chapters of that story, which treat of railroad life in Colorado, we made up our mind that the author used a dictionary of Western slang and labored to make the hero and heroine work up as many of the words as it was possible to force through their lips. As the hero was an educated engineer and the girl a refined young lady, it was scarcely painting true to nature to make them more familiar with slang than a Leadville bartender. The other stories, however, indicated that Balestier had dropped the slang dictionary and was using his ears more. There was a power and vigor in his writings that promised a great future. We feel that in the premature death of this author literature lost a star whose rays were just beginning to shine.

During a recent visit to McAdam Junction, N. B., we were much interested in the motive power office building, which is said to be the finest belonging to the Canadian Pacific out of Montreal. It is remarkably well kept, and contains drawings giving full details of the standards belonging to the road. The designing and work was all done under the direction of Mr. G. A. Haggerty, master mechanic. He has built the shops twice and done a wonderful amount of work with limited facilities.

A patent was granted last month to F. W. Dean, Boston, for an intercepting-valve for compound locomotives. The valve is in use on the engines designed by Mr. Dean, of the Old Colony and the Lehigh Valley railroads.

(52) W. W. R., North Platte, Neb., writes.

Do you know of any car starter that applies its power against the car instead of the wheels? *A.*—We have seen such a car starter, but cannot tell where.

(53) E. L. Penruddocke, Weatherly, Pa., asks

While a locomotive is running under steam, which is the fulcrum—the rail at point of contact with the driving-wheel, or the side of the driving-box against which the engine is pulling? *A.*—At the rail. Those who argue that the axle-box is the fulcrum, ought to consider where the fulcrum of a bicyle would be

(54) C. A. H., New York, says

I inclose you a cutting from a daily paper giving an answer to a correspondent, saying That the cost of a first-class locomotive is from $22,000 to $25,000, and that a drill engine costs from $6,000 to $10,000. How is this? *A.*—A first-class eight-wheel locomotive of 18 x 24-inch cylinders costs about $8,000. Larger engines cost a little more, but $10,000 is an outside price. Switching engines cost from $6,000 to $8,000.

(55) Machinist, Buffalo, N. Y., asks

An eight-wheel passenger engine, Schenectady build, came into shop with forward driving axle bent so much that at the inside of journal it ran out of true three-sixteenths ($\frac{3}{16}$) of an inch. The journals and tires were turned and engine sent out. What effect would this have on valve motion, and what remedy could be applied other than new axle? *A.*—We know of no remedy, a new axle would be a cure.

(56) R. A. C., Buffalo, asks.

Was the Westinghouse air-brake the first kind of a brake that gave the engineer the power of holding the train? *A.*—No. There were a great number of continuous brakes tried before the Westinghouse brake was introduced. Steam brakes that operated the shoes by means of chains, compression brakes and numerous other forms were tried before the Westinghouse, but none of the inventions came within sight of being a success.

(57) Subscriber, Portsmouth, Va., writes

After the application of the brakes, how far do you think it is possible that a train of twelve cars would go down a grade of six inches to the 100 feet, the train moving at the rate of six miles an hour? The cars being equipped with hand brakes, the locomotive with hand brake on the tender, and engine reversed. *A.*—It is not possible to figure out such a problem. No one can tell the exact pressure used with hand brakes, how long it took to apply them cuts some figure, but the weight of cars, etc., is a big factor in the problem. How big is a piece of chalk? is as easy a question.

(58) C W W and G. C. M., Slovall, N. C., write

To settle conflicting ideas and arguments, will you please explain in your next issue, what holds valve No. 17 down in engineer's equalizing discharge valve when the valve is placed in *running* position. Please give us a full explanation and oblige. *A.*—When the valve is in running position air passes through feed port, lifts valve 21 and enters the cavity leading to train-pipe, it comes up under main valve 13 through direct application port and goes down through a small hole called the "equalizing port" (shown in Fig. 3, Plate D8., W. A. B. Catalogue), the pressure here keeps the piston 17 down.

(59) "Quick Action," Armstrong, Mo., writes.

1. On the Santa Fé passenger engines here I noticed under the running-board a circular cast-iron box with a bolted cover and air-pipes connected (I don't mean the small reservoir connected to the brake-valve). What is it for? *A.*—You probably saw a Boyden train signal. 2. On a coach I noticed a pipe running from the brake cylinder to a reservoir. What is this for? *A.*—We don't know. 3. Please explain the compressed air train-signal apparatus? *A.*—Signals are given by a reduction of pressure in train-pipe, which blows a whistle in the cab. Send to the Westinghouse Company for catalogue.

(60) J. E. J., Greenville, Pa., writes

1. I am informed by a reliable man that he has been running a small stationary engine for twenty-six years, and that the cylinders were never oiled or lubricated. Can this be true? *A.*—Very likely it is. In the early days even locomotives used to be made without any means of lubricating the cylinders. With low pressure steam and small cylinders there is not much use for lubrication. 2. I understand that there is a steamer on Lake Chautauqua that has a boiler carrying steam of 500 pounds pressure, and that the steam from the cylinders all returns to the boiler. Also, that the boiler has no safety-valve. Can this be so? *A.*—Water-tube boilers are made that carry safely the pressure named. When a surface condenser is employed, all the steam from the cylinders is condensed and returned to the boiler. We do not believe the boiler is used without a safety-valve.

(61) K. Ty., Sedalia, Mo., writes

1. Why are the cranks of a locomotive set at right angles? *A.*—To enable the piston on one side to exert the greatest power at the periods when that on the other side is doing little or nothing to propel the engine, through the crank being at or near the centers. 2. What is the unit of a grade and how do you know what per cent. a grade is? *A.*—American engineers generally speak of a grade being so many feet to the mile. That is the number of feet ascended each mile. When the calculation is made by percentage it is reckoned on the rise in each 100 feet. For instance, a grade that rises 1 in 100 feet is one per cent. and is close on 53 feet to the mile; that is, to give it accurately, 52.80 feet in 5,280 feet. 3. Is 640 tons an average train on a grade of 58 feet per mile for a mogul with cylinders 19x24-inches, driving-wheels with 50-inch centers, and carrying 150 pounds of steam? *A.*—It is rather a heavy load for that grade.

The Cooke Locomotive Works, Paterson, N. J., have lately completed the building of two cylinder compound locomotives. She has been running on the Delaware, Lackawanna & Western under the immediate supervision of Master Mechanic W. H. Lewis.

## Houston Shops of the Southern Pacific.

I don't propose to burden my readers with minute descriptions of all the railroad shops I visit. They are too much alike, but will only touch upon unusual features.

Like all S. P. shops, those at Houston are well built structures of brick, with large clean yards and considerable many flowers here and there.

These shops are exceptionally well supplied with tools and materials. They have their own foundry and make most of the castings for the Atlantic system.

A large brick stack stands in the yard and a tunnel carries the smoke from the shop boilers to it. Around this tunnel are arranged a lot of steam pipes through which passes the steam for heating the immense plant, for this is claimed a marked economy.

They have a splendid roundhouse of some twenty-four stalls.

On a platform overhead in the machine shop is located a home-made air-compressor that is much more efficient than a number of brake-pumps, and much cheaper.

There are two single-acting cylinders set upright on the base, and standards from either side extend up some two feet, carrying boxes for a horizontal shaft with two cranks to operate the pistons and a tight and loose pulley.

To the belt-shipper there is a rod connecting with a four-inch cylinder fast to a post below the platform, and a valve is so set that when a certain pressure, say 100 pounds, is reached in the shop drum, air enters this cylinder and shifts the belt to the loose pulley; when the pressure falls below the standard pressure, the air escapes from the small cylinder and the belt is shifted for work. A variation of half a pound will shift the belt, so that whatever air is wanted is supplied, no pops waste any, and a constant pressure is maintained automatically.

In this shop they are systematically putting new boilers into their engines after a certain service. They had already got in ten of them at the time of my visit. They buy them from the makers, and we noticed that the upper rows of side stays were but 2¼ inches from center to center, and in some new boilers that had come with stays 4½ inches apart, they put in two extra rows between those already in.

This road, in common with many, is putting on neat, cast-brass numbers on the sand box instead of painted ones, they are cheaper than gold leaf, last as long as the engine does and are always kept clean. I should think builders would never use anything else.

The best Krupp wheels are used for all engine trucks.

They have in use the most murderous looking pilots I ever saw. Under the pilot proper is bolted a half-inch steel knife that is ground off on the top side to a sharp angle; this forms a sharp point at the front of the pilot ten inches wide and narrows down till at the heel it only extends out four inches.

When an animal falls down in front of that it is cut into slices without further ceremony, which, after all, is better than having them roll up under the engine and landing it in the ditch; the knife also makes a good step for the trainmen, but I couldn't help thinking of their legs.

They are making a lot of metal boxes with glass sides to go on top of caboose cars and metal numbers that designate the train will be hung over the glass.

Many of the engines are equipped with steel rod cups, no brass about them, and they seem to be far stronger and just as good.

They are not afraid to cut up old locomotives here, which is a good sign, the tendency is to use these old-timers until, like the one hoss shay, they go all to pieces at once, but there is such a marked tendency for the boiler to suddenly go away somewhere—and take someone with it—that they should be discouraged.

General Master Mechanic Ryan has probably had more experience with deep wells than any other man in the business, and is using water from wells, on the west end, that is pumped 2,200 feet. This is done with compressed air of from six to eight hundred pounds pressure per inch.

Some years ago Mr. Ryan devised a pump for a 1,300 foot well to be operated by air, such a well is too deep for rods, and the bore, eight inches, prevents other well-known forms from being employed.

His plan was to send down a cylinder with piston, and connect the case with air-supply and water-discharge pipes so that it might work by pulsations. This pump worked, but not very satisfactorily; one day Mr. Ryan climbed to the top of the water tank to get a breath of air, and noticed that, though the pressure was not sufficient to operate the piston, water spurted out of the delivery. He reasoned that the piston packing leaked, but if a leak would pump water why not the straight pressure? The pipe was hoisted out and the piston removed, and the casing lowered again, when, lo! it pumped water better than before.

Several wells were equipped with these pumps, having foot valves only, as shown in the right-hand cut on page 201, but another plan was soon tried without piston or valves, as shown in the left-hand cut, and these are now employed.

The tube which answers the purpose of a pump cylinder is some thirty-two feet long, and the water-delivery pipe extends down into it six feet. The drawings, from which this sketch was made, were for a comparatively shallow well—only 600 feet deep. The water comes from pipe in distinct pulsations, as though being lifted by a direct plunger.

The S. P. is the one road of the South that tries to buy the best in the market regardless of cost, and there is nothing about the Houston shops that any of the officers need be ashamed of. J. A. H.

The daily papers have contained accounts lately of several accidents due to people falling from trains while passing from one car to another. This kind of accident happens most frequently on suburban trains, where passengers find it necessary to pass from car to car in search of seats In New England, nearly all suburban cars have the platforms protected by gates, and it appears to us very short-sighted on the part of railroad companies in other parts of the country to neglect supplying this additional security to their passengers. Platform gates cost little, they are not unsightly, and they cost next to nothing for maintenance. The damages that would be recovered for one accident to a passenger by falling from the unprotected platform would more than pay the expense of making a great portion of the equipment safe by the putting on of gates. How such a measure of safety is persistently neglected is one of the mysteries connected with railroad management.

A correspondent in an esteemed contemporary exclaims "Why does the law not step in to prevent the pernicious practice of ticket-scalping?" After long study of the loss of revenue to railroads that flows from the scalping system, we are inclined to exclaim with numerous dashes—Why do the railroad companies persistently foster the business of ticket-scalping?

One of our correspondents writes enthusiastically about the performance of the ten wheelers that were delivered last month by the Rhode Island Works to the Chicago & West Michigan road. The engines have cylinders 18x24 inches, driving wheels 54 inches, carry 160 pounds pressure of steam and weigh in working order 98,700 pounds.

# BALDWIN LOCOMOTIVE WORKS.

—ESTABLISHED 1831.—

ANNUAL CAPACITY **1,000 LOCOMOTIVE ENGINES.**

Adapted to every variety of service, and built accurately to standard gauges and templets. Like parts of different engines of same class perfectly interchangeable.

## COMPOUND LOCOMOTIVES.

Broad and Narrow-Gauge Locomotives; Mine Locomotives by Steam or Compressed Air; Plantation Locomotives; Noiseless Motors for Street Railways, etc.

BURNHAM, WILLIAMS & CO., Proprietors,

**PITTSBURGH, PA., U. S. A.,**

**MANUFACTURERS OF THE**

# WESTINGHOUSE AUTOMATIC BRAKE

## THE WESTINGHOUSE AUTOMATIC BRAKE

is now in use on 24,000 Engines and 262,000 Cars. This includes (with plain brakes) 200,000 Freight Cars, which is about 20 per cent. of the entire Freight Car equipment of this country and is about 80 per cent. of those engaged in interstate traffic, affording the opportunity of controlling the speed of trains by their use on railways over which they may pass. **ORDERS** have been received for 140,000 of the **IMPROVED QUICK ACTION BRAKES** since December, 1887.

The best results are obtained in freight train braking from having all the cars in a train fitted with power brakes, but several years' experience has proven conclusively that brakes can be successfully and profitably used on freight trains where but a portion of the cars are so equipped.

Below is a graphical illustration of the progress made in the application of the **AUTOMATIC BRAKE** to Freight Cars since its inception:

| Year | No. Per Year | Grand Total. |
|---|---|---|
| 1881 | 105 | 105 |
| 1882 | 1,065 | 1,160 |
| 1883 | 4,998 | 6,158 |
| 1884 | 15,051 | 21,207 |
| 1885 | 10,410 | 31,617 |
| 1886 | 8,846 | 40,566 |
| 1887 | 9,281 | 49,844 |
| 1888 | 27,696 | 77,540 |
| 1889 | 26,065 | 103,605 |
| 1890 | 50,502 | 154,107 |
| 1891 | 39,061 | 193,168 |

**193,168 Freight Cars** fitted with the **WESTINGHOUSE AUTOMATIC BRAKE**, which is nearly 20 per cent. of the entire freight car equipment of this country.

## Test of a Dean Compound Locomotive.

We have received particulars of a series of tests made under the supervision of Mr. F. W. Dean, to find out the relative economy and efficiency of a compound locomotive as compared with two simple engines. The work was done on the Old Colony Railroad and the engines experimented with were a compound built by the company having the Dean arrangement of cylinders and steam distributing appliances, but in other respects the standard engine designed by Mr J. N. Lauder, and two of the ordinary standard locomotives.

Four trips were made with each engine. The average load for one simple engine was 382 tons, of the other 387 tons, and of the compound 390 tons. All other conditions were about even for all the engines, except in the coal used. The simple engines used Pocahontas coal on all the trips, while the compound had that kind of coal only on the first trip, Cumberland coal having been used on the last three trips. As Pocahontas coal is of superior quality to the Cumberland it was felt that the compound did not get entire justice. The average consumption of coal for the four runs of each engine was 7,615 pounds for one simple engine and 6,464 pounds for the other. The compound burned 4,559 pounds. This makes out a fuel saving of about 40 per cent. in one case and 30 per cent. below the other engine. The average weight of water used was 50,918, 43,522 and 37,903 pounds respectively. This gives the compound the advantage to the extent of 26 per cent. against one engine and 12 per cent. as compared with the other. The water evaporated per pound of coal was 6.7, 6.75 and 8.3 pounds. This is remarkably good evaporation for engines pulling a heavy freight train at an average speed of 26 miles an hour. The engines all have fireboxes that give 19.2 square feet of grate with a total heating surface of 1,362 square feet for one simple engine and 1,372 square feet for the other, while the compound has 1,354 square feet. The simple engines are noted for their efficiency and economy, so that the compound had a foe worthy of her steel when entering the conflict.

A splendid reproduction of a photograph of this engine is shown herewith.

OLD COLONY COMPOUND—DEAN SYSTEM.

## The Biter Bit.

When a smart rogue having property adjoining a railroad sets himself to work to manufacture claims for damages against the corporation he rarely fails to succeed in obtaining money unjustly. This is a little more certain when the railroad happens to be elevated and has the reputation of being controlled by one of the Money Barons. The men who work up claims against railroad companies sometimes over-reach themselves even when the victim is the Manhattan Elevated. The particulars of a case in point lately reached us. Mr. Thomas, a property owner on one of the avenues, sued the Manhattan Elevated for heavy damages caused to his property abutting on one of the railroad stations. It was alleged to obstruct the light from a corner house and to greatly depreciate the value of a saloon on the ground floor. The jury found a case for the plaintiff and required the company to pay heavy damages or move their station. The company decided to move their station, and now the lessee of the saloon is suing the proprietor for $10,000 damages due to his loss of custom caused by the station being moved.

---

We have the authority of a Cincinnati paper that a muskrat tied up the Cincinnati, Portsmouth & Virginia railroad for ten hours and did hundreds of dollars' worth of damage last month. The rat gnawed a hole through the embankment that protects the road from the canal, and the water washed out 100 feet of road and let out all the water in a six-mile length of the canal.

Put up all your pipe-joints with graphite use it on bolts and nuts, cover gaskets with it for hand-hole plates, and use it on all joints and bolts in and around the front end, and when you want to get the work down it will come without the use of cold chisel and sledge. In making pipe-joints, if some of it gets into pipe, it blows through as easily as oil and does not harden into a shot to destroy the efficiency of injectors, lubricators or what not. It is the only lubricant that doesn't burn away and is especially valuable for wash-out plugs or other boiler joints

## A GRASSHOPPER ENGINEER.

### Incidental Reminiscences in the Railroad Experience of Joseph York.

Joseph York is to-day one of the oldest living locomotive engineers, and has had, withal, a varied and interesting experience, meeting daily with incident and accident, but never of a serious nature.

Mr York was born at Henrietta, N. Y.,

January 14, 1819, and is, therefore, over seventy-three years of age When he was yet a little child his parents moved to the, then, wilds of western New York, where the boy grew to man's stature, with few advantages and hard work

Mr York had an older brother who was employed as musician with a show when a youth, and in 1835 turned up on the B. & O. Railroad, and in the spring of 1837 he came home on a visit. At that time the subject of this sketch had never seen a railroad, but when his brother returned to Baltimore in June, 1837, Joseph York went with him. He immediately went to firing on a Grasshopper engine, and the following summer found himself in charge of one of these original and interesting insects

The original Grasshoppers had tenders as shown in the picture here reproduced, those still in use carry their coal and water on the engine.

As can be seen in the picture there was a fan on these engines to increase the draft, but it is not generally known that this fan was driven by a steam wheel upon whose blades the exhaust steam acted before escaping up the exhaust-pipe.

A rather curious accident is depicted in another sketch. These Grasshoppers when hard at work bobbed around so much that it was impossible to fasten a broom on them anywhere that would keep on the rail half the time, and it soon became the custom in snow to run a small push-car in front of them to carry the brushes.

One day Mr. York was pulling passenger with one of these cob-choppers that bobbed around so lively that it got its drawhead over that on the car and closed up on it; then the crank on the gear shaft, that conveyed the motion to the wheels, came down on top of the car frame, and, instead of smashing the car, it lifted the engine off the track and she turned a sommersault into the ditch, the engineer and fireman making tracks for high ground.

After running this class of engines and the old-fashioned Norris dome engines until the spring of 1839, Mr. York had the tramp fever and quit, going the rounds of the roads of the country and soon finding himself on the Georgia Railroad running a Baldwin half-crank engine out of Augusta; this class of engine is shown in our sketch.

What the men had to contend with then can be imagined by looking at this picture. There was no cab to protect them from the elements; a simple railing to prevent their falling off; no steam-gauge or gauge-lamp, and no head-light.

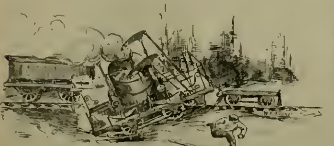
One night there was a big political meeting at a town on the line, and some one piled a lot of rails on the track. There being no headlight, the obstruction was not seen until struck. The negro fireman declared that "old Gabriel had done blowed his ho'n", but a rail struck the wooden frame of the truck, shivered it from end to end, but prevented the derailing of the engine.

In the spring of '40 Mr. York went to work for the old State road of Pennsylvania. Here he had his first experience with the Winans engines known to history as the "Crabs" These engines had vertical boilers, but horizontal cylinders, they were

RUNNING ON VERBAL ORDERS.

intended as an improvement on the Grasshopper and were geared much the same.

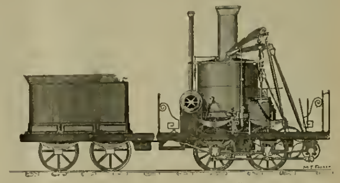
This class of engine is also shown in our sketch; the gearing was so arranged that when a cow was struck, it acted something like the feed on a sewing machine and helped them in further



LIFTING HERSELF INTO THE DITCH.

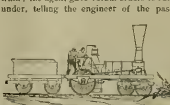
In the fall of the same year, 1840, Mr. York returned to Baltimore and went to work in the Winans locomotive shops, but was immediately selected to take the first Crab to the Western Railway, now a part of the Boston & Albany. The renowned Major Whistler was then in charge of the road.

Our sketch shows one of these old-timers that went through a shallow bridge with Mr. York, near Chatham, on the old Hudson & Berkshire, now a part of the B. & A



THE ORIGINAL "GRASSHOPPER."

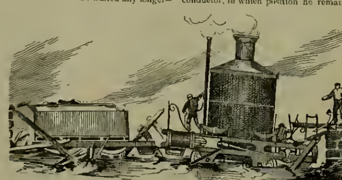
They did some queer railroading in those days, and Mr. York recalls an incident of it. One day he left Pittsfield, Mass., as second section of a passenger train, the agent gave verbal orders to run under, telling the engineer of the pas-



BALDWIN HALF-CRANK.

senger train to tell the crew of a certain passenger that they were to meet, to stay where they were until the second section came.

The passenger crew delivered this message to the already belated passenger, and the engineer, after the manner of his more modern brethren, kicked, saying that he had waited there long enough and he would be d——d if he waited any longer—and he didn't. The result is shown in the sketch—the Crab and the Norris rubbed their noses together.



A "CRAB" IN THE POND.

After this, Mr. York concluded to go West and give up railroading, but he didn't like it very well, and in a few years we find him back on the road.

In 1853 he was on the N. Y. & E., and in 1856 took a prominent part in the strike on that road, being one of the engineers discharged on the general order that to get off the switch on any pretext was a dismissal.

In the winter of '56 Mr. York got a job on the Michigan Southern, but soon came East, and in 1857 went to running on the D., L. & W. out of Scranton, where his older brother, Capt. York, was at work and well known.

A curious accident happened to Mr. York and proved, among other things, that he was a man for an emergency. He was running the ten-wheeler "Niagara," and coming down the mountain one day he discovered a huge hemlock tree across the track, there was no time to stop, nor even to attempt to stop. The tree looked sound, and in Mr. York's judgment would ditch the engine, anyway, he concluded it would be healthier on the ground, and he and the fireman hit the sod.

The "Niagara" struck the tree, surged back against her train of coal "jimmies" with force enough to uncouple herself from them, broke the tree in two and struck out down the grade alone.

The train was not running fast and York and his fireman were soon on it and over to the first two cars; these they cut off and poled them away, and soon they were flying after the truant. They passed a telegraph station, and five miles from where she started they re-captured the "Niagara," none the worse for her trip.

The conductor and trainmen brought the train along slowly, coupled up, and went in without trouble. No one need have known about the incident had the lone engine not been reported at the telegraph station.

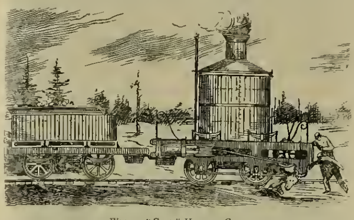
Mr. York was one of the first engineers on the Atlantic & Great Western, the broad-gauge road that connected the then broad-gauge Erie with Cincinnati. He went here in 1860, and for nine years ran an engine, or had charge of the men running them.

In 1869 Mr. York decided to give up running the head end and became a passenger conductor, in which position he remained continuously for twenty years, or until he was seventy years of age.

He then retired to a little home of his own at Meadville, Pa., where he still resides.

Mr. York has seen all and been a part of the development of the great railroad system of this country. When he went to work in 1837 there were no more than a dozen railroads in America, and the South Carolina road was the only one in the world with 100 miles of track. Now there are upward of 175,000 miles of road, some 35,000 locomotives, and more than a million of people earning their bread as railroaders.

Great improvement has been made in all railroad appliances since 1837, the "Grasshopper" and the "Crab" have been supplanted by the "Mogul" and the "Con-



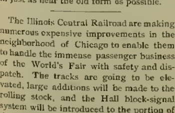
WINANS "CRAB" HERDING COWS.

solidation" and the "Snake-head" has been improved off the face of the earth. The engineer of to-day don't carry a pail of spikes and a maul on his engine to fasten down those cheerful harpoons that used to come up into cabs and cars and "muss things up."

Mr. York has a very wide circle of railroad acquaintances, and many friends of the long-ago who have been scattered to the four winds will be glad to see by this sketch that "Joe" York is still in the land of the living, and pretty well at that.

In all the years that Mr. York has railroaded he never killed but one man, and that one walked into a bridge ahead of him in Scranton yard. He had never had an accident serious enough to cause death and claims that it was his proverbial "good luck." But after a tolerable long observation of lucky men on railroads we know that "luck" oftener means good judgment, skill, some nerve and a natural liking for and adaptation to the work.

Mr. York is one of but two living men who are known to have run the original Grasshoppers and Crabs, and has recently made an agreement with the officers of the B. & O. Railroad Company to take



A "SNAKE-HEAD."

charge of a Grasshopper at the Chicago World's Fair next year. The company are now putting one of these old engines in just as near the old form as possible.

---

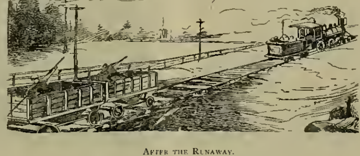
The Illinois Central Railroad are making numerous expensive improvements in the neighborhood of Chicago to enable them to handle the immense passenger business of the World's Fair with safety and dispatch. The tracks are going to be elevated, large additions will be made to the rolling stock, and the Hall block-signal system will be introduced to the portion of the company's lines where traffic will be heavy.

---

Some of those who are inclined to be a little "skeery" about the safety of radial-stayed boilers may be interested in the report of Superintendent of M. P., W. H. Thomas, of the E. T., V. & G. to the Master Mechanics' Association. They have had three big wagon-top boilers with radial stays carrying a pressure of 180 pounds per square inch. These have been in service for eighteen months without the failure or removal of a single radial stay.

## Relative Merits of American and English Locomotives.

Our friend and rival, Mr. M. N. Forney, has been engaged for the last year or two in the patriotic duty of vindicating the character of the American locomotive from the aspersions and slanders imposed upon it by the representatives of British locomotive interests. A London engineering journal has been noted for years as an unfair and scurrilous assailant of everything pertaining to American machinery, and particularly railroad machinery. Mr.



AFTER THE RUNAWAY.

Forney took up the cudgels with this paper in his *Railroad and Engineering Journal*, and the following is the conclusion of his latest defense, which has become very much of a flagellation:

"To explain the fact which we have proved by statistics, that American locomotives run farther, pull heavier loads, and cost less for repairs, he (the English editor) says they must therefore wear out sooner. Surely it cannot be expected that we will seriously answer such reasoning. Esteemed contemporary, how do you know they wear out sooner? who told you they did? or—what is probable—did you only imagine they do? What evidence have you to show that they are short-lived? There are locomotives in this country which have been in continuous service for over fifty years. Are there any English engines of that age in service? No table of mortality has ever been constructed to show an average 'prospect of life' of American locomotives; but, esteemed contemporary, seriously, if they wear out faster the expense of renewals ought to show in the repair accounts, because all companies, in this country, which keep their accounts properly, charge renewals of old engines to 'repairs.' Now, as the repairs of our engines cost less than yours do—even with more costly materials and higher wages—it would seem to show that in reality they are longer lived than yours."

* * * * *

"You say 'Our locomotive is adapted to our requirements and the locomotive of the United States to the requirements of Brother Jonathan.' But how about the railroad managers

"'From Greenland's icy mountains,
To India's coral strand,'
or
Where Afric's sunny fountains
Roll down their golden sand'!

—those are the people who are, or should be, open to conviction, and who will be interested in knowing that this discussion has shown that American locomotives *run farther in a given time, pull more, cost less for repairs, burn less fuel in proportion to the loads hauled, and last longer, than English locomotives do.*

## Chicago Elevated Railroad.

The people of Chicago are to be congratulated on the fact that they have now an object lesson in city rapid transit which is likely in course of time to develop into a net-work of railroads that will enable people in that city of long distances to reach remote points in a reasonable time. The concrete lesson is the Alley Elevated Railroad, which was opened for regular business on June 6. The structure is very substantially built and is capable of carrying with safety ordinary surface railroad trains. The handling of passengers and of trains is done in much the same fashion as that made familiar to so many people by the elevated railroads of New York.

We clip the following notes from the *Railroad Gazette* about the equipment of the road. The locomotives were built by the Baldwin Locomotive Works. They are compounded on the Vauclain system and weigh 29 tons fully loaded, with 40,000 lbs. on the drivers. The boilers are unusually large and have a firebox suitable for anthracite coal, coke or anthracite slack. The cars were built by Jackson & Sharp, of Wilmington, Del., and in general arrangement are much like those of the Manhattan Elevated, being finished with mahogany inside, with cane seats, etc. The doors are double and arranged so that when one-half is opened the other is opened at the same time, and by pulling one handle only, the two halves of the door being connected by wire ropes running over pulleys. The platforms of the cars are about a foot wider than those used in New York. The cars are lighted with Pintsch gas, and equipped with the Westinghouse automatic air-brake. The value of this brake for elevated service was shown on a trial trip made. The brake releases instantly, and applies with the "service" or "emergency" application, as desired. It is automatic, and in case a train breaks in two while mounting the two per cent. grade going in and out of the World's Fair grounds above the Illinois Central tracks, both portions of the train will be automatically stopped. There are many improvements on the "Alley" road that are not to be seen on the New York Elevated. The stations are arranged conveniently, with the waiting-rooms on the ground floor, and long covered platforms above on the structure. The road will be equipped with automatic block signals and railings for the platforms on the side next the track as well as on the other side and ends.

---

On the M., K. & T. road they use stiff coiled springs on the studs between the packing-glands and the nuts that hold them on. These keep the gland up to the "wadding" and prevents a blow from cutting all the hay out when once started.

## Electric Locomotives.

If electric motors do not soon crowd steam locomotives off the railroads it will not be because they have not been properly advocated by the friends of electric traction. In a recent issue the *Electrical Engineer* says that Mr. Henry Villard has made a contract for electric locomotives to do the switching for the Northern Pacific at Chicago. The engines will be not less than 700 horse power, which is more powerful than our heaviest switching locomotives. The Thomson-Houston Co. are also building an electric motor of similar power.

It is said that the Baltimore & Ohio intend to equip the Baltimore belt railroad with electric locomotives and the necessary power plant. Although various reports have been published as to the details of this work, it was not until the close of last week that the details of the contract were finally settled. As far as can be ascertained, the contract involves the building, for delivery early next year, of three 80-ton locomotives, which are to develop, approximately, a draw-bar pull of 31,000 lbs. at 15 miles an hour. A station of about 2,500 horse power will be installed with four units and direct coupled engines and generators. This station will be midway in a run of 12,000 ft. The maximum work required of each locomotive in developing this draw-bar pull is to move a 1,200 ton freight train over a grade of about eight tenths of one per cent. at 15 miles an hour, and in passenger service to move a 500-ton train at 30 miles an hour over a similar grade. Each locomotive will also be expected to serve as a reserve or assistant engine for the regular steam locomotive just outside the tunnel, when the latter is hauling a freight train up a grade of $1\frac{8}{10}$ per cent. All told, there will be about 200 trains a day of each class. The tunnel is also to be lit by electricity.

## How Iron May Hold Its Own Against Steel.

There are many engineers and others whose views on structural material are well worthy of respect who continue to entertain opinions strongly adverse to steel for many purposes where strength and durability must be combined. Much of the feeling against steel is due to the failures that have resulted from the use of bad forms, yet there is no doubt that iron is preferable to steel for many purposes. But steel is making steady headway into favor and is rapidly replacing bad iron. If all iron-makers had combined to put on the market nothing but good reliable material, the advance of the steel age would have been much slower than it is, for iron had long an extremely firm hold on those who were anxious to combine strength, durability and reliability. When Krupp, of Essen, in 1847, made his first steel cannon, military engineers ridiculed the German metallurgist and exclaimed that he would be offering them glass guns next. That sentiment extended then to all the early attempts to introduce steel for engineering purposes, but ridicule, prejudice and interest in other material all failed to delay the progress of steel into favor. The only thing that can now retard the movement is the production of inferior grades of steel and the urging of grades such as Bessemer into lines for which they are unsuitable. This is being done to some extent, and the iron men may profit by it and hold their own by supplying a material that will prove more reliable than the other.

---

The tendency toward diversity of forms where uniformity is desirable in railroad machinery is well illustrated by the great variety of center plates for cars that are in use. A committee of the Master Car Builders' Association took strong grounds in favor of establishing standard center plates, and the railroad companies will now have an opportunity of settling the matter. A standard form of stake pocket has also been recommended.

## A Pioneer Locomotive Builder.

The following sketch of the professional experience of Mr P. I. Perrin (with photograph), an honorary member of the Master Mechanics Association, reached us too late for incorporation in the group we published last month

In July of 1836, learning that Seth Boyden, of Newark, N J., a man of remarkable ingenuity and perseverance, proposed to turn his attention to building locomotives I engaged with him I had previously some experience in the details of such work at Lowell, Mass.

P. I. PERRIN.

The first locomotive was completed at the works in Newark in 1837, and was placed on the Morris & Essex Railroad For the next nine years my time was about equally divided between stationary steam engine work, and running a small machine shop in Pawtucket, R I, and farming.

In the Spring of 1846, Willard W Fairbanks retired from the firm of Fairbanks, Bancroft & Co, in Providence, R I, where I was then employed Their business was steamboat engines, with boilers and repair work Mr Fairbanks then organized the Taunton Locomotive Manufacturing Company, at Taunton, Mass.

These works are believed to be among the first (if they are not the first) in this part of the country built and especially designed for locomotive building Other parties were building, but relied upon other work for principal support

W W Fairbanks was elected agent and treasurer of the new company, and George S. Griggs, the master mechanic of the Boston & Providence Railroad, was a stockholder and director At the request of the agent I accepted the position of draughtsman and foreman of the company in June, 1846

The first business was to build a stationary steam engine to furnish power for the new locomotive shop, the foundation of which was then being laid

The agent obtained castings for the engine from his former works in Providence with no plan or drawings to work by. The work was done in a small shop, with a few second-hand tools The stationary engine was completed in time to start the new shop in December following

In order to secure an early completion of the first locomotive, Mr. Griggs kindly furnished nearly all the castings for the first locomotive from his patterns

With the assistance of Mr. B F. Slater, a thorough and practical mechanic and locomotive engineer from Mr. Griggs' shop in Roxbury, the first locomotive was completed and run first for trial on the Taunton Branch R R, May 19, 1847, and named "Rough and Ready." A more appropriate name could not have been selected.

This was a day of small beginnings prosecuted under difficulties.

It was soon found that some more accurate method for quartering the crank-pins for coupled drivers was necessary. It was in the early part of the year 1849 that I designed and built a machine by which the holes for crank-pins in a pair of wheels could be bored quartering at the same time

This was accomplished with great accuracy and saving of time and labor, and was the first machine built for that purpose, so far as I know

In June of the same year we built another machine from the same patterns for the Philadelphia & Reading Railroad Company, on which was placed a card marked "Patent applied for," but neglected to prosecute the claim and secure a patent This appears to have been the original machine, the basis of all subsequent improvements, which has performed so important a part in locomotive construction up to the present time The first locomotive that was run west of the Mississippi River was built at these works in 1852 for the Missouri Pacific Railroad and was shipped on a sailing vessel via New Orleans, and landed at St Louis in December of that year

Mr Edward Piers, a locomotive engineer, sailed with the locomotive, and started it on the road He is now (1892) a resident of Taunton

During my connection with the works for forty-two years (though among the smallest in the country) about one thousand locomotives have been built and distributed in various parts of the country—in nearly every State of the Union—and in South America and Canada I was a stockholder over thirty years and a director twenty-five years, and resigned in 1888

At the annual meeting of the stockholders of the Taunton Locomotive Manufacturing Co. the following resolutions were unanimously adopted

*Whereas*, Mr P. I. Perrin, agent and treasurer of the Taunton Locomotive Manufacturing Co, wishing to retire from the cares of active business, has tendered his resignation.

*Resolved*, That in accepting Mr. Perrin's resignation, the stockholders desire hereby to express to him their thanks for the valuable services which for so long a term of years he has rendered to them. That he has conducted its affairs with strict integrity, unwearied energy and great ability the success of the company in the past sufficiently shows. The best portion of his life has been passed in its service, and it is gratifying to know that, as a director, he will still give to it the benefit of his long experience and wise advice

*Resolved*, That these resolutions be entered upon the records of the company, and that the clerk send a copy of them to Mr. Perrin.

## A Stay-Bolt Drill.

The accompanying illustration fully explains a very neat device used in the Chicago & Northwestern shops at Winona, Minn., the invention of Master Mechanic Wm. McIntosh

STAY-BOLT DRILL FRAME.

The drill is driven by a Stow flexible shaft and is held in place by the framing shown The brackets are bolted to the side of the boiler and have slots long enough to admit of their being raised or lowered

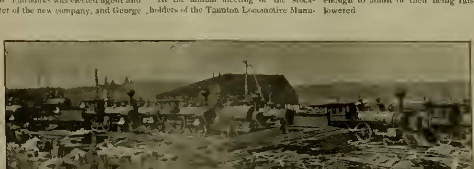
The rod is long enough to reach from end to end of the firebox, the drill is slid along from one stay to another in a row, and then the collar is lowered on the rod to bring the drill to the next row

The angle of the drill can be changed so as to insure the hole being in line with the bolt.

This is one of those ingenious devices that save time and money.

## A Locomotive Boneyard.

The annexed engraving is rather small to do justice to the subject treated. The place shown gives a graphic history of locomotive development in Europe and America. It shows the tracks at McAdam Junction, where worn-out locomotives are stored waiting for the cupola and forge. The engines originally belonged to a variety of small roads that have been absorbed by the Canadian Pacific, and they represent the product of more different builders than are to be seen in any other place. They are the product of the United States, Canada, England and Scotland. There are engines there which now look small articles but in their day were the pride of their builders and the admiration of engineers. Side by side in a state of helpless decay now stand locomotives on which an expert can yet see the marks that speak of Baldwin, Rogers, Manchester, Portland and Mason. Others have lost all traces of identity, except to the men who were familiar with locomotives over thirty years ago Foreign makes are well represented by engines from Kingston, Ont, Dübs, Glasgow, Sharp, Stewart & Co., Manchester, and others. An edifying feature about the old British locomotives is that they have been made as nearly American as circumstances would admit.



THE BONEYARD.

---

One of our correspondents is excited because he has learned that one of the Webb compound locomotives has been running at the rate of 111,000 miles per year. He beseeches us to find particulars about some American locomotive that is beating the Webb engine record. In last month's LOCOMOTIVE ENGINEERING a case is mentioned on page 191 of a locomotive running on the Louisville and Nashville that makes 120,000 miles a year. We have no doubt that this is equaled or exceeded on other roads.

---

A dictionary of electrical words, terms and phrases, by Edwin J. Houston, A M, has just been issued by Spore & Chamberlain, New York. This is a work of real merit and ought to be in the library of every man who is in any way interested in electrical matters. It costs $5.

## Locomotive-Running Among the Bush-whackers.

By Old Soldier.

My next trip from Nashville was a special with a General aboard, whose name, I believe, was Stromer. I understood afterward that he had orders from the Commanding General for Sherman's army to advance. I left Nashville about 9.30 P. M. with orders to run to Murfreesboro as quick as I could go; nothing was said about safety, I had only one coach. Well, we got there pretty quickly for those times, for the General kicked and swore that I made a mile a minute and that I had used no judgment, and furthermore he did not want to go back unless I had regular running orders. God bless his dear old soul. He had very little idea what dangers he had passed through besides fast running. My engine and crew were held there a day or two, as there were three or four other crews that used to follow up the army to take them supplies. When we left there, I think we left in two or three sections; I was head section. We proceeded on to Tullahoma. There the road had a branch to Winchester. We arrived there without any serious accident, but with a good many big scares. My memory fails in regard to dates. The next day I started back to Nashville with my engine. We then put on a regular passenger train from Nashville to Winchester; I got one of them. It is 90 or 91 miles from Nashville to Winchester, and our engines double that every day. This run was re-opened up without any accidents occurring for some time.

The Government had stockades built at all bridges and a company of soldiers left at each one to guard the bridges. There was a good-sized bridge over Elk river. At the south end of this bridge there was quite a large hill. The road-bed formed quite a curve and ran in close to the approaches of the bridge.

I left Winchester one night some three or four hours behind schedule time. I had four coaches and baggage car well loaded with army men and sutlers and as the road and all bridges and grades were in good shape for those times, and as I had run over that part of the road that morning and Elk river bridge was well guarded with Yanks, I felt pretty safe. The old girl skipped along at a good pace and I was making 30 or 35 miles an hour when I struck the curve approaching the bridge and saw a reflection of light from around the curve. Pat Crosby was firing for me this trip. I remarked to him that the boys were having a good time at the bridge, then Pat yells "Stop her, the bridge is on fire." Then I saw a lot of Johnnies swinging fire-brands. I had got in sight of the bridge this time and could see clear across it. I called off brakes, as I felt them being put on pretty strong. I had a good old-time Roger engine, with the outside angle iron for a running-board, and was now running about 45 miles an hour. Pat says: "Great God! are you going to try and cross that burning bridge?" I said "Pat I can see the rails and I think we can get across it safe." You see the Johnnies had routed our men and fired the bridge and block-house, torn down the telegraph wires and shut off all communication. I do not think there was one railroad man among them, if there was they would have torn up the tracks and come further around the curve to flag me. I often think how great their surprise was that they did not capture that train and engine. They flagged me so close to the bridge that I could not stop until I would get half-way across the bridge, so I made up my mind I had as well be launched into eternity quickly as slowly. Poor Pat was going to jump, but I grabbed him and told him not to do so for the jump would kill him sure, for at that time she was turning those wheels and dropping the rods about as fast as steam would do it. The blaze was scorching the engine and coaches. I guess a good many passengers were praying while the Johnnies were cursing. I got more than half-way across the bridge before they commenced firing into us, but we were going about as fast as their bullets. They said afterward that most of the Johnnies were crowded together expecting to have a good time robbing the passengers. Oh, Lordy! how it tickles me every time I think about how they got left.

The reader must not imagine that the bush-whackers were a sample of the Southern army; they mostly consisted of deserters from both sides. They would not stand and give a square fight, but would assault, and rob, and commit all kinds of depredations against both armies; the Johnnies were about as afraid of them as we were.

I forgot to remark in my other reminiscences that James Hevey's picture of the roundhouse and depot grounds is good. Jim is an old-time friend of mine, or at least, he was in our boyhood days. I have not seen him since 1864.

Well, to continue. I got back to Nashville without any further trouble on that trip, and had a couple of lay-over days and a good rest, and prepared for other hair-breadth escapes which I have not time to write up at present, but will try and get them ready for you in the next issue.

Remember, dear reader, that at this time we hardly passed twenty-four hours without some poor fellow of the train crews being either knocked over or captured.

(*To be continued.*)

## St. L. & S. F. Shops, Springfield.

At the Springfield, Mo., shops of the St. Louis & San Francisco road, they make complete tenders for a little less than $700 and they are good ones. No calked joints are indulged in for tanks, but a strip of tar paper is placed in each seam, and no trouble is had from leaking. Extra heavy sheets are used in the coal pit and two hollow cast pillars, each side of the manhole, carry the overflow water to the ground.

Oak is only worth $14 per thousand here and tender frames are made of it, while it is so cheap that it is preferred to metal for brake-beams.

Mr. Groves makes a strong, plain hand-car, with wooden wheels at a cost of but $32, in lots of ten or more.

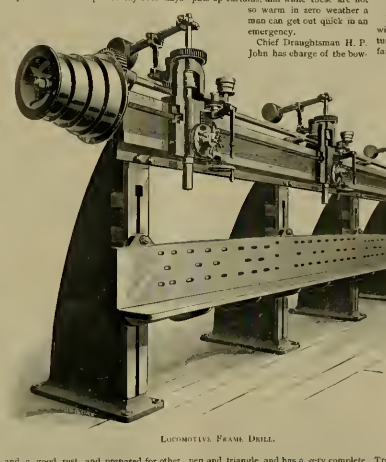
The roundhouse is not a very good one for the big engines now used and the machine shop is dark, but they have a most excellent planing mill and a good paint shop, a new iron-clad store-house is the latest addition to the plant.

Everywhere about the shops there is evidence of internal improvement. A new Westinghouse compound engine has taken the place of the old stationary; new tools are seen here and there; the wheel-work has all been arranged in one corner of the shop, and machines for other work arranged so as to require the least possible amount of handling of material.

They are using three boilers of their own make for the motive power of the shops. These have a water-arch and some other peculiar internal arrangements, they give good service and are smokeless with soft coal.

Mr. Groves is not a believer in cab-doors for consolidation or other engines where the boiler extends through the cab, but puts up curtains, and while these are not so warm in zero weather a man can get out quick in an emergency.

Chief Draughtsman H. P. John has charge of the bow-pen and triangle, and has a very complete and elaborate set of detail drawings and specifications of everything that is made at the shops. The plans for car-work are the best we have seen, and will be published in a future number.



Locomotive Frame Drill.

Before the recent awful flood of water and burning oil that overwhelmed the towns of Titusville and Oil City, Pa., the D., A., V. & P. road had condemned a bridge they owned in Titusville because it was alleged that the abutments were not safe. This bridge was the only one in the place that withstood the flood. It resisted the ramming of buildings, oil-tanks, cars, timber, flood and fire, and all the other safe bridges in town went down. This seems almost like a rebuke to engineering.

The Congressional Labor Committee are investigating into the condition, hours of labor, etc., of Government employés. It is admitted that the eight-hour law has been evaded in many ways by those in charge, and it is expected that the present committee will submit a report urging a strict enforcement of the law.

## Locomotive Frame Drill.

The engraving on this page shows the latest form of special drill produced by the Universal Radial Drill Co., of Cincinnati, O., who make a specialty of drills.

This machine seems to be designed for especial usefulness in railroad shops, and could, of course, have more heads if desired. The makers also furnish it with a bed-plate or base if desired, and a power device for raising and lowering the table comes extra.

The spindles have power and hand-feeds and are counter-balanced. The following are the principal dimensions of the machine.

Length of rail and work-table, 24 ft.

Greatest distance spindles to table, 4 ft 9 in.

Least distance spindles to table, 2 ft. 2 in.

Adjustment (vertical) of table, 2 ft. 7 in.

Extreme centers outside spindles 23 ft.

Closest centers outside spindles, 12½ ft.

Feed of spindles, 15 in.

Diameter of spindles, 1¹⁵⁄₁₆ in.

Height of floor to top of rail, 7 ft. 3 in.

---

Do not spend your precious time in wishing and watching for something to turn up. If you do you will be like the famous Micawber and forever be wishing and watching while you are drifting upon the rocks of penury or of unrespected old age. Things don't turn up of themselves; you must turn them up. Idleness and indifference never accomplished anything. It takes energy and push to make headway in the world, and an active, energetic, persevering man is sure to succeed. If he cannot do one thing he will find something else. If he cannot succeed in one direction he will in some other. He will not waste his time in idleness. There is no lack of work no lack of opportunities. Do what comes to your hand, and do it well. True progress is from the less to the greater. Quit re-solving and re-resolving, and begin doing.

There is no part of a freight car that has led to so much discussion among those responsible for keeping cars in running order, as the truck. At the last Master Car Builders' convention this subject was brought up anew by a report on "Freight Car Truck Frames." The committee investigated the rigid-center truck, the swing-center truck and the Fox pressed-steel truck. The conclusion arrived at was that the rigid-center truck is coming rapidly into favor, and the swing truck going out of use. The belief was expressed that the Fox truck possessed good points, but that it had not been long enough in use to be recommended.

The Baldwin Locomotive Works have issued a pamphlet descriptive of their compound locomotive, and give the reasons why compounds are better than simple engines, together with suggestions for conducting simple tests for fuel economy. Every engineer who is interested in the latest form of locomotive should write to the Baldwin Locomotive Works, Philadelphia, for this pamphlet, it will cost nothing and contains a great deal of information.

Employés of the Grand Trunk are not to smoke while on duty or in uniform, must not occupy the same seat with a passenger, and must remove their hats when passing through dining-cars or those in which officials of the road may be seated.

## Running Repairs—Tire Wear.

Quite an important matter to master mechanics is to know at what points on a driving-tire the greatest amount of wear occurs. One benefit derived from this knowledge is that it aids a person to determine as to whether an engine is properly counterbalanced or otherwise.

It is a well-known fact that a driving-wheel not properly counterbalanced will slip at certain points in the stroke, and a consequent wearing of the tire at these points more than at other points is the result, which, if prevented, would insure a much longer life to the tire. Then, when worn spots occur where they would not occur if caused by improper counterbalancing, it would be safe to conclude that the trouble was with the material of which the tire was made. Hence it appears conclusive that to determine the cause of tires wearing unevenly, it is necessary to correctly locate the low spots on each relative to the pin, and also to know the difference in wear from one point to another around the wearing surface of the tire.

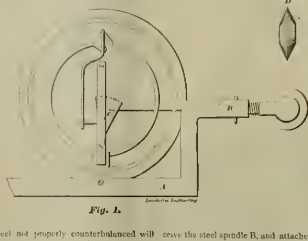


*Fig. 1.*

To accomplish this object, our master mechanic, Mr. E. A. Williams, devised the following method, and employs the appliances described, obtaining very satisfactory results.

After having gotten a pair of driving-wheels into the lathe, we draw a chalk line across the wearing face of each tire at the point where a line drawn from the center of shaft and through the center of pin would intersect the tire, and from this mark we mark off the face of each tire into thirty-six equal parts. Then marking the first line back of the pin No. 1, the second mark from pin No. 2, we number each line consecutively. No. 36 will thus fall upon the line directly opposite the pin. After numbering the lines, we place in the tool post of the lathe a gauge arranged by our machine-shop foreman, Mr. J. H. Hickman. He made a ¼x¼-inch steel bar, A (Fig. 1), and drilled the straight part to receive the steel spindle B, and attached the small end of this spindle to the geared quadrant C, in a small steam gauge. In the larger end of the spindle is cut a slot into which fits a small steel wheel about 1¾ inches in diameter, whose edge is turned down thin as shown by D; fine teeth are then filed in the edge; a slot is then cut through the straight part of bar A of sufficient length to allow the hand of the gauge to make one revolution, when spindle B is pressed against the quadrant C, a small steel pin is passed through the slot, which it fits loosely, and made fast in spindle B. A small spiral spring is wound around the larger part of spindle, and bearing on the shoulder holds the indicator hand of gauge at O when no pressure is applied to small wheel in end of bar A. A sharp-pointed indicator was then attached to small pin in spindle B and the indicator hand of gauge placed at O, a scale was then clamped on top of bar A and the spindle was pushed in 1/16 inch and the position of indicator-hand marked on gauge dial; fifty of these spaces thus indicated were then marked on the dial.

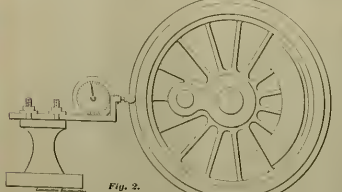

*Fig. 2.*

After placing this arrangement in the lathe as shown by Fig. 2, the driving-wheel is stopped when mark No. 1 on tire is opposite small wheel in spindle. The small wheel is then pressed against the tire until the gauge-hand is at No. 20. Then, as the driver revolves, mark in a column on a piece of paper each number that the gauge indicates. The smallest number indicated is the lowest spot in the tire, and (calling the head of the column of figures No. 1) its position in the column will correspond with the number of the chalk line across the face of tire at which the low spot occurs.

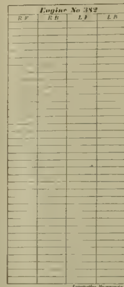

*Fig. 3.*

Now, to correctly determine the difference in wear at the various points around the tire a chart represented by Fig. 3 is used. (This is a rough chart made by the lathe man.) Horizontal lines divide this chart into 36 spaces, corresponding with the chalk lines across the tire. Perpendicular lines divide it into columns, one of which is used for each driving-wheel. Now the position of the smallest number in the column of figures first made is marked O in a corresponding position in the proper column on the chart. For instance, should the smallest number in the column be the fifteenth number from the top then the O is placed in space No. 15 on the chart, and the driver is revolved, and stopped when line No. 15 is opposite the gauge-wheel. The gauge is then run forward until the wheel just touches the tire, but not hard enough to move the indicator hand. The lathe is then started, and as each line on tire passes under the gauge-wheel the number indicated by the hand is written on the chart in the space corresponding with the number of the line passing under the gauge-wheel. We thus correctly obtain the difference of wear from line to line expressed in one hundredths of an inch.

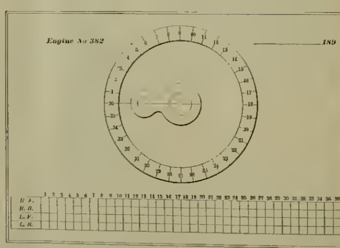

*Fig. 4.*

For an office record Mr. T. A. Fogue (our engineer of tests) has a goodly number of printed charts, Fig. 4, and when the shop foreman hands in his charts (Fig. 3) Mr. Fogue transfers the numbers to chart No. 4, and keeps them for reference, so that at a glance one may see the position of the low spot relative to the pin, and can also see the difference of wear between any two points.

To ascertain the thickness of the tire in the tread at point O, or thinnest point, I made a gauge of which the following is a description. Take a block of brass or iron, A, Fig. 5, and cut a slot in it through which pass a square, B, which is held in any desired position by thumb-screw at back (not shown), the slot should be cut about ½-inch from face C. This square is made of ⅛x1-inch steel. In the top arm of the square cut a slot ½x2 inches, into which fit a brass piece, D; this piece carries a 5/16x3/16x4-inch scale, E, which passes freely through piece D, when the thumb-nut at back is loosened. When the nut is tightened both the brass piece and scale are clamped firmly to the square blade. This blade is 3¼ inches long, and the upright part of square is 5¼ inches in length. A square groove ¼x1-inch is planed in the upper surface of block A, into which fits a hinged piece P which is ¼x1 5/16x4¾ inches. The hinged end of this piece is left 1 inch wide, so that when it is placed in the position shown by Fig. 5 the upper edge of it is in line with the upper surface of block A. The piece P has lugs riveted to the under side of it which forms a slot through which a ⅛x1x5¼-inch scale, G, passes. The edge of this slot is ½ inch from end of piece P.

To obtain the thickness of a tire with this gauge you throw the piece F into the position shown by the dotted lines, and press face C of block A firmly against the turned rim of wheel center, at the same time pressing the upper edge of block A against that part of the tire which overlaps the wheel-center (see Fig. 6). Now loosen the thumb-screw H, and the square will drop through block A until the blade touches the tire at high point 1. Tighten thumb-screw and loosen thumb-nut at back of square blade; this allows scale E to drop to wearing surface of tire. Now move brass piece D in the slot in blade until the end of scale reaches the lowest point of wearing surface of tire. Then tighten the thumb-nut and remove the apparatus. Now drop piece F, Fig. 5, into the position shown, and pass scale G upward until its upper end touches the lower end of scale E. The distance from block D indicated by lower end of scale E is the amount the tire is worn hollowing. The distance from upper edge of piece P on scale G is the thickness of tire at thinnest point.

Now, the gauge could have been made by leaving off piece F and graduating the upright part of the square. Then the difference indicated by scale and square would be the thickness of tire. But, while finding the difference is where mistakes would be liable to occur, and I consider that the expense of putting in piece F is overcome by the benefit derived from having the scales show exactly the amount of wear and the thickness of tire.

## Trouble with Spring Packing.

One of the greatest difficulties that I ever encountered in railroad life, remarked Mr. Morris Sellers, was in getting the men to agree to the change from spring to steam packing in the cylinders. The road had used from time immemorial common spring piston packing, and it seemed as if all the engineers imagined that their packing should be set out every time their engines were three hours in the roundhouse. The expense for piston work was enormous, and I determined to end it by employing steam packing in the form of plain cast-iron rings.

There was an old engineer on the road named George Mason, who was justly regarded as one of the best runners on the road, but he was violently tortured by a chronic belief that his piston packing was blowing. I resolved to give him the first set of the new packing. On mentioning to him what I intended doing he was very indignant, indeed, and guessed he was not going to have his engine ruined by any such nonsense. That was precisely the way he spoke. I did not get mad, as I had good cause to do, but reasoned with him that the new packing did very well on other roads, and I felt assured that he would like it if he once had a trial of it. So the new packing was put into the 66 and George took out his train but got nowhere, and come in next day with three cars short of a full train.

I asked what the matter was and was told it was that new packing. The engine blowed through so badly that she would not pull the full train. I had the cylinder heads taken off and the packing examined, and, as I expected, it looked in perfect order. Next day, when George was ready to go out, I went on the engine and rode out with him ten miles. The engine was working as well as George would permit her, but he was nervous, and kept saying he could hear the steam blowing through, and on this account he could not do the engine justice. He believed the engine was working badly and that she would lose time, and his belief contributed to bring about delay. As I expected, he returned late with a reduced train.

I felt assured that the man was trying to do his best, but he had made up his mind that the packing would not work and he was unconsciously working against it.

Mason reported to me on his arrival with the old story, so I said to him I would put back the old packing on one condition, and that was, that he should get along by having it examined only once in two weeks. That seemed a long time for George to go without seeing into the cylinders, but I told him I could not keep the work going at the rate packing was being examined, so he consented to run the two weeks. With this agreement made I walked with George to the roundhouse and gave the foreman, Mr. Power, orders to change the packing. The engineer was so delighted that he waited around till the machinists finished the job and then went home happy.

In the meantime I told Mr. Power to get reliable men round after night and put the steam packing back into the cylinders of the 66, which was done, and none of the enginemen knew anything about the change.

George Mason got around in the morning and went out like a man with a burden lifted off his back. The conductor, on seeing the engine, asked if he would lay out two or three cars, but George answered that old 66 was herself again, and could take a full train with the best of them.

The next time I saw him I asked how the engine did now, and he answered "splendidly," and went on with a tirade against steam packing.

When Mason had been running about a week without his packing being examined, which was an unprecedented length of time with him, he came into the roundhouse and told the foreman that she was blowing a little, but he guessed he could make out the two weeks. At the end of next trip, however he wanted to have the packing examined, but Mr. Power refused to touch it, reminding him of the agreement made with me. Mason came to me then and said he would like the two weeks to begin from that day. He knew the packing was not blowing much, but he was beginning to hear it, and he thought perhaps the steam packing had put the pistons a little out of shape and felt confident there would be no trouble in getting them to run the two weeks after they were once put just right.

I consented to have the packing examined and told him to wait and see how it looked. When the machinist got the followers off, the engineer looked at the piston, rubbed his eyes and looked again, then made a rush to the cab for his coat and hurried home.

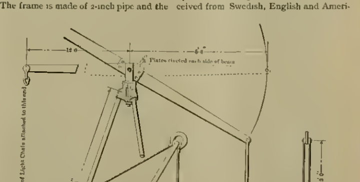
I directed Mr. Power to have another man ready in the morning to take the engine out if Mason did not get around, but he was there on time and took his train over the road on time also. On returning he came to me with tears in his eyes and protested that he was the worst idiot out of the county lunatic asylum. There never was any more trouble with his packing and the lesson had a very beneficial effect upon the rest of the engineers. No more objection was made to the steam packing as it was introduced.

## Coolidge's Car-Wheel Lifter.

The engraving on this page shows a very handy little rig for lifting car-wheels on and off cars, the design of F. H. Coolidge, agent for the American Brake Co. at Atlanta, Ga.

There are only two small castings, the top of the tripod and the foot piece, of which there are three used.

The frame is made of 2-inch pipe and the



lever is made of 6 x 1-inch bar-iron or can be drawn from an old axle—in fact, the whole thing can generally be made of scrap material, and the designer says the cost is not above $40 when new material is used.

Eighty wheels have been loaded on a car in thirty-five minutes and with fifty per cent. of the labor required to load by hand.

Mr. Coolidge has taken out no patent, but says he will be glad to furnish blue prints to any road that wishes to build one. Several roads in the South are now using this device.

The cut explains the lifter better than words can.

## One Wheel Slid Flat and the Other Not.

The general foreman of locomotives and cars at a division point on an Iowa railroad writes us. "I have something about a car that I think will cause quite a little discussion among the readers of Locomotive Engineering. I received a car the other day and the car repairer reported to me that there was a card on the car for one flat wheel, slid flat 3½ inches, while the other wheel was all right and was not scratched on the tread at all. The wheels were under an air-brake car which was empty when I received it. I have been trying to find out how one wheel could slide flat 3½ inches and wheel on opposite end of axle could be all right. The chill seemed to be all right. Wheels were both tight on axle.

"I have asked several different ones and all say they never before heard of such a thing happening. John Burns (traveling engineer) did not want to believe it, but I took him and showed him the wheels. The only way I can account for it is that the road that the car was on took off one wheel and put a new one on and let the other one go as it was."

We have heard before of cases of one wheel being slid flat while the other on the same axle was not damaged. Perhaps some of our car builder readers will help our correspondent to an explanation of the phenomenon.

A Swedish paper announces that the Baldwin Locomotive Works have delivered a locomotive to the Borringe Ostratorps Railway. This locomotive was designed by a Swedish engineer and bids were received from Swedish, English and American builders. The American manufacturers received the contract, not only on account of being the lowest bidders, but also on account of the time required for delivery. Other bidders required a year's time, while the Baldwins delivered the engine within ten weeks after receiving the order.

# LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

Address all communications and make all orders and checks payable to

LOCOMOTIVE ENGINEERING,
912 TEMPLE COURT, NEW YORK

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } Editors and Proprs.
JOHN A. HILL, }

J. W. CURHAN, Manager Advertising Department

## Subscription Price.

$2.00, postage paid to any part of the world. Single Copies 20 cents

## Special Notices.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary. Always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office New York, as Second-class mail matter.

FOR SALE BY NEWSDEALERS EVERYWHERE.

Publishers' Agents

American News Company, New York
International News Co., London, England
W. Williams, 21 Fink's Building, Melbourne, Australia.

## Special Notice.

We have to announce that the May edition is entirely exhausted and no more subscriptions can commence with that number. The June issue is the farthest back we can go now. Agents will please have all subscriptions begin with June until further notice. We don't intend to do much back-number business but to make a live paper, covering our field up to the month of publication, and to deserve the reputation given us by the general manager who wrote, "It is the most interesting railway paper published."

## Some Sensible Laws in the Interests of Railroad Men.

The railroad men of the State of Ohio long ago realized that if they wanted any laws passed favorable to themselves, or wished to prevent the passage of laws detrimental to their interests, that the way to go about it was the way corporations or organizations of politicians did.

They elected a legislative committee and sent them to the capitol to lobby.

There are 35,000 organized railroad men in the State, and the balance of power is but 10,000, so the members of the orders agreed to drop politics and use their ballots to enforce fair laws.

S. D. Hutchins, one of the best engineers on the "Big-Four" road was put at the head of this committee, and their work was done so fairly, so honestly, and the demands made were so just and so manifestly in the interests of the whole people of the State, that not even the officials of the roads could enter a protest.

They have secured the passage of a law that prohibits the signing away of any rights of an individual, that prevents the withholding of any part of a man's pay for insurance, hospital funds, watch inspection, color-blind tests or what not; which makes every man with authority to give any orders to another his superior officer, and not his co-employé, which prevents the "baby act" crawfishing from responsibility and charging it to negligence of a co-employé.

Another law limits the hours of service on railroads to ten hours, prevents the use of men who have worked for 24 hours and demands extra pay above the *per diem* extra for over-work.

A law has been passed that prevents the employment as engineers or conductors of any person who has not had an experience of at least two years. This prevents the equipment of the road with dangerous men in case of a dispute between the men and the company.

A sensible color-blind law provides that each company shall, at its own expense examine the eyesight of its engine and train men at least every two years, and especially provides that the examination be "in the distinct colors in actual use by such road"—no optical delusion tests of shades as an excuse to get rid of men who are not wanted.

An effectual Anti-Pinkerton law has been devised and passed.

One new law is in force that should be universal, and that is the compelling of the transmission of messages on the occasion of a wreck. All people are made to suffer painful suspense when a wreck has occurred when friends are on the road, but the wives and mothers of the railroad suffer the most. How often does it happen that a dozen women stand for hours around a telegraph office waiting with tearful eyes and breaking hearts for the forbidden news from the wreck, knowing that on one or more of them the blow must fall, and each apprehensive for the safety of some loved one. Preventing the transmission of news to these women, these wives and mothers, is the refinement of torture and it ought to be a crime. It can hurt the road no more for the truth to be known one time than another.

Most of the railroad men are unwilling to support a good committee to shape legislation, and then curse the unfair laws enforced upon them.

When broad-minded men are sent, not the blatant talkers, but the solid thinking men, men who know their own rights, and the rights of others—aye, there's the rub, *the rights of others*. It can do no good and will always do harm in the end to be unfair. When good men are sent, well backed up, good, fair laws can be placed upon the statute books of any State, and certain rights and certain protection afforded thereby that could never be secured by all the grievance committees in the land.

The railroad men of the country can well afford to profit by the example of the men of Ohio; there is reason and sense in their work.

## Locomotive Tests.

The Railway Master Mechanics' Association and the American Society of Mechanical Engineers have both had committees during the last year investigating the practicability of establishing a standard method of conducting locomotive tests. The committee of the Master Mechanics' Association reported progress, and that of the Mechanical Engineers submitted a preliminary report in which certain recommendations were made. In the beginning of this report allusion is made to the necessity for conducting locomotive tests so that accurate results may be secured, and the difficulties encountered in doing this are dwelt upon. The fact is conceded that locomotive testing is conducted under such unfavorable circumstances and surroundings that many of the exact methods employed in testing stationary engines or boilers cannot be used. Locomotive tests should therefore be always made with a special train when possible, so that the same cars are used for the different trips and the weight of train is uniform. The committee then proceeded to give particulars of how the coal measurements should be made. They favor having the coal placed on the tender in weighed sacks, and a weighed quantity which will first be used placed on the tender. There appears to be uncertainty as to how the weight of ashes and cinders should be ascertained when it becomes necessary to clean the fire on the road.

Detailed particulars are given of how the indicator should be applied, and the kind of reducing motion to be employed. Three forms of motion are illustrated, a pantagraph motion, a swinging pendulum and a parallel motion. The most approved means should be employed to find the speed of the engine at the time indicator diagrams are taken, and these should be taken at mile posts.

The following is a synopsis of the general directions recommended. A drawing of the boiler should be supplied, giving all particulars of heating surface, grate area, the openings in the grates, volume of smoke-box, arrangement of draft appliances, etc. Boilers should be thoroughly cleaned before tests are made. The capacity of the boiler for steam-making should be measured by the number of British thermal units taken up every hour by the water and steam in the boiler. The temperature of the air should be noted. A good water meter should be employed to determine the amount of water fed to the boiler. The coal should be dry when used. A record of the temperature of the smoke-box gases should be made by a good pyrometer placed near the flue-sheet. The exhaustion of the smoke-box should be shown by a mernometer gauge. The quality of steam furnished should be determined. Samples of gases passing from the flues to the smoke-box should be analyzed.

The committee publish drawings of some of the apparatus they consider best for ascertaining the information referred to, and give particulars of the methods to be followed. The report does not assume to be final, and therefore does not propose a standard method of tests. It gives many valuable suggestions that will, no doubt, be of service to those making locomotive tests, more especially to beginners at this kind of work. We doubt, however, if it is practicable to establish a hard-and-fast set of rules for the testing of locomotives. The engines and boilers are operated under such varying conditions that, in securing accurate results, very much will always depend upon the skill, judgment and experience of the man in charge of the tests. We consider that the line of tests followed by Mr George Gibbs in testing the compound locomotives on the Chicago, Milwaukee & St. Paul Railway, and described in the report on Compound Locomotives, read at the Master Mechanics' Association, as being superior to the methods recommended by the committee of the Society of Mechanical Engineers.

## Deserve Promotion.

"There is no chance for a man to get on on railroads without he has some friend to push him," writes a correspondent who tells that he has gone through the course of machinist apprentice, fireman and engineer and is again working at the machinist trade. In a badly spelled, wretched written epistle, he goes on at considerable length abusing railroad officials for habitually suppressing men of ability. Some people appear to derive peculiar consolation from emptying the vials of their discontent and bitterness upon the devoted head of an unoffending editor, and the letter quoted from is representative of a class. Very often the complaints are carried to the editorial sanctum and poured forth there. We have great sympathy with men aspiring to rise above the rank of an ordinary workman, and, therefore, we listen as patiently as we can to all those who feel constrained to complain about obstacles being thrown in their way. It is sad to tell, however, that the greater portion of the men with grievances are themselves the greatest obstacles to their own success in life. Most of the men complaining about not getting on do nothing whatever to recommend themselves from being taken out of the ranks.

In the mechanical department of railroads the first upward move that a man receives is usually to be appointed a foreman or a traveling engineer. If the officer making these appointments is wise and has the interests of his employers at heart he will select men who have striven by acquiring knowledge to equip themselves for higher positions. It is not enough that a man is a first-class machinist or carpenter or engineer that he should be selected for promotion. If he has worked for promotion he has acquired all the knowledge within his reach of the science of his business. These are the kind of men who have led the armies in the industrial campaign that has reared the great industries of this country, and it is only such men who will continue to come to the front. A man who is the best machinist in a shop, but has no conception of how to speed a shaft or how to figure on the strength of a bolt, has no right to expect to be made a foreman. Ignorant and inefficient men are sometimes selected for promotion, but it is not the rule, and their employers are to be commiserated. To the ignorant grumbler and complainer that we are best acquainted with we would say, you are receiving the treatment you have earned. If you have sound ambition you will try to do something to prove that you are more worthy of promotion than the others around you. Those who have not the stamina to qualify themselves as leaders have the right to remain followers.

## The Art of Molding.

Of all the mechanical arts, that of molding has been the most difficult to formulate and to reduce to a system. Since the origin of metal-founding the molder has been pleased to shroud his methods in certain mysteries, which, to him at least, seem essential to perfect castings. It may be said of this trade, more than any other, that the traditions of generations cling to it. Like the good housewife of the olden time whose bread was often sweet and delicious and occasionally intolerable, the man of rammer and trowel will alternately score success and failure under apparently the same conditions. He can always tell why his casting is good, but can rarely give a reason when it is bad. There is much which can be accounted for in this; perhaps, more that cannot be.

In all other industrial branches the senses of touch and sight are always at the command of judgment. In the machine-shop, contact between the workman and his work is always possible; an error may be detected as soon as made, and corrected at once; there are no final chances upon which the success of the machinist's job depends. With the molder, it is different. The conditions which insure bad work, and cannot be anticipated, are numerous. There may have been a bar in the "cope" under enough tension to induce a "drop" when the additional "strain" of clamping was put on, the core, with which he had nothing to do beyond setting, may have been made with no reference to free "venting," and a "blow" follows pouring. His troubles do not end here; the melter may have been in a careless mood to the extent of dull iron, and a casting with "cold-shuts" is his reward; if his foreman make a wrong estimate on the amount of iron necessary to "pour" his mold, and give him too little, another loss will be charged to his account. There is much beyond the control of the molder, in the art of metal-founding, which tends to make bad castings. His strongest influence upon the quality of his work lies in skill which cannot be verified by caliper, gauge, or rule.

---

The Long Island are changing from vacuum to automatic air, but it is rather a slow job, none of their suburban cars had been changed yet when the seashore business broke out anew and ten new suburban engines had to be equipped with vacuum. The Westinghouse was used.

## Hard on the Wheel Makers.

Several years ago the Master Car Builders' and Master Mechanics' Associations agreed upon a guarantee for cast-iron wheels which has been working considerable injustice to the car-wheel makers. Where a wheel fails to perform the guaranteed mileage the maker has to credit the user with a sum representing the loss due to the shortcoming of the wheel. There are a few causes of failure specified, such as sliding, etc., for which the maker is not held responsible. The maker is, however, held responsible for sharp flanges, cracked hubs and several other common causes of failure that may very readily be due to circumstances over which the maker has no control. This source of injustice has been discussed very freely at various meetings lately, and it was investigated and reported on by a committee of the Master Car Builders' Association. There is some disposition to relieve the wheel makers from part of the unfair responsibility attached to them, but railroad men are very much inclined to act on the knowledge that they have got the wheel makers under the harrow, and that it is best to keep them there.

## Wellington on Train Resistance.

The account which appeared in our June issue of the run made by Mr. Angus Sinclair with the locomotive pulling the Empire State Express has been made the subject of an exhaustive analytical article by the *Engineering News*. Mr. A. M. Wellington, author of the well known book, "Economic Theory of Railway Location," is one of the editors of the *Engineering News*. He has devoted more attention and investigation to the subject of train resistances than any other engineer known to the public, so that the remarks of his paper on the part of our article relating to train resistance are of peculiar value. We regret that want of space prevents us from reproducing the whole article. Referring to the tests recorded in our article it begins:

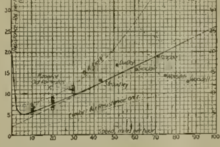
"The observations are among the most important evidences on record of the actual resistance of trains at high speeds. Perhaps we might even go farther, and say that they are the most important, especially as they are reasonably consistent with the mean of the few other records which have been obtained for speeds of 50 to 75 miles per hour, while presumably far more trustworthy and decisive than any of these prior records. As such they are a real contribution to technical knowledge. We trust, though we hardly expect, that they will attract the attention they deserve, and we recommend electrical journals, especially, to reproduce them, as having an important bearing on pending efforts to obtain very high speeds by electric power, and going far to indicate that those efforts may be successful."

After giving the leading particulars about the route, the train, the speed and the resistance recorded, *Engineering News* makes comparisons of the data with those of a famous run made by Mr. Wm. Stroudley on the London, Brighton & South Coast Railway, and published in the Transactions of the Institute of Civil Engineers, 1885, with the figures of train resistance found by Mr. P. H. Dudley in his tests with dynamometer car, and with the discoveries made on air resistance alone by Mr. O. T. Crosby in experiments with a high speed electrical driven car. It is demonstrated by figures that Mr. Sinclair's record agrees substantially with the most reliable data relating to train resistances and the annexed diagram, for which we are indebted to *Engineering News*, has been plotted to give a graphic illustration of the rate of train resistance in pounds per ton.

On this subject our contemporary says "The element of axle friction only in train resistance is fairly determined at about 4 pounds per ton for passenger and loaded freight cars, and 6 lbs. per ton for empty freight cars at a speed of 10 to 30 miles per hour. The general law of friction is also well determined that at very high journal speeds the lubricants are so well carried around between the metallic surfaces that the friction is greatly reduced, and may almost become evanescent. Mr John W. Cloud and others have directly observed this fact in railway service that at high speeds the journal friction proper may be less even than 2 lbs. per ton.

"It is now an admitted fact that the axle friction at the instant of starting is now many times greater than after the vehicle is once under way, and that the drop from this high resistance, while very rapid, is by no means instantaneous, but requires a speed of from 5 to 10 miles per hour before the normal rate is attained. The starting resistance at times rises considerably above 20 lbs. per ton, *i. e.*, a car on a 1% down grade, which gives an accelerating force of 20 lbs. per ton, will not always start of itself without aid. A force of 16 lbs. per ton will very rarely start a car in motion. A fair average is about 20 lbs.

"All these various data we have plotted on a little diagram reproduced herewith, to which we have added a solid black line to show what the evidence at hand appears to indicate as to the true rate of train resistance in pounds per ton. The six observations on high speed trains are shown by small circles with the name of each observer attached. Above and below these are shown by dotted lines (1) the old Clark formula as one extreme and (2) the Crosby formula for air resistance as the other. The range of the older formu-



las at 10, 20 and 30 miles per hour is shown at the left. There have been some showing still higher resistances than Clark's, but they have not met general acceptance For the most part they fall below Clark's at low speeds.

"Considering that the Worsdell observations are known to need small correction at least, Mr. Sinclair's two records come extraordinarily near to giving the mean of the four others. If we add to the Worsdell observations 6 lbs. and 10 lbs. per ton respectively, which would be the effects of a 0.3% and a 0.5% grade (15 and 26 ft. per mile), they would fall exactly on the line which we have drawn as the "weighted mean" of the six, allowing most weight to Mr. Sinclair's observations.

"Is it possible to find in this diagram any support for the theory that train resistance varies as the square of the velocity? We are unable to do so; especially as it is easy to see how the facts which we have narrated should make resistance observations within a narrow range of low speeds only appear to indicate that the velocity resistances vary as the square or even a higher power, when they really varied directly with the velocity. We by no means give our adhesion to the latter theory. We are merely weighing evidence. We do say that so far as the existing evidence as to high speeds goes, all of it supports the latter theory and none of it the older and heretofore accepted theory. If the solid line on the diagram gives a true mean of trustworthy experiments, then the resistance of passenger trains at speed is given by the equation

$$R = 0.24\ V + 2,$$

or perhaps as accurately and more simply:

$$R = \tfrac{1}{4}\ V + 2.$$

Both these forms are subject to a slight increment for difference in axle friction at speeds below 40 miles per hour, increasing as the speed falls, which is a more or less variable quantity and for practical purposes may be neglected.

We shall watch with much interest to see how further developments correspond with this formula It is entirely possible that they may discredit its form, or even its substance. But until they do, and for the present, experimenters at high velocities of over a mile a minute can have no better guides as to the true resistance, we think, than the above formula, and this fact at least seems to be now established beyond peradventure, that high-speed train resistances are very much lower than has been heretofore supposed, or than has even seemed possible.

---

Men become awfully careless sometimes, and engineers should check themselves in the development of this fault, for fault it is. How often a slow flag is placed along the line on account of a bridge or something and left there indefinitely Men slow up at first, then the bridge is fixed and they run by the flag without seeing it. This is gross carelessness, the flag should be reported and then removed. Not long ago the citizens of Orange, N. J, noticed that the crossing gates of one of the important streets crossing the D., L. & W. tracks were not being closed, and an investigation showed that the watchman was dead in his shanty and had evidently died some days previous. More than one hundred passenger trains had passed this crossing, and not one engineer had reported the absence of the protection due himself and the public. This was carelessness. Yes, it was worse—a neglect of duty! There is a well-defined but unwritten law among railroad men that failure of orders or the use of safeguards must not be reported for fear some one will be blamed Safe operation of a railroad depends upon every link in the chain—each man doing his whole duty and neglecting none, and insisting upon every other man doing his. Take nothing for granted, run by rule and order, you are playing with human life—your own life.

---

The Eugene V. Debs Publishing Co. is the name of a concern recently established at Terre Haute, Ind. That this house will put thousands of good books into the hands of the railroad men of this country goes without saying to those who know the untiring energy of the man at the head of the house. Eugene V. Debs is so well known to the workingmen of this continent that he will only need to announce his venture to have a thousand men come forward to help him. Mr Debs will hereafter publish J. E. Phelan's "Air-Brake Practice," formerly published by us, and "Progressive Examinations of Locomotive Engineers and Firemen," published by J. A. Hill. He will handle all books and pamphlets needed by railroad men and mechanics, but will make a specialty of good, cheap books. If energy, honesty and industry count for anything, the Eugene V. Debs Publishing Co. is sure of success.

---

When this issue of LOCOMOTIVE ENGINEERING reaches its readers, one of its editors will be in mid-Atlantic, on his way to try and find something of interest in the shops and on the roads of the Old World. John A. Hill and wife sailed for Europe on June 25th, on the great German greyhound "Ems," of the North German Lloyds. Mr. Hill will be absent about two months, and it is hoped that he will find many interesting things to write about in the Old World. Germany, France, Switzerland, Holland, Belgium and Great Britain will be visited.

## PERSONALS.

The Roberts dummy hose coupler is meeting with quite a sale, it seems to be appreciated.

Mr. E. Evans, long master mechanic of the Baltimore & Ohio Southwestern lines, has resigned.

Mr. J. G. Neuffer has been appointed master mechanic of the Baltimore & Ohio Southwestern lines.

Mr. A. G. Stewart has been appointed master mechanic of the Pennsylvania Company at Wells, Pa.

Mr. Geo. W. Cook has been appointed roundhouse foreman of the Wisconsin Central, at Waukesha, Wis.

Mr. Geo S. McKee, master mechanic of the C C. C & St. Louis at Chicago, has been transferred to Mattoon.

Mr E. Harvey, a well-known engineer, has been promoted to the position of roundhouse foreman, at Calera, Mex.

Mr. W E Wallace has left the Gould Car Coupler Co to be chief draughtsman of the C B. & Q, at Aurora, Ill.

Mr Samuel Rea, a well-known civil engineer, has been appointed assistant to the president of the Pennsylvania railroad.

Mr. Geo. W Parker has been appointed road foreman of engineers of the Black Hills division of the F. & Elk H. Railroad.

Mr. J. H. Berry has been appointed master mechanic of the C. C. C. & St. Louis at Cincinnati. This is a new office there.

Mr. J W Roberts has been appointed master mechanic of the Chicago & Southeastern. He was formerly on the C. C. C & I. Railroad

Mr. J M Sheer, who has been acting as master of rolling stock for the Ohio & Mississippi for several years, has been appointed to the position.

Mr C H Platt, for several years general manager of the Grand Central Station, New York, has been appointed general superintendent of the New York, New Haven & Hartford.

Mr F M Lawler, for some time master mechanic of the Big Fours at Mattoon, Ill., has been transferred to Brightwood where he takes charge of the principal repair shops of the system.

W E Miller, one of the most experienced passenger engineers on the Vandalia line, has been appointed traveling engineer. We believe this is the first time the "Van" has had an officer in this position.

Mr. A. W. Gibbs has retired from the position of superintendent of motive power of the Georgia Central, and the mechanical department will in future be run by the general superintendent.

Mr. John Grace has been appointed superintendent of motive power and construction of the Pavenir de Matehuala Railroad of Mexico. He was formerly general superintendent of the Monterey & Gulf road.

Owen Owen, general foreman of the D. & R. G. shops at Salida, Col., has been made assistant master mechanic of the second division in charge of the west end. Owen came up from the ranks, and the sequel of his success is summed up in the remark of an official of the road when he said, "Owen Owen knows his business—and attends to it."

Mr H. L. Leach, Jr, master mechanic of the Cheshire Branch of the Pitchburgh Railroad, has been transferred to the Tunnel division of that road.

The office of master mechanic on the South Carolina road has been abolished and that of superintendent of machinery created. E. M Roberts will fill the higher office and draw the better salary as modestly and as regularly as he did in the old place.

A correspondent writes informing us that E Mills, Oil City, Pa., one of our subscribers, lost his life in the terrible disaster that overtook that place last month, and that every member of his family perished, consisting of himself, wife and five children.

Mr. George Gilmore has taken charge of the motive power and machinery of the railroads in Jamaica in place of Mr. Sague, who has gone to the Schenectady Locomotive Works as mechanical engineer. Mr. Gilmore was at one time in the service of the Erie

Among the members of the Railway Master Mechanics' Association who expect to send sons to compete for the scholarships at the Stevens Institute are W C Ennis, John Medway and J. D. McIlwain R W. Bushnell talks of sending his son, Edward, to try for one of the scholarships in the Stevens Preparatory School.

W D. Lee has been appointed superintendent of the Rio Grande Southern Railway, in addition to his other duties as assistant master mechanic, with headquarters at Ridgway Junction, Colo. Brother Lee is an old-time engineer of the D. & R. G., was traveling engineer of the third division for a long time, and is the right man in the right place.

Mr. Herbert Higgins, who has been connected with the Northern division of the Great Northern Railway for the past ten years as general foreman of machinery, resigned recently to accept a position on the A., T. & S. F. Railway at La Junta, Col. On his departure the employés presented him with several pieces of solid silver as a token of esteem.

A highly respected Western correspondent sends us a rather lengthy account of the life of Mr. A. D. Kilbourn, master mechanic of the Southern Pacific at Dunsmuir, Cal. From the account, we learn that Mr. Kilbourn rose from the footboard to his present position, and that he is one of the most efficient and popular master mechanics on the Pacific coast.

Mr. J. W Philbrick writes us, saying that the point in his biographical notice in the June number of LOCOMOTIVE ENGINEERING, crediting him with building in Waterville the first locomotive built in Maine, was not correct. The Portland works had been building locomotives for twenty years before that time. We might say that the mistake was not ours

Mr David Patterson, general foreman of the Union Pacific shops at Omaha, Neb., for the past year, has been appointed master mechanic of the Utah division of the U. P. with headquarters in Salt Lake City, *vice* A C. Hinckly, resigned Mr. Patterson has worked his way up, starting in as machinist apprentice at North Platte, Neb., in 1868, and is counted a good man in the motive power department. He has never worked for any other road.

General Manager Tucker, of the Phillips & Rangeley Ry., has posted the following notice "Mr. L. H. Wheaton having resigned the office of train master and track supervisor, Mr. George Phillips has been appointed superintendent, with office at Phillips. He will have charge of the motive power, maintenance of way, and car departments and train service, and his orders will be respected and obeyed accordingly Mr Phillips will report to the general manager."

On June 14th, Mr. Joel West, master mechanic at West Burlington, Iowa, for the C., B. & Q, was appointed master mechanic of the lines in Iowa for the same company, with headquarters at West Burlington, Iowa. Mr. West has been in charge of the machine shops at West Burlington since they were built, and has turned out a great many engines which give the best of satisfaction Mr. West has been master mechanic at different points of the "Q." system for the past twenty years.

Mr. J L. Greatsinger, who was lately elected president of the Duluth & Iron Range, rose through the mechanical stepladder He was successively fireman, engineer, engine-house foreman and master mechanic. Four years ago he went to be master mechanic of the road of which he is now president, then was promoted to be general superintendent, and subsequently made general manager. Mr. Greatsinger is a member of the Master Mechanics' Association, and takes a warm interest in the affairs of the organization.

Sydney Dillon, one of the oldest railroad managers in the country, died at New York, last month. Mr. Dillon is best known to railroad history as having been the leading manager in the building of the Union Pacific. The biographical sketches of his life say that he was born in 1812 and that he entered railroad life as an errand boy on the Mohawk & Hudson. As this road was opened about 1835 he was a fairly old boy, but it is certain that he did his first work on that road. Of late years Mr. Dillon has been closely identified with the Gould roads.

H M. Davis has resigned from the position of M M. of the Tunnel Division of the Fitchburg R. R. Mr. Davis has been connected with the road almost continuously since 1870, when, after serving his apprenticeship in Manchester, N H, he entered as a machinist in the shops in Fitchburg, Mass., and rose to the position of foreman under Master Mechanic W. A Foster. In 1884 he left the road for six months, going to Taunton, Mass, but the same year accepted the position of master mechanic of the State road under A W Locke, general manager He continued in that capacity until the Fitchburg took this road in 1887, when he became foreman of the shops, and later, when the new shops were built at Williamstown, he was transferred there to take charge. In November, 1890, he came back to Fitchburg as master mechanic of the Tunnel Division.

O. A. Haynes, formerly master mechanic of the St. Louis, Iron Mountain and Southern, died at Lebanon, Mo, May 20th, aged 64 years. He was born in Massachusetts, and in 1852 became superintendent of large locomotive works at Springfield, Mass. In the winter of 1854-55 he assisted in constructing the Providence & Bristol Railroad, and in 1856 he went to New York, being with the Rome, Watertown & Ogdensburg. In 1871 he became master mechanic of the Iron Mountain & Southern, and in 1882 went to Texas as superintendent of machinery for Gould's Southwestern system. In 1885 he returned to St. Louis as general inspector of locomotives and machinery, which position he held until 1888, when the office was abolished He was then agent for the Missouri Car and Foundry Company until January, 1891, at which time the Carondelet Electric Light & Power Company was organized, and he was elected general manager.—*Railway Age.*

Mr. Edwin M. Herr, for several years master mechanic of the Chicago, Milwaukee & St. Paul, with charge of the West Milwaukee shops, has been appointed superintendent of the Grant Locomotive Works, Chicago. Mr. Herr has had a varied and valuable railroad experience. When a lad he learned telegraphy and entered railroad service, rising to the position of station agent. Thinking that the mechanical department offered a better field for an ambitious young man, he left railroading for a time and entered an engineering school. After finishing this course he went into the West Milwaukee shops and worked as a machinist for a year or two. Then he accepted a position in the engineering laboratory of the C., B. & Q., which he left to become superintendent of telegraphs of that road. This position he held for several years, but his heart being in engineering work he left there to be master mechanic of the West Milwaukee shops. No man is more deserving of advancement in his chosen profession, and we congratulate the Grant Locomotive Works on their choice.

## CONVENTION NOTES.

The Shawnee & Hocking Valley Railroad have ordered fourteen engines from Baldwin's. They will be fitted with all the most approved appliances for convenience in handling and will have Jerome rod packing

The Brooklyn & Brighton Beach Railroad people have been experimenting with the Strohm Automatic Electric Block signal system and we have received very favorable reports. The system is so arranged that in case of two trains getting upon the same block, appliances are put in operation which automatically shut off the steam of the engine and apply the brakes. Several public trials of the apparatus were made and everything worked very satisfactorily.

Not long ago Superintendent of Motive Power Joseph McConnel, of the U. P., changed a 19x24-inch ten-wheeler with a 62-inch wheel, with the hope of getting better time out of her on grades and with heavy trains. He cut her wheels down to 51 inches and shortened her eccentric blades from $92^5_8$ inches to 45 inches. This made her valve motion quicker, and did away with a great deal of the tendency to tear the lever out when running shut off.

There was one thing left out by the committee appointed last year by the Master Mechanics' Association to investigate the subject of iron and steel which deserves to be considered. That is the form of test piece to be used. The form of test piece used very materially affects the results as to tensile strength and elongation. There is quite a diversity in the form of test pieces, and this is a point where there ought to be uniformity. We hope that in the report submitted next year this committee will recommend a standard form of test piece.

A very good point was made by Mr R. H. Soule during a discussion on air-brakes He quoted from a report, the words "When the construction of freight brake gear has become more uniform," and remarked As chairman of the committee on standards to report at the convention, he was prepared to report that there was hardly any standard of this association which commanded more respect and which had been adopted more fully than the standard freight brake gear. His report would also show that iron brake-beams were in almost general use.

On the 26th of April, engine 921, a Wootten firebox consolidation, 20x24-inch cylinders, weighing 100,000 pounds, took an immense train—the heaviest we have ever heard of—over the P. & R. road. There were 250 coal cars, four-wheeled, and a caboose behind the engine. The train was 2,566 feet long and weighed 860 tons; it was hauled 68 miles in eight hours, the engine burning seven tons of buckwheat coal, worth 35 cents per ton at the mines. The engine was fitted with the Smith triple expansion exhaust pipe, and carried 140 pounds of steam The road is practically level.

A very good practice has been adopted by Mr. John Mackenzie, of the N. Y., C. & St. L., with his car inspectors. When the new book of "Rules of Interchange of Cars" comes out, he subjects each inspector to an examination of how he understands the various rules. No inspector begins making decisions under the new rules until it is found that his interpretation of each article agrees with that of his chief. Under this system it is the head of the department who decides each case that arises. If this practice were generally followed there would be fewer disputes at interchange points.

The French Spring Co. are directing attention to the fact that the Morris V-shaped band has now been in use on locomotive springs for four years and is proving a very decided success. Its use improves the riding of the engines and makes the spring more durable. Among all the springs that are in use there has been no case of breakage reported. The reduction of band on the short plates imparts increased motion, and prevents the tendency to force the small plates against the band that so often leads to breakage and deficient elasticity when rectangular bands are used.

The Stow Manufacturing Co., Binghamton, N Y., has published an illustrated catalogue of their apparatus. Any one not perfectly familiar with the numerous ways that power can be transmitted by flexible shafts should send for this catalogue. Business is reported to be very brisk with this concern, which indicates that people are rapidly learning the advantage of using flexible shafts. The flexible shaft first took a place as a standard tool in dentistry, then gradually obtained a foothold among machinists, and at the present writing wherever, on account of weight or position, it is desirable to take the tool to the work instead of the work to the tool, the flexible shaft is considered almost indispensable in a well regulated shop.

During a discussion on cast-iron wheels at the Master Car Builders' Convention, Mr. J. N. Barr, of the Chicago, Milwaukee & St. Paul, surprised the members by making a statement that about 40 per cent. of the wheels in locomotive trucks failed by "shelling out," and that only 17 per cent. of wheels under cars failed from this cause. Mr. Barr had devoted careful attention to the subject and there was no question that his figures represented common practice. The tendency of those who heard the statement was at once to conclude that the action of the brake-shoes had the surprising effect of preventing the tread of the wheel from the defect called "shelling out." Reflection, however, brought to mind the fact that truck-wheels have never to be removed for the causes that lead other wheels to an end of their usefulness. Sliding flat spots and cutting of flanges send a great proportion of other wheels out of service Truck-wheels are entirely exempt from the trials of sliding and they are not removed very often for sharp flanges. When all the facts are considered, it is not surprising that such a large proportion of truck-wheels are removed for shelling out.

## Railroad Mechanical Conventions.

The friends of both the railroad mechanical associations have reason to be gratified with the work done at both the conventions held at Saratoga last month. The papers presented in the form of reports were unusually valuable and interesting, and the discussions that were excited by the various subjects introduced brought out much valuable information.

The address of President Kirby, of the Master Car Builders' Association, was full of congratulation of the good work performed by the association. No one is better able than Mr. Kirby to appreciate the condition of railroad rolling stock now as compared with what it was before the work of this association began. The work done was the arresting of individual movement toward a chaotic condition of cars that would have seriously retarded the free movement of freight. There is a great deal to be done to secure the desirable condition of uniformity, but there is great reason to be thankful for the work accomplished.

The most important work done by the M. C. B. Convention was the adoption of the recommendations of the committee which reported on Instructions for Air-brake and Train Signal. This was also adopted by the Master Mechanics' Convention, and there is now a uniform code of rules on this important subject.

As usual, a great part of the time devoted to the Master Car Builders' Convention was spent in discussing the Rules of Interchange of Cars. It seems a pity that a code of these rules cannot be adopted that would work without alteration for five or six years. The changes constantly introduced in these rules are very confusing to the men who are required to enforce them.

Unusual interest was manifested in the Master Mechanics' Convention, owing to the anticipated report on compound locomotives; many of the members having been instructed by their management to ascertain all they could on the subject. This probably helped to increase the attendance, for it was by fifty names the largest convention ever held.

The address of President Mackenzie indicated plainly the growing popularity of the association, which has doubled in membership within five years. While referring to President Mackenzie it seems merely justice to say that he made a remarkably able presiding officer, and that he has exerted a powerful influence in favor of the association of which he was president for two years.

The reports submitted were notable for the amount of original research represented, and they were all got out in a shape that was highly creditable to the committees. All the others were, however, overshadowed by the report on compound locomotives, the credit for which was due to the chairman, Mr. George Gibbs. This report is of a character that would excite the greatest attention in the highest engineering society in the world, and it is certainly the best paper that has ever been submitted to the Railway Master Mechanics' Association. It is a paper hard to condense, and we regret that time prevents us from giving extracts from it in this issue. We strongly advise those interested in compound locomotives to obtain a copy of the report and of the discussion that followed the reading of it. The report and discussion make a contribution to the literature on compound locomotives well worthy of being studied and preserved. The report was discussed for more than four hours, and at the end of that time the subject did not seem to be exhausted. The views expressed were highly diverse in character and it cannot be said that either side had much the advantage of the other. There were speakers who were very ardently in favor of compound locomotives for every species of service, and others who were strongly impressed with the belief that the movement in favor of that kind of engine is merely a popular fallacy likely soon to pass away. A great number of the speakers were able to judge respecting the merits of the question under discussion, for they either had compound locomotives in use or had enjoyed opportunities for watching the performance of that kind of engine. When we dispassionately weigh the evidence presented, it appears certain that the report of the committee and the discussion thereon have been favorable to the compound locomotive.

The report on tests of iron and steel elicited a lengthy discussion in which considerable information was imparted relating to steel. A departure from established practice was made by permitting steel experts who were not members of the association to express their views. The members present were certainly the gainers by the innovation. The report and the discussion thereon indicated that the steel used in fireboxes is by no means perfect for the purpose, but how the matter could be remedied was not clearly shown. There appears to have been more complaints within the last year of steel sheets failing than there have been since the material became recognized as the best metal for fireboxes. The probability is that the demand for cheap steel has a good deal to do with the failures.

After being on the roll of subjects for five years the question "Can we indorse, from a mechanical standpoint, the action of the Master Car Builders' Association in recommending the vertical plane type of coupler as a standard?" has been at last answered in the affirmative. It is satisfactory to find both associations agreeing on this important question.

The report on boilers for high-pressure locomotives and the discussion thereon strongly brought out the fact that radial stay boilers and the Belpaire boiler are making rapid progress into popular favor. They also showed that high-pressure steam or a pressure above 150 pounds to the square inch is getting to be very common. The line of weakness about boilers carrying steam of this tension is the stay-bolt. An interesting discussion arose on the methods of increasing the durability of stay-bolts, and numerous valuable suggestions were given.

The report on standard bolts and nuts was a paper of high value and is likely to exert a good influence in directing the attention of railroad men to the necessity for adhering to standards. There has been no endeavor in the interests of interchangeability and uniformity so important as the establishing of standard screw threads, and any tendency to depart from this standard is that of wandering into the wilderness of chaos. It is a common thing for parties ordering tops or screws to specify from $\frac{1}{64}$ to $\frac{1}{32}$ above the standard size. The men who do this kind of thing are the class that can never leave well enough alone. They are so overpowered with the importance of having ideas of their own that they will breed no end of confusion to ventilate their own egotism. When this report was under discussion a motion was adopted directing that a circular be sent out to railroad managers and others, urging the importance of keeping to standards when ordering rolling stock. We have no doubt that this action will be productive of good results.

The convention did a very graceful act in the finish of its work by electing as next President, Mr. John Hickey, who was prevented through a death in his family from being present.

---

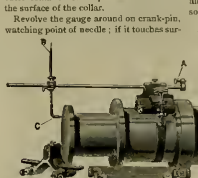
A number of tests were made lately at Cleveland with the Chapman jack which proved that the jack would bear an enormous pressure without failure. This jack has become exceedingly popular with engineers, because it is always clean, always oiled, and always ready for business, no matter how long it may be since it was last in use.

## Standard Crank-pin Gauge.

The standard crank-pin gauge illustrated in the annexed engraving is a tool that ought to be used in every engine house. It is applicable to any form of engine having a protruding crank-pin, but it is particularly useful for locomotives where bent crank-pins are extremely common. Besides indicating when crank-pins are bent this gauge shows when the pin is worn. Bent or distorted crank-pins are destructive to the machinery of the engine and dangerous, so that it is highly important to have an easy means of demonstrating whether or not they are all right. This is furnished by the gauge shown, and it will determine in a few minutes the existence of any defect.

To determine if crank-pins are at right angles with face of hub or disk, or parallel with crank-shaft, mount the gauge on crank-pin as shown in cut, set up testing-screw A until it touches the face of crank-pin hub, revolve gauge around on journal of crank-pin; watch point of testing-screw; if it touches face of pin-hub all around, the pin is at right angles. If it is open at one place on face of hub and touches at another, the pin is certainly bent. To determine if journal of crank-pin is round and true with center of crank-pin, mount gauge as shown in cut, excepting adjust the straight point of needle B to rim of outer collar of crank-pin until it touches the surface of the collar.

Revolve the gauge around on crank-pin, watching point of needle; if it touches surface of collar all around, the journal is round and true with center of crank-pin, but if the needle touches surface in places and shows open in other places, the journal is out of round or eccentric.



With a pair of hermaphrodite calipers, from the rim of collar on outer end of crank-pin scribe a center, then on outer end of crank-pin with a pair of dividers inscribe a circle on end of pin, draw diameter lines, mount gauge on crank-pin as shown in cut, set bent end C of needle B on intersection of circle and diameter line, revolve gauge around on journal of crank-pin, and the amount of eccentricity of journal of pin will be transferred at once from journal to outer end of crank-pin.

The gauge is manufactured by M. C. Hammett, Troy, N. Y.

## Stevens Preparatory School.

In the report submitted by Secretary Sinclair to the Master Mechanics' Association mention was made that an arrangement had been effected with the Trustees of the Stevens Institute of Technology, to admit scholars to the Stevens Preparatory School. There will be openings for two scholars in September next. This is an excellent school for youths preparing for college, and those passing through it receive training that enables them to enter an engineering college without difficulty. Members of the Master Mechanics Association would do well not to neglect the opportunity offered in connection with the Stevens School.

---

The following are the officers elected by the Railway Master Mechanics' Association at the Saratoga Convention: President, John Hickey, superintendent of motive power Northern Pacific, St. Paul, Minn.; First Vice-President, William Garstang, superintendent of motive power Chesapeake & Ohio, Richmond, Va.; Second Vice-President, R. C. Blackall, superintendent of motive power Delaware & Hudson, Albany, N. Y.; Treasurer, Orlando Stewart, superintendent of motive power Fitchburg Railroad, Charlestown, Mass.; Secretary, Angus Sinclair, Editor Locomotive Engineering, New York.

---

The recent orders received and shipment made of the Eberhardts' improved automatic tools for electrical and other work demonstrates very clearly that there is an increasing demand for good substantial tools which will stand the severe test of use in shops which are run to produce dividends on the money invested. Those who put their money in new enterprises should see to it that their plants are fitted up with tools of this character, which, although requiring a greater outlay in the start, will pay over and over again in the dividend-earning capacity of the plant.

---

We are in receipt of several letters from firemen telling what perfect idiots their engineers are, and stating their reasons for believing them such. As a rule, this is an indication of a young, fresh, throttle-struck fellow who thinks he knows all about locomotives three months after he sees one. Don't be too critical, boys, "keep cases" on the old man and see how it is that he gets along knowing so little—but don't give yourselves away as critics. We've all been there. You won't think you know so much in five years from now.

---

A friend of the paper writes:

We broke the flange on pony truck and got off track pretty bad. While we were working at the engine, Dennis, the fireman, was trying to get water in her, but both injectors declined to put water into boiler and furnish it at the same time. We were getting the jacks and frogs into shape for an effort when Dennis stuck his head out of the cab and said "If ye's don't git her on purty soon, we'll have to *cut and run* for wather." Dennis was a Spaniard.

---

The E. T. V. & G. have issued an order that conductors and engineers must pass a satisfactory examination on air-brakes to remain in the service. The boys are reported to be hunting information with a will now.

---

A new eight-wheel engine has lately been built in the Muskegan shops of the Chicago & West Michigan. She has cylinders 17x24 inches, 62-inch wheels, carries 160 pounds steam pressure and weighs 84,000 pounds.

---

There are some interesting special tools in the machine shops of the Cambria Iron Works. There are a great variety of multiple drills, one gang drill having twenty-four spindles. They have also planers cutting in both directions.

---

The Buffalo, Rochester and Pittsburg cars were let as follows 400 to the Berwick and 100 to the Buffalo Car Co.

---

The car shops of the N. C. & St. L. were burned on the 20th of June, together with seventeen cars that were undergoing repairs.

---

The Jacksonville, St. Augustine & Halifax River Railroad are about to contract for five locomotives, fifteen coaches and two drawing-room cars.

---

The Brooks Locomotive Works have taken an order from the Buffalo, Rochester & Pittsburgh Railroad for nine engines for delivery in September.

Sets in flush with side of car. Its great merit proven by long years of continuous use on thousands of cars. Sold on royalty basis. Blue prints, sample fittings and full particulars furnished on application.

WAGNER CAR DOOR COMPANY,

## AMERICAN FLUSH CAR DOOR.

Sets in flush with side of car. Runs on rollers. Absolutely tight car, utmost ease of motion. We furnish the fittings for this door out of refined malleable iron. Blue prints, sample fittings and full particulars furnished on application.

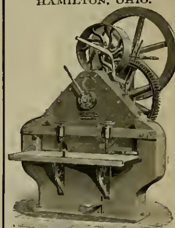
AMERICAN CAR DOOR COMPANY.

INDIANAPOLIS.

Chicago Office, 323 Phenix Building. ED. J. EAMES, Agent.

## The Long & Allstatter Co.

HAMILTON, OHIO.



Double, Single, Angle-Bar, Gang, Horizontal, Twin, Boiler, Spacing, Gate, Multiple, Belt and Steam-Driven

PUNCHES and SHEARS

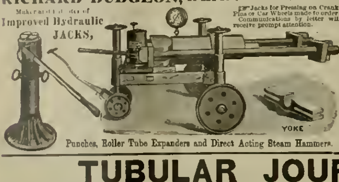
OVER 300 SIZES.

## RICHARD DUDGEON, 24 and 26 Columbia St., New York.

Maker and Patentee of

Improved Hydraulic JACKS,

Jacks for Pressing on Crank Pins or Car Wheels made to order. Communications by letter will receive prompt attention.



Punches, Roller Tube Expanders and Direct Acting Steam Hammers.

## WANTED, POSITION

—By a young man with eight years' experience as machinist and foreman, and seven years as chief draughtsman, on locomotive and car work. Address, MECHANICAL ENGINEER, Care LOCOMOTIVE ENGINEERING.

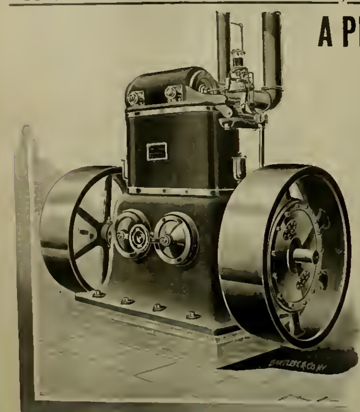
# TUBULAR JOURNAL BEARINGS

enable railway cars to be started with but one-tenth the power required with other brasses. Thirty (30) per cent. coal saving realized with trains of four or more cars. Journal heating entirely done away with by removing the cause. Cost of lubrication practically nothing, and every bearing guaranteed to yield 200,000 miles of service. Great economy and uniform reliability secured.

THE MENEELY BEARING COMPANY, - - - - WEST TROY, N. Y.

# A PLAIN STATEMENT OF FACT.



THE Compound Engine, when non-condensing, so far from possessing an economy superior to the simple engine, has been decisively proven, "much to the disgust of the stockholder," to show normal economy only at or about its rated power, and to fall off in economy faster than a simple engine as the load falls off; moreover, very much faster under the extreme light loads that are common at times in many industries. This point is at last reluctantly admitted by the more candid builders of such engines, most of whom now advise against compounding for variable loads. The reason is in their inability to divide the load and range of temperature proportionately and automatically between the cylinders at all points of cut-off. Hence, the low-pressure cylinder expands its steam below atmosphere under a moderately early cut-off, thus converting itself into an Air Pump, and becoming a load upon the high-pressure cylinder instead of a co-laborer with it. This point was distinctly foreseen by the designers of the Westinghouse Compound Engine, and an entirely new principle was worked out, making expansion below atmosphere impossible under any load, however light. **For the first time in the history of Steam Engineering, either Simple or Compound, is built an engine which maintains essentially uniform economy, irrespective of load,** and hence for the first time the Compound Non-condensing Engine has been made practicable. The results, demonstrated by test, show that where an ordinary Compound will range from 25 lbs. to 70 lbs. water per H. P. per hour from full to quarter load, the Westinghouse Compound, between the same limits, will range from 23 lbs. to 29 lbs. We have not deceived ourselves in this matter, and propose that the facts shall be understood. To those interested in the nicer points involved we will be pleased to send a reprint of the Paper read by Mr. F. M. Rites on this subject at the late meeting of the American Society of Mechanical Engineers at San Francisco.

## Furniture Car of 60,000 Pounds Capacity.

Mr. W. S. Morris, superintendent of motive power of the D., L. & N., C. & W. M. and S. V. & St. L. R. R. system of roads, has recently constructed at his Muskegon shops a furniture car possessing some novel features. Besides the admirable construction, as shown by the drawings, every possible inch of space for storage consistent with the height and width allowable, has been utilized. The inside finish is smooth and flush, and the height in the clear throughout (with a total height of 12 feet 3¾ inches from top of rail to top of running board) is 8 feet 7½ inches inside. This desirable gain of inside space is made possible, *first*, by the design of the truck (Fig. 1.) where the top of arch-bar is no higher than the top of the M. C. B. box plus the thickness of the arch-bars; *second*, the form of body bolster used being of iron and housed in the main timbers (Fig. 2) allowing the underside of the sills to come down to within 29¼ inches of top of rail; *third*, the last and most important feature is the "Morris Patented Roof," dispensing entirely with carlines and throwing into the interior of the car the space usually occupied by the carlines and the ceiling boards. This is a decided step in advance of present methods. To support the roof, taper sheathing (Fig. 3), or carline-shaped planks, form a self-supporting roof sheathing with roof slope on top, and their bottom side forming a continuous horizontal interior ceiling without carlines, rods or other obstruction. At each side-post a corner band of ½x2½-inch iron is screwed to outside of plate and to the underside of sheathing, being let in flush therewith. This taper sheathing is made from plank 3 inches thick sawed down to the desired thickness at the eaves. These are cut from a long plank, say 15 or 16 feet in length, from which are sawed out three 9-foot 6-inch roof pieces.

Comparing the dimensions of this car with the car recently adopted by the Pennsylvania Company, the difference is at once apparent:

| | Morris Car | Penn Car |
|---|---|---|
| Inside measurement in the clear: | | |
| Height. | 8' 7½" | 8' 7" |
| Length | 40' 0" | 40' 0¾" |
| Width | 8' 9" | 8' 6" |
| Outside over all: | | |
| Height | 12' 3¾" | 13' 0¼" |
| Length | 40' 8½" | 40' 11¼" |
| Width | 9' 4½" | 9' 3¾" |
| Cross sectional area. | 75 47 sq. ft. | 72 96 sq. ft. |
| Cubical contents. | 3,018 75 | 2,922 89 |

It will be noticed that the Pennsylvania Company's car is 8½ inches higher outside than the Morris car. Assuming that this height is the maximum allowable height and figuring the Morris car on the same basis of length and width inside, and the totol allowable height above the rail outside, then the two cars would compare as follows.

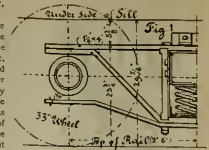
| | Sectional area in square ft | Cubical contents |
|---|---|---|
| Morris car | 79 33 | 3,178 29 |
| Pennsylvania Co. | 72 96 | 2,922 89 |
| In favor of Morris car. | 6.37 | 255 40 |

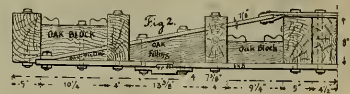
In furniture cars the net inside height is of every consequence, hence the plan is worthy of close scrutiny.

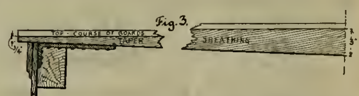
Engineer S. Harney has been promoted to be roundhouse foreman of the Florida Midland at Kissimmee, Fla.

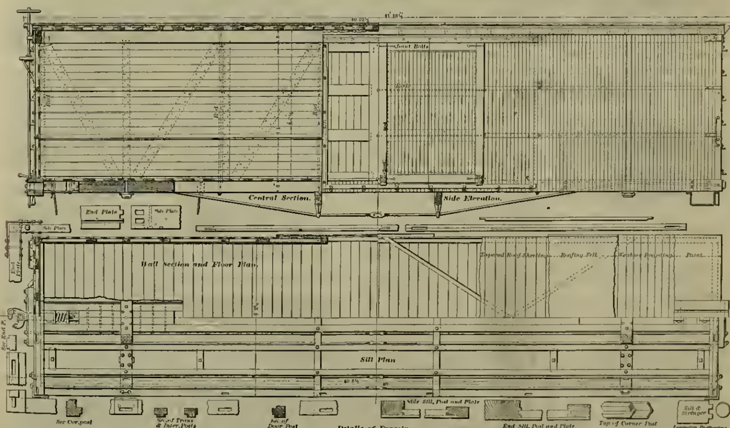
## Cars of Great Seating Capacity.

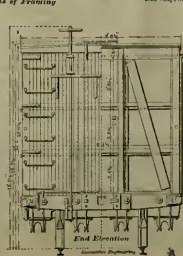
The annexed engraving represents the plan of cars that are in some respects the most extraordinary railroad cars in the world. They are run on the Quebec, Montgomery & Charlevoix Railway, and provide seating accommodation for over 100 persons. The cars were designed by Mr. W. R. Russell, superintendent of the road, and are intended to carry the crowds of pious pilgrims who visit the shrine of St. Ann at Beaupré, near Quebec. The pilgrims are mostly poor people who cannot afford to pay a high railway fare, and the company transporting them has gone to the limit of carrying the people comfortably at low cost.











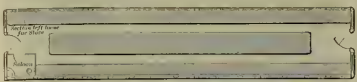
Mr Russell, writing to us about the cars, says "The plan of construction was carried out exactly as shown in the blue-print, with the exception that the width was increased to 9 feet and 10 inches. As regards the carrying capacity of the car, I have, as I told you when in Quebec, counted 135 seated in one car. On the 2d of August last, train No 35, with ten of these cars, carried 1,402 passengers, and a special, on the same date, carried 982 passengers in eight cars.

"On July 12th last, train No. 33 carried 1,428 passengers in eight of these cars and four regular cars, accommodation of the latter 56 seats each, and a special on same date carried 1,275 in eleven cars—eight pilgrim cars and three regular.

"Of course these are extreme cases, and

I would have put more cars on the trains had I been able, but the facts remain that these crowds were handled as above, and show the cars' suitability to our work. The car weighs about 36,000 pounds, is lightly framed and well built. We have twelve of them altogether, and I think from present indications we will have them all filled on many trains during the coming summer.

"The cars were built by Messrs. Jackson & Sharp, Wilmington, Del., and incidentally I will say that they were turned out with great rapidity—four of them were built, completed, painted and shipped between the 1st of July and the 21st of July, 1889. This is the more remarkable as the cars are, I think, four inches wider than the ordinary car built by this firm."



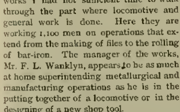
## Grand Trunk Shops at Montreal.

The shops of the Grand Trunk Railway at Montreal are in some respects different from any other establishment of the kind on this continent. The purpose of the works is not only to build and repair locomotives and cars, but to manufacture from the raw material many of the appliances used in all departments of the road. This is following the English practice and however wise, or otherwise, the policy may be, it requires a large establishment to carry on the work. During a brief visit to the works I had not sufficient time to walk through the part where locomotive and general work is done. Here they are working 1,100 men on operations that extend from the making of files to the rolling of bar-iron. The manager of the works, Mr. F. L. Wanklyn, appears to be as much at home superintending metallurgical and manufacturing operations as he is in the putting together of a locomotive or in the designing of a new shop tool.

The greater part of the shop tools used are of English make, but they are the best of their kind and are well placed and run with all the vigor that comes from the general use of contract work. There are many tools specially designed for certain operations, which they perform very expeditiously and accurately. The holes in the tumbling shafts are bored in their own centers in a special machine and they come out true every time. They are putting retaining rings on all their driving-wheels and have several special tools for performing the work of forcing in the bolts and riveting them. They have a form of quartering machine which was new to me. It has a milling attachment for cutting the key-seat in the axle.

The work of the different departments is grouped together and every facility provided for convenience in production in handling and in the distribution afterward. The tool-room of the works is one of the best in the country and is well furnished with all the small appliances necessary in a shop where accuracy of reproduction is rigidly enforced.

They have a peculiar way of weighing the engines and one that is well worthy of imitation by American roads. A fulcrumed lever is employed of the form illustrated in the annexed engraving. The toe of the lever is placed under the tire of each wheel and the weight extended on the long arm till the wheel is raised off the rail. One apparatus is required, of course, for each wheel. The expense of a set is not great and it supplies a highly convenient form of weighing apparatus that is always ready for use and easily applied.



The erecting shop for locomotives has a capacity of about 50 engines and is arranged in two rows on the stall plan, with a transfer table between the rows. There were about 40 engines in the shop, many of them undergoing very heavy repairs. The engines receiving heavy repairs are all grouped together in the place where material can best be moved to and from them. When I first visited these shops the locomotives were of rather mixed designs with a strong tendency toward the British forms with which the road was originally equipped. At that time the men in charge said that there were good points peculiar to the British and to the American locomotive, and that it was the intention of the Grand Trunk Railway to secure the benefit of both. When next I walked through the shops I found that the British features were becoming smaller; this time I found that the only English peculiarity left was the painting of engine and tender a bright color. They use straight boilers, but that is quite common among American locomotives.

Several peculiarities of the shop are well worthy of imitation. Great care is bestowed upon protecting the boilers and cylinders from climatic influences. The boilers are covered with mineral wool put on in a manner that insures the exclusion of coal. The cylinders and steam chests are cast with an outside casing, and this is filled with mineral wool. Those familiar with the enormous waste of heat due to inferior boiler and cylinder covering will agree that the Grand Trunk people follow a profitable practice in systematically providing the means to save heat.

Speaking of cylinders, I would say a word about the foundry, which is a pet of Mr. Wanklyn's, and is conducted with unusual skill. Their cylinders are rather a difficult pattern to cast, but they have not lost one for over a year. They are putting in a Tabor molding machine which is in line with their ordinary policy of having the most approved tools for producing work.

This company has long been an example to others in machinery for boiler-making work. Punching, shearing, flanging and riveting have all been done by hydraulic machinery for years, and the shop compares yet very favorably with the most modern American shops which have profited by the experience of two continents in selecting the most approved forms of boiler-making machinery.

A. S.

## Goldsboro Shops of the T. & P.

Opposite New Orleans a little above Algiers is the little town of Goldsboro, the terminal of the Texas & Pacific at the Gulf.

The shops are not large and show only too plainly to the initiated that the machinery department is subject to those depressing chills caused by some such order from Wall Street as "Cut down your pay-roll 80 per cent. on the 15th."

I didn't say a word to anyone there about it, but I would have been willing to gamble then and there, when I got into the shop, that the choking process had been going on for some time—it's just as plain to a railroad man as the symptoms of mumps to a doctor.

Master Mechanic Addis makes the best of everything and was bringing some engines through the shop, but everywhere was the evidence of lack of men and material.

A moderate-sized eight-wheeler seems to be the usual machine used; most of them have short fronts and the Brown stack, a huge cast-iron balloon with a six-inch pipe from the large part of stack back to the ash-pan. This affair the men call the "elephant trunk." Cinders are supposed to go back to the ash-pan and try it again, but very often the acre or so of fine netting in the stack stops up and then the gases ignite at the ash-pan end of the "trunk"; then the decks, cab, and, sometimes, the men take fire. Lately they have been amputating the trunk close up to the stack and turning it into the front end.

Formerly the blow-off pipe was carried to the ash-pan and this was cleaned out in this way, but they soon found that fire was often set by coals that escaped the blast and the pipes were taken out one side.

All around the shops are breastworks—not to keep out Yankees, but to keep out water; the Mississippi River is within a few feet of the shops.

Trains are ferried over the river to New Orleans on large transports. One of these boats was at the dock undergoing repairs. During the war this craft was a gunboat of the turtle-back type, her turrets having been removed and a couple of twenty-foot patches put over its holes. She was one of the iron gunboats made in such a hurry for river work, her plating being only ⅜ of an inch thick; the soldiers called them "tin-clads."

All the tools are in a part of the roundhouse, which is a very good building. I noticed that the stationary engine was set up very high and the big fly-wheel was entirely aboveboard; this was done to keep away from the water.

Up in Mr. Addis' office I observed a valve-motion model that had just arrived as a premium for a club of eighty-five subscribers to LOCOMOTIVE ENGINEERING, so it can be seen that the men on the road are anxious to keep abreast of the times, which, in fact, I find the rule rather than the exception in the South.

J. A. H.

## Locomotive Pattern Boiler with Extra Firebox for Burning Refuse.

At the shops of the Buffalo, Rochester & Pittsburgh road they have a locomotive boiler set up on an extra brick firebox long enough to take in anything likely to be thrown away at a planing mill. The box is big enough to burn shavings and saw-dust alone, and will take in ten-foot stuff; old cross-sills, car siding or ties without cutting.

## A Novel Car Coupler.

A new car coupler has been invented by Mr. William D. Williams, of Ogden, Utah. The inventing of a car coupler is not a rare event that would naturally call for special dispatches and the loud heralding through the land that something of a novel character is about to be submitted to the long-suffering race of railroad men, who have to give reasons why their companies should not patronize the newest invention. The inventing of car couplers is a monument to the fertility of American inventive genius, and shows the infinite resources of the human mind in producing diversities of forms designed to perform uniform functions. To be sure there are many of the patented car couplers that are curious, principally on account of the mystery that enshrouds "the new and valuable part" on which a patent is supposed to hang.

But there is no mystery as to the novel features of Mr. Williams' car coupler. The drawbar consists essentially of a head with two horns, a big teat and a jaw. One horn bends gracefully upward and the other is set downward. There is a movable strap which in action falls down and embraces the upper horn. When two heads of this kind are butting against each other, both the upper horns are embraced by the straps and the teats are pushed into the open jaws. It would be certain to make a secure coupling if the heads were of the same height.

---

A paper was lately read by Mr. A. H. Bauer, electrician of the Pullman Car Co., on "The Lighting of Railway Cars by Electricity," which gave particulars of no end of difficulties encountered in keeping an electric system in good working order on railroad trains. The expense is very great, and the system of depending on the locomotive for power is not considered reliable. He considers that some practical method of driving the dynamos by the car axle essential to the permanent success of electric lighting of railroad cars.

---

When a committee of one technical society is co-operating with a committee of another society, it might be considered common courtesy to ascertain the exact name of the organization if it is mentioned in print. A committee of the American Society of Mechanical Engineers, co-operating with a committee of the American Railway Master Mechanics' Association in regard to locomotive tests, writes about the "American Association of Railway Master Mechanics."

---

There seems to be a queer state of affairs existing on the Northern Railway of Spain, says the *Railway Herald*. It is stated that at Barcelona two thousand of the company's employés struck work last Saturday for an increase of working hours. They worked nine hours a day, but demanded longer hours with a proportionate increase of wages. At the same time a number of men employed at the same company's shops at Valladolid are reported to have struck for a reduction of hours. Why don't they change places, and so settle the difficulty?

---

A terrible accident happened on the C. C. C. & St. L. last month through the failure of an engineer or a telegraph operator to remember a change of time due to a new time card. The result was a head collision, causing the death of seven men and the injury of several others.

## Safe Railway Working on the New South Wales Railways.

*Editors* :

In reading the back numbers of the Locomotive Engineering, I came across some able articles on safe railway working, with regard to proper signaling of trains, and as your journal advocates any system of signaling that will keep trains apart, I will give you an insight to the different systems adopted on the New South Wales Railways.

When the present commissioners, Messrs. Eddy, Oliver and Fehon took over the New South Wales Railways there was not 30 miles of block signaling, and what there was, was confined to the suburban lines in and about Sydney and Newcastle.

I now give you the last return to July, 1891, showing number of miles of line in which the traffic is worked under the absolute block system; also, number and percentage of places which have or have not points or signals interlocked, since the commissioners took control of our railways:

| Date to end of | Number of miles of line opened for traffic. | | | Number of miles of line on which the traffic is worked under the *Absolute Block System* | | |
|---|---|---|---|---|---|---|
| | Double. | Single | Total. | Double | Single | Total. |
| Oct., 1888. | 71½ | 2,042½ | 2,114 | 28 | Nil. | 28 |
| July, 1890. | 78 | 2,103 | 2,181 | 72¾ | 189¼ | 262 |
| July, 1891. | 124 | 2,058¼ | 2,182¼ | 118¾ | 207½ | 326¼ |

| Date to end of | Number and Percentage of Places which have or have not *Points and Signals Interlocked* | | | | |
|---|---|---|---|---|---|
| | Number of Places. | | | Percentage. | |
| | Interlocked | Not Interlocked | Total. | Interlocked. | Not Interlocked. |
| Oct., 1888. | 104 | 318 | 422 | 24.63 | 75.36 |
| July, 1890. | 176 | 294 | 470 | 37.45 | 62.55 |
| July, 1891. | 234 | 262 | 496 | 47.17 | 52.83 |

The quadruple and double line out of Sydney are worked by Tryer's three-wire block instruments from signal-boxes about a mile apart. The greater portion of single lines are worked by the electric staff and tablet systems. To give a minute description of the different systems would take up too much of your columns. The commissioners are doing away with the old staff and ticket system, and where it is necessary are putting down crossing stations seven to nine miles apart and working it under the electric staff system; by so doing they get less stoppages and faster running—because the drivers know, when they get a staff or tablet, that they have a clear road, and if they have to stop or they break down there is no flagging to be done. For it is an impossibility to have two staffs out at the one time without breaking open the electric machine column, and I believe that when the commissioners' term of office expires in three and a half years, our New South Wales railways will be among the safest in the world with regard to safe railway working.

Our new South Wales signals say go or stop. The drivers have the biggest say as to where and how the signals are faced, by order of the commissioners, taking care at the same time to have the back light of the signals in view of the signalman.

Quick Action.

*Newcastle, N. S. W., Australia.*

## Another Air-Brake Puzzle.

*Editors* :

The following is not intended for the columns of the Ananias Club, but relates to an actual occurrence. A fast mail train was within one mile of a regular stopping point when the train parted. The air-brake applied automatically on the detached section and stopped it, but brakes on engine and forward cars were not affected. The engineer made the station stop, his brakes applying and releasing all right. It was night, and while waiting for the conductor's signal to start, he noticed there were no markers showing at rear end of train and investigating, found he had but three cars, two express and a P. R. R. box-car. The section that had broken away consisted of three postal-cars and a combination coach, the train parting between the box-car and first postal-car. Every stop-cock was open in the whole length of train pipe, excepting, of course, the one at the rear end of the last car. It was before the road had adopted the train air signal and the line of bell-cord had been passed up over the roof of the box-car; when the train parted the signal bell did not ring, and this fact, in connection with the peculiar action of the brake, furnishes material for a first rate air-brake puzzle.

Will W. Wood.

*Terre Haute, Ind.*

## Air-Brake Talk.

*Editors* :

In discussing the matter of plugging service exhaust the fact seems to be lost sight of that the equalizing feature would then be completely destroyed, while, if preliminary exhaust-port were plugged instead, there would, in case of passenger trains, be less liability of brakes being disturbed should a Frost light, or other reservoir on train, leak back into train-pipe after air on space above piston 17, plate D 8, had balanced by leaking through packing ring, and beside the train hand would not be subjected to so great a strain. It is also less work to plug the small port for this accident occurs so seldom that no one would want to carry anything specially for this purpose if it can be avoided.

In the same article Brother Desoe is called down in his statement about braking successfully on service-stop with small reservoir cut out; now, when two old air men disagree about such things each must have reasons for it, and I wish to try and explain, if I can, why such differences are not contradictory. The hole in preliminary exhaust bush in the latest brake-valves furnished measures $\frac{1}{16}$-inch, while on an occasional old one the hole will be as small as one-sixteenth, and besides has often accumulated scale or gum, thus contracting this opening, and it is my experience that such valves can be used in service-stop in this case and the difference hardly noticed on train. As to reservoirs with too great a volume there is, I believe, a tradition about pouring in melted rosin to reduce space.

About the stop-cock business, same page, the only explanation that seems at all reasonable is that, if used as shifting engines, main reservoir could control air governor through this cock, or brakes could be applied, and by cutting out the A stop-cock, and opening the B, the brake could be left on without getting too much air on short trains. In this connection, I would ask if experience does not prove it unwise to carry reserve pressure on two or three car trains when brakes are in good order.

I have often watched engineers do the one-second act and then put brake handle on lap and the change of expression in their faces when they roll by always puts me in mind of a little boy who is going to get an apple which he hid, but which some other boy has stolen. Probably friend Kidder knows something about this also.

I will try to make this clear, as I am often asked about it on the road. To illustrate, if we were to pour water through a bung-hole into a barrel until it is full and then roll the barrel over till the hole was underneath, then have a brick for a stop (or on lap) a few inches back and return the barrel to it, the hole would still be at the bottom and the water would all run out, and the same thing occurs with air in brake-cylinder in like case. When brakes are applied the pistons in triple valves are pulled down and air is admitted to brake-cylinder through graduating port in slide valves. With the release the piston is pushed up and as soon as it reaches the top begins to supply air to the auxiliary reservoir while air escapes from the brake-cylinder through exhaust port in slide-valve and will until brake-cylinder is empty. Now, if the engineer in this case would note the position of train hand, release his brakes *and immediately reduce train-pipe pressure again* until it was a few pounds below what it was before, he would have let *some of the air* out of his brake-cylinders and then *pulled* the triple-valve pistons down again so *air could not exhaust* from port in slide-valve. There is here and there a man who eases off the other way in stopping when his brakes are on too hard, but it will be found if investigated that he has merely kicked off the first couple of brakes.

Another point that I should like to mention in this article is, would it be considered the wisest course to pursue in case of possible accident to use the emergency stop on short passenger trains when brakes are working well? I have known cases where they would have stopped in a shorter distance in service-stop. The wheels would not have been slid and the terrible blow struck against the rails (*especially on curves*) would have been distributed more evenly and with less danger. How would such emergency stops compare with hammer blows or cannon shot? Is there not some air man who has made this his hobby and who could furnish us with his conclusions which would make very interesting reading, and which would be of great benefit to such emergency men as go to extremes unnecessarily?

George Holmes.

*Roanoke, Va.*

## That Gauge-Pipe Puzzle.

*Editor* :

Will W. Wood, Terre Haute, Ind., asks why the two gauge-pipes shown in the cut are connected. I will say this cock is placed there to enable the engineer to run either automatic or straight-air. In running straight-air this stop-cock connecting the two pipes should be open and cock (*a*) closed. By so doing the pressure will show on gauge whether brakes are on or off. The "pump regulator" or governor and both hands on the duplex-gauges will all work together. In running with automatic air this cock must be closed and stop-cock (*a*) open, this will allow one pointer on the gauge to work, also allow train-pipe pressure to governor when running; but when pressure is reduced in train-pipe by applying brakes the pump will pump an excess of air, thus insuring a quick release of the brakes. On three-way cocks a single gauge is mostly used, with two cocks, near three-way cock, in two gauge-pipes that run into one, this runs to gauge, with a branch running to governor.

The brakes should work all right in either case, either automatic or straight air.

Fred B. Armstrong.

*Camden, N. J.*

## Obstacles to High Piston Speed.

*Editors* :

One of the great difficulties of obtaining high speed with the locomotive, and the small load possible to haul, is due to the immense power necessary to keep the engine alone in motion. If we assume an 18x24-inch engine with 69-inch wheels, at sixty miles per hour, we find that the piston has to start from a state of rest at each stroke, and reach a speed of 30.6 feet per second at the middle of the stroke, and this in the space of one-twentieth of a second.

A falling body having the speed of 30.6 feet per second will have dropped through 14.6 feet as per the formula:

$$8\sqrt{h};$$

hence the work of each stroke of getting up this speed in the piston (and which must be done before a pound of careful hauling work is performed, and neglecting entirely the resistance of the wind, friction of balance of engine, etc.) is equal to lifting the piston, crownhead, part of main rod, etc., through a space of 14.6 feet.

If we assume this weight to be 650 pounds, we have $650 \times 14.6 = 9400$ foot-pounds. The pressure per square inch of piston necessary to accomplish this would be $\frac{9490}{252.7} = 37.5$ pounds.

The engine would make 292.5 revolutions per minute, and at each revolution the work of 9,490 foot-pounds would have to be performed twice in each cylinder; that is $292.5 \times 2 = 585$ feet that this weight would have to be lifted through in one minute for one cylinder.

Then the horse-power would be

$$\frac{585 \times 9490 \times 2}{33000} = 336.4 \text{ horse-power,}$$

which is alone consumed in keeping the two pistons up to speed.

It is clear that the average pressure of 37½ pounds per square inch, necessary to accomplish the work, is only necessary to be maintained through the first half of each stroke, so that the useful work performed is largely that due alone to the average pressure in the cylinder for the last half of the stroke, which is manifestly much less than that for the first half. This will be quite clear if we take an indicator card, and divide it centrally in its length and compare the area of the half due to the first half of the stroke with that due to the last half.

Frank Corbett.

*Brooklyn, N. Y.*

## That Bent Side Rod.

*Editors* :

My idea as to cause of bent side rod of the engine of I. F. Wallace is, that either wedges were down or there was considerable lost motion between driving journal and brass (the latter of which is hardly probable, as he says the engine was out of the shop only six months), and perhaps the engine slipped and caught the rail again at about lower quarter on right side, the engine on left side just passing forward dead center. Side rods are always freest on the dead centers. He says that he found everything all right on left side. I think he could not have moved left side rod laterally on pins. I also fail to understand how he did not detect bent side rod as soon as it occurred.

## Trainmen vs. Train Robbers.

*Editors:*

Your clipping from *The Railway Conductor* and comment on the same in the April issue of your paper aroused an echoing sentiment in my heart, and I thought that the relation of a personal experience would prove interesting to your readers.

On the night of September 23, 1889, about the hour of ten, the north-bound passenger train on the Gulf, Colorado & Santa Fé R. R. was held up in true Jesse James style about ten miles south of Fort Worth, Tex. The night was dark and starless—just such a night as would suit the most scrupulous or fastidious train robber—and I knew instinctively just as soon as the train commenced to slow up in that gloomy, desolate section, that the knights of the road were at hand, for I knew we had no more stops before reaching Fort Worth, and we didn't need either fuel or water, but soon we were at a dead stand, and almost instantly the word was passed back, "Train robbers!" Then several rifle shots rang out ominously on the calm night air; this was a warning to the too adventurously inclined to keep their heads in and not endeavor to see too much. Then there was hustling to secrete valuables and money, and the passengers in the forward car did a very sensible thing in extinguishing the lights; we in the second car didn't think of this. I was accompanied by my wife and two children. I remember very distinctly that my hope was that no "big brave" or ex-desperado would be senseless enough to show fight and thus draw the fire of the robbers on the crowded and frightened women and children—and men too—in the coach.

I had a pistol, but it was snugly packed away in my valise in the very box that contained it when I purchased it, on first taking up my abode in Texas, but I had long before given up the idea that there was any use for such a weapon in that good State; in fact, I never once thought pistol till some minutes after the stoppage the conductor came in the car and asked if any one could spare him a revolver or two, several gentlemen present spared him their guns very willingly and promptly.

But previous to this, while the passengers were hiding their wealth I was getting in my work, too. I had about $40 in silver, which was stowed away in the valise by the side of the unerring pistol, which I thought was safe enough; then I had a roll of currency in my inside pocket, not a very large amount, to be sure, but more than I would care to give away for charity's sake, much less willingly to our present interviewers. So I seized a pliant moment to transfer this roll from my inside pocket to that of my little boy (aged about four), taking care not to let him know what I was doing, so that he couldn't give the "snap" away when the robbers tackled us. But our precautions were in vain; the road agents had larger game in sight than the passengers. It seems there was a large consignment of silver in Mexican dollars in transit that night, and that is what the brigands were after, and got, though exactly how much is not known, such things being only known to the two interested parties—the robbers and the robbed.

It is safe to say, however, that several thousand dollars were secured. The mode of procedure in this case was the popular one; two robbers got on between the engine and express car at the last station passed, and when their rendezvous was neared they "took care" of the engineer and fireman and persuaded them to stop; the express car was then detached, and the engineer induced to pull it down the track a mile or so, where they looted the car at their leisure and then decamped, leaving the enginemen to find their way back without an escort. We got to Fort Worth about two hours late, the heroes and heroines of a thrilling experience. No clue to the perpetrators of this robbery was discovered till some eighteen months after its occurrence, and then, through the medium of an old letter that came into the hands of the police of Fort Worth, some of the robbers were brought to justice.

Now, for the benefit of those who have never experienced a train robbery, and feel very heroic when they hear of one, and wish that they had been there so that they could show the world how the "truly brave" would resist such unlawful acts, I will say that there are two very discouraging circumstances connected with affairs of this kind that tend to throw a damper as it were on any ebullition of personal courage; one is, you never knew how many of the robbers you may have to contend with; and the other is, a sort of vague realization that the robber is not out on this expedition just for fun, but if necessary to his ends he will shoot; and further, you see, and have to acknowledge that he "has the drop."

I remember a young fellow-townsman of mine, Henry Brown, a son of one of Tennessee's ex-Governors, who gave up his young life to this mistaken idea of chivalry—one man resisting unknown odds. It was on one of the railroads in New Mexico some years ago. Young Brown was express messenger, and sealed his devotion to what he considered his duty with his blood and life. Again, more recently, a train was held up on the Illinois Central at Duck Hill, Miss. There was on board (as passenger) a young engineer of the road (Chester Clark, I think his name was), who could not brook the idea of sitting idly in the car and allowing the train to be robbed, so he borrowed a Winchester from another passenger and got out to have a pop at the robbers. The usual result—the robbers popped first, and Mr. Clark was a dead man. Now these two men virtually threw their lives away for a mere sentiment. I mention these two incidents to rather impress on the minds of those who are not familiar with this particular development of our civilization, that if they imagine for a moment that the average train robber will not back up his arguments to the death, they are wofully mistaken; therefore, it is better to suffer the temporary embarrassment of being robbed of a few dollars than risking the certainty (almost) of being killed, and also jeopardizing the lives of others in an indiscriminate fusillade.

## Be Exact About Your Statements in Air-Brake Puzzles.

*Editors:*

Regarding those technical queries presented to the readers of this paper, why are not the propounders of air-brake puzzles, etc., more accurate in their statements? In attempting an answer, one must not presume anything, but accept the facts exactly as given. One of Tink's letters in the May number is an example. Engine and tender-brakes were operated by a single triple-valve. When the pump was started, the "brakes" applied. Now the possibility of the hose being cross-coupled between engine and tender undoubtedly occurred to every air-brake expert who read his letter; but the idea was rejected, owing to the inference drawn from his use of the word "brakes," for, in the case in question, the tender-brake only could apply.

Another correspondent knew of a three-car train with quick-action triples, the third one being defective. The pin controlling the opening of graduating-valve was broken, the valve holding shut. If he had said that this triple went full on shortly after the other brakes had applied, there would not have been space in this paper for all the correct answers, as this pin is the weakest point and really the only weak point about the Westinghouse triple-valve. With nearly every passenger train in the country, a half-minute sometimes means a half-mile, and his statement that after an 8-pound reduction a train could possibly run a half-minute before a triple with this defect would operate is decidedly an exaggeration. Westinghouse triple-valves are not built that way.

An error occurs in my article in the May number referring to the emergency-piston as being 1½ inches, when it should have been printed 2½ inches in diameter.

## Lining by Counter-bore of Cylinder.

*Editors:*

I have been asked several times within the last few months by engineers and young mechanics if the method laid down by P. H. Zwicker in his *Revised Practical Instructor* for machinists, engineers and firemen is correct and practical.

In giving directions how to line an engine, Zwicker says "that the counter-bore should always be used in centering the line." This is erroneous, as the piston in operation bears no relation to the counter-bore. When an engine has been in use for several years, the cylinders are often found very much out of round. I have found cylinders worn to an oval, being worn out at the bottom, so that the vertical diameter would measure from $\frac{1}{32}$ to ⅛ of an inch larger than the horizontal diameter.

To set a line in a cylinder worn the least possible measurement out of truth by the counter-bore is a delusion and a snare. One object in setting a line is to get the center of crosshead directly in line with center of cylinder, and if the crosshead guides are set with a line centered from counter-bore, they will be found too high when piston-rod is keyed to crosshead.

## Air-Brake that Set in Full Release.

*Editors:*

Having gone wide of the mark in trying to answer one of the problems in the last issue of your paper, permit me to propound one myself for some one else to stumble over, and also, of course, for the general information of your readers. It is taken from actual experience on the road, and is warranted genuine.

A train composed of an engine and eight coaches was running up a slight grade at about twenty-five miles an hour. The handle of the engineer's valve stood in the running position, when the engineer thought he felt the brakes dragging. From force of habit he tried to let them off by pushing the handle to release position, when they immediately set so hard as to nearly stall the train, releasing, however, before coming to a complete stop. What was the cause, both of the application and release?

The engineer's valve was one of the improved Westinghouse pattern, and in good condition. There were other conditions noted by the engineer which showed the writer very clearly just what was the cause of the trouble, but as these might make the solution too easy, they will be omitted in the hope of stimulating the thinking faculties of our well-known air-brake men.

## Lubricator Experience in Australia.

*Editors:*

In answer to Mr. D. B. Hutchin's sight-feed lubricator puzzle in March issue, I beg to state I was running a passenger engine with Detroit improved-pattern sight-feed lubricator. I filled the lubricator and closed all the valves till starting time, when I opened them myself, and they worked all right to the end of the division. The fireman banked the fire, steam-gauge showing 130 pounds of steam, closed all valves on and to lubricator. Drained lubricator and refilled it with oil. Stood for four hours and could see the oil was going out of lubricator; tried valves and found they were shut; when starting time came opened all valves and then the oil did not work through the feed glasses, and I could not make out where the oil was going to until I got to the locomotive depot, when I found it was in the boiler, so I came to the conclusion the lubricator valves were not steam tight. The pressure of steam when fire was banked was 130 pounds, and when the fire was turned over for return trip the steam-gauge showed 90 pounds. Now, did the reduction from 130 pounds to 90 pounds cause a vacuum in the steam passage from lubricator to boiler, which I believe it did? Will some one else give their opinion, and why it did not work right on the return trip? I worked the valves just the same as when I came out on the first trip.

## Relyea's Brake Puzzle.

*Editors:*

It is a long time since I gave the readers of the Locomotive Engineering a "conundrum" on air-brake difficulties, and having "resumed business at the old stand" after a satisfactory trial of dissipating, I thought I would give the boys a little one to study on for a while. So here goes.

One of our engines has been giving a great deal of trouble on account of tender-brake setting while running along, and sometimes it would set while standing in the house, but the driver-brake would not set every time the tender-brake did, only once in a while, when maximum pressure was up.

Now, the natural conclusion was that there must be a leak in train-pipe or its connections, that caused the brake to set, so I had the pipes examined thoroughly, but found no leaks. I then examined triple-valves on both tender and driver brake, and they were found to be in perfect working order. The brake-valve was the next thing to examine. I did so, but found nothing there. I scratched my head with both hands, and even then I found nothing wrong. Well, she made another trip and when she came back the same report came of the tender brake "going on."

Now, while this engine was making this last trip, I remembered that a long time ago I had the same thing occur on an engine equipped the same as the one I am writing about. So when she came back I went to work where I had located the "troublesome trouble," and sure enough there it was. This engine is equipped with latest style of engineers' brake-valve and governor standard triple-valves and push down driver-brake cylinder. Now, what made this brake set when there were no leaks in any joint of any pipe, and triple-valves all right, also engineer's valve?

W. F. Relyea.

*Syracuse, N. Y.*

We will have to ask all correspondents to send, on a separate sheet, an answer to their puzzles in practice. These will be kept until the next paper and published with the answers. The third month is too far away for an answer—readers lose interest. Another thing; many may feel hurt because their answers do not appear, we only publish one answer the same; there has probably been twenty answers to Oil Can's puzzle practically like the one published.

## Train-Running for the Confederacy.

By Carter S. Anderson.

When you ask me for something interesting from our side of the fence during the war, for 20,000 railroad men to read, you touch a very tender chord in my heart. With railroad men there is a brotherhood which lives and operates without organization, and which knows no State limits nor party lines. Railroads have the lead of all the many improvements in the present fast and enlightened age; they will likely continue ahead and distance their rivals. Electricity is cutting a mighty dash and doing all the talking, but the steam horse does nearly all the work.

But to comply with your request: I wish I could recall the scenes of thirty years ago and paint them life-size for all railroad and American brothers to see, and humbly ask them not "to do so any more." Do not let us haul any more "troop trains" internally, but let us in future head them all toward our borders.

Well, I will try to tell you something of the part the Virginia Central R. R. men (now Chesapeake & Ohio) performed in 1862 in moving a division of General Lee's army from Richmond to join General Jackson in the valley of Virginia, and then bringing the whole army thus combined under Jackson along down and placing it in the rear of General McClellan.

To commence: General McClellan had swung around in the Chickahominy until he tapped our Virginia Central and R. F. & P. Railroads, and had destroyed the South Anna River bridges on both roads. This caught some of our railroad men in Richmond, and a good many of our engines, cars and men were out on the long end. Those of us who were caught in Richmond were at once put into the militia, doing local duty about the city.

I remember the first day we were out we came in sight of the Blue as we were stationed on Strawberry Hill. Then we were put at Young's Mill, and then east of Richmond, where we were put on picket duty on the Darbytown road. My beat was right alongside of the road, and from 6 to 12, the pass-word being "Geo. Washington."

Everything was quiet until about 9 o'clock, when I heard a footstep firm and regular. My musket was at once brought to bear in that direction, when I remembered just in time that my first duty was to call, "Halt! and give the pass-word!" Which I now did with all the dignity of a railroad Confederate soldier.

The traveler, who was an old darky, replied:

"Hy! What this gwine on here now? Dis de fust time I been ever ax fur a pass sence I been had Liddy at Miss Jane Darby's, and dat been ever sence four years arter de stars fell in '33 and two years arter Mass Josephus brought Miss Delia home. Young boss, is y'awl our folks or is y'awl de Yankees?"

I answered him that he couldn't see Liddy that night, but to go home.

The old fellow retraced his steps muttering that "'twas a mighty bad sign." I never saw him again. My time was out at 12 o'clock and I very soon, without any preliminaries, such as devotions, etc., measured my full length on the soft, wet pine tags, and resting my weary head between the projecting roots of a pine tree, was soon sleeping soundly and sweetly as those alone can sleep who have nobly saved their country (!) Some great man once said that the three noblest words in our language were "Do your duty;" but I, as well as our great men, do my own thinking, and there are only two plain little words I like better: "Duty done."

I awoke to hear the news that we were ordered to town and that all Virginia Central Railroad men must report at once to our superintendent. Upon reaching our office, corner 17th and Broad streets, we received orders from Col. H. D. Whitcomb, our general superintendent, who had preceded us to Charlottesville, to report to him there, having left passes for us via the R. & D., South Side & Orange, Alexandria & Manassas Railroads. We arranged accordingly and left early the next morning, having as our fellow passengers, on our and other sections of the R. & D. troop trains, about 12,000 of Lee's men. When we reached Charlottesville we found that Col. Whitcomb had already collected there everything that could turn a wheel on that end of the road, and ordered us to arrange crews to suit ourselves, remarking that, in consideration of the enormous task of moving such an army with so limited a power, he would be glad to have one sober man in each crew, and that he had best not put all the whisky men together. The solid, firm and feeling manner in which he said this had the effect he doubtless desired. The detachment sent from Lee to Jackson had no time to lose and demanded immediate transportation and listened to no excuses.

I remember well that hot June day we loaded the troops at the old Lynchburg Junction of the C. & O. R. R., near the University of Virginia. Our cars were very rough, the most of our coaches were in Richmond and we had only freight cars, work-train flats, caboose cars and such as were scattered about on that portion of the road. The soldiers, and officers especially, complained heavily, and curses thick and fast fell upon us as we worked and sweat to get them loaded. All at once in a loud tone bawled out a Confederate officer to our superintendent: "You railroad men are a set of blockheads." It fired my young blood. Col. Whitcomb's answer was indeed like "apples of gold in pitchers of silver." Said he, as he stood, coat off, in the broiling sun: "Well, sir; if we *are* blockheads, we are trying to do our duty." His noble answer satisfied the brave Confederate, who returned the soft answer: "Well, then go ahead and nobody shall interfere."

This little spat made us all, soldiers and railroad men, friends together, and we soon had everything on board and moving along our serpentine track about the base of those little ragged mountains between the University and Ivy Creek. Everything was serene, and not a murmur did we hear as the cool and refreshing mountain breezes fanned our heated, weary and hungry bodies. In a few hours the whole detachment was with General Jackson, who had reached Mechum's River with a large part of his Valley army. We received orders from General Jackson at once, after unloading our Richmond troops, to run through the Blue Ridge tunnel and bring him the remainder of his army. We had to go right on, and about day-break the next morning we ran out of Blue Ridge tunnel and discovered at once our passengers as they lay along the little valley that runs parallel to the C. & O. R. R. between the Blue Ridge tunnel and where Basic City now stands. We whistled and rang in order to wake the soldiers and get them aboard, which they very gladly and promptly did. We took them on, carefully running our trains back to Mechum's River. As soon as we reached there we found that everything there was on the move back to Charlottesville, which we had so hurriedly left. Then commenced the funniest experience of my life, for about two or three weeks, as well as I remember (I am writing entirely from memory).

All was curiosity and speculation as to the movement of the army. We had thought that Lee was re-enforcing Jackson in the Valley so that he could go on to Washington, a belief which lost but little force when we turned back from Mechum's River, as we concluded that Washington could be reached more easily from Charlottesville than from the Valley. All the cavalry and artillery took the county roads, and a large part of the infantry. The army used our trains to their fullest capacity, "riding and tiring" fashion.

When we reached Charlottesville we had orders to unload, but very soon those we unloaded going on and those in rear coming walking up, we reloaded the tired ones and got orders to take them to Gordonsville. "Ah! I told you so," was in every mouth. "To Washington from Gordonsville is the nearest route of all." So it was. Well, the whole army got together there, or nearly all of it. It seems to me we stayed at Gordonsville a day or two. While there we received orders to head our trains all toward Washington and load them. Of course, then all doubts were removed, and all the subordinate officers, soldiers and railroad men fully believed that Jackson was going to Washington. The trains stood loaded all day, some of us pulled down a mile or two toward Orange C. H. Toward night, however, we got orders to unload and get our trains all back to Gordonsville.

Suddenly, very early the next morning, we were aroused by our agent, Mr. Addison Gooch, rattling his stick along the outside of the cars in which we slept. He informed us that he had orders to tell the men that every engineer who was not ready to move his train in 45 minutes would be shot. The wood which we used was very sorry stuff with which to start a fire, being not much more than half seasoned and four-foot wood at that, which we had loaded on our tenders from the ricks as we came along on the road. But of all the impromptu inventions to increase heat and make the "pot boil," that morning's experience took the "rag off the bush." In making up our crews at Charlottesville, it fell to my lot to have for my engineer John W. Whally, running the little Roger engine named "Monroe." John Wesley, a ginger-bread free negro, was firing for him. Mr. Whally could not get steam on Monroe, all he could do. He got mad with John Wesley, and it got John out of sorts, and it looked as though the Monroe got mad too, and would not burn her wood nor steam at all. It began to be serious.

Every other train but ours was ready, and the officers gathered around watching anxiously and very supiciously our movements, and I found out that some suspicion had arisen as to Whally's loyalty, his pedigree not being known to any of our people. I felt sorry for Whally. He and I had made many a trip together under trying circumstances, and he had many a time saved me from a whipping by taking my part. He was a powerfully built man and fully 6 feet 6 inches high. I hunted around and found some old barrels in the rear of the depot, one of them an old tar barrel. I knocked them to pieces, and Samuel Wood, brakeman, and myself got the barrels on the engine. Just as I stepped on the footboard I saw Mr. Whally open his box and get all of his waste and pour on it all the oil he had and put it in. He then rolled in the old barrel staves. She began to roar. He took courage and looked around for any and every thing that would make the fire burn the wood which was choked into the firebox. I saw Whally take up the cushion, on which he sat when running, and poke it into the firebox. It was very greasy and added much to the fire. Whally then seemed to forget himself. He had as fine clothes as any man on the road, but when he was running on his engine he did undoubtedly wear the greasiest clothes any mortal ever saw. Whally had taken off his coat and laid it on the box in place of the cushion which he had burned. He snatched the coat up and rolled it into the firebox and commenced to unbutton his pants to follow suit. But John Wesley, his fireman, said, "Mars Whally, don't do dat; here's my coat," and in he dashed it. When the gauge of the Monroe in a few minutes showed 140 pounds of steam, the officers took off their hats and waved them and shouted: "Hurrah for Whally and Monroe!"

Our trains were now all ready loaded and headed eastwardly. Orders came to go to Louisa C. H., and no further unless ordered by the Government and on their own responsibility. Then began again speculation, betting and arguments indescribable as to what Jackson was going to do or where on earth he was going. We reached Louisa in a few hours and unloaded all the troops. In fact, it seems that nearly all the army there got together and lay encamped around and below Louisa C. H. The opinion seemed to prevail that it was nearer from Louisa C. H. to Washington than from Gordonsville (and, by the way, there is not much difference), and that Jackson had decided to come down from Gordonsville to Louisa C. H. and to go from there to Washington. This was the prevailing belief among the subordinate officers, soldiers and railroad men.

We remained at Louisa C. H. several days, including one Sunday, and a memorable Sunday it was. Our trains lay east and west of Louisa, covering about four miles of main track. We had to leave space between trains in those days to pump up, the valuable injectors we now use not then being known, or rather we had none. Everything was quiet; nothing seemed to be going on except there was reported a great religious revival among the soldiers who were then encamped in the groves below the C. H. Sunday morning all of us railroad men gathered around the telegraph office at Louisa to try to hear what would be done. We had no rations, scarcely, and there were so many soldiers about that it was impossible to buy anything to eat. By 12 o'clock noon more than half of the railroad men were drunk. We drank during the war mostly new apple brandy, and it is a very hot and fiery dram. A great many of the soldiers and the subordinate officers had come to town too and gotten drunk, and it was the jolliest crowd at the depot you ever saw. All at once—Squeel! squeel! loud, long and distressingly, we heard an engine coming from toward Richmond. We could not understand what on earth it could be, as we had with us every engine we had. "It must be a Yankee engine pulling McClellan's troops," said every one. It was soon found out, however, that some official had run the gauntlet from Richmond and had gotten a little R., F. & P. engine that happened to be outside of Richmond, and a little coach, and was making his way to Charlottesville.

The urgent request came to us to move all of our trains far enough to allow the little courier train to take the siding at Louisa, and then to back down east of Louisa until she could run out of the west end of the switch. But, "here's the rub!" More than half of us drunk, every engine cold, nobody knew anything, nor had anybody seen anybody else. It was with the greatest effort on the part of all who had sense enough to appreciate our situation, that we got the trains far enough west to let the courier train in, and then about the same trials to get them back down below the Court House, so that the little courier train could run out the west end and go on to Charlottesville. It took the best part of the day to get the track clear. In the meantime, it took so long for us to get the track open that the messenger man had either gone to see some of the officers or was getting his dinner, so that all of the railroad men and thousands of idle soldiers had gathered around to examine, criticise and find out all about this crew and its errand. My engineer, Whally, was pretty drunk.

He went around and *chinned* the little engine, made a great many ridiculous remarks about her, and finally bet $20 that he could hold the little engine with ten men and could thus prevent her moving until he said so. Knowing the importance of the occasion, I begged Whally not to attempt such a thing, it was too serious, but the soldiers told him to go ahead. Somebody took the bet and Whally selected his men.

Presently here came the messenger, got upon the coach and told his engineer, "Go to Charlottesville; minutes are hours!" About twenty strong men dropped their strength against the coach, "Chow, chow,

chow, spow, spow, spow," went the little engine. I feared every minute that I would hear a shot. The engineer made several vain trials, and seeing his point gained Whally said, "Give her a push, boys, and let her go," and off she shot amid the loud cheers of the soldiers. It was the most ridiculous sight I ever witnessed.

I have taken so many sidings that I have failed to make my terminal, and will have to stop and wait until you give me right of track to finish my trip. How we took those 30,000 troops and placed them within a day's march of McClellan's rear, moving with muffled whistles and bells off the engines—of this I will tell you in another letter if I can find time.

*Richmond, Va.*

## Machine Molding.

At the San Francisco meeting of the Society of Mechanical Engineers, a highly interesting paper was read on "Machine Molding" by Mr. Harris Tabor. The paper contains many interesting facts about the molders' art generally, the difficulties that are encountered in making good castings, and apathy of many foundry proprietors concerning the needs and comfort of molders. The growth of the aids to molding that have culminated in the molding machine are traced, and then a great portion of the paper is devoted to describing the design and working of the molding machine invented by Mr. Tabor, which was illustrated in LOCOMOTIVE ENGINEERING of February last. The paper concludes:

"The absorbing question, What is the economy in machine molding? is very difficult to answer. The product of machines will vary in different foundries, as much as the product of the molder. What may be called a fair day's work is an unsettled question. From the standpoint of manufacturer and workman, it is too small in some localities and too great in others. A machine that will mold 175 flasks, 16x16x10 inches deep, with two men to operate it, in one foundry, would, under precisely the same conditions, mold 250 in another. One manager may surround his machine with little conveniences for handling work, and thus increase his product, while another would compel his machine men to work under disadvantages. The treasurer and practical shop-man of a foundry were observing the operation of an automatic machine, with watch in hand; a complete half mold in 16-inch nowel, or as they would say out West, drag, 5 inches deep, had just been made and turned on the floor for inspection in ten seconds after the sand was put in the flask, when the treasurer asked the question, 'How many molds can be made in a day?' Before the writer could reply the shop-man said, 'That is not the question; the question is, How many molds can we take care of?' A better answer could not have been given.

"The first machine of our automatic type has been in use about a year. The conditions are not favorable, all the sand is handled by shovels, and the flasks and molds are carried to and from the machine by hand. The flasks used in this case are 14x17x10 inches deep, and weigh 70 lbs. The sand in flask, when rammed, weighs 156 lbs. Two men on this machine make 200 molds per day, and average during the working hours from 27 to 34 molds per hour. These men have made and carried away 158 nowels in one hour and thirty-five minutes, and have made 200 complete molds, ready for clamping, in less than five hours. We must keep in mind that these two men must shovel into flasks over 31,000 lbs. of sand, and carry off the same amount, in making 200 molds; they must also handle twice 14,000 lbs. of iron in flasks. Two hundred molds, under these conditions, is too much for five hours' work. But this number is not too much for a day's work for two men. A greater product might be obtained from an additional man, or from a conveyor for elevating sand to a hopper over the machine. A system of handling the molds after they are made would also add to the machine's capacity."

On June 10th, C., R. I. & P. engine No. 901, engineer F. T. Holland, ran from Goodland to Jennings, Kansas, a distance of 82½ miles, in 87 minutes. The 901 is one of the new express engines built at the company's shop at Chicago, and it was illustrated in the *Locomotive Engineer* in September, 1891.

## A Fast Run on One Side.

On May 27 Engineer William Laster, of the E. T., V. & G., ran engine "21" from Birmingham, Ala., to Selma, Ala., with one side disconnected, a distance of 104 miles, in two hours and forty minutes, making twenty stops.

## My Grief With a Big Smoke Stack.

BY SAM SHORT.

I handle the best article of its kind for railroad use, but, strange to relate, I sometimes hear of cases where my goods do not give satisfaction. The cause, of course, is pure prejudice. The careful nursing that the best thing in the market requires to maintain popularity naturally makes me watchful of the influences that work sometimes to condemn a good thing offered for railroad use. When a manufacturer who feels sure that he has a good thing finds that it fails to give satisfaction to railroad men, he naturally feels aggrieved and says hard things about the men who failed to make the thing a success. Sometimes he may have just ground for complaint but as a rule he has not.

It is undoubtedly true, however, that things are sometimes forced upon railroad men that have no merit and are floated entirely by proprietary interests. Compelling the use or protracted trial of these things is an annoyance to the individuals who are in charge, and loss to the company trying them.

When I was master mechanic of the Prairie Southern, we had no end of trouble with fires from spark-throwing. We were using the ordinary diamond-stack, but all the engines had very small boilers and small nozzles had to be employed to make steam, with the result that the engines all threw sparks. There was no mistake about that. My general officers tortured me with complaints about fire-raising, and annoyed me with impracticable proposals of remedies. Sparks and fire made my life a burden. Those who complained took no share of the blame to themselves, although they had stocked the road with small boilered engines without consulting with me.

Well, our G. M. called me to his office one day and informed me that he had ordered half a dozen of the Duplex Down-Draft Patent Stack that was said to be doing wonders as a spark-arrester on the road where its inventor was superintendent. The stacks were duly delivered. There was nothing striking about them except their size. The diameter of the diamond was greater than the diameter of the boiler, and the diamond was well filled up with a cone. The first of the stacks to be tried was put on the 87, one of our best steaming engines on the road. During the first trip she lost two hours with a through train on the first division from want of steam. I was duly roasted by the G. M., and told to get all the stacks put on the engines without delay, and to make sure that there be no more loss of time on the road.

I ignored the order about putting on the other stacks and went out on a local next day with the 87. The engine steamed very badly. About half our time was spent in the smoke-box trying to get the lift-pipe in a position that would improve matters, but it was no use. We returned the blackest and bluest party that ever had started out to make an engine steam. My foreman boiler-maker, a very good workman and ingenious man, expressed the belief that he could make the engine steam if I would let him make a peculiar petticoat pipe. I was in the humor to agree to anything, even if the article were made with a bustle. He produced a pipe that was fearfully and wonderfully made. No improvement in steaming resulted. Smaller nozzles were tried with some improvement. Still smaller with the result that the engine got the train over the road on time with a large increase in the coal used.

The other stacks were put on freight engines. By reducing the nozzles, steam was made after a fashion, but the engines would not pull the trains they had formerly handled with ease. The next complaint made to me was that the engines were stalling on every hill. Then I was told in a stinging telegram that the engines were causing delays by leaving their trains to run for coal.

Finally the G. M. sent for me and expressed his disapprobation of my conduct toward the improved smokestacks. It was painfully evident to him that I had opposed these stacks through personal prejudice. The result was that the stacks were throwing about as much fire as the old ones, and the engines having them on were disorganizing the train service. He expressed the highest personal regard for me. It pained him to know that I was more obstinate than an army mule, but he hoped that I was not beyond the influence of reason. (He is an all-fired, bitter-sweet talker.) Those engines had to be made a success, and all the power was to be equipped with them.

It was a hard dose to swallow, and I was in a hole. I had moved my family from the East just six months before; had furnished a comfortable home and was still in debt. To pull up again was to be a great hardship on others besides myself. I considered the situation for a day or two, wishing to do the manly part, yet reluctant to break up the home nest.

Spark-arresting and smokestacks had been an absorbing theme of conversation between me and the different railroad men who dropped into my home of an evening. When I went home one evening, shortly after receiving what I considered my ultimatum from the G. M., Mrs. Short was unusually patronizing, and had the air of being burdened with suppressed wisdom. I know, from experience, that this betokened some impending domestic revelation of great importance. After supper the revelation came in the form of facts about spark-arresters.

Mrs Short was always an interested listener of our shop talk, and had been in the habit of posting herself through the books in my library on the topics discussed. It seemed she had been studying spark-arresting as revealed in the Master Mechanics' Reports, and she had prepared a whole bureau of information on the subject for my benefit. She had marked a number of reports and discussions on the subject, and believed that the facts and theories advanced would solve my difficulties. This was the surprise she had prepared for me. I was less sanguine, but I spent the evening reading up the experience of others with spark-arresters of all kinds.

Next day the purchasing agent sent me a requisition for drawings of the stack saddles of all the engines, so that the new stacks might be ordered. I spent the evening writing an essay on smokestacks and spark-arresters, using the Master Mechanics' Reports as reference, and sent it to the G. M., with my resignation annexed. I did not forget to mention that the real trouble with the Prairie Southern engines was that the boilers were too small, and that spark-throwing was caused by forcing the fires; a thing that must be done to generate the steam required by the big cylinders.

That afternoon the G. M. surprised me by walking into my office. He was inclined to talk spark-arresting, and fortunately I was fresh from the best authorities, like a boy crammed for a college examination. The result of the interview was that the order for the new smokestacks was countermanded, and I was directed to send the brightest engineer in the employ of the company to the home of the big smokestack on a mission of investigation. His report settled the stack question to my satisfaction.

Nothing was ever said about my resignation, except by Mrs. Short. She claimed the credit of straightening out the kink in my affairs, and insisted on getting the full reward. She expects still to be rewarded every time the fashion in women's garments changes.

The moral of the story to me is, never tell your wife the whole truth when she does you a good turn, or you will hear from it even after many days.

## Three-Cylinder Locomotives.

Mr. John Riekie, locomotive superintendent of the Northwestern Railway of India, whose triple-expansion locomotive we commented on in our May issue, writes to the *Engineering News*:

"I have read the note in your issue of February 20 on my three-cylinder locomotive, based upon a description in a European paper, and regret very much that my proposed system has not been correctly reported. The engine is not at work, and the design is for three single-acting cylinders with cranks at 120°. My twenty-five years of locomotive practice have caused me to consider that the pulling of the locomotive-wheels in turns by cylinder and piston is wrong in principle, causing heavy wear and tear, and setting up an ugly surging, sinuous motion, resulting in a waste of power. Were we to turn the wheel by pulling or pushing at a constant point, we should, I think, have a more steady running engine, and my proposed single-acting engine was designed to meet this. The compound system I advocate is also unique, and is designed to use the steam up by continuous expansion. Converting the high-pressure cylinder into a steam-chest during the return stroke of the piston enables this to be accomplished. I have a steam-pump working on this system, and it is a great success, giving a gain of nearly 100 per cent.

"We use chocolate-color paint for our locomotives, and white, green and yellow for the first, second and third-class cars. I have for many years advocated Russia iron for boiler-covering, but we are fully twenty years behind England in all we do in this country, and another generation must spring up before we can expect India to be as go-ahead a nation as America."

Good molding machines in a foundry where there is a fair amount of duplicate work may be made as profitable as the turret lathe has been in the machine shop. It has been said of the turret lathe that its limit is set by the ingenuity of the tool-maker. If pattern-maker be substituted for tool-maker, and a fair amount of "nerve" in foreman be added, the same may be said of the molding machine. Like the turret lathe, its best results are obtained when operated by unskilled labor, or men trained only in the use of the machine. When the foreman has a reasonable amount of patience at the start, coupled with a disposition to make good castings cheaply, there is no doubt of his success in machine molding. If these qualities are lacking, it is better to defer the introduction of machines until the foreman has been brought to see their advantages, or has been supplanted by a more progressive man. — *Harris Tabor, in paper on Machine Molding.*

Supt. Wightman, of the Pittsburgh Locomotive Works, has recently patented a boiler-head brace that has many advantages. The ends are made separate from the rod proper, the latter being threaded at each end, right and left, the fork end for the head and the lug to rivet to the sheet of boiler are drop-forged and then threaded, the rod being upset at each end and threaded; thus the whole brace is made in the machine-shop and without welds. It requires no measuring and fitting, and when put up exactly the same tension is put upon each brace in a set. The Pittsburgh shops almost make a boiler by machinery now, their hydraulic flanging-machines doing especially nice and fast work.

There are over 3,000 locomotives in service in the United States that are not on regular railroads, but are on plantations, in the pineries, around mines and mills. There are over 6,000 cars owned by private roads.

## Earliest Instructions for Enginemen.

In an English industrial magazine, dated 1846, there is published a series of instructions for locomotive enginemen, which we believe were the first directions put in print. The following are the principal parts.

The most important part of the engine-driver's duty is the observance of signals, respecting which no general rules can be given, as the systems of signals vary upon different railways; but a strict attention to the signals fixed upon and a constant watchfulness to see that the rail is free from obstruction, constitute the most important part of the duty the engine-driver has to perform. He should constantly be upon the foot-board of the engine, so that the regulator, the whistle or the reversing handle, may be used instantly if necessary; at the same time he must see that the level of the water in the boiler is duly maintained, and that the steam is kept at a uniform pressure. In feeding the boiler with water and the furnaces with fuel, a good deal of care and some tact are necessary, as irregularity in the production of steam will often occasion priming, even though the water be maintained at a uniform level, and an excess of water will of itself occasion priming, while a deficiency is a source of obvious danger. The engine is generally furnished with three gauge-cocks, and water should always come out of the second cock and steam out of the top one when the engine is running, but when the engine is at rest the water in the boiler is rather lower than when it is in motion, so that when the engine is at rest the water will be high enough if it just reaches to the middle gauge-cock. The boiler should be well filled with water on approaching a station, as there is then steam to spare, and additional water cannot be conveniently supplied when the engine is stationary. The furnace should be fed with small quantities of fuel at a time, and the feed should be turned off just before a fresh supply of fuel is introduced. The regulator may at the same time be partially closed, and if the blast-pipe be a variable one it will be expedient to open it widely while the fuel is being introduced, to check the rush of air in through the furnace door, and then to contract it very much as soon as the furnace door is closed, in order to recover the fire sooner.

The proper thickness of coke upon the grate depends upon the intensity of the draft, but in heavily loaded engines it is usually kept up to the bottom of the fire door. Care, however, must be taken that the coke does not reach up to the bottom row of tubes so as to choke them up. The fuel is usually disposed of on the grate like a vault, and if the firebox be a square one, it is heaped high in the corners the better to maintain the combustion. In starting from a station and also in ascending inclined planes, the feed-water is generally shut off, and, therefore, before stopping or ascending inclined planes the boiler should be well filled up with water. In descending inclined planes an extra supply of water may be introduced into the boiler, and the fire may be fed, as there is at such times a superfluity of steam. In descending inclined planes, the regulator must be partly closed, and it should be entirely closed if the plane is very steep. The same precaution should be observed in the case of sharp curves or rough places on the line, and in passing over points and crossings.

To ascertain whether the pumps are acting well the pet-cock must be turned, and if any of the valves stick they will sometimes be induced to act again by working with the pet-cock open, or alternately open and shut. Should the defect arise from a leakage of steam into the pump, which prevents the pump from drawing, opening the pet-cock remedies the evil by permitting the steam to escape. Should priming occur from the water in the boiler being dirty, a portion of it may be blown out, and should there be much boiling down through the glass gauge-tube the top cock may be partially closed. The water should be wholly blown out of the locomotive boilers three times a week, and at those times two mudholes at opposite corners of the firebox should be opened, and the boiler be washed internally by means of a hose.

On approaching a station the regulator should be gradually closed, and it should be completely shut at about half a mile from the station if the train be a heavy one, and the train may then be brought to rest by means of the brakes. Too much reliance, however, must not be put upon the brakes, as they sometimes give way, and in frosty weather are nearly inoperative; in cases of urgency the steam may be thrown upon the reverse side of the piston, but it is desirable to obviate this necessity as far as possible. At terminal stations the steam should be shut off earlier than at roadside stations, as a collision will take place at terminal stations if the train overshoots the place at which it ought to stop.

There should always be a good supply of water when the engine stops, but the fire may be suffered gradually to burn low towards the conclusion of the journey. So soon as the engine stops it should be wiped down, and be then carefully examined. The brasses should be examined occasionally, to ascertain whether the wheels are square on their axles, by the application of a gauge, and whether the axles have any play, which should be prevented. The stuffing-boxes must be tightened, the valve gear examined, and the eccentrics be occasionally looked at, to see that they have not shifted on the axle, though this defect will generally be intimated by the irregular beating of the engine; the tubes should also be examined and cleaned out, and the ashes emptied out of the smoke-box through the small ash-door. If the engine be a six-wheeled one, it will be liable to pitch and oscillate if too much weight be thrown on the driving-wheels, and where such faults are found to exist, the weight upon the driving-wheels should be diminished. The practice of blowing-off the boiler by the steam, as is always done in marine boilers, should not be permitted as a general rule in locomotive boilers when the tubes are of brass and the firebox of copper, but when the tubes and fireboxes are of iron it may safely be done. Before starting on a journey the engineman should take a summary glance beneath the engine, but ought first to assure himself that no other engine is coming up at the time. The regulator, when the engine is standing, should be closed and locked, the eccentric-rods be fixed out of gear and the tender-brake screwed down. The cocks of the oil vessels should at the same time be shut, but should all be opened a short time before the train starts.

Most of the accidents attended with loss of life upon railways have been occasioned by persons jumping on or off the train whilst in motion, and many cases might be cited of engine-drivers and stokers having been killed by falling off the engine—in some cases from the coupling of the engine and tender suddenly giving away. The most frequent causes of collisions are fogs, and the absence of a uniformity of time at the different stations along the line in consequence of their difference of longitude. Collisions have sometimes occurred from carriages having been blown from a siding upon the rails by a high wind; and the slippery state of the rails, or the fracture of a brake, has in some cases caused collision at a terminal station. Collision has also taken place from one engine having overtaken another, in consequence of the imperfect condition of the first engine from a leaky tube or otherwise.

When a tube bursts, a wooden or iron plug must be driven into each end of it, and if the water or steam be rushing out so fiercely that the exact position of the imperfection cannot be discovered, it will be advisable to diminish the pressure by increasing the supply of feed-water. Should the leak be so great that the level of the water in the boiler cannot be maintained, it will be expedient to drop the bars and quench the fire, so as to preserve the tubes and firebox from injury. Should the wooden casing of the boiler catch fire, it may be extinguished by throwing a few buckets of water upon it, or if the engine is at a station, it may be brought under the water crane. Should the piston-rod or connecting-rod break, or the cutters fall out, or be clipped off as sometimes happens to the piston-cutter when the engine is suddenly reversed upon a heavy train, the parts should be disconnected; if the connection cannot be restored so as to enable one engine to work, of course the valve of the faulty engine must be kept closed. If one engine has not power enough to enable the train to proceed with the blast-pipe full open, the engine may perhaps be able to take on a part of the carriages, or it may run on by itself to fetch assistance. The same course must be pursued if any of the valve gearing becomes deranged and can not be rectified upon the spot.

Before leaving a station the engine-driver should always assure himself that he has the requisite supply of coke and water, and should not trust to the attention of the stoker respecting such matters. Besides the firing tools and rakes for cleaning the tubes, he should have with him in the tender a small oil tank and a small tallow chest, a bag of waste, some rope yarn, gasket, canvas, and white lead, two small oil cans, an oil syringe, spanners, and one shifting key, a chipping hammer, chipping chisels and a file, a coal hammer, some wooden and iron plugs, and an iron plug-holder, a sheet-iron bucket, a screw-jack, two crowbars, a chain and some wooden wedges. The whole of these articles should be arranged in the tender in suitable places, so that the engine-driver may know where to put his hand upon any article, and can see at a glance whether any of them are missing. A few spare bolts of different sizes should also be carried. To economize fuel in locomotives a variable expansion gear is very desirable, which may be adjusted to the load, and the blast-pipe must be worked with the least possible contraction. At stations the damper should be closed to prevent the dissipation of the heat. Anthracite has been tried for locomotives instead of coke, but it crumbles down into a powder and forms a compact mass upon the bars, which prevents the admission of an adequate supply of air to the furnace. If the area of grate be enlarged, however, it appears probable that anthracite may be used if mixed, for economizing fuel. The practice appears to us to be commendable enough, but it should be coupled with the publication of the consumption of the locomotives of different makers, as no amount of care on the part of the engine-driver will suffice to correct the vices of an imperfect machine.

---

The general manager of a stock-car line some time ago was getting a large number of new cars built and he decided to use elliptic springs under the whole of them. The extra cost was a heavy item, but he says that the cars rode so much better that the company was more than repaid in six months for the extra expense by the improved condition of the stock carried. In connection with this subject a good authority on springs says that a spiral spring is cheaper at first and will be more durable and will ride better than a short elliptic spring, but a long elliptic spring is the ideal cushion to absorb the jar of the cars. If a little more attention were bestowed on trucks to enable elliptic springs of proper length to be applied, that form of spring would push all others out of the market for cars carrying material liable to suffer from rough riding.

## Activity at the Cooke Shops.

The Cooke Locomotive & Machine Co. have just completed an order for twenty-two ten-wheel engines for the Houston & Texas Central Railroad Co. They have 19x24-inch cylinders and 54-inch driving-wheels. Weight of engine, light, is 96,500 lbs. Equipped with Richardson-Allen balanced valves and Westinghouse brake equipment, schedule W M.

The Cooke works are now engaged on three fast passenger anthracite coal-burning engines for the Delaware, Lackawanna & Western R. R. Co.'s main line. Cylinders, 19x24 inches, drivers, 64½ inches diameter, Krupp tires, Boies wheels on both engines and tenders, Richardson-Allen balanced valves and Westinghouse brakes, schedule W.

Also three large ten-wheel engines, having cylinders 21x26 inches, drivers 56 inches diameter, for the Everett & Monte Cristo Railway, Washington.

Delivery of the twenty consolidation and five ten-wheel passenger engines for the Louisville & Nashville R. R. will commence this month, and continue throughout July and August, 1892.

Orders have lately been booked as follows:

One mogul switching and three additional eight-wheel passenger engines for Delaware, Lackawanna & Western R. R. Co.

Three eight-wheel passenger engines, with 18x24-inch cylinders, for the Evansville & Terre Haute R. R. Co.

One eight-wheel passenger engine, anthracite coal burning, with 18x24-inch cylinders, 66-inch drivers, for the Lehigh & Hudson River R. R. Co.

Their two-cylinder compound locomotive engine is being tested on the N. Y., L. E. & W. R. R. between Port Jervis and Susquehanna, and, if it proves economical with fuel, it will no doubt meet with favor from railroad men, on account of the extreme simplicity of all its parts.

## To Light the World's Fair.

There was a vigorous fight among the different electric lighting companies to secure the contract for lighting the World's Fair, and Mr. George Westinghouse, president of the Westinghouse Electric Co., has obtained the contract for furnishing the incandescent electric lighting plant, and is to install 92,622 lamps, alternating current, for $399,000, under a bond of $1,000,000, and is given until June 10 to file his bond and close the contract. This makes Mr. Westinghouse the winner in a big fight against the electrical combine, consisting of the Edison General, Thomson-Houston, and allied electric companies. When the bids for furnishing the plant were opened, the trust proposal was $18.50 per lamp capacity, or $1,713,567. Several smaller concerns submitted greatly lower bids, so much so that the management thought the combine was trying to "squeeze" the Exposition. While these bids were being considered, the La Roche Co., of Philadelphia, backed by Mr. Westinghouse, came forward with a bid of something like $7 a lamp. The trust met this reduction with a bid of $5.95 a lamp. Then Mr. Westinghouse told the directors if they would advertise for new bids he would submit a proposal agreeing to furnish the lights at an average of $5.38 each, or a total of $499,319. He executed a bond in the sum of $500,000, supplemented with a cash deposit of $50,000, to carry out his agreement. Accordingly new bids were advertised for, and when they were opened it was found that the combine had not lowered its proposal, while Mr. Westinghouse dropped down to $399,000, or $4.25 per lamp capacity. He bid on an alternating current alone.

---

The next meeting of the Grand Lodge of the Brotherhood of Locomotive Engineers will be held at St. Paul, Minn., in May, 1894.

## Running at the Rate of 115 Miles per Hour.

At the Convention of the American Society of Mechanical Engineers, held at San Francisco in May, there was a paper read on the Electric Railway as applied to Steam Roads, by B. J. Dashiell, in which some interesting particulars were given of experiments with a high-speed electric locomotive. A circular track nearly two miles in length and 28-inch gauge was built and a motor run on it as fast as the power would propel the machine. The motor rested on four wheels 28 inches diameter and had a wheel-base of 9 feet. Each axle carried a gearless motor. The extreme length of the machine was 21½ feet, and it was built with pyramidal ends to reduce the air resistance. The weight of the motor was not given, but we think it probably weighed about two tons. The propelling power was supplied by a high-speed automatic engine of 100 horse-power, running at 300 revolutions per minute, and driving an Edison electric dynamo. The electric current was taken from an overhead T-rail.

The performance is thus described by the author. During these experiments we experienced only three derailments, two of which occurred at 45 and 80 miles respectively, and were due to a portion of the road being poorly ballasted. These two derailments were toward the center of the circle, the car leaving the rail only, and running along the guard rail. In the third derailment, which was due to not enough elevation in the outer rail at the place of derailment, the car, following the well-known law, went off at a tangent, climbing the guard rail and running along a six-foot fill, and then out in a field a distance of about 1,000 feet from the place of derailment. The car at this place was going at a speed of 115 miles per hour; the highest speed made, as taken between by two of the five observers stationed at intervals along the track, according to grade, being 118 miles. The longest continuous run was 22 minutes at various speeds, with a mean of 68 miles per hour; another run of 9½ minutes averaged nearly 80 miles per hour.

## A Rotary Spark-Arrester.

The inventors of the spark-arresters that call into requisition fearfully and wonderfully made smokestacks have been taking a rest lately, but this line of invention is

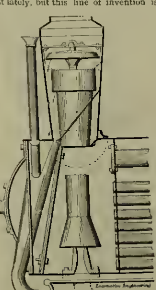

Fig. 1.

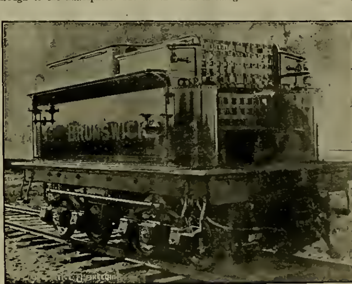
not entirely abandoned. Less than a month ago a patent was granted to Mr. L. C. Mabie, of Richmond, Va., for a form of spark-arresting stack that throws most of those who have gone before entirely into the shade. We illustrate Mr. Mabie's invention. It is surprisingly ambitious. The mechanism seen in Fig. 2 are revolving turbines with the hot air and gases as motive power. One revolves to the right and the other to the left and they are expected to keep whirling all the time when hot air is passing into the stack. Their functions are to jerk all sparks into the side recesses of the stack and also to take out of the gases the minute particles of carbon that constitute smoke. We do not just see how the gases are going to get through to the atmosphere, but the inventor, no doubt, has settled that in his own mind. The plan is not absolutely original, but it is worked out in greater detail than anything in this rotary spark-arresting line has been done before.



New Brunswick Tender.

## New Brunswick Tender.

Our engraving shows the standard form of tender used on the New Brunswick Railway before the road was absorbed by the Canadian Pacific. It was designed by Mr. G. A. Haggerty, master mechanic. The water is beneath the coal, except a small coal space in the front. An attractive feature about the tender is the substantial and convenient form of coal boards. The frame is wood and the body of the tender of steel.

Fig. 6.

There is a very fair Ananias Club reporter on the Chicago *Herald* who devotes himself to concocting railroad lies. The man has a fertile imagination that may gain its owner reputation should he drift into a department of literature where the free-play of fancy would not make the writer ridiculous. One of his latest efforts is the working up of a story to the effect that N. G. French, superintendent of bridges of the Illinois Central, whittles out the design of his bridges. The story as told combines the amusing and the ridiculous very artistically. We have no doubt whatever that all the bridges designed by Mr. French are whittled into shape. There is an engineering department of the road which attends to that business.

The Chicago & Northwestern Railway people are remodeling their yards at the Chicago passenger depot and putting in a new central electric and heating plant. The main pipe of the heating plant will be 1,500 feet long. For the electric plant 250 horse-power engines will be put in and five boilers will be provided to supply steam for the engines and for heating purposes.

## Mysterious Failure of Steel Sheets.

The mechanical department of one of our principal railroads had a curious and edifying experience lately with the failure of steel sheets. Sheets from one of the best steel makers cracked badly on being flanged. Other sheets were put into the heating furnace and on the attempt to flange them being made, cracking and fraying of the worst kind resulted. The men in charge concluded that something of an intensely serious nature was the matter with the steel and they were about to report the failure to the maker when someone suggested that they try heating the same steel in a blacksmith's fire. This was done and the steel showed the very finest flanging qualities.

There was considerable mystery about how the heating furnace made the steel brittle, and the lining was cleaned out and rebuilt, after which the sheets came out and flanged without showing any defect. The question then arose, what was the matter with the furnace before it was relined? The question could not well be left unanswered, because the causes that were at work to deteriorate the sheets might become active again. An investigation was instituted. The furnace had been used occasionally for other purposes than heating plates, and it was remembered that phosphor bronze driving-boxes, about to be broken up for melting, had occasionally been heated in the furnace where they could readily be broken. No doubt, pieces of these boxes had accumulated in the furnace.

To find out whether or not this substance would exert a prejudicial effect upon steel, a piece of good steel was heated and ground phosphor bronze sprinkled over it. The steel acted then as if it was rotten. It had absorbed sufficient phosphorus to destroy the metal. This railroad company are now very careful to keep phosphor bronze away from all fires and furnaces where steel is heated.

## A New Throttle Valve.

A new double throttle valve is shown herewith that has recently been brought out by the Schenectady Locomotive Works.

As will be seen at a glance, two small, double-seated balanced valves are used instead of one large one; the levers are so arranged that one valve is opened entirely before the other one leaves its seats.

The picture shows the right hand valve wide open, the left one closed. It will be seen that the cross-arm connecting the two valves is not lifted from the center, but from a point nearer the right valve; when this valve is opened, the cross-arm strikes a lug on the valve casing, and a further movement of the throttle will open the left valve.

This admits of a very slight opening of the throttle to move the engine, etc.

It is hoped that this valve will be easier to keep tight than the usual one of large diameter, and be much easier handled.

New Throttle.

The Philadelphia & Reading road have in service at the present time a number of locomotives which have nozzles equal in opening to a single tip 10¼ inches in diameter. These engines are fitted with the Smith triple-expansion exhaust-nozzle of the improved form. Mr. Smith's original nozzle had twenty-four passages in it—the new one has but four—two for air and two for steam. These pipes were put on the Reading road solely to prevent fire and this is accomplished to a wonderful degree. Mr. Paxton, superintendent of motive power, says he has personally investigated the matter and gone out on the engines at night to try and find fire, but has failed to do so. One of the engines fitted with this pipe has recently pulled the heaviest train ever hauled over the road. The opening of the nozzle was larger than the passage through the saddle. From a number of experiments that we have seen recently we are satisfied that there is something in the principle on which Mr. Smith makes his pipe that deserves a thorough trial at the hands of our best railroad men. The original pipe did good work but stopped up badly—we know of pipes that have been running ten months now without clogging

The Eugene V. Debs Publishing Co., of Terre Haute, Ind., will soon bring out in book form, "Simple Lessons in Drawing for the Shop," by Orville H. Reynolds, mechanical engineer of the N. P. Ry., formerly contributed to the columns of this paper. These articles tell in plain language how to learn to make good working drawings with a ten-dollar set of instruments, and ought to meet with an immense sale in this country where there is a chance for every shop man and apprentice who tries to get up. The same concern will also publish "Locomotive Running Repairs," by L. C. Hitchcock, general foreman of the "Soo" shops at Minneapolis, the last article of which appears in this paper. There has never been a practical book on running repairs gotten out, and this work from the hands of a practical man has been highly appreciated and will doubtless meet with a large sale. Both books will be fully illustrated and gotten out in a substantial but cheap form.

## Articles in Pressed Steel for Railways and Car Construction.

Made to Interchange with any Standard.

**Office & Works, PITTSBURGH, Pa.**
Western Office, 523 Phenix Building, Chicago.
Eastern Office, 909 Drexel Building, Philadelphia, Pa.

**Pressed Steel Drawbar Attachment.**

Our Pressed Steel Drawbar Attachment commends itself to all for its simplicity and strength.

**Pressed Steel Stake Pockets.**

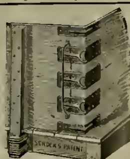
*For Gondola, Flat and Coal Cars.*

No change whatever is necessary in substituting steel pockets for cast iron, as we make them to interchange in bolt-hole centers and inside dimensions.

**Pressed Steel Corner Bands.**

*For Gondola and Box Cars.*

Our Pressed Steel Corner Bands, as shown in cut, are heavily embossed. The inside corner bands are ribbed the opposite way so that they may lay flat against the timber. Besides being very strong, they add materially to the appearance of the car. At about the same cost as common wrought-iron bands.

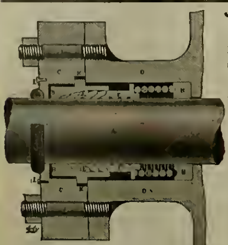


**Pressed Steel Center Plates.**

Made to interchange with present standard

By the use of our articles the weight of your car will be decreased from 800 to 1,200 lbs. The cost of repairs reduced to a minimum. All without material increase in cost of construction. We will be pleased to give full information and quote prices upon application.

# JEROME METALLIC PACKING.



STANDARD.

This Packing is the Standard Metallic Packing all over the world and is now more generally adopted and in use on more Locomotives than any Metallic Packing in use. Give the JEROME a trial and be convinced. Put it in competition with any other Packing and be convinced of its superior merits.

OFFICE AND WORKS:

## A New Method of Keeping Up Air-Brakes.

The Boston & Albany is one of the few roads in the country that tries to get the best results, regardless of expense. When anything is proven to be best for their conditions it is adopted then and there.

Recently, the motive-power department has been trying to devise a system of air-brake inspection and reports that would prevent a road failure of the brake, and require the least work and trouble of those who were responsible for its success.

To this end an air-brake inspector was appointed, who had authority to order all needed repairs and changes, and provision was made for a report to the superintendent of motive power of all defects, no matter how slight.

A list of the usual ailments was prepared, and each disease numbered. This sheet reads as follows:

WESTINGHOUSE AIR-BRAKE EQUIPMENT.

It is very important that the air-brake equipment on locomotives should be maintained in the best possible manner. To accomplish this, the standard of inspection must necessarily be high; therefore, to help you to bring the equipment up to this standard, the following defects, when they exist, must be reported by engineers and inspector of air-brakes on blanks furnished them for that purpose.

1. When, with 125 pounds steam pressure, the 8-inch pump will not compress from 20 to 70 pounds pressure of air in main reservoir at the rate of 200 cubic inches per second.
2. When air-valves have not proper lift.
3. When lubricator is not working properly.
4. When the brake-valve handle is not working easily, and the stops, for various positions of handle, cannot be readily distinguished by feeling, as the spring on the handle approaches them.
5. When the engine is not coupled to cars, and the main reservoir pressure equalized with auxiliaries, the brake-valve handle cannot be placed in "running position" and left in this position without the brake setting.
6. When, on account of leaks, a reserve pressure of 15 pounds cannot be maintained with brake-valve handle in "running position."
7. When feed-valve spring does not hold a reserve pressure of 15 to 25 pounds in main reservoir.
8. When rotary-valve leaks so, with brake-valve handle on "lap," that it will release the brake after it has been applied, with a reduction of 10 pounds or less. This applies to engine alone.
9. When the piston-valve does not move freely, and close tight, with handle on "lap," after applying brake with a train.
10. When locomotive brakes are applied, with a reduction of 20 pounds of air, and will not stay on at least five minutes and hold the shoes rigid against the wheels.
11. When the driver-brake piston travel is less than 2 or more than 5 inches.
12. When the tender-brake piston travel is less than 6 or more than 10 inches.
13. When any of the levers strike or catch on tender or truck frame, or the levers or pistons do not return promptly to their place after air is released.
14. When any of the brake-shoes, heads, rods, hangers, levers, safety-chains or hooks are lost or broken.
15. When steel brake-beams are bent more than 1 inch out of horizontal line either way.
16. When the black hand of air-gauge is at 70 pounds, and the brake-valve handle in full release position, the red hand shows a difference of 5 pounds or more.
17. When governor stops the pump 3 pounds either above or below 70 pounds.
18. When the governor requires a reduction of more than 5 pounds before admitting steam to pump.
19. When there is not a plug-cock in brake-pipe to cut out engineer's valve, when more than one engine is used.
20. When there is no drain-cock in main or auxiliary reservoirs.
21. When a pipe and cock are not provided from tender cylinder to foot-board of engine for releasing tender-brake.
22. When there is no oil-cup on those driver-brake cylinders placed next to the firebox.
23. When the rear end of tender is not supplied with a hose having a good gasket, also a dummy coupling.
24. When the forward end of engine is not supplied with same equipment as rear of tender.
25. When a spare hose is not carried, and in good condition.
26. When safety-valves are used on the main reservoir, or any part of the piping.

A. B. UNDERHILL,
Supt. Motive Power.

*Springfield, March 1, 1892.*

Now, when a train comes in with any defect, say, 11 and 17, the air-brake inspector fills out a blank furnished, as follows:

DAILY REPORT OF AIR-BRAKE SERVICE.

.......... ..........189

To A. B. Underhill, Sup't Motive Power,
Springfield, Mass.

Number of engine.......................
Engineer.......................
No. of cars in train.......................
No. handled by engineer.......................
Left.......................M.
Arrived.......................M.
Condition of brake on engine, "*Defects 11–17.*"
Remarks.......................
.......................
.......................
Inspector of Air-Brake.

This goes to the superintendent of motive power, and is a short and complete report, easily filed and taken care of.

Blanks are furnished for engineers to report the condition of their brakes, and it is not necessary to describe the defect, but to simply put an X opposite the printed report of work needed. Here is this blank complete, it is the best thing of the kind we have seen

BOSTON & ALBANY RAILROAD.
*Motive-Power Department.*
REPAIRS TO AIR-BRAKE EQUIPMENT.

To foreman of engine house at..........

Pump.—
- Will not run.
- Will not compress air fast enough.
- Pack upper stuffing-box.
- Pack lower stuffing-box.
- Does not get oil enough.

Throttle-valve.—
- Needs grinding.
- Needs packing.

Regulator.—
- Needs to be adjusted. X
- Requires too great a reduction of air.

Air-gauge.—
- Needs to be tested.

Engineer's brake-valve.—
- Handle moves hard.
- Rotary-valve leaks
- Piston-valve leaks.
- Feed-valve leaks.
- Handle spring is weak or broken.
- Reserve pressure is not right.

Piston travel.—
- Too much—tender-brake cylinder.
- Too much—driver-brake cylinder. X

Leaks.—
- Driver-brake leaks off.
- Tender-brake leaks off.
- In brake-pipe—train line.
- Between pump and engineer's valve.

Hose.—
- Defective at rear end of tender.
- Defective at forward end of engine.
- Defective between engine and tender.

New shoes.—
- On driver-brake.
- On tender-brake.

Brake cut-out.—
- On tender, on account of..........
- On engine, on account of..........

Miscellaneous.—

Engineer.................. Engine, No..........
Date..................189

Note.—Mark X in margin opposite repairs needed.

Tired runners will appreciate the X scheme. What is the matter with a report of engine-work on the same plan, especially where they are chain-ganged?

---

A special train of vestibuled cars designed throughout on the American plan has been built for the Emperor of Germany. Some of the German roads are also introducing vestibule trains and dining-cars for ordinary passengers. This is likely to lead to a revolution in the design of European cars, for a dining-car is of little use if the passengers from the whole train cannot obtain access to it while the train is in motion, and the American plan of car construction is the only one that provides means of free intercommunication throughout the train.

---

At the annual meeting of the directors of the Consolidated Car-Heating Co., at Albany, on June 7th, the secretary reported large sales of heating equipment, averaging $1,000 per day for the year, and a dividend of 1½ per cent. was declared.

## Driving-Box Brass Jack.

The engraving shown herewith represents a new tool just put on the market by Watson & Stillman, of this city. It was especially designed for putting in and taking out brasses of locomotive driving-boxes, but is admirably adapted to a large variety of railroad work. The operating power is a 20-ton base-style hydraulic jack of special make, mounted in the upper platen, with the cylinder and base counterbalanced; and, as the operating lever in regular jack would be too high for convenient manipulation, a special jack is used and a device is attached to the rods, and at this position the jack is operated the same as it would be at the jack proper. The movement is 12 inches and the full opening between the lower platen and the bars is regularly 18 inches. The lower platen is made 30x48 inches and has a hole 4 inches in diameter through its center for forcing work through when the plug which fills it is removed. The counterweight is so situated that it is not in the way, and is held in place when moving the press around the shop. The truck-wheels are 8 and 10 inches in diameter by 3 inches face.

The Long Island have just put into service ten new suburban and three switching engines. The suburbans are Baldwin compounds.

## Wanted—A Better Paper.

The demand for educational mechanical papers is well illustrated in the following letter from Mississippi. It is published *verbatim*:

WATER VALLEY, MISS,
May The 16 | 92

Edctors and Propriter off the LocomotiVe engineer Sirs

I Cannot Say that your Paper has Ben Interesting to us at All and Can say that we learnt But little from its Collumons while you Publish Some facts that is wourth while Reading thare is the Biggist Potion of your littel Paper Dewelling on the Most Commo news In the Countery from the Rio grand to Paciffic slope

And thare has Ben lots of articils Published & your Paper that was not admired By Rail-Rood employes through out the land and you Mintion In your notice of Renewal that Rail Road men Seldom Read nothing Bitter than the Police Gazett and I for one look upon the Paper Spoken of far Superor to the Locomotive Engineer for it is knowen By all that the Police news is one of the Beast Spoarting In the Continent and spoart is all that is Expected of it while you Claim that your Paper is the Beast mecanical Paper out and for the Past months your Paper has Ben full of Artecils that was a shame to waste good Paper with Print So now I wish that I Could Sit Down and have a long talk with you and Refreash your memory of the Past and show you whare you have taken the wrong steap In life that is what of out your Publication matters I do not like your style of writing at all as for me I dont want to hear you Discuss nothing like you have Ben Discussing I should think If you would Discuss matters on the Political matters of the Day and lit By gons Reast you you would Come a Grade deal Better In the futher So we do not want your Paper no more, feeling sorry for the field you have Ben laboring In for the Pas year

We Remain Truley
J. R GOFFENY
W. G. RAY
JAS. B. TUCKER
Water Valley Miss

This trio have their names all signed by one hand, but evidently don't appreciate this paper. If they can be induced to even read a good "spoarting" paper, the company ought to buy it for them. We were awfully broken up when we got this withering letter and have worried about it nights for fear it would get out that three such men washed their hands of us, the only thing we can do in the case is to publish the paper for the thousands who do appreciate it (devoid of *spoart* or politics) and patiently wait for the Kintergarden to get in its work on these truants.

---

Engineers know something once in a while: they know a thing when they see it and feel it, anyway. Not long ago, Supt. Vreeland, of the N. Y. C. & N., bought a carload of Wyoming coal of good quality, but had it shipped in the same cars as the cheaper grade in use. He did not even tell the master mechanic. It was carefully watched and noted what engines were equipped with it. The next day he met one of the engineers, who said "Say, Mr. Vreeland, I got a tank of mighty good coal yesterday—best I ever saw you buy. Made a round trip with the tank and had some left. I could run on two tons a day less with that kind of truck." "You're off," said the super., "just cleaned your nozzles, or the fireman was careful, or something; there's no record of any different coal than usual being bought." "I don't care for the record; that coal was better; it burned something like Wyoming we used to get on the Delaware in '67." During the week every man but one who had tried the coal came and spoke about it, and that one gave the coal-heaver a cigar and asked if he didn't have some more of that coal with the little red streaks in it.

## NEW BOOKS.

BOYD'S BUSINESS DIRECTORY OF PHILADELPHIA FOR 1892. C. E. Howe Co., 234 South 8th st., Philadelphia, Pa.

This is the usual business directory with the addition that it contains the residence of all the business men as well as their office address. It contains upward of 1,500 pages.

## Trip Reports in New South Wales.

Some of the men in this country think they are bandaged with too much red tape, but they can thank their lucky stars that they are not the worst off in this respect. One of our interested subscribers in Australia sends us a blank trip report used on the road on which he is employed.

x

| STATIONS. | Miles. | Arr. H. | Arr. M. | Dep. H. | Dep. M. | Particulars of Time Lost. At Stations | By Signals. | By Loco. | Other Causes. | Load. Attached. Wagons. Empty. | Loaded. | Carriages | Detached. Wagons. Empty. | Loaded. | Carriages |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

[Here follow thirty-four blank lines.]

Time lost by Locomotive

(Date)............189 . (Signed)............Guard.

NOTE.—The Guard must fill in this Statement of the running of his Train, and at the end of his journey hand it back to the Driver.

The sheet is 8¼ x 13¼ inches, with a form on each side.

Observe that the driver must hand the blank to the guard before starting and receive it before detaching his engine from the train. This seems a very cumbersome document compared with our neat little bound slips 3 x 5 inches.

But the Australian is noted for his fair and square dealing—he is the inventor of the best mode of balloting—and this document prevents conductors and engineers lying about the delays. The guard is not going to put down delays to "engine not steaming" unless it is true—for the engineer sees his report. We have reproduced both sides of the blank, full size, leaving out the blank lines.

---

The pamphlet on "Economy of Way," by Benjamin Reece, has been in such demand by a great many railroad officials for distribution amongst their trackmen, that a very large second edition has been ordered, and the Q. & C. Company, 703 Phœnix Building, Chicago, Ill., will send them to any officials desiring copies that have so far not been provided with a sufficient quantity.

---

Pedrick & Ayer, of Philadelphia, are busy at present on several larger sizes of the Richards open side-planer. They are making one for Geo. B. Cresson, of Philadelphia, that is to plane a piece 42 inches wide and 12 feet long. They are also building one for the Detroit Electric Works, to plane 30 inches by 10 feet.

A two-car special was recently taken over the Chicago & Northwestern pretty lively. From Chicago to Cedar Rapids, 220 miles, was made in 4 hours and 30 minutes; 3 hours and 54 minutes actual running time, or at the rate of 56 miles per hour. This work was done from Chicago to Clinton, 138 miles, by engine 274, an 8-wheeled 18x24 engine, with 68-inch wheels, built at the company's shops. Engineer Geo. Murdock had hold of her crank. From Clinton to Cedar Rapids, 82 miles, the train was pulled by engine 663, a Schenectady, same size as the 274, in charge of Engineer "Andy" Sloan and Fireman C. M. Goodrich. The men on the road give these crews great credit for their run. Murdock had not been over the division on which he ran for 13 years, and Sloan had made 113 miles on freight with the same engine that day. Part of the track was new and soft from the rains. Andy says he will throw the 663 over this 82 miles of road in 75 minutes just as soon as it is in good shape and they give him a show.

---

A committee of the Master Car Builders' Association, appointed to investigate the steel-tired car wheels and report on the same, made a report that about 25,000 of such wheels are in service. Most of the information received relating to defects of the wheels was about the tires. There was little said about defective centers, but the committee found that none of the bolted centers are entirely free from trouble with loose bolts.

## The Oirish Debater.

"Years ago, when I was running on the Little Miami," said the visiting member from the South, "we had a green brakeman in our crew.

"One dark night he had to go back and flag in a piece of dense woods, and as he stood among the shadows, a little uncomfortable for the gloom, an old-man-owl sitting on a limb near by called out:

"'Whoo, whoo?'

"'Patsy Considine, sorr,' answered the gafter, promptly.

"'Whoo, whoo?' inquired the owl.

"'Oi'm brakin' behind for Jerry Patterson.'

"'Whoo, whoo?'

"'Oi live in Xenia, if that's phwat ye want to know.'

"'Whoo, whoo?'

"'Me father woorks in the gas house.'

"'Whoo, whoo?'

"'Oi'm a brakeman, Oi tell ye, an' Oi haven't a dommed cint, so there.'

"'Whoo, whoo?'

"'Howly Mother, phwat is it ye're hunting for. Oi belong to Father Ryan's —'

"'Whoo, whoo?'

"'Well, be jabbers, if ye want to git me bio-graphy yez can inquire of the trainmasther, who kapes tab on me purson-nal ree-cord; dommed little information ye'll be gittin' from Patsy Consi—'

"'Whoo, whoo?'

"'Ah, go t' th' divil wid ye. Phy don't yez come down forninst me loike a man, an' Oi'll—'

"'Whoo, whoo?'

"'"Hoo, hoo" yersel', ye dorty backbither of a —'

"'Whoo, whoo?'

"'Ax me back.'

"'Whoo, whoo?'

"'Oh, go to hill; Oi'll answer no more of yer foolish questions. If Oi cud git me two oyes on yer durthy mug, Oi'd putt ye in mournin', so Oi would.'

"'Whoo, whoo?'

"'Phwat's der matter wid yer, Patsy?' yelled Patterson, as he came up with his lamp, 'phwat are ye doin' talkin' to yersel' an' quarrelin' wid owls an' bats; come along wid ye, we've bin phwistlin' yez in for the past quarther-hour!'

"After that the boys called Patsy the Oirish debater,' and finally shortened it to 'Parnell,' and 'Parnell' he is to this day."

## Doc. Kellgore—Swiper.

'Talkin' o' liars," said the old-timer, borrowing a sniff of snuff from Pap Snow, "Talkin' o' liars makes me think o a thief I had onct out at the front on the 'Park.' He watched the engine nights. He were a youngish cuss from Kansas City, an' his dad bein' a doctor we called him Doc. He was the worst thief I ever see. He stole handkerchiefs from every passenger conductor on the road—'swiping a wipe,' he called it.

"The canaries (we had about sixty of 'em) used to wash their clothes on Sunday, and Doc never failed to get the best pair o' socks that were hung out. They would put 'em on the bushes to dry, and Doc would look down there and say:

"''Pears to me I see red socks on them vines, when socks is red they is ripe. I gather my fruit when ripe. Swipes, old boy' (he allus called hisself Swipes) 'git in yer work.'

"An' I want to take an' tell you right now, that it didn't make any difference how many 'tarriers' was a watchin', he'd get the socks all hunky.

"We were at the end of the road, and not in a very good position to draw supplies, but Doc 'found' the 30 and her crew. Every day or two we would find new oil cans, a new scoop or a new slash bar. We had an old, small-sized headlight, and Doc tried every reflector on the road in it, but couldn't make it go. This was one of the sad things of his life.

"Onct I had to go to the shop, and the machinists found thirteen packing wrenches on her. I come near gettin' fired for that.

"One day when we were about a mile from Buena Vista, Doc he says to me, says he, 'Baldy, old man, I'm a-going to walk up to the city; is there anything your heart desires for the 30, for if there is you know that Swipes will reach for it?'

"'Well,' says I, lookin' down outen the cab, 'yes; I think it's a sorter an ornery, no-'count watchman that can't git a lookin'-glass for the engine he takes keer of.' Dock went off laffin'—he was a norffel good-natured soul.

"Well, gentlemen, that evening I were sittin' on the front buffer readin' a week-old paper an' a pryin' up a hunk o' bull beef from between my molars, when Doc showed up with a big bundle.

"'Now let up on yer darn kickin' about a lookin'-glass to admire your whiskers in,' says he, 'here you are: compliments o' Swipes.'

"That young cuss had a lookin'-glass about fourteen by thirty inches square, a soap dish, bar of soap, four towels, a comb and brush with about four feet of brass chain fast to each, and one of them foldin' hat racks.

"'I'd a got the tub, Baldy, but she was fast to the wall, but I hope you wont hold that out against me,' says he.

"The young villain had taken a bath and then threw everything out of the window but the tub. He felt kinder beat out about not gettin' that, and was minded to go back for it, but I talked him out of it."

## The Change that would Make Her Steam.

Ed. Woods is an engineer on a northwestern railroad. He is one of the men who knows his business and runs his engine with full authority over the whole machine. Ed. is a good engineer to fire for, but he quietly asserts his authority when it comes in question, and there is never any mistake as to who is running things on the machine when Ed. is at the throttle. Things were rushing on the road some years ago, and the master mechanic was hiring nearly everything that came along calling itself an engineman.

A fireman of the genus tramp was assigned to Ed. Many tramp firemen are first-class men if they can be induced to let whisky alone, but this Abe Funk was of the kind who have to go searching for jobs because no man will put up with them for more than two trips.

After they started out the engine steamed badly. The fireman was one of the class that fill up the firebox and then climb on to the seat for twenty minutes' devotion to the god of idleness. Ed. several times stopped the over-loading of the firebox and gave directions how he wanted the engine fired, but Abe paid little attention. He had points that might have made him a success in a political-run town, but as a fireman he was a failure.

As the steam pointer crawled steadily toward zero, Abe appeared bound to make some remarks, so he went over to the right-hand side and made some disparaging remarks about the engine and the engineer.

"If Neil Blount, of the Wabash, was running this scrap heap, you bet your best brogans he would make her steam. There was never no busted kettle got away with Neil. Why, pard, Neil would make an engine steam when the biler was so full of mud an' scale that ten buckets of water would choke her to the whistle"

"Won't you add about two buckets to that count?"

"Nary a bucket."

"How did Neil manage?"

"Manage to make a bloomin' washtub steam? He was up to all kinds of tricks. No cripple mill could get ahead of Neil. He'd change the petticoat pipe, and if that didn't work he'd change the traps, and if the trap didn't steam after that he'd change the smokestack. You bet, Neil would change things till they were just right."

"Well, I can make this engine steam with very little change."

"Is that so, pard? I wish you would do it right away."

"Yes, I shall do it when I get in. It is a very simple job. I shall change the fireman."

## A Limerick Engine.

One evening last winter the pay-car of the Lake Shore & Michigan Southern arrived at Adrian and the venerable paymaster sent out notice that he would hand out the greenbacks to engineers, firemen and other trainmen. In the line that formed outside the pay-car was Tim Gaffney, an old engine-house sweeper. When he reached the inside, the paymaster objected.

"Why, Gaffney, you are not an engineer."

"Beggin' yer pardin," said Gaffney, "it's meeself as is the furst kind av an engineer."

"What kind of an engine do you run, Gaffney?"

"Well, sur, Oi run a Limerick engine, wid two stharting-bars and ime whale."

Gaffney got his money.

## How Revolutionizing Inventions Worry Railroad Officials.

A wild-eyed inventor of a life-saving (?) and train-paralyzing device recently sat in the holy of holies and told us that the measly railroad officials of this country would rather go howling down the grade of time a menace to the traveling public than to make everybody as safe as Pike's Peak by adopting his calamity-coupler. He said railroad men didn't appreciate the inventors of the day, and he said he was an inventor.

We were painfully reminded of the foundation upon which this man's charges were made a few days ago, when there fell into our hands some correspondence between the motive power officials of two big roads:

R. D. W., S. M. P.:

Please note inclosed clipping from the technical column of one of the New York papers.

Its simplicity will commend itself to your mechanical sense of fitness. Now, as one of the traveling public, I have noticed great clouds of smoke from R. & D. engines. If they could all be converted upon this principle, think what a boon you would confer by feeding them on pure, hot oxygen!

In another paper I find the following explanation of the benefits of such treatment. "Oxygen is to hydrogen as pure gin is to water and gin."

Hoping and trusting that I shall soon see all of the smoky, dirty R. & D. engines altered on this principle, I remain,

Yours truly, A. W. G.

*Savannah, Ga.*

THE ITEM.

Another arrangement for securing a smokeless locomotive is announced, there being no smokestack, but the exhaust opening is left full open to the area in the saddle casting, the stack and saddle are taken off, and the stack opening increased to twenty inches in diameter. There is placed over the exhaust and lifting-pipe, twelve inches at the bottom and end, tapering to fifteen at the top, and forty inches long, a sheet-iron pipe, and this pipe, twenty inches in diameter, sets over that resting on top of the extension front. Over this is the ordinary dome-casting. This casting is perforated with 2,000 $\frac{1}{16}$-inch holes extending half around the casting, and in the forward compartment is located a pressure-blower in such position as to admit free action to the flue-sheet; the pressure-blower is connected by direct friction to a small rotary engine, and is also connected direct by an air-pipe extending from the front end of the engine back under the truck of the locomotive to the ash-pan—the ash-pan and dumpers having asbestos joints and shutting firmly, thus making the ash-pan air-tight. The air from the fan, drawn down through the perforations, is heated to a high temperature by exhaust-steam and heated gases. The result is, by this method, a fire is fanned by a constant blast of pure, heated oxygen of seven-ounce pressure, this air being made hot by the heat that would otherwise be wasted. Circling the firebox door are innumerable small holes or air-jets. Hot oxygen uniting with carbon forms a gas, completes the combustion, and prevents all smoke

E. M. R., L. M.

Inclosed find clipping from the technical column of a New York paper, by which you will see that the problem is solved—at last the smokeless locomotive is born! Your attention is called to the singularly clear and full explanation of the devices for preventing smoke. The writer is a genius.

A. W. G., as you will notice from his screed inclosed, discovered this measure, and now that he flocks by himself, makes this audacious fling at his old nest. I think he is brooding over the recollection of an inspection which was made over his road, and the comments thereon, when the smoke was so bad that the sky was darkened and the chickens went to roost.

Yours truly, R. D. W.

*Atlanta, Ga.*

There were some queer rules and practices in the early history of railroading in this country, but there were few oddities that beat the old wrecked-coal law of the D., L. & W., done away with but a few years ago. By this finding, all coal spilled off cars in transit, by wreck or otherwise, belonged to the train dispatcher. If a car pointed its nose down the bank, the dispatcher assisted it all he could, and dispatchers managed to get to wrecks and have their say. After a while the dispatcher was required to "divvy" with the operator, and finally the company took the whole business.

The electric traction people are after the New York Elevated Railroad Company again. Several years ago the Field crowd tried to substitute their motors for the locomotives, and they were followed by the Daft Co. and then by the Sprague Co. Other interests are now trying to obtain the opportunity of demonstrating what they can do to operate the elevated railroad trains by electricity. If they can prove and guarantee that the cost of operating would be less, and that the work can be done expeditiously and with perfect reliability, they are likely to have the opportunity of operating the trains.

On June 11th, Richard Tremain, government boiler inspector in New York City, died. "Dick" Tremain was for many years general foreman of the N. Y. C. & H. R. shops in Syracuse, to which city his remains were sent for interment.

(62) J. T. W., Willard, Texas, asks.

"Do very loose side rods have any effect on the power of locomotives?" *A.*—No.

(63) M. M. & M., New York, asks.

What is the correct spelling of the word spelled pein, peen, pene, etc.? What does the word come from? *A.*—The correct spelling of the word is pene. It is derived from the root *pen* to thrust in, and belongs to the same class of words as penetrate.

(64) J. A. C., Nashville, Tenn.

No; an advertisement in this or any other paper for a position as locomotive fireman, you being inexperienced, would do you no good. There are too many men applying direct for the work. Reach the M.M. of some road through an engineer or shopman.

(65) C. A. M., Paterson, N. J., asks:

What is the rule for figuring the horse-power of a boiler? *A.*—In stationary boiler practice with ordinary draft it is usual to figure about 15 square feet of heating surface to the horse-power. With forced draft much less surface will represent the steam-making capacity for a horse-power.

(66) W. W. Clements, Raleigh, N. C., asks:

What keeps piston 17 in engineer's brake and equalizing-valve on its seat? *A.*—More air-pressure above than below seat; the valve of its own weight and the friction in its case prevents its rattling around. In order to lift it the pressure below must be enough greater than that above to overcome this weight and friction.

(67) J. A. N., Northampton, Mass., writes:

We had a steam-pipe collapse on this road; the engineer had the throttle open when it was done; it flattened it the whole length. What caused it? *A.*—Pressure was greater than the strength of the pipe, which had probably been weakened in some way. It often happens that the pipe flattens the whole length, as when any part loses its round and strong shape it is shut up in a wave.

(68) J. A. M., Albany, N. Y., says

Is there any State in the Union where locomotive engineers are required to have a certificate before they can run, and would a man smart on figures, be likely to get along quickly in such States? *A.*—We believe that a certificate is required in Alabama, and perhaps in other States. We should not advise any one to go expecting a job on the grounds of being able to pass the examination required.

(69) A. M. R., Brooklyn, N. Y., writes.

I have been in charge of stationary engines for three years, and always used tallow for valves and cylinders, and I never found any thing better. I am now firing a locomotive and find that they use oil which is not nearly so good a lubricant as tallow and is more expensive. Why do railroad companies pay more for an inferior material? *A.*—Tallow was abandoned by most railroad companies because it contains an acid which corrodes the cylinders. Good valve oil is as economical for lubrication as tallow.

(70) A. C. G., Beatrice, Neb., asks:

Please let me know through your valuable paper how much difference one notch in the quadrant makes in the admission of steam? In other words, if the reverse-lever is placed one notch back on the quadrant, how much difference will it make; at what point of the stroke will the steam be cut off, in inches or fractions of an inch? *A.*—There is no fixed rule; it used to be customary for builders to mark the quadrant; the point of cut-off for each notch. Most builders now make as many notches in the quadrant as can be gotten in. An extra notch on the quadrant may mean almost anything—depends on the make of the engine.

(71) J. L. R., Terre Haute, Ind., writes:

I want to know something about metals that melt at low temperature. I am told that some metals melt below the boiling point, and if that is so it would interest several of your readers to hear about them. *A.*—A variety of alloys melt about the boiling point of water or lower. Mercury is a metal which does not become solid until the temperature is 39 degrees below zero. Bismuth 8 parts, lead 5 parts, and tin 3 parts, makes an alloy which melts at about the boiling point of water at sea level. Bismuth 5 parts, lead 3 parts, tin 2 parts and 1 part of hot mercury added makes a metal that solidifies only at 140 degrees Fahr. A mixture of bismuth, tin, lead and cadmium can be made which softens by the heat of the hand.

(72) G. G., Bakersfield, Cal., asks.

1. What is meant by inside clearance? *A.*—When cavity in valve is wider than exhaust-port and both bridges. 2. Which takes place first, compression or expansion? *A.*—Depends upon what part of stroke you commence to count it at; expansion follows admission. 3. What is meant by back-pressure? *A.*—Pressure that retards the piston; compression is back-pressure. 4. What causes an engine's cylinders to squeak hooked up with a very light throttle (more throttle will stop it)? *A.*—When hooked up there is an excessive compression that lifts the valve at each end of stroke; it is higher than chest pressure. 5. Why does the cross-head not occupy the same position in the guides when pin is on the top and bottom quarter? *A.*—It does if cylinder and wheel centers are in line; when cylinders are above the wheel center, the cross-head is pulled back on lower quarter by the increased angle of the main rod. 6. Is it necessary to disconnect an engine with a broken frame? *A.*—Depends on how and where broken.

## Tests of Iron and Steel.

A very valuable report was submitted to the Master Mechanics' Association by the committee appointed to investigate the critical temperature of iron and steel and other questions relating to iron and steel considered of value. The report is peculiarly valuable because its conclusions are drawn from facts ascertained by original investigation. A great many tests were conducted under the supervision of the chairman of the committee, Mr. William Smith, superintendent of motive power of the Chicago & Northwestern. The scope of investigation aimed at demonstrating what was in the claim that iron and steel were brittle at a certain temperature; what were the causes at work leading to the failure of firebox sheets; what is the best material for tubes, and the principal causes of stay-bolts breaking.

The claim that iron and steel are dangerously brittle at a temperature varying from 500 to 800 Fahr., was clearly proved by numerous experiments. It was also shown that iron is fully as brittle as steel at the critical temperatures.

In the examination of firebox sheets it was found that the center of the plate becomes spongy, and that a thin surface next to the fire and one next to the water assumes a consistency different from the center. It was concluded that the part next the fire became permanently expanded, and that this action had something to do with the breaking of stay-bolts.

"It has been claimed that annealing a sheet would restore it to its original condition; with this object in view your committee took a piece of such a sheet, carefully annealed it by heating to a red heat, then placing it between two pine boards and allowing it to remain until cold. The center was then cut out as in the other cases, and the result was the same as with the piece not annealed. This apparently clearly demonstrates the fact that annealing an old sheet of steel does not restore it to its original condition.

"In order to determine the temperature of a sheet in a firebox when the engine is being fired up, an experiment was made with two thermometers located as shown by the accompanying engraving.

"One thermometer was placed in the water space and the other in a drilled stay-bolt, with the bulb at the inner sheet, as shown. The boiler was a stationary vertical one, and was fired with oil and rosin wood. The maximum difference in temperature between the water and firebox sheet, as shown by the thermometers, was about twenty-five degrees.

"An endeavor was made to devise an apparatus that would represent a stay-bolt riveted into the sheet, to be subjected to vibrations in order to determine which material would resist the greatest amount of vibration. The apparatus in which the test was made is shown in Figure 4. This arrangement gives in vibration a full motion of three thirty-seconds of an inch at the end of the stay-bolt, and at the same time allows a stress in the direction of the length of the stay-bolt somewhat similar to that which occurs in boilers, the strain put on the stay-bolt being equivalent to a pressure in the boiler of 150 pounds per square inch. A test was made in this way of four pieces of mild machinery steel; the average number of vibrations before breakage was 21,539, the pieces standing respectively 7,950, 96,060, 14,168 and 54,358 vibrations before breaking.

"Eleven samples of iron were tested in the same way, the average number of vibrations before breaking being 6,568, the lowest being 3,120, the greatest 12,480. The result of these tests would indicate that steel is a better material for stay-bolts than iron; at the same time the experience of a number of members of your committee with steel stay-bolts has been seriously against them. They failed in service, and deductions drawn from the test, as made, are entirely misleading.

"The investigation, as described above, is not sufficient to enable your committee to offer any specific directions for drawing up specifications for iron and steel for firebox purposes, and they therefore have in this particular no definite recommendations to make.

"The results of the investigations so far may be summarized as follows:

"1st. Steel or iron should not be worked at a temperature between a normal temperature and a perceptible red heat.

"2d. So-called 'blue heat' makes steels and irons more brittle, but some are apparently less affected by the 'blue heat' than others.

"3d. The test of steel or iron at a 'blue heat' is not a criterion by which to judge of the action of the same in the firebox.

"4th. Iron at a blue heat is more seriously affected than steel.

"5th. There is apparently a mechanical disintegration going on in plates exposed to the action of fire, water and scale in a firebox.

"6th. Steel tubes do not seem to be as durable as iron tubes."

---

In the Cambria Iron and Steel Works they turn all the crank-pins from solid bars, five or six pins being made from one blank. They have very powerful axles for doing the work, and finish the crank-pinks ready for fitting.

## Various Uses of Compressed Air in Train Service.

By Paul Synnestvedt.

On looking over the pages of one of our leading railroad papers the other day, the writer noticed a number of devices to be used in train service, operated by compressed air from the brake system. Amongst these were train signals, bell ringers, smoke consumers, headlight covers, sand-feeding apparatus, and a device for opening and shutting the firebox door, all of them supplied from the main drum, besides which there were several drawing their supply from the train-pipe, such as car lighting and water-raising apparatus, used on many sleepers, and signal whistles attached to rear-end hose.

The constant increase in the number of such mechanisms brought up the question as to whether this heavy drain on the air-brake system will interfere in any way with the action of the brake itself. One result already apparent is the additional emphasis it gives to the need of a large capacity pump even on passenger trains. Another result is that more knowledge is required on the part of the engineer to avoid difficulty with his brake. These devices are no doubt a great convenience, but the statement of the inventors that they do not take sufficient air to cause a noticeable effect on the brake is not strictly correct, even if, as they say, all that is necessary is to "just break the joint of the valve."

No one has any adequate conception of the amount of air that will escape from such a broken joint until he has experimented with a smoke consumer, that delivers air to the firebox from the main drum through a number of 16-inch nozzles. It takes a pretty good pump to hold the pressure to or above 20 pounds against such an escape port, even with a high steam-pressure, and it would not require many more patent appliances auxiliary to the air-brake to produce nearly as great a leakage from the drum as this.

The next thing in order now is an automatic coal-heaver and apparatus for moving the reverse lever and throttle, and who knows but before long even engineers and firemen will be superfluous?

The amount of air used by these applianres is practically just so much *leakage*, and whether the difficulty encountered as a result of this will be great enough to cause serious trouble with the brake, depends on the amount of the leakage. No engineer need be told that leakage in the air-brake is a bad thing, and if of any considerable extent may cause much trouble. However, it is also known that if an engine is supplied with a pump of large capacity and an accurately working governor, quite a leakage may be permitted without interfering to any great extent with the action of the brake.

I have heard many well-posted men say that a moderate leak was of very little moment, provided it was from the main drum and its connections, and not from the train pipe, but it will be seen on reflection that this is an error, for it is not only a constant drain on the pump, but it will, under certain conditions, result in dragging the brakes.

The moral of this is, not that these conveniences should be done away with, but that when they are used it should be with a pump of large capacity, and a governor in good working order.

---

The "Railway Officials' Directory" is a neat little pocket list of the railroads and railroad men of the country; it is in very compact form, and much prized by supply men who do not want to carry around an immense book loaded down with advertisements. It is published by the *Railway Age*, of Chicago.

---

The C., B. & Q. have ordered 54 locomotives of the Rogers Works. Fifty of them will be moguls.

# Cast Steel Works of FRIED. KRUPP, ESSEN, Germany.

**Represented by THOMAS PROSSER & SON, 15 GOLD ST., NEW YORK.**

These works cover an area of 1,200 acres, employ about 18,000 men, have the most improved plant, and stand unique, from the fact that they have their own Ore and Coal Mines, Blast Furnaces, etc., and that *every* stage of manufacture is under their own supervision, and are not (like others) dependent on the open market for a miscellaneous assortment of crude material, which, in connection with 75 years' experience, enables them to turn out a product of a very superior quality, second to none, and at the same time the different grades of Steel are always of the *same uniform* quality.

**Locomotive Tires, Crank Pins, Piston Rods, Spring Steel, Steel-Tired Wheels, Etc.**

After a test of over 25 years the "KRUPP TIRE" has proved itself the best in the market. If a reliable article is wanted, which will give satisfaction, get KRUPP'S.

# SCHENECTADY + LOCOMOTIVE + WORKS,

**SCHENECTADY, N. Y.**

LOCOMOTIVES OF STANDARD DESIGN FOR ALL CLASSES OF SERVICE,

OR FROM DESIGNS FURNISHED BY RAILROAD COMPANIES.

## COMPOUND LOCOMOTIVES,

**Showing an Economy of 15 to 30 Per Cent. in Fuel and Water.**

**ANNUAL CAPACITY 400.**

## Run of the Cooke Compound Locomotive on the Erie Railroad.

By ANGUS SINCLAIR.

For several weeks during the months of June and July, the compound locomotive recently built by the Cooke Locomotive Works was pulling freight trains on the New York, Lake Erie & Western. The engine was in charge of Mr. Charles D. Cooke, superintendent of the works, and was run by Mr Sam Dunning, the engineer for the builders, taking turns on freight service with other engines. As this was the first compound locomotive built by the Cooke Locomotive & Machine Co., they were naturally anxious to learn how the engine compared in service with other compound locomotives. With the view of getting the opinion of one who has had considerable experience with compound locomotives, President Cooke requested that the writer should watch the working of the engine during some runs, and make whatever tests might be thought necessary in order to find out the capacity and efficiency of the engine

The engine, as may be seen by the annexed engraving, is of the ten-wheel two-cylinder type of compound. The cylinders are 19 and 27 inches diameter, with a stroke of 24 inches. The exhaust steam from the high-pressure cylinder passes through a pipe in the smokebox to the steam-chest of the low-pressure cylinder, the pipe and steam-chest forming a receiver, which has a cubical content about equal to the volume of the high-pressure cylinder. No intercepting-valve is employed, but means are provided for admitting steam from the boiler direct to the receiver, to assist in starting. The device that admits this steam is operated by the throttle-valve, and closes automatically when the throttle-lever is pulled out about 2 inches.

Excepting the arrangements for compounding, the engine is in all respects the same as a group of ten-wheel engines recently built for the Illinois Central Railroad, and conforms to that company's standard. It is a well proportioned engine for cylinders 19 x 24 inches, and 64-inch driving wheels, with a steam pressure of 150 pounds on the boiler As a compound, steam of 165 pounds pressure is carried, but she is not as powerful as the simple engine would be at the lower steam pressure. The boiler is of the wagon top, firebox variety, with radial stays binding the outside and inside shells. The diameter of the boiler at the smallest ring is 58 inches, and a total heating surface of 1766.6 square feet is provided. The firebox is 96 inches long and 42 inches wide, set with the mud-ring above the frames. There is a grate area of 28 square feet.

The valve arrangements are about the same as they would be for a simple engine. The travel is 5$\frac{5}{16}$ inches. The high pressure valve has $\frac{3}{4}$-inch outside lap, and the low pressure valve $\frac{15}{16}$ outside lap. Both valves are line and line inside. The high-pressure valve is set with $\frac{1}{16}$ inch lead, and the low-pressure valve with $\frac{1}{8}$ inch The piston clearance of the high-pressure cylinder is 6.75 per cent., and that of the low-pressure cylinder 11.8 per cent.

On June 29 the writer accompanied Mr. A. E. Mitchell, superintendent of motive power of the New York, Lake Erie and Western, to Hornellsville, N Y., and the following day took part in a test of the Cooke compound locomotive, in the course of a run of 140 miles from Hornellsville to Susquehanna. The work was done under the immediate charge of Mr P. N. Hibbits, mechanical engineer for the railroad company. A record of the coal and water consumed was kept and indicator diagrams were taken at intervals.

A train of seventy-six empty cars was hauled all the way, the total tonnage including engine being 881.1. The road is nearly level all the way and the train was considerably within the capacity of the engine. A number of diagrams were taken when the engine was starting the train, the pencil having been pressed to the drum at the time the throttle was opened and kept on till a good start was made From these we found that the method of admitting boiler steam to the receiver worked satisfactorily. This direct pressure was reduced down to about half the pressure of the boiler, so that no excessive back-pressure was encountered by the high-pressure piston. The high and low-pressure diagrams, Nos. 1 and 1a, were taken in starting, and show the maximum tractive-power developed by the engine. This is a little over 12,000 pounds. The simple engine carrying 150 pounds boiler-pressure would exert more than 1,000 pounds additional traction, which shows the necessity for a compound locomotive carrying extremely high-boiler pressure. This appeared to be the only weak point the engine had, and it is one that can easily be remedied. The diagrams shown give a fair representation of the way the engine was worked in taking the train along Cards 3, 4 and 5 were taken in the notch where the most of the work was done. The steam follows the high-pressure piston about 65 per cent. of the stroke. In all the low-pressure diagrams there is a falling off in the steam line immediately after the beginning of the stroke until the period that high-pressure exhaust takes place, when the low-pressure steam line holds up and even inclines to rise. As the links are hooked up, the steam is admitted more evenly to the low-pressure cylinder. The best distribution of steam is shown on diagram 6, where the high-pressure valve is cutting off at about half-stroke. It will be noticed that a decided increase of lead would be likely to improve the low-pressure diagrams

The following are the leading particulars of the diagrams. The throttle-valve was full open when all the cards were taken.

| No of Card | Boiler Pressure | Revolutions Per Minute | Reverse Lever Notch |
|---|---|---|---|
| 1. | 164 | 80 | 1 |
| 2. | 160 | 120 | 3 |
| 3. | 162 | 156 | 4 |
| 4 | 166 | 108 | 4 |
| 5. | 156 | 128 | 4 |
| 6. | 161 | 140 | 5 |

The run of 140 miles was made at an average speed of 20½ miles an hour. The time lost at stations was 3 hours. In doing the work 15,005 pounds of coal was consumed and 98,100 pounds of water was used This was an evaporative duty of 8.6 pounds of water to the pound of coal

The total weight of the engine is 128,500 pounds, of which 97,000 pounds are on the drivers and 31,500 pounds on the truck.

Figures which I have received of other trips made by the engine show that in four trips the coal used per ton-mile was .094, .12, .09 and .07 pounds respectively. That is very low, even for trains of about one thousand tons weight.

IMPRESSIONS OF THE ERIE RAILROAD.

The whole of the front platform of the engine was surrounded by close panels about five feet high, which made an excellent protection for the men taking diagrams and gave convenient means of access from one side of the engine to the other. The place also afforded an excellent "coigne of vantage" from which to view the working of the railroad and the beautiful scenes we were passing through.

The writer sat in that box nearly ten hours, and the impression received, as a result of very close watching, was that the Erie was one of the best operated railroads he had ever seen. All the main line is double tracked and has block signals the entire length. The division we passed over has broken slag ballast and as fine a track to ride on as there is in America. Everywhere along the line there are evidences of the whole working staff performing their duties with vigilance and care.

It is well known that of late years this road has been remarkably free from accidents. The cause of this can readily be seen in the business manner in which the men responsible for the safety of the trains perform their duties.

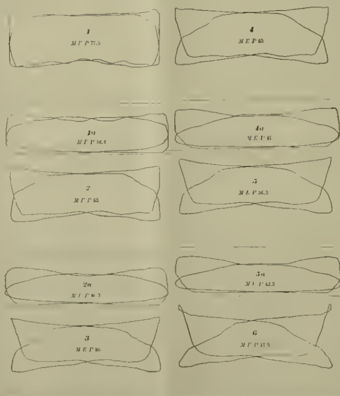
The block system is absolute for passenger trains and permissive for freight trains. That is, no passenger train is admitted into a block until the latter is perfectly clear and no other train is permitted to enter a block while a passenger train is in it. As the blocks are too long to move freight trains in this way without delaying the traffic, all other than passenger trains are worked by the permissive system. This permits two or more trains to be in a block at once under certain restrictions. If a freight train arrives at a block tower before the preceding train has got off the block, the signalman cannot lower his signal but he puts out a green signal which gives permission to the engineer to proceed with caution. When trains are stopped between stations the rules for protecting the rear are carried out as rigorously as if there were no stationary signals employed for the protection of the trains. In the course of the trip we saw repeatedly examples of how strictly the trainmen obeyed the rules respecting flagging. There were other evidences of the zeal of the men in striving to prevent accidents even in cases where rules were not the origin of their actions. When we entered a block where there was another train in front and met a train coming from the other direction the enginemen invariably gave signals that caution was necessary.

The officers in charge evidently do their best to keep alive that every-day vigilance so necessary to prevent accidents and so difficult to maintain in constant vigor. But their efforts are made comparatively easy by having an excellent class of trainmen. There were in all directions evidences that the *esprit de corps* of high and low is exceedingly good. It is a remarkably healthy sign when all classes of men, from the brakemen upward, are heard boasting about their road.

The country traversed is well worth writing about. I have traveled over all the leading railroads in America. There is no attractive route in the British Isles that I have not examined, and I have done considerable traveling on the continent of Europe. After seeing all the beautiful and attractive scenes that this experience yields, I am firmly convinced that the Erie Railroad, in its route from Jersey City to Buffalo, traverses the greatest variety of beautiful scenery to be witnessed on any single railroad. And yet the traveling public hears little about the scenic attractions of this magnificent route.

From Hornellsville to Susquehanna the line traverses a series of valleys with wood-covered hills on each side, that are always pretty and at times rise into impressive grandeur. All that make scenery attractive to the eye are present in their most alluring forms. Mountain, stream and lake, smiling fields round prosperous farms, shady woods and beetling rocky crags, all combine to form pictures of beauty and sublimity. Only one thing is wanting to make some of the regions traversed as attractive as the Trossachs—the romance of human association and the bard to people the scenes with life and reminiscences.

Between Waverly and Elmira, in a spot where the railroad follows the banks of that noble river, the Susquehanna, there is a scene greatly resembling one of historic interest. To the north of Perth, in Scotland, where the River Tay is seen sweeping round a beautiful valley with wooded heights beyond, the view is so impressive that beholders seldom forget it. Historians say that when the Roman army, on the first invasion of Scotland, reached the top of the hill from which this view was seen they stopped in admiring silence and then exclaimed "*Ecce Tiber!*" The scene on the Susquehanna is very much like the scene above Perth, with the exception that the Tay is a puny creek compared to the Susquehanna, and that the hills of Pennsylvania are much bolder than those that fringe the Tay at the spot spoken of.



DIAGRAMS FROM COOKE COMPOUND LOCOMOTIVE.

A correspondent of the *Railway Herald*, who has been investigating the performance of compound locomotives in France and England, makes a report to the effect that engineers are divided as to the value of the application of the compound principle to locomotives; this is not to be wondered at when we consider the great number of designs which are being tried or even introduced by the various companies who, during the past ten years, have been experimenting on this subject in order to find the best system, namely that which combines together economy and simplicity.

## Steel and Iron Tubes.

During the discussion at the Master Mechanics' Convention on tests of steel and iron, Mr William Forsyth said:

"I have a word to say in regard to steel tubes which may be of some value. I agree with the conclusions of the committee in the fact that steel tubes do not seem to be as durable as iron tubes, and that has been our experience with steel tubes. The fact of the matter is that steel blooms can be made a great deal cheaper now than iron blooms and the tendency of the manufacturer is to supply steel tubes at the same price as the iron tubes and thus force them into the market. A steel tube at the same price as an iron tube, I do not believe is as good. There may be steel tubes, solid drawn and seamless which are as good as iron, but they cost a great deal more. In addition to the trouble from corrosion with the steel tube, we have found the trouble with the weld. It is very difficult to weld a steel tube and make it stand in locomotive service. So I will caution our members to look out for this matter when manufacturers try to give them steel tubes of ordinary quality at the same price as iron tubes."

## Criticism of the Link Motion.

A young machinist, writing to us about valve motion, mentions that he was under obligations to Mr P. Leeds, of the Louisville and Nashville, for explaining to him very clearly why the link-pin is put back from the central radius link. He also says that he heard Mr Leeds make the statement that a good long motion would develop more power at half-stroke than any other valve gear. Our correspondent then proceeds:

"I claim that this is a great mistake on his part, as there never was a slide valve worked by link motion at half-stroke that did not wire-draw the steam, because the link motion closes the ports so slowly. I never saw a card taken from a locomotive that the steam line did not fall off considerably before the cut-off took place. Such is not the case with a Corliss engine, as the steam line is nearly parallel to the atmospheric line until the cut-off occurs. It is safe to say that a Corliss engine will give as large a mean effective pressure at one-third stroke as the average locomotive at half-stroke—I mean where the cylinders are the same size and the piston speed and boiler pressure are the same. If you are calculating the horse power, it is an indisputable fact that a Corliss or a Wright engine will have a much greater mean effective pressure, cutting off at half-stroke, than a locomotive cutting off at the same point. When you take a card from a locomotive, cut back in the first, second or third notch, you can see where compression commences, reducing the area of the diagram and consequently giving a smaller mean effective pressure. The Louisville and Nashville has freight engines that actually have $\frac{3}{8}$ of an inch lead when they are working in the first notch. Now, compression would commence very early in such a case like that, and the lead opening is all the opening an engine gets with link motion working in the first notch."

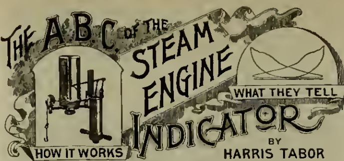
[Our correspondent evidently has not studied the subject on hand very thoroughly, or his experience with indicating locomotives is probably too limited to make him a reliable judge. With a well-designed link motion at slow speed, a diagram will be taken at half-stroke that is as good as one taken from a Corliss engine. We have repeatedly seen diagrams taken from locomotives at half-stroke that could not be improved. The objections raised to the increase of lead when the engine is hooked-up, are founded on imperfect knowledge. The compression complained of is a necessity for the conditions under which locomotives are run when the reverse lever is drawn close toward the center.—EDS.]

Rather a striking statement in relation to the labor cost of making open-hearth steel was made by the strikers in the Homestead mills trouble. It says: There are 112 tonnage men affected by the proposed reduction. They produce on a daily average of twenty-four hours 336 tons of steel ingots. In Schoenberger's open-hearth department, at the same number of furnaces as in No. 2, 168 tonnage men are required to produce 192 tons of steel ingots. At one particular place in the two mills the Homestead man would receive $14.15 per ton; in Schoenberger's he would receive $18. In Homestead if any accident occurs to the heat of the steel the men get no pay for it, while in Schoenberger's they would be paid by the day, be the steel good or bad.

In order to relieve "the difficulty of finding one's railway carriage after leaving it to enter the station," we are told that one of the great French lines has had the inspiration of putting conspicuously on every door "a natural history plate, presenting the figure of some bird, beast, reptile or insect." Perhaps stupid people may find help in trying to remember that their car is the frog car, or the rattlesnake car, or the hog car, or whatever the "natural history plate" may indicate, but it would seem that for travelers of ordinary intelligence the simple expedient of having the cars numbered would answer; or at any rate that the plan of naming the vehicles, which is in use on a thousand or more sleeping cars in this country, would meet the requirement.

During a little dispute about the handling of our mails last month, the fact was brought out that if the edition of LOCOMOTIVE ENGINEERING for June were piled up flat, it would make a monument 130 feet high, and if laid end to end they would stretch out a little over five miles. Twenty-one thousand two hundred and eighty copies were sent out.

Several have asked us the weight of the engine and train that made 91.7 miles per hour recently on the Central of New Jersey. The run was made Feb. 26th with a four-car train; the engine and tender, ready for the road, weighed 208,700 pounds, and the train weighed 230,000 pounds.



The ideal indicator card from a steam engine cylinder is one that gives the largest mean effective pressure with the lowest terminal pressure. The reason is plain. The mean effective pressure represents the amount of work done, and the terminal the cost, in steam. Hence it is that an indicator card with a large area and expansion line running down near the atmosphere always commands admiration. If the particular card in question does not show the best duty, its lines are such that we know the elements of economy are in the cylinder from which the card was taken. There are certain conditions in the construction of steam engine cylinders, independent of the valve gear, which govern the degree of economy. For instance we know that if an engine have an abnormally large clearance (waste room between the piston when at the end of its stroke and the valve face) no amount of argument on the part of its builder can make it economical. The waste room at the ends of the cylinder must be filled with steam, at the boiler's expense, before the piston has any movement. If the clearance be small, say 3 per cent., the loss on this account will be trifling; but if the clearance amount to 10 or 12 per cent., which is quite common practice, the loss will be considerable. The steam used to fill the clearance gives no return in the way of power, up to the point of cut off, beyond this point, however, the increased volume, due to clearance, raises the expansion line somewhat and reduces slightly the loss in the early part of the stroke. Condensation is another serious loss that comes from large clearance. The temperature of the cylinder follows closely the temperature of the steam within it. During exhaust the walls of the cylinder and ports are cooled by the low temperature of the steam after it has expanded, doing work; its flow to the atmosphere through the ports continues this cooling process until live steam from the boiler is ready to enter, and again go through the same reduction in temperature due to expansion. Large clearance necessarily increases the wall surfaces of the ports and adds to the cooling influence of the cylinder.

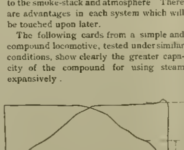
Independent of clearance, the expansion of steam in a cylinder, if carried too far, is a source of loss. It is doubtful if steam at 150 lbs. can be expanded more than four times in a single cylinder on a locomotive without loss. An indicator card would show gain with six expansions, but there would be losses due to condensation which the indicator does not make clear. In stationary engines of the "Corliss" and "Buckeye" type, with clearance as low as 2 per cent., expansion is carried much farther with excellent results.

When it is desirable to expand steam beyond economy in one cylinder it is the practice to put several cylinders, each succeeding one larger, in one train and expand the steam successively through them. By this means the range of temperature in each cylinder is kept down, and condensation is prevented. It is true that the multi-cylinder plan exposes more metal to the action of the steam, but the absorption of heat from the steam is less on account of the lesser range of temperature that is encountered in each cylinder. When two cylinders are used in a train the engine is commonly called compound, three cylinders are termed triple expansion and four quadruple. Thus far four cylinders is the limit in a practical way. In locomotive practice multi-cylinders have not been carried beyond the compound type in this country. In England and on the Continent several locomotives have been built with triple expansion. It is yet doubtful if any benefit can come from expanding through more than two cylinders for railroad work.

We have, in this country, what may be classed as two distinct types of compound locomotives, viz. the "Vauclain," built by The Baldwin Locomotive Works, which has four cylinders, one high-pressure and one low-pressure on each side—in other words two compound engines. On each side one cylinder is above its mate and the pair are connected to a crosshead midway between. Both compounds exhaust in one stack, as in the ordinary locomotive. A common steam-pipe with a branch leading to each engine supplies the steam. One valve distributes the steam in each pair of cylinders.

The other type is what may be classed as the two-cylinder compound, with the high-pressure cylinder on one side and the low-pressure cylinder on the other. The arrangement of cylinders in this case is the same as in the common locomotive. Steam is first taken in the high-pressure cylinder and then passed to the low-pressure, thence to the smoke-stack and atmosphere. There are advantages in each system which will be touched upon later.

The following cards from a simple and compound locomotive, tested under similar conditions, show clearly the greater capacity of the compound for using steam expansively.



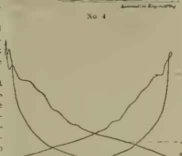
No. 1.

No. 2

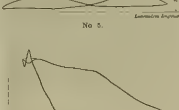
No. 3.

No. 1 was taken from a simple engine, cutting off steam at about ⅝ths of the stroke. The steam was expanded from a pressure of 156 lbs. to a terminal of 101 lbs. and at that pressure exhausted to the atmosphere. No. 2 was taken from a com-

No. 4



No. 5.



No. 6.

pound, carrying steam full stroke, expanding steam from a pressure of 165 lbs. to 34 lbs. No. 3 is also a card from simple engine cutting off at about ⅓d stroke and expanding steam from 154 lbs. to 61 lbs. No. 4 is from compound with an initial pressure of 147 lbs. which was expanded down to 16 lbs. The diagrams tell the whole story. In one case the steam was thrown away with only one-half its useful work applied, and in the other expansion was carried so far that but little loss occurred. Nos. 5 and 6 are cards from the same engines at a higher speed. In No. 5 we find expansion carried to the extreme in a simple engine, with a terminal pressure of 36 lbs.

Indicator spring .... 80
Simple cylinders .... 18 x 24 inches
Compound cylinders .... 11½ x 19 x 24 inches
Diameter of driving wheels .... 56 inches
Engines identical in all respects, except cylinders and valves.
Single nozzle .4⅛ inches diameter on compound
Single nozzle . 4⅜ inches diameter on simple engine

## Steel Cars for Mines.

A pressed steel coal car has been made by the Leeds Forge Company, Limited, Leeds, England, under the Fox patents, for use in underground workings. These cars are designed more particularly for carrying coal and are adapted to be used either in the pits or for taking coal from the pit mouth to boats or cars for shipment. The under frame is made of pressed steel parts ¼ inch thick, and is not unlike the Fox freight car truck used in this country, except that the framing has end sills. The truck is 7 feet long and 4 feet wide. The sides of the body are $\frac{3}{16}$ inch thick and are corrugated to give rigidity and obviate the need of stays or stakes. The total weight, including wheels, axles and springs, ready for use, is 720 pounds. These cars have proved very satisfactory in English colliery work on account of their light weight and small cost for repairs.

## Electricity Considered as the Future Motive Power for Railroads.

By J. E. Phelan.

It is conceded by all that electricity may sometime be the motive power for railroads. It is urged by many that such conditions are now at hand and possible.

Yet in railroad circles—among the hands and those contributing to the mental food of the railroad army—there is an unknowable essence about the subject more charming than satisfactory.

Railroad men to-day want information regarding electric railroads in simple terms and comprehensive phrases, getting posted in electric terms to many seems like a forced study of French in order to take a visit to Paris.

As Sinclair has recently simplified the problem of train resistance so that it can be presented in an understandable way, somebody should now "rise up" and present the problem of electrical railroading understandingly to the railroad army.

Air-line railroads building regardless of commercial conditions and natural obstacles, bearing trains shooting through space like the flashing of meteors, may be possible, but seem to a practical mind rather improbable—at least for some time to come.

Half a century since, the application of steam power to highways of commerce presented conditions inferior in point of development to the conditions governing electrical motive power as applied to railroads to-day.

This anxious expectancy of some combination saying "Let it be done," and immediately having the conditions of steam railroads revolutionized by the introduction of electrical appliances displacing steam power seems altogether improbable, yet such phenomenal change has revolutionized horse-car lines in street railway service.

To one familiar with all the details of a modern standard gauge road, the problem of similar change viewed in a probable light is a formidable one.

Taking the *Electric Review* as authority, the first commercial electric railroad in the United States was in service about six years ago.

To-day, within the United States, we have two thousand miles, or more, of track utilized by electric railroads.

The average cost per car-mile of horse railroads is about 5.7 cents, of cable, 2.5 cents, of electric, 2.2 cents, and of steam, as applied to street railroads, 5 cents.

The rapid application of electricity to street railroads for new lines, and substituting in many places established horse-car and steam lines, coupled with the comparative statement per car-mile, is self-evident that, at the same rates for transportation, profits are in favor of electric lines.

If similar conditions of comparative cost of operation of standard railroads by electricity, as compared with steam power, can be demonstrated, all reasonable minds can confidently anticipate revolution in motive-power appliances.

Granted that electric railroads are operated at less than one-half the cost of horse car lines and others (this statement includes relative proportion of fixed charges, labor for operating, cost of maintenance and all incidental expenses—everything being comparatively new), there may be an element of expense not appearing at the present time that may appear later as the expense for repairs of equipment increases and increasing cost of maintenance from year to year as renewals become necessary. Notwithstanding such prospects, a wide margin exists in favor of electrical roads with equal rates of transportation.

Further, has not the capital for recently constructed lines been obtained at a lower rate of interest than capital invested in lines showing a higher cost per car mile?

However, it will take only a short time to demonstrate such conditions for or against electric appliances.

The interesting question that needs to be answered understandingly now relates to the possible conditions permitting the favorable use of electric appliances on standard railroads as substitute for steam power.

We have account of the storage battery system having been put to practical test several years before the overhead system of trolley wires came into general use, yet the latter has taken the lead in practical application and popular methods.

It is announced in current publications that one prominent railroad in the United States has just contracted for three eighty-ton electric locomotives to be used in pushing trains through the belt line tunnel in a prominent city. These locomotives are expected to have a capacity to propel a passenger train of five hundred tons, at a speed of thirty miles an hour. This sounds well until a writer later on states that this power is to be delivered early next year, thus making prospects doubtful.

While it is announced that electric motors have been suggested as a more economical means for switching cars at terminals on Prussian state railways, we are left in the dark regarding details.

With electric locomotives yet in the uncertain stage, with the storage battery system antedating methods now in general practice, it seems most probable that the means of applying electricity to standard railroads would follow out the direction of development indicated in successful practice on street railways and inter-urban lines.

A most eminent authority has announced two different systems with both overhead and surface conductors as practically ready for trial in demonstrating the possible application of electricity to standard railroads.

The practicability of overhead conductors has been proven in street railway lines, while the possibilities of surface conductors remains for demonstration.

While all such promises are interesting, so far we have failed to find what we are seeking, viz.: a reasonable idea of how and by what practicable means electric appliances can be used for motive power on standard railroads in substituting steam.

We find able men quoted as pronouncing such prospects visionary.

We know it requires energy to produce motion. As railroads are conducted to-day, thousands of locomotives are distributed along the various lines representing so much stored energy for the propulsion of traffic. Each locomotive is given a train represented in tonnage according to the locomotive's capacity to pull such given tonnage over maximum grades.

All who are familiar with locomotive service know that the maximum power of a locomotive is taxed only for a fraction of the mileage run on ordinary standard railroads; hence we know that an enormous possibility in the way of motive power in the aggregate returns but a fraction in the line of results in execution, when compared with what such power might accomplish if kept in line of exertion to full capacity constantly.

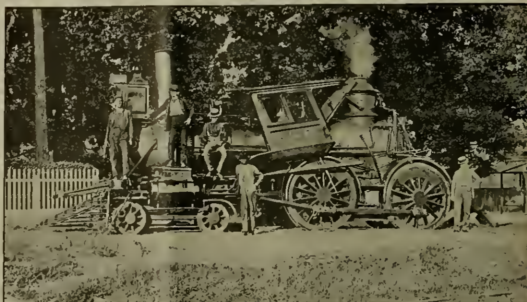
With electricity applied to the operation of standard railroads, as I understand, it would be a matter of concentrating at a given point a plant for the production of electrical energy sufficient to accommodate the full demand of traffic.

This centralized electric plant "corresponding to an aggregate of all the steam locomotives" for a given district would furnish constant power for all demands coming from its prescribed district.

Why is it not as reasonable to figure on an electric plant supplying the electrical energy necessary to supply the demands of given districts as readily as a water-works plant supplying the demands of consumers along various and numerous lines of consumption? The practical side of this principle is illustrated in the successful operation of the two thousand miles or more of electric line in various stages of development to-day.

Yet, while utilizing the steam locomotives to full capacity for only a fraction of time used or mileage run, we have authority for the statement that the total electric energy produced at a central station suffers a loss of forty per cent between the point of production and the point of utility in line of results in propulsion of traffic.

Let the management of a standard rail-



Hard on the Enginemen.

road abandon the maintenance in operation of all the locomotives required for a given district, thus cutting off the expense of water supply, fuel, shop expenses, wages of all employés necessary for maintenance and operation of locomotives, and in place of such appliances substitute an electric plant of sufficient capacity to supply energy sufficient for all demands of traffic, the expenses would be interest on

A Tender that Jumped.

the capital necessary to establish such a plant, interest on the capital invested in the abandoned machinery and appliances necessary in operation with steam, plus cost of operation and maintenance of the newly acquired appliances.

If the standard railroad involved happens to be located along the courses of rivers of good current and volume, ample for the production of power necessary for the production of electrical energy required in operation, the great item of economy under such conditions is readily recognized where applicable for all seasons of the year. Otherwise, the problem merges into the comparative consumption of fuel in producing electrical energy as compared with the amount consumed in the operation of a given number of locomotives.

It does not seem possible to realize economical results from establishing such centralized power plants for the operation of electric locomotives, working under conditions similar to steam locomotives in all respects, excepting the kind of power used.

But in light of success accomplished in electric railroads to date, it does seem possible to revolutionize the manner of moving traffic on standard railroads by the introduction of electric appliances and the establishing of centralized power stations in place of numerous locomotives.

I understand a problem is met with in the direction of conducting the electric current for long distances, continuously involving increased conductivity and amount of conducting material, involving a serious question of cost.

The idea of operating a standard railroad, with individual cars—passenger and freight—each carrying its own motor and starting whenever loaded and continuing without delay to destination, is a novel one, but in line with the progress of a busy world.

With power furnished by overhead or surface conductors from a central power station, and such power equal to the fluctuating demands of traffic, while produced with the least expenditure of necessary energy—to say the least such a possibility is not visionary but simply practicable and depending on cost of operation in comparison with other methods.

Such conditions would seem to involve a double-track railroad to accommodate perennial train service.

If capital is bold enough to make this experiment and returns are made in a convincing and profitable manner, we may look for revolution in the motive power of standard railroads.

Otherwise, the development of electric railroads must follow along the extensions of electric lines now existing where the natural field for development will be created and the cost of experimenting merged into the cost of construction and operation.

With standard railroads, operated for half a century or more with steam power, and remarkable development still continuing, it seems very reasonable to look for the development of electric railroads along the line of evolution until merging into the broad field of operation on standard railroads.

## Mormon Joe—Robber.

By John Alexander.

I'm on intimate terms with one of the biggest robbers in this country. He's an expert at the business, but has now retired from active work. The fact 'o the matter is Joe didn't know he was robbin' at the time he did it, but he got there, just the same, and come mighty nigh doing time in the Penitentiary for it, too.

Maybe I'd better commence at the begining and tell you that I first knew Joe Hogg in '79, out at the front, on the Santa Fé. Joe hailed from Salt Lake City and had run on the Utah Central, which gave him the nickname of "Mormon Joe," a name he never resented being called, and to which he always answered. I never did really know whether he was a Mormon or not, and never cared; he was a good engineer, that's about all I cared for. Joe took good care of his engine, wore a clean shirt and behaved himself—which was doing more than the average engineer at the front did.

I remember one night Jack McCabe—"Whisky Jack," we used to call him—made some mean remark about the Mormons in general and Joe in particular, and Joe replied: "I don't propose to defend the Mormon faith; it's as good as any, to my mind. I don't propose to judge or misjudge any man by his belief or absence of belief. All that I have got to say is, that the Mormon religion is a *practical* religion. They don't give starving women a tract or tramps jobs on the stone pile. The women gets *bread* and the tramps work for *pay*. Their faith is based on the Christian Bible, with a book added—guess they have as big a right to add or take away as some of the old kings had—so bigamy is upheld by the Bible, but has been dead in Utah for some years. It can't live, for the young people are against it. In Utah the woman have all the right a man has, votes, and is a *person*. (Since cut out of proposed constitution.) Before the Gentiles came to Salt Lake the Mormons had but *one* policeman, no jail, fifty saloons, no houses of prostitution—now the Gentile Christian has sway and the town is full of them. I guess you could argue on the quality and quantity of rot-gut whisky a good engineer ought to drink better than on theology, anyhow."

I never heard any of the gang twit Joe about the Mormons again.

I didn't take an awful sight of notice about Joe until I came in one night and the boys told me that Joe was arrested as an accomplice in the robbery of the Black Prince Mine in Constitution Gulch.

This Black Prince was a gold placer owned by two middle-aged Englishmen. They had a small stamp mill run by mule power, and a large number of sluice-boxes. They always worked alone and said they were *developing* the mine. No one had any idea they were taking out much *dust*, until the mill and sluice-boxes were burned one night and the story came out that they had been robbed of more than thirty thousand dollars.

Each partner accused the other of the theft. Both were arrested and detectives commenced to follow every clew.

Joe's arrest fell like a thunder-clap among us. The Brotherhood men took it up right away and I went to see Joe that very night. It was said that Joe had visited the Black Prince the day before, and had been seen carrying away a large package the night before the robbery.

Joe absolutely refused to say a word for or against himself.

"The detectives got this scheme up and know what they are doing," said he, "I don't. When they get all through you'll know how it'll come out."

To all questions as to his guilt or innocence, to every query about the crime or his arrest, he replied alike to friend and foe:

"Ask the sheriff; he's doing this."

He was in jail a long time, but nothing was proven against him, and he was finally released.

Neither of the Englishmen could fasten the crime on his partner, and they sold out and drifted away, one going back to England and the other to Mexico.

Joe ran awhile on the road and then took a job as chief engineer of a large stamp mill in Arizona, and going there he was lost to myself and the men on the road, and finally the Black Prince robbery passed into history, and nothing remained but the tradition, a sort of a myth of the mountains, like Capt. Kidd's treasures, the amount only being increased by time. I believe that the last time I heard the story it was calmly stated that thirty million dollars was taken.

When I was out West last time I got off the train at Sante Fé, and when gunning through the baggage for my *kiester* I saw a trunk bearing on its end this legend: "Mrs. Jos. Hogg."

While I was "gapping" at it, as they say down East, a very nice looking lady came in, leading a little girl, glanced along the lines of trunks, put her hand on the one I was looking at and said:

"That's the one, yes, the little one. I want it checked to New York."

Just then a fellow with whiskers on his chin and a twinkle in his eye came in and took charge of the trunk, the woman and the child, and with the little one's arms around his neck, bid them good-by and got them into their seats in the sleeper.

I watched this individual with a great deal of interest, he looked like my old friend "Mormon Joe," only for the whiskers and the stockman clothes.

Finally he jumped off the moving train, waived his hand and stood watching it out of sight, to catch the last glimpse of the (to him) precious burden bearer, he raised his hand to shade his eyes, and as he did so I saw that it was minus one thumb, and I remembered that "Mormon Joe" left one of his under an engine up in Colorado—I was sure of him.

There was a tear in his eye as he turned to go away, so I stepped up to him and asked:

"Any new wives wanted down your way, Elder?"

He glanced up, half angry, looked me straight in the eye and a smile started at the southeast corner of his phiz and ran around to his port ear.

"Well, John, old man, I don't mind being *sealed* to one about your size, right now. I've just sent away the best one in the wide world. Old man, you're looking plump; by the Holy Joe Smith, a sight of you is good for sore eyes!"

Well, we storted, and—but there ain't no use in me telling you all about it—I went home with Joe, went up a creek with a jaw-breaking Spanish name for miles to a very good cattle ranch, that was the property of "Mormon Joe."

Joe only quit running some three or four years ago, and the ranch and its neat little home represented the savings of Joe Hogg's life.

His wife and only child had just started for a visit to England, where she was born.

The next day we rode the range to see Joe's cattle, and the next we started out for a little hunt. It was sitting by a jolly camp fire back in the hills of New Mexico that "Mormon Joe" told me the true story of the robbery of the Black Prince mine and the romance of his life.

Filling his cob pipe with cut-plug, Joe sat looking away over space toward our hobbled horses and then said:

"Old man, I reckon you remember all about the Black Prince robbery. I don't forget that you were the first man that came to the cooler to see me while I was doing time as a *suspect*. Well, coming right down to the point, *I had the dust all the time!* and the working out of the mystery would be rather interesting reading if it was written out, and as you are such an accomplished liar, I wouldn't be surprised if you made it the base line of one of them yarns of yourn—only mind you don't go too far with it, for it's as curious as a lie itself. I would not try to improve on it if I was you.

"About four days before the robbery I was introduced to Rachel Rokesby, daughter of one of the partners in the Black Prince. I met her in what seemed to be a casual way at Mother Cameron's hash foundry, but I found out, a long time afterward, that she had worked for two weeks to bring about the introduction.

"I don't know as you remember seeing her, but she was a quiet, retiring, well educated, rosy-cheeked English girl—impressed you right away as being the pure, unrefined article, about twenty-two karat. She chinned me about an hour that evening, and just cut a cameo of her pretty face right on my old heart.

"Well, course I saw her home that evening and tried my best to be interesting, but if a fellow ever in his natural life becomes a double-barreled jackass its just immediately after he falls in love. Why he ain't as interesting as the unlettered side of an ore sack.

"But we got on amazing well; the girl did most of the talking and along toward the last, mentioned that she was in great trouble—of course I wa'nt interested in that at all. I liked to have broke my neck getting her to tell me at once if I couldn't do something to help her, say for instance, move Raton mountain up agin Pike's Peak.

"I went home that night promising to call on her the next trip, not to let any one know I was coming, not to tell anybody I had been there, not for *worlds* to repeat or intimate what she told me, and she would tell me her trouble from start to finish, and then I could help her if I wanted to. Well, I wanted to, *bad*.

"I went up to the Rokesby's cabin next trip in; it was dark, and as I went up the front walk, I heard the old gentleman going out the back, bound for the village 'diggins.' I had it all to myself—the secret I mean.

"When I went in I got about a forty-second squeeze of a neat little hand, and things did look so nice and clean and homelike that I had it on the end of my tongue to ask right then to camp in the place.

"After a few commonplaces she turned around and asked me if I still wanted to help her and would keep the secret if I concluded in the end to keep out of her troubles. You bet your life, old man, she didn't have long to wait for assurance—why I wouldn't a-waited a minute to have contracted to turn the Mississippi into the Mammoth Cave, if she had asked it.

"'Well,' says she, finally, 'it is not generally known, in fact, isn't known at all, that the Black Prince is a paying placer, and that papa and Mr. Sanson have been taking out lots of gold for some time, *they have over fifty pounds of gold dust and nuggets hidden under the floor of the old mill!*'

"'Well,' says I, 'that hadn't ought to worry you so.'

"'But that isn't all the story,' she continued; 'we have discovered a plot on the part of Mr. Sanson to rob papa of the gold and burn the mill and sluice boxes to hide the crime. You will find that every tough in town is his friend, because he buys whisky for them, and they all dislike papa, if he carried out his plan we would have no redress whatever. All the justices in town can be bribed. The plan is to take the gold, burn the mill, and then accuse papa of the crime. Now, can't you help *me* to fool that old villain of a Sanson and put *papa's half* of the money in a safe place?'

"I thought quite a while before I answered, it seemed strange to me that the case should be as she stated and I half feared I might be made a cat's-paw and get into trouble, but the girl looked at me so trustingly with her blue eyes and added:

"'I am afraid I am the cause of all the trouble, too. Papa and Sanson got along well until I refused to marry him, after that the row began—I hate him. He said I would *have* to marry him before he was done with me—but I *won't!*'

"'You bet you won't, darling,' says I, before I thought. 'Pardon me, Miss Rokesby, but if there is any marrying done around here, I want a hand in the game myself.'

"She blushed deeply, looked at the toe of her shoe a minute, and said:

"'I'm only eighteen, and am too young to think of marrying. Suppose we don't talk of that until we get out of the present difficulties.'

"'Sensible idea,' says I. 'But when we are out, suppose you and I have a talk on that subject.'

"She looked at the toe of her shoe for a minute, again turned red and white around the gills, looked up at me, shyly at first, then fully and fairly, stretched out her hand and said:

"'Yes, if you care to.'

"Course, I didn't *care*, or nothing—no more than a man cares for his head.

"I guess that was about a half engagement, anyhow, it's the only one we ever had. She said it would be ruinous to our plans if I was seen with her then or afterward, and agreed to leave a note at the house for me by next trip, telling me her plan—which she should talk over with her father.

"A couple of days later I got in from a round trip and made a dive for the boarding house.

"'Any mail for me, mother?' I asked old Mrs. Cameron.

"'No, young man, I'm sorry to say there ain't.'

"'I was anxious to hear from home.'

"'Too bad, but maybe it'll come to-morrow.'

"I was up to fever heat, but could do nothing but wait. I went to bed late, and raising up my pillow to put my watch under it, I found a note, it read:

"'Midnight, July 17.

"'Dear Joe:

"'Just thought of that rule for changing counter-balance you wanted. There has always been a miscalculation about the weight of counter-balance; they are universally *too heavy*. The weights are in pieces; take out *two* pieces, this treatment would even improve a mule sweep. When once out, pieces should be changed or placed where careless or malicious persons cannot get hold of them and replace them. All is well; hope you are the same; will see you sometime soon.

"'Jack.'

"Here was apparently a fool letter from one young railroader to another, but I knew well enough that it was from Rachel and meant something.

"I noticed that it was dated the *next night*; then I commenced to see, and in a few minutes my instructions were plain. The old five-stamp mill was driven by a mule, who wandered aimlessly around a never-ending circle at the end of a long, wooden sweep, this pole extended past the post of the mill a few feet, and had on the short end a box of stones as a counter-weight. I would find two packages of gold there at midnight of July 17.

"I was running one of those old Pittsburghs then, and she had to have her throttle ground the next day, but it was more than likely that she would be ready to go out at 8.30 on her turn; but I arranged to have it happen that the stand-pipe yoke should be broken in putting it up, so that another engine would have to be fired up, and I would lay in.

"I told stories in the roundhouse until nearly 10 o'clock that fateful night, and then started for the hash foundry, dodged into a lumber yard, got onto the rough ground back of town and made a wide detour toward Constitution Gulch, the Black Prince and the mule sweep. I crept up to the washed ground through some brush and laid down in a path to wait for midnight. I felt a full-fledged sneak-thief, but I thought of Rachel and didn't care if I was one or not, so long as she was satisfied.

"I looked often at my watch in the moonlight ... lock everything was as still as death. I could hear my own heart beat against my ribs as I sneaked up to that counter-balanced sweep. I got there without accident or incident, found two packages done up in canvas with tarred string handles, they were heavy but small, and in ten minutes I had them alone with me among the stumps and stones on the little mesa back of town.

"I'll never forget how I felt there in the dark with all that money that wasn't mine, and if some one had have said 'boo' from behind a stump I should have probably dropped the boodle and taken to the bush.

"As I approached the town I realized that I never could get through it to the boarding-house or the roundhouse with those two ... that looked like country sausages ... awhile on it and finally put them ... an old scraper beside the road, and ... without them to the shops. I got ... my seat-box a clean pair of overalls ... jacket and came back without being ...

"I wrapped one of the packages up in ... and boldly stepped out into the glare of the electric lights. I remember I thought ... too darned enterprising.

"One of the first men I met was the night ... hal, Jack Kelly. He was reported to be a Pinkerton man and was mistrusted by most of the men, but tried to be friendly and 'stand in' with all of us. He slapped me on the back and nearly scared the wits out of me. He insisted on treating me, and I went into a saloon and 'took something' with him, in fear and trembling. The package was heavy but I must carry it lightly under my arm, as if it were only overclothes.

"I treated in return and had it charged, because I dare not attempt to get my right hand into my pocket. Jack was disposed to talk, and I feared he was just playing with me like a cat does with a mouse, but I finally got off and deposited my precious burden in my seat-box under lock and key—then I sneaked back for the second haul. I met Jack and a policeman on my next trip, and he exclaimed:

"'Why, ain't you gone out yet?' and started off, telling the roundsman to keep his bunkos off me up to the shop. I thought then I was caught, but I was not, and the bluecoat bid me a pleasant good night at the shop yard.

"When I got near my engine I was surprised to see Barney Murry, the night machinist, with his torch up on the cab—he was putting in the newly-ground throttle.

"Just before I had decided to emerge from the shadow of the next engine Barney commenced to yell for his helper, Dick, to come and help him on with the dome cover.

"Dick came with a sandwich in one hand and a can of coffee in the other. This reminded Barney of his lunch, and, setting his torch down on the top of the cab, he scrambled down on the other side and hurried off to the sand dryer, where the gang used to eat their dyspepsia insurance and swap lies.

"After listening a moment to be sure I was alone, I stepped lightly to the cab and in a minute the two heavy and dangerous packages were side and side again.

"But just here an inspiration struck me. I opened the front door of the cab, stepped out on the running board and a second later was holding Barney's smoking torch down in the dome.

"The throttle occupied most of the space, but there was considerable room each side of it and a good two feet between the top of the boiler shell and the top row of flues. I took one of the bags of gold, held it down at arms length, swung it back and forward a time or two and let go so as to drop it well ahead on the flues; the second bag followed at once, and again I held down the light to see if the bags were out of sight, satisfied on this point, I got down, took my clothes under my arm and jumped off the engine into the arms of the night foreman.

"'What did you call me for? That engine is not ready to go out on the extra,' I demanded, off hand.

"'I ain't called you—you're dreaming.'

"'Maybe I am,' said I, 'but I would 'a swore some one came and called under my window that I got out at 2 to on a stock train, extra.'

"Just then Barney and Dick came back and I soon had the satisfaction of seeing the cover screwed down on my secret and a fire built under it—then I went home and slept.

"I guess it was four round trips that I made with the old pelter, before Kelly put this and that together, and decided to put me where the dogs wouldn't bite me.

"I appeared as calm as I could, and set the example since followed by politicians, that of 'dignified silence.' Kelly tried to work one of the 'fellow convict' rackets on me, but I made no confessions. I soon became a martyr in the eyes of the women of the town. You boys got to talking of backing up a suit for false imprisonment; election was coming on and the sheriff and county judge were getting uneasy, and the district attorney was awful unhappy, so they let me out.

"Nixon, the sheriff, pumped me slyly to see what effect my imprisonment would have on future operations, and I told him that I didn't propose to lose any time over it, and agreed to drop the matter for a little nest-egg equal to the highest pay received by any engineer on the road. Pat Dailey was the worst hog for overtime, and I selected his pay as the standard and took big money. I wasn't afraid of re-arrest, I had 'em for bribery.

"Whilst I was in hock I had cold chills everytime I heard the 313's whistle for fear they would wash her out and find the dust, but she gave up nothing.

"When I reported for work the old mill was out on construction, and they were disposed to put me on a mill pulling varnished cars, but I told the old man I was under the weather and 'crummy,' and that put him in a good humor, and I was sent out to a desolate siding, and once again took charge of the 'fence,' for the robber of the Black Prince mine.

"On Sunday, by a little maneuvering, I managed to get the crew to go off on a trout-fishing expedition, and, under pretext of grinding in her chronically leaky throttle, I took off her dome cover and looked in; there was nothing in sight.

"I was afraid that its cooking of two months or more had destroyed the strength of the canvas bags; then again the heavy deposit of scale might have cemented the bags to the flues. In either case, rough handling would send the gold to the bottom of the boiler, making it difficult if not impossible to recover, and worse yet, manifest itself sometime and give me dead away.

"I concluded to go at the matter right, and after two hours of hard work managed to get the upright throttle-pipe out of the dome. I drew her water down below the flue line, and, though it was tolerably warm, I got in.

"Both of my surmises were partially correct; the canvas was rotted, in a measure, and the bags were fastened to the flues. The dust had been put up in buckskin bags first, and these had been put into shot-sacks; the buckskin was shrunken but intact. I took a good look around before I dared take the treasure into the sunlight; but the coast was clear, and inside of an hour they were locked in my clothes-box, and the cover was on the kettle again and I was pumping her up by hand.

"I was afraid something would happen to me or the engine, so I buried the packages in a bunch of willows near the track.

"It must have been two weeks after this that a moon's wagon stopped near the creek within half a mile of the track, and hobbled horses soon began to hunt grass, and the smoke of a camp-fire haunted the clouds.

"We saw this sort of thing often, and I didn't any more than glance at it, but after supper I sauntered down by the engine, smoking and thinking of Rachel Rokesby, when I noticed a woman walking towards me pail in hand.

"She had on a sunbonnet that hid her face and she got within ten feet of me before she spoke—she asked for a pail of drinking water from the tank—the creek was muddy from a recent rain.

"Just as soon as she spoke I knew it was Rachel, but I controlled myself for others were within hearing. I walked with her to the engine and got the water. I purposely drew the pail-full, which she promptly spilled, and I offered to carry it for her.

"The crew watched us walk away and I heard some of 'em mention 'mash,' but I didn't care, I wanted a word with my girl.

"When we were out of earshot she asked without looking up:

"'Well, old coolness, are you all right?'

"'You bet, darling.'

"'Papa has sold out his half and we are going away for good. I think if we get rid of the dust without trouble we may go to England. Just as soon as all is safe you shall hear from me; can't you trust me, Joe?'

"'Yes, Rachel, darling, now and forever.'

"'Where's the gold?'

"'Within 100 feet of you, in those willows; when it is dark I will go and get it and put it on that stump by the big tree, go then and get it. But where will you put it?'

"'I am going to pack it at the bottom of a jar of butter.'

"'Good idea, little girl, I think you'd make a good pawnbroker. How's my friend, Sanson?'

"'He's gone to Mexico; says yet that papa robbed him, but he knows as well as you or I that all his bluster was because he only found *half* that he expected. I pride myself on getting ahead of a wicked man once, thanks to our hero, by the name of Hogg.'

"It was getting dusk and we were out of sight, so I set down the pail and asked:

"'Do I get a kiss this evening?'

"'If you want one.'

"'There's only one thing I want worse.'

"'What is that, Joe?'

"My arm was around her waist now, and the sun bonnet was shoved back from the face. I took a couple of cream puffs there, where they were ripe, and answered:

"'That message to come and have that talk about matrimony.'

"Here a man's voice was heard calling 'Rachel,' 'Rachel,' and, throwing her arms around my neck, she gave me one more kiss, snatched up her pail and answered:

"'Yes, I'm coming.'

"Then to me, hurriedly:

"'Good-by, dear, wait patiently, you shall hear from me.'

"I went back and put the dangerous dust on the stump and returned to the bunk car. The next morning when I turned out the outlines of the wagon were dimly discernible away on a hill in the road; it had been gone an hour.

"I walked down past my stump—the gold was gone.

"Well, John, I settled down to work and wait for that precious letter that would summon me to the side of Rachel Rokesby, wherever she was, but it never came. I have never got a line from her from that day to this."

Joe kicked the burning sticks in our fire closer together, lit his pipe and then proceeded:

"I was hopeful for a month or two; then got impatient, and finally got angry, but it ended in despair. A year passed away before I commenced to *hunt* instead of waiting to be hunted, but after another year I gave it up and came to the belief that Rachel was dead or married to another. But the very minute such a treasonable thought flashed through my mind my heart held up the image of her pure face and rebuked me.

"I was discharged finally for forgetting orders—I was thinking of something else—then I commenced to pull myself together and determined to control myself. I held the job in Arizona almost a year, but the mill company busted; then I drifted down on to the Mexican National, when it was building, and got a job. A few months later it came to my ears that one of the engineers, Billy Gardiner, was in one of their damnable prisons for running over a Greaser, and I organized a relief expedition. I called on Gardiner, and talked over his trouble fully.

"He was in a loathsome hole of a 'dobie, full of vermin, and dark. As I sat talking to him I noticed an old man chained to the wall in a little entry on the other side of the room. His beard was grizzly white, long and tangled. He was hollow cheeked and wild eyed, and looked at me in a strange, fascinated way.

"'What's he in for?' I whispered to Gardiner.

"'Murdered his partner in a mining camp. Got caught in the act. He don't know it yet, but he's condemned to be shot next Friday—to-morrow. Poor devil, he's half crazy, anyhow.'

"As I got up to go the old man made a sharp hiss, and as I turned to look at him, he beckoned with his finger. I took a step or two nearer, and he asked in an audible whisper:

"'Mr Hogg, don't you know me?'

"I looked at him long and critically, and then said:

"'No. I never saw you before.'

"'Yes, that's so,' said he, 'but I have seen you many times. You remember the Black Prince robbery?'

"'Yes, indeed; then you are Sanson?'

"'No, Rokesby.'

"'Rokesby! My God, man, where's Rachel?'

"'I thought so,' he muttered. 'Well, she's in England, but I'm here.'

"'What part of England?'

"'Sit down on that box, Mr. Hogg, and I will tell you something.'

"'Is she married?' I asked eagerly.

"'No, lad, she ain't, and what's more she won't be till she marries you, so be easy there.'

"Just here a pompous Mexican official strided in, stepped up in front of the old man and read something in Spanish.

"'What'en hell did he say?' asked the prisoner of Gardiner.

"'Something about sentence, partner.'

"'Well, it's time they was doing something; did he say when it was?'

"'To-morrow.'

"'Goodnough, I'm dead sick o' this.'

"'Can't I do anything for you, Mr. Rokesby—for Rachel's sake?'

"'No—yes, you can, too, young man; you can grant me a pardon for a worse crime nor murder if you will—for—for Rachel's sake.'

"'It's granted, then.'

"'Good, that gives me heart. Now, Mr. Hogg, it was me that robbed the Black Prince mine. I took every last cent there was, and I used you and Rachel to do the work for me and take the blame if caught. Sanson was honest enough, I fired the mill myself.

"'It was me that sent Rachel to you; I admired your face as you rode by the claim every day on your engine. I knew you had nerve. If you and Rachel hadn't fallen in love with one another I'd a lost though; but I won.

"'Well, I took the money I got for the claim and sent Rachel back to her mother's sister in England. You may not know, but she is not my daughter; she thinks she is, though. Her parents died when she was small, and I provided for her. I'm her half uncle. I got avaricious in my old age and went into a number of questionable schemes.

"'After leaving New Mexico I worked the dust off a little at a time and wasted the money—but never mind that.

"'It was just before she got aboard the ship that Rachel sent me a letter containing another to you to be sent when all was right—I've carried it ever since—somehow or other I was afraid it would drop a clew to send it at first, and after it got a year old I didn't think of it much.'

"He fumbled around inside of his dirty flannel shirt for a minute and soon fished up a letter almost as black as the shirt, and, holding it up, said

"'That's it.'

"I had the envelope off in a second, and read:

"'DEAR JOSEPH:

"'I am going to my aunt, Mrs. Julia Bradshaw, 15 Harrow Lane, Leicester, England. If you do not change your mind I will be happy to talk over our affairs whenever you are ready. I shall be waiting. "'RACHEL.'

"I turned and bolted toward a door when Gardiner yelled:

"'Where are you going?'

"'To England,' said I.

"'This door, then, sir,' said a Mexican.

"I came back to the old man.

"'Rokesby,' said I, 'you have cut ten years off my life, but I forgive you; good-by.'

"'One thing more, Mr Hogg; don't tell em at home how I went—nothing about this last deal.'

"'Well, all right; but I'll tell Rachel if we marry and come to America.'

"'I've got lots of honest relations, and my old mother still lives in her eighties.'

"'Well, not till after she goes, unless to save Rachel in some way.'

"'Good-by, Mr. Hogg, God bless you—and—and, little Rachel.'

"'Good-by, Mr. Rokesby.'

"The next day I left Mexico for God's country, and inside of ten days was on a Cunarder eastward bound. I reached England in proper time; I found the proper pen in the proper train and was deposited in the proper town, directed to the proper road, and house, and street, and number, and had pulled out about four yards of wire attached to the proper bell.

"A kindly faced old lady looked at me over her spectacles, and I asked

"'Does Mrs. Julia Bradshaw live here?'

"'Yes, sir; that's me.'

"'Have you a young lady here named Rachel R——?'

"The old lady didn't wait for me to finish the name, she just turned her head fifteen degrees, put her open hand up beside her mouth, and shouted up the stairs.

"'Rachel! Rachel! come down here, quick.'

"A door opened upstairs and I caught a twinkle of No. 2 slippers on the upper stairs, when the old lady continued:

"'Here's your young man from America.'

"Another aged woman opened a side door and looked for a minute, while Rachel and I were so close together that you couldn't tell which of us wore the bustle, and I heard her say:

"'He's been long enough coming—I never did see such faith, though. Lord, I *do* hope he's half as good as she thinks he is.'"

---

The Brooks Locomotive Works are working on engines for the Great Northern, the Cincinnati, Hamilton & Dayton and the Big Fours. They are quite busy.

## The Pennsylvania Railroad Locomotive Building Shops.

At Juniata, two miles from Altoona, the Pennsylvania Railroad Company have shops devoted to the construction of new locomotives. The shops were designed and equipped regardless of expense, the one aim concerning them being to provide every facility of the most approved kind for doing work accurately, expeditiously and cheaply. The men in charge having the courage of their convictions that a perfect although expensive plant was an investment certain to produce fertile returns, the company are reaping the benefit in getting locomotives built at a cost not approached in any other railroad shop.

The shops are built on a level plot of ground, a short distance from the main line, that gives plenty of room and is convenient to the yards. The machine shops are built parallel with a small opening between them. At the end of these is a transfer table pit, and beyond this the boiler and blacksmith shop set side by side like the others, the whole four principal buildings forming a parallelogram. The offices and minor buildings are located at the most convenient points outside of the main group.

The shops are turning out three heavy locomotives per week, which represents a great deal of work. As the writer walked observingly through the various shops he was struck with the small number of men employed to turn out so many engines. A closer study of the operations made the matter plain. Nothing is done by men that can be conveniently performed by tools and power methods of handling material. There are about 880 men in the shops, so that one locomotive represents about 1,760 days of labor.

Entering the grounds—after a brief call at the office, which is opposite the entrance—the first place examined is the power boiler shop, which is separate from the other buildings, and so located that the steam distribution can be accomplished with the least amount of piping. This is a neat, clean building, with good boilers, fired with mechanical stokers. The coal is supplied by traveling buckets, and the ashes removed by similar means. There are no coal piles around and no ash heaps to disfigure the place.

Next we go to the machine shop, which is a two-story building, the light work being done above and the heavy work below. This place convinces me that a two-story machine shop is an excellent arrangement for concentrating work compactly, although I used to be prejudiced against the plan. The good methods now in use for elevating and lowering material and work overcome the old objections to this form of building.

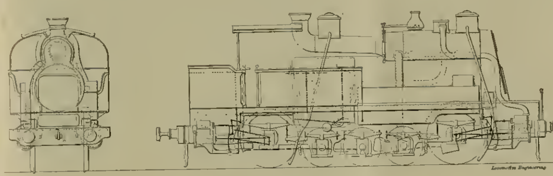
Standing on the ground floor of the machine shop we see a line of shafting on each side, each driven by a Westinghouse engine. The heavy tools are set toward the middle of the shop, but a clear space is left in the middle for the passage of material. An overhead traveling crane moves all material and puts the work on the heavy tools and takes it off. The shafting arrangement enables the heavy tools to be operated by the shortest belts. It also provides for the grouping of tools to best suit the movement of the work to them and from them. The lighter tools are set nearest the windows, where they have the advantage of the best light. Care has been taken to place the tools so that the work will always be advancing, and also that the movements from tool to tool will be as short as possible before the article is finished. For instance, the movements that a cylinder makes lead it but a short way into the shop before it is passed into the other building. It comes in at the east end of the shop and is immediately placed on the boring machine. From there it goes to a planer at hand, and another small step takes it to the drill press, where it gets the finishing touches, and is then sent out by the side door to the erecting shop opposite. A similar system is adopted with all other work not only here but in all the other shops.

The wheel, tire and axle work is done in the erecting shop, and the best of tools are employed. The rough material enters at one end and goes through the successive operations in regular order.

To me the most interesting part of the establishment was the boiler shop. So far as my experience has gone it is the best equipped boiler shop in this country or anywhere else. Hydraulic power is employed for all purposes, riveting, flanging, forming, punching, shearing, and for handling material. On entering the shop one is naturally struck with the great amount of work on the floor and the few men engaged upon it. Remaining in the shop a few minutes watching the tools soon makes the matter plain. There is no time lost in tedious handling of the heavy weights that boilermakers have to deal with, and the various operations were performed so quickly that a few men perform a large amount of work without much exertion. The tools here are also admirably placed to keep the various operations in close order. For instance, the sheets for a shell on entering the shop are laid out, and any required cutting or punching is done at the next step. Another movement takes the material to the rolls, from whence it is but a few steps to the hydraulic riveter. Then by a succession of easy movements it goes to the points where the dome, firebox and minor attachments are put on, every operation being facilitated by the most approved tools. Besides the overhead cranes that handle a great part of the loads to be carried from place to place there are numerous lifts and small cranes that serve the principal tools in all the shops. Good tools are a very great aid to the production of work, but the best of tools avail little without the proper organization that regulates the movements and keeps everything going like clockwork. The organization in these shops is conspicuously good and reflects very great credit on Mr. H. D. Gordon, the superintendent in charge, and the able foremen that are assisting him.

The blacksmith shop is well worthy of attention. Like the others, it is very well supplied with every kind of tool that can save labor and increase production. It is a clean, well-lighted shop, remarkable free from gas, good exhausting apparatus being employed to keep the atmosphere fresh. The furnaces in the shop are heated by gas generated in another building, in which the converters have the coal fed by means of mechanical stokers. The gas for forging may not produce a better job than coal, but there is certainly economy in the labor saved, and in the prevention of waste of coal. The gas is also a great promoter of cleanliness and order in the forging shops.

There are numerous minor points well worthy of notice. The shops are well lighted by electricity and heated by the Sturtevant system. A good many machine tools that cannot be conveniently reached by belts are driven by electric motors and this means of transmitting power is highly spoken of. There are many special tools, many of them very ingenious and not found elsewhere. We know of no place where a railroad mechanic could spend a day to better advantage than in the Juniata shops. A. S.



A CURIOUS OLD FRENCH LOCOMOTIVE.

## An Old French Double-end Locomotive.

American travelers in France seldom fail to be struck with the great variety of forms of locomotives to be seen. Some of the designing engineers appear to have exerted their ingenuity to produce odd shapes and peculiar arrangement of the mechanism. The engine shown in our engraving is one of the most striking of certain curious engines that came in fashion for a short time about thirty years ago. It is a double-ender in the fullest sense of the word, having sets of cylinders and driving wheels at each end. This form of engine has been taken as the pattern for certain forms of compound locomotives that are now to be found on several French lines.

The boiler is of peculiar form, having a large steam drum on top through which the gases from the smoke-box pass and escape by a stack set at the back end. Several modifications of this design have been tried in America, but they have not proved a success. The boiler has lately been tried again in England, which gives the old machine new interest.

---

We have in a former issue mentioned a partly railroad partly East Indian story by Rudyard Kipling and the late Wolcott Balestier, that has been running through the *Century Magazine*. The story is now finished and we are afraid it has done nothing to redeem railroad life as a field of romance. To be sure the railroad part was a very small caudle appendage that came first, but the situations were tame and unnatural, the species of story that educated railroad men or especially women, do not indulge in was made to pass as raciness. The denouement of the story was simply ridiculous. Mr. Kipling is more at home portraying the wayward life of fast "unnative" residents of India, or in recording the habits and aspirations of beer-guzzling soldiers than he is in delineating the sentiments and actions of American railroad people.

---

During a recent trip over the Michigan Central we found that numerous improvements had been effected during the year. The company are evidently preparing to be ready to handle the heavy Fair business next year. Considerable increase in double tracking has been made, and they are interlocking all switches as fast as possible. The intention is to put down track tanks this summer to permit of long runs being made without stoppage. A number of very handsome station buildings have been erected, that at Niles, Mich., being one of the handsomest road-side stations in the country. At this place they have hot houses for raising flowers and a bouquet is given to every lady in each train.

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

Address all communications and make all orders and checks payable to

LOCOMOTIVE ENGINEERING,

912 TEMPLE COURT, NEW YORK.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } Editors and Proprs.
JOHN A. HILL, }

J. W. CURRAN, Manager Advertising Department.

Subscription Price.

$2.00, postage paid to any part of the world. Single Copies 20 cents.

Special Notices.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary; always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as Second-class mail matter.

## Settling the Size of an Inch.

We are constantly hearing of agitations being carried on to change our standards of measurement, and many people unreflectingly conclude that it would be a fine thing to introduce the French system of measurement with the meter, which is 39.3704 inches in length, as a basis. Those people seldom have learned anything about the difficulties there were encountered in establishing an exact inch as the basis of our measurements. Every boy who carries a well made steel scale now has in his pocket an inch that is the same length as the inch measured by instruments made specially to secure accuracy. The inch of every well regulated shop is of precisely the same length as the inch of any other shop of similar character. It is within the memory of men still young when a very different condition of affairs existed. The inch marked on the rules of different makers was seldom approximately the same, and the best of measuring scales rarely made the inch the same length and 1-32 inch difference on the foot was not considered out of the way. In fact there was no accurate unit of measurement on this continent till very lately.

Railroad engineering men are entitled to some share of the credit due for reforming the prevailing confusion in measurements. A committee of the Franklin Institute of Philadelphia made the first important move toward getting a standard system of screw threads introduced, and it was in connection with this that the need for an accurate inch came to be recognized. When the famous engineer, O. B. Chanute, was in charge of the mechanical department of the Erie in the early '70's he decided to have interchangeable screw threads used in a large number of cars to be ordered. When he entered into details the first difficulty encountered was finding the correct length of an inch. He applied to the various Government arsenals and shipbuilding yards and obtained scales giving the standard inch they were working to. On a comparison being made it was discovered that none of the reputed accurate inches were exactly the same length. Mr. Chanute was a highly influential railroad officer and a leading member of the principal engineering society of the day, and he had good opportunities for making the anomalous condition of American measurements well known to the engineering world. He hied hither and thither seeking for a true inch like the ancient philosopher searching for an honest man, and his quest was equally fruitless.

The agitation, however, brought about the necessary reform. The question was taken up by the Master Car Builders' Association, and a committee was appointed to select a firm to make gauges for standard screw threads. The choice fell upon the Pratt & Whitney Co., Hartford, Conn., and that company displayed wonderful enterprise in providing the country with a correct standard unit of measurement.

The labor performed was enormous, and the expense incurred was not less than $25,000. The first thing to be done was to ascertain the length of the standard British yard, which was the original gauge of our measuring rules. This yard was made with great care, in 1760, and was deposited for safe keeping in a strong room in the Houses of Parliament in London. Its length was based on a natural unit made by the vibration of a pendulum beating seconds at the level of the sea, in the latitude of London. It was supposed that this would provide the means of restoring the exact yard should the standard bar be lost or destroyed. The Houses of Parliament were burned in 1834, and the standard yard destroyed. When scientists undertook to restore the standard yard from the natural unit, they found that the vibrations of the pendulum were susceptible to influences that induced errors. After a most laborious and painstaking investigation, it was determined to restore the standard yard by measurements taken from various yards that had been made with great care, and compared with the standard yard of 1760. This yard, then constructed, is known as Bronze No. 1, and is the British national standard yard. It is kept in the strong room off the Old Palace Yard, Westminster, London.
