To obtain an accurate transfer of this yard was the first work undertaken by the Pratt & Whitney Co. They engaged the services of Professor Rogers, of Harvard College Observatory, Cambridge, Mass., who is probably the first authority in the world on measurments and measuring instruments. The work was successfully performed, and very few connected with the vast interests that are enjoying the benefit of the accurate system of measurements established realize the great importance of the work that was accomplished.

The details of designing gauges and measuring appliances to introduce the accuracy of science into shop practice were carried out to a great extent by Mr. George M. Bond, of the Pratt & Whitney Co. This was done in such a practical manner that, within a few months after the standard measurement was established in this country, numerous shops were working to gauges that gave absolutely correct divisions of the yard. Although the yard is the standard of reference, the inch is the real standard of the machine shop. Among others who did valuable work in promoting the reform in our standards of measurement, were Mr. M. N. Forney, of the *Engineering and Railroad Journal*, and Professor Denton, of the Stevens Institute of Technology.

## Inventors Who Do Not Read Papers.

Considering the unparalleled channels now constantly engaged spreading mechanical information to every part of the earth, it is surprising how many people who ought to be informed are ignorant of things they are directly interested in knowing. The agitation stirring some Western cities for some months in regard to the prevention of smoke has started a movement in the direction of inventing smoke-preventing devices for locomotives. This line of invention has been quarried into as deeply as the line of inventing car couplers, yet many overgrown children with inventive tendencies are working on problems for the prevention of smoke without inquiring what has been done in this line before. Their labors are almost certain to end in disappointment. They invent things that were patented before they were born, and only learn the facts after paying a patent attorney to make application for a patent.

We were stimulated into reproaching inventors for not inquiring into what had been done in any appliance they incline to invent by a visit yesterday from a man with an arrangement for burning petroleum oil in fire-boxes or furnaces. It was a very crude affair, but the amazing thing about it was that the inventor expected to secure a foundation patent, for he had never heard of petroleum being successfully used in the generation of steam.

The men who are not aware that the problem of using petroleum as fuel in locomotives was solved years ago are profoundly ignorant of what is going on in the locomotive engineering world. The use of petroleum compounds for locomotive fuel is as common in Russia as the use of anthracite coal is for the same purpose in this country. A few locomotives in this country employed on special service are burning petroleum, and all the engines in the country would probably be using it if it were not that liquid fuel is more expensive than coal.

## A Remedy for Bad Feed Water.

The Chicago, Milwaukee & St. Paul Railroad people say that the boiler purge they are using for neutralizing the destructive effects of lime and magnesia in the feed water is a thorough success. A new engine was supplied with the water purifier regularly from the time she first left the shop. She has now run nearly 300,000 miles and has not cost a dollar for boiler work. This is phenomenal for locomotives running out of Milwaukee. The ordinary experience has been for engines to require the tubes to be taken out and cleaned every 50,000 miles run. After a locomotive has done the work represented by that mileage, the firebox begins to show leaky seams and stay bolts. Calking begins and is called for with increased frequency till new side sheets must be put in. If an engine runs 200,000 miles without getting new side sheets she is making an unusually good record.

Few master mechanics have any confidence in the doctoring of feed water, and in all directions we hear that chemicals for this purpose are a delusion and a snare that lead railroad companies to spend money that is worse than wasted. Now, how is it that the Milwaukee people have made a success of this while others have generally made ridiculous failures? We will venture an answer. The others never gave remedies for bad feed water a fair chance.

The experience of the C., M. & St. Paul people is rather edifying. When the purge was found satisfactory for one engine, it was supplied to all those running out of Milwaukee. A certain quantity was put on each tender at the beginning of the run, and the enginemen were instructed to put into the tank a measured supply every time water was taken. The thing went on smoothly. It was some one's business to examine the purge cans every time an engine came in, and they were found regularly to be empty. Results were expected soon, and the master mechanic kept watching the engines as they were washed out, expecting to see the old scale coming out in loads, but it did not come out. Months passed, and the boiler work kept up about the same, but the purge cans continued to come in empty. The master mechanic began to suspect that there was a colored person in the wood pile and he called in the enginemen and questioned them about how the purge was used. They all declared with the utmost unanimity that the purge was put regularly in the tenders.

A week or two passed and the boilers showed no symptoms of improvement. The master mechanic then took all the purge cans off the engines and employed a man to put half the quantity the engines had been using into the tenders before the engines left the roundhouse. Two or three days afterward a deputation of engineers waited on the master mechanic and represented that they could not run the engines with the quantity of purge they were receiving. He expressed the opinion that it was strange that they could not now get along with half the quantity that they were using when they applied it themselves and they were compelled to admit that they had been regularly throwing the purge away. They were informed that they must try to get along with the new order of things. The engines gave trouble with foaming at first and needed more than usual care in running, but this difficulty greatly diminished after the compound had been in use for a few weeks.

When the purge was systematically put in, the boilers soon began to show an improvement, and after the practice had been inaugurated six months, a very great improvement was perceptible. The shops do not now have to devote half the attention to boiler work that was regularly called for before the feed-water remedy was applied. Boiler repairs were what called the majority of engines into the shop formerly, but now it is rare that an engine has to be taken in till repairs of the machinery are necessary. The boiler purge has effected a revolution in the work. Why cannot other roads tortured with bad water apply this remedy?

## Attempts to Discredit Block Signals.

During the month we have heard considerable talk of a detestable character among railroad men about the accident that happened on the Pennsylvania Railroad, at Harrisburg, Pa., toward the end of June. A heavy passenger train was running in two sections. The first section was stopped outside the station at Harrisburg, but within a block protected by signals. The signal operator, by mistake, permitted the second section to pass into the block, and it crashed into the hind end of the first section, killing twelve persons and injuring about twenty others. Rear-end collisions of a fatal character are, unfortunately, extremely common on this continent, and this one would not call for comment from us were it not for the lamentable tone many railroad officers have indulged in concerning it. The Pennsylvania Railroad, undoubtedly the best managed railroad in the country, has the trains operated under a block signal system, and this is the object of attack and disparagement by some of the men responsible for inferior roads having no mechanical provisions for promoting the safety of trains. The kind of talk indulged in is: "There now, that is the result of your high-toned signal system. Signals and all the complexity and expense attending them are nothing more or less than a tempting of Providence. As a means of running trains safely give me well-trained crews that depend upon themselves alone."

This is the species of sneering opposition that has been offered to every improvement introduced into railroad operating. If the sentiments of the kind of men who still oppose a signal system had been followed railroads would still be using strap rails and operated with locomotives without cabs.

The Harrisburg accident was a very sad one, but the most striking thing about it was the reminder that the human element can never be eliminated from railroad operating, and it is human to err. When a railroad company has provided all the most approved appliances for securing safety, the officers are not to blame if a link in the human chain that does the operating should suddenly fail. There is a signal system now in use, so thoroughly perfected, that the signalman in a tower cannot lower his signal until the man in the tower ahead releases the actuating lever, which he does when a train passes out of the block. If the Pennsylvania Railroad had had this system in use the accident might have been averted, but the company is not greatly to blame for not having the very latest inventions in use. The management have displayed an enterprising willingness to provide the best appliances, and that is all that can reasonably be expected of any railroad company. We have heard opinions expressed that the Harrisburg accident has given a serious blow to the public confidence in signals. If it has, the blow has struck people whose judgment is worthless. It is just as well to say that railroad companies ought to go back to hand-brakes, because the automatic air-brake has sometimes failed to prevent collisions. Those who take the unction to their souls that the Harrisburg accident will screen them from blame for having no signal system, should a serious accident happen, will find themselves rudely awakened to the consciousness that the demand for a good signal system is still marching on. This is a movement like that in favor of power-brakes and safety couplers. Failures with the apparatus in use may temporarily check the public demand for improvements, but the sensible sentiment in favor of the best mechanical aids being provided to help the human worker will prevail in the long run.

## Making Safety Appliances Compulsory.

A bill has passed the House of Representatives making provision for the compulsory use by railroad companies of safety appliances, and it is said to have been reported on favorably by the Senate Committee. There is every likelihood that it will pass the Senate, and in that event it will become a law, for the President is known to be very favorable to the measure

The law, of course, only applies to cars and locomotives engaged on interstate business. It requires that after July 1, 1893, all new locomotives shall be equipped with power driving-wheel brakes, and that after July 1, 1895, all locomotives must have these brakes. After July 1, 1895, it requires that all new cars and all cars that go into the shops for general repairs be equipped with automatic couplers, and that after 1898 all cars must be provided with automatic couplers. It requires that after July 1, 1895, all new cars and those that undergo general repairs must be equipped with power brakes on every wheel, the same to be operated from the locomotives. Three years later all cars will be required to fulfill the above conditions respecting brakes.

On or before July 1, 1893, all railroad companies are required to give particulars relating to the height, form, size and mechanism of freight-car couplers deemed essential to secure uniformity. They are also required to certify to the number of cars they have engaged in interstate business. If companies owning 75 per cent. of such cars agree upon the details of a coupler requisite to secure uniformity, automatic action and safety in service, such coupler will be declared standard for use in interstate service. If the railroad companies shall fail to establish a standard, then the Interstate Commerce Commissioners are empowered to select a standard. After July 1, 1898, railroad companies will be at liberty to refuse any car not provided with the appliances required by this act. Railroad companies are made responsible for accidents caused by rolling stock not provided with the safety appliances mentioned; and employés and others injured by rolling stock not equipped with safety couplers and brakes shall not be deemed guilty of contributory negligence.

The American Railway Association is required to designate the standard height for draw-bars, and if it fails to do so the Interstate Commerce Commission is authorized to find out and establish a standard height. After July 1, 1893, cars must not be used in interstate traffic if they fail to comply with the requirements of this standard.

We have no fault to find with this law, and the railroad companies that have been struggling to prevent its enactment deserve no sympathy. The more enterprising railroad companies in the country are voluntarily equipping their cars with safety appliances at a rate which will not leave much extra effort to be made when the law becomes operative. It is high time that the companies which systematically hold back and do nothing should have the spur of compulsion applied to accelerate their action. These are the people who have made compulsory laws necessary, and it is only fair that they should suffer most.

The apathy of many roads to do anything to promote safety in car handling has been well illustrated in the case of the height of drawbars. There has been a standard height since 1872, but a great many companies have paid no attention whatever to it, although diverse heights of draw-bars has been a fruitful cause of accidents in car coupling. It is a very wise action to put a compulsory end to this inexcusable condition of affairs.

## Gland Metallic Packing.

The superintendent of motive power of one of our leading railroads, which has adopted the use of metallic gland packing for all the locomotives, on being asked lately how he was pleased with the change, replied that it was the most satisfactory improvement that had been put upon the locomotive since the injector was introduced. In the first place, he said, the packing is much cheaper than any of the fibrous varieties, but its leading merit is that it takes away a common cause for the failure of locomotives on the road. When glands are packed with hemp it frequently gives out before a heavily loaded engine can get over a division. This causes troublesome delay if the train has to be held till the packing is done. More than one accident has happened through trains being delayed unexpectedly while the engineer was packing a gland. Very few accidents will cause more expense than would be incurred in putting metallic packing upon all the engines. Delaying this improvement is one of the short-sighted policies common with those who do not understand their own best interests.

Another objection to the fibrous packing is, that when the contents of a stuffing-box suddenly blows out there is frequently no time to pack it, and the gland moves to and fro with the piston-rod and gets broken. This makes a failure of the engine reported against the mechanical department. In other cases when an engineer has to pack a gland on the road he gets nervous and hurried, and in screwing up the gland breaks a stud Result, another failure of engine. The metallic packing obviates all this trouble It makes a mechanical job and provides for the work of renewal being done by men who know how heavy a twist a stud is likely to stand. The fibrous packing for the rod is in line with fibrous packing for the piston-head, which was abandoned so long ago that few engineers are now aware that the piston-head was ever made steam-tight by the use of a hemp ring.

## Too Great Fertility of Rules.

In these days, when railroad officers of the martinet type are attempting to lay down hard and fast rules for every action of train men, a paragraph from a letter written by our correspondent, Paul Synnestvedt, is worthy of earnest consideration. He says, "There is no question but that some men are recklessly free with their use of the emergency action of the valve, and all reasonable measures should be taken to remedy this evil; but I cannot help saying, in behalf of those whose lives and limbs may be in danger, that considering the fast time made by the trains of the present day, the large number of trains run on the same track, many of them only a few minutes apart, and in general the many dangers that threaten the passenger as well as the railway employé, it is best that too many restrictions should not be put on the actions of our locomotive engineers, else they may hesitate in case of doubt; and it is assuredly true that when running at a speed of 60 miles an hour 'he who hesitates is lost.'"

American railroad men have been famous for the ability displayed to overcome difficulties as they arise, and for meeting unexpected emergencies with success. The qualities that have proved so valuable in this way have been developed through the men being permitted to use their own judgment. Railroad operating is now exceedingly complex, and more formulated rules are necessary than formerly, but care should be taken that rules are not made so numerous that an impression is given that the judgment of the man is no longer considered of value. We recently called upon a railroad manager who was wrestling with the formation of a book of rules for train men, and he had got material more voluminous than the Old Testament, and yet he was seeking more suggestions. His aim was to cover every event that could possibly happen and lay down directions about what was to be done. This sort of paternal management is not likely to produce good results. It is impossible for men to commit to memory voluminous rules, so the effect of issuing a code of this kind is the taking away personal responsibility without supplying a practical substitute. It is much safer to depend upon a man who will act promptly on his own judgment when an emergency arises than on one who tries to remember what rule is laid down to apply to the case.

---

There are some statements made in C. B. Conger's letter on "Brakes," in another part of this paper, that ought to receive the earnest attention of men in charge of railroad rolling stock. Mr. Conger says "In the list of questions and answers on the automatic air-brake, the order is given that on freight cars the engineer may set the air-brake when the brakemen are setting the same brakes by hand, but on passenger coaches never. The Pennsylvania Company run a line of freight cars equipped with air-brakes which can be set by hand from either end of the car. One end has the brake worked from the end of car for tunnel use, the other is operated from the roof of car. When the brake is being set from the top of car by hand, and air is applied, it will set the brake against the brakeman same as a coach. There is another feature about this arrangement; if the slack is taken up some on brake chain at that end it changes the leverage on that truck by moving the fulcrum 7¼ inches further away from the power, so the braking strain is increased from 8,500 pounds to 14,000 pounds, in round numbers. There is a fulcrum pin working in a slot in a bracket between the power and coupling to hand brake; as long as this pin rests at the end of the slot the braking strain is the same on each truck; take up the slack with the hand brake, it is changed. Why is this?"

On another page will be found an article on Electricity Considered as the Motive Power for Railroads, by Mr. J. E. Phelan, superintendent of the Northern Pacific Railroad, which is well worthy of careful perusal. Railroad men familiar with existing motive power are very reluctant to admit the possibility of steam locomotives being displaced by motors operated by electricity. In their opposition to change they generally act like the ostrich, which pushes its head into a sand bank to hide the approach of danger. Making believe that electric motors cannot succeed in moving heavy fast trains will not do anything to avert the change. If development of electric machinery shall ever lead to a point where electricity will be cheaper than steam locomotives the change will soon be made. It then behooves progressive railroad men to look the question fairly in the face, and be prepared with the necessary knowledge to fall easily in line should electric motors take the place of steam locomotives.

---

A correspondent wishes to know why it is that master mechanics and other railroad officers will not hire men for firemen who are over twenty-five years of age. We believe that young men are preferred for this business because they are likely to learn the part requiring skill more readily than older men. The arguments in favor of hiring young men as firemen are the same as those in favor of the novices for any business. Certainly the railroad companies have the right to establish a rule regarding the age at which men will be admitted to any kind of employment. From the experience we have had with men who succeeded in being started as firemen after they were thirty years of age and upward, we think it is wise for the railroad companies to keep the age below twenty-five years.

---

Our readers will be gratified on finding that Captain Anderson continues in this issue his highly interesting account of his experience "Train Running for the Confederacy." In one part of the narrative a most exciting incident is described, where an act of coolness and determination seemed many times put in imminent peril by the insane actions of one intoxicated engineer The story is told with dramatic effect that draws the readers into the scenes depicted. The articles will be continued in our next issue Captain Anderson, writes as if another letter would finish his interesting story, but we are in hopes that he may be prevailed upon to continue writing on the subject he is so familiar with. We find that the various articles on railroading in the South during the war time, are greatly valued by our readers.

Our readers appear to reverse the common order of things in the summer months Most journals find it almost impossible to get correspondents to write articles for them during the heat of summer, but we have received more letters last month than ever before. We have devoted more than usual space to the correspondence, and yet there are several good letters crowded out. While thanking our correspondents for their attention, we request the excuses of those whose letters do not appear.

A correspondent who is evidently inclined to be sarcastic wishes to know if the constitution and by-laws of the Brotherhood of Locomotive Firemen forbid the ringing of the engine bell at public crossings. He says that for the last five years he has noticed that the firemen always jump down and begin putting in fire every time the engineer whistles for a crossing. We fancy that a tendency of this kind can be best restrained by the individual engineer.

When the Master Car Builders' Association adopted the vertical plane or Janney type of car coupler as standard, there were many members of the Master Mechanics' Association who believed that a serious mistake had been made, and a committee was appointed to find out whether or not the vertical hook type of coupler could be recommended from a mechanical standpoint The committee dragged along for four or five years without doing or saying anything in particular. There was for a year or two an inclination to find fault with the M C. B. coupler, but no decided action was taken in that direction. At the last meeting it was strikingly shown how much progress had been made among master mechanics on the coupler question. The committee reported, indorsing the action of the Master Car Builders' Association in relation to car couplers, and the action was cordially supported by the convention. There was not a single voice raised in favor of keeping the subject open.

We understand that the smoke inspector of the City of Chicago has written a letter to President Miller of the Chicago, Milwaukee & St Paul Railroad, saying that the locomotives belonging to his road make less smoke than any engines operating within the city limits. President Miller has credited this gratifying stote of affairs to Mr. J. N. Barr, superintendent of machinery, and Mr. Barr, on the other hand, avers that all the credit is due to an intelligent road foreman of engines, who understands combustion, and gave the enginemen and firemen directions as to how smoke could be made a very small nuisance. Some of the roads running into Chicago are badly in need of road foremen of engines like the Milwaukee man.

## NEW BOOKS.

RAILWAY CAR CONSTRUCTION. A work describing in detail and illustrating with scale drawings the different varieties of American cars now built. By William Voss. Published by National Car and Locomotive Builder, New York.

This is a practical work, written by a master car builder, thoroughly familiar with every detail of car designing and construction, and having the language and expression necessary to tell what he knows. It is the only book we know about on car construction. It is likely to become a manual for those requiring information on the subject. Few manuals have been written that required so little correction or modification. Mr Voss takes up the construction of freight and passenger cars in detail and illustrates the work as it progresses by profuse use of drawings, every step being made clear. Among the leading subjects treated are freight car bodies, floors and framing, sheathing and roofs, freight car trucks; power-brakes; passenger cars, passenger car superstruction; passenger car trucks, etc. It is a book which every man interested in the construction or maintenance of cars ought to have convenient for reference.

## The Official Railway List.

We have been looking anxiously for the last few weeks for the 1892 edition of this useful book, and are now pleased to tell our readers that it has made its appearance. It has the old familiar look, only it has kept pace with the business manager and has become a little fatter than it was a year ago. The increase of volume means increase of useful information, and we are glad to put up with the augmented weight to our traveling bag, where this book goes regularly when we go out to see people and things of interest. We cannot imagine how people who have to refer to the names and addresses of railroad officials can get along without the Official List. It is sold for $2 by the publishers, Rookery, Chicago.

By arrangement with the Pennsylvania Railroad Company the Cooke compound locomotive pulled passenger trains all the way on its journey to Chicago. The engine is reported to have done excellent work throughout the entire journey. Those in charge thought of offering to run from Jersey City to Chicago on one continuous train, but after proper consideration the plan was abandoned, although they had confidence that the long run could have been made successfully.

The South Side Elevated Railroad people of Chicago are substituting the Jerome rod packing for the United States packing on several locomotives.

## PERSONALS.

Mr. A. T. Ellis has been appointed roundhouse foreman of the Union Pacific shops at La Grande, Oregon.

Mr. F. W. Deibert has been appointed master mechanic of the West Milwaukee shops of the Chicago, Milwaukee & St. Paul.

Mr. W. B. McPhail has been appointed master mechanic of the Ohio Southern Railroad, at Springfield, Ohio, vice A. E. Trempe, resigned.

Mr. H. A. Fritz, who has been a draughtsman in the office of the mechanical engineer of the Illinois Central, has been promoted to be chief draughtsman.

Mr. M N. Davis has been appointed foreman of the machinery and rolling stock department of the Denver & Rio Grande, with headquarters at Minturn, Colo.

Mr R. J. Turnbull has been appointed master mechanic of the Seattle & Montana Railway and of a number of proprietary lines. His headquarters is in Seattle.

Mr M K Barnum, a member of the Master Mechanics' Association, has lately been appointed foreman in charge of the North Platte Division of the Union Pacific system.

Mr. Henry Millholland, who has been connected with the mechanical department of the Pennsylvania railroad, has been appointed mechanical engineer of the Gould Coupler Company.

Mr. William Finley, who has been master mechanic of the Brooklyn & Brighton Beach for a number of years, has been appointed general superintendent of that road, with headquarters at Brooklyn, N Y.

Mr. Henry A. Barnes, who at one time was superintendent of motive power of the Wisconsin Central and left that road in 1887, has been appointed general foreman of the Illinois Central shops at Chicago.

We regret to learn that Mr. Robert Derby, who has been appointed master mechanic of the South Florida Railroad at Sanford, Fla., has been very sick for some time. We understand that he is now able to get around.

Mr. Richard English, who has been division master mechanic of the Atchison, Topeka & Santa Fé, at San Marcial, N. Mex., has been appointed general master mechanic of the Atlantic & Pacific with headquarters at Albuquerque, N. Mex.

Mr. F. A. Stinard, of Paterson, N J., and for some years master mechanic of the Greenwood Lake Railroad, has been appointed the agent for the Pennell Water Purifier. We bespeak for Mr. Stinard a kind reception from railroad men generally.

Mr. A. W. Gibbs, late superintendent of motive power and machinery of the Central of Georgia, has been appointed master mechanic of the Atlanta & Charlotte Air Line division of the Richmond & Danville, with headquarters at Atlanta, Ga.

Mr. D. J Durrell, mechanical engineer of the Illinois Central, has resigned that position to accept a similar one with the Illinois Steel Co. Mr. Durrell is succeeded on the Illinois Central by Mr. A Rosing, who for the past year has been with the Grant Locomotive Works at Chicago.

The announcement has been made by H. M. Flagler, president of the East Coast line, that Mr. W. L. Crawford has been appointed general superintendent. There has been a regular reorganization among the officers of this party which includes a great many small roads.

Mr. W. S. Cox has been appointed air-brake inspector and instructor of the Atlantic system of the Southern Pacific, with headquarters at Houston, Tex He will have charge of the inspection of air-brake equipment and instruction and examination of all employés whose duties require them to use the air-brakes

The large number of railroad supply friends of Mr. Joel H. Hills among our readers will be sorry to hear that he died suddenly last month. Mr Hills was agent for the Granular Metal Company, of Boston, and was one of the most esteemed members of the supply fraternity. His departure makes a blank that many will feel.

The announcement is made that the office of superintendent of motive power of the Richmond & Danville Railroad Company has been moved to Washington. This takes Capt. Wade back to that city. How this office was transferred from Atlanta is one of the mysteries of railroading that none but those making the order can understood.

Mr. E Hedley was appointed master mechanic of the Brooklyn Elevated Railroads last month. Mr. Hedley has been for several years general foreman of the Manhattan Elevated Railroad shops in New York City, and was known as a particularly able man in carrying on the elaborate system of repairs followed in the Manhattan shops.

We have letters from our partner, Mr John A. Hill, intimating that he is absorbing all there is to be seen and heard in Germany, but he had not found time to put any of his impressions on paper. Mr. Hill has been devoting a great deal of his time to visiting railroad shops in Germany and Holland, and is pleased with the kindness shown him at every place visited.

Mr Clarence H. Howard has been appointed Secretary of the Safety Car Heating and Lighting Co., with headquarters in New York. Mr. Howard has been for a year or two Superintendent of the St. Charles Car Works, and previous to that was a master mechanic. He is a particularly popular young man, and we anticipate will make a great success in his new position.

The absorption by the New York, New Haven & Hartford of the New York, Providence & Boston has led to the announcement that Mr L M. Butler has been appointed master mechanic of the Providence & Worcester Division. Mr. Butler is one of the ablest mechanics in New England, and has lately received several tempting offers to take him away from Providence.

During the Master Mechanics' and Master Car Builders' Convention, Mrs. George W. McGuire was active soliciting subscriptions for the Fresh-Air Fund for children at Cleveland. She met with very great success, as is testified by an item we lately find in a Cleveland paper, to the effect that the lady named handed in $60.50 to the *Leader* office as a contribution for this very benevolent purpose.

Mr. Robert B. Reading has been appointed general foreman of the New York Elevated Railroad shops at 145th street, New York. Mr. Reading is a technical school graduate who went into a shop and worked at the bench on leaving college. He fired for some time on the Erie, and has lately been assistant foreman of the Elevated shops at 98th street, and before that was in the drawing office.

Mr. J. J Ellis has been appointed general master mechanic of the Chicago, St. Paul, Minneapolis & Omaha, to succeed his brother, Mr. Matthew Ellis, resigned on account of ill health. Mr. Ellis has been acting master mechanic for about two years, the hope being entertained that Matthew would get better. The latter is reported to be suffering from brain trouble, from which he is not likely to recover sufficiently to resume work again.

John A Hall, of Chicago, editor of the *Switchmen's Journal*, was killed at the Relay depot, East St. Louis, in attempting to board an outgoing train of the Cairo Short Line The train was already in motion and Mr. Hall grabbed at the railing with one hand, but the momentum was too great, and he fell between the cars and was crushed to death. Mr. Hall exerted great influence among switchmen and it was always exercised wisely.

Mr. C. F. Ward, who has been at Costa Rica for about a year, has returned to the northwest as master mechanic of the Duluth & Winnepeg and Duluth, Messabi & Northern roads, with headquarters at Duluth, Minn. Mr. Ward left the St. Paul & Duluth to be superintendent of motive power of the Santa Fé and Gulf system at Galveston, which he left on account of his health not being good there. He is one of the ablest shop managers in the country.

Nearly every railroad mechanical convention brings some new man to the front. This year the new man brought into prominence at the Master Car Builders' Convention was Mr. J J. Hennessey, master car builder of the Chicago, Milwaukee & St. Paul. He was chairman of the Committee on Wheel Guarantee, on which he submitted a good report. On the floor he displayed great readiness in debate, with good ideas to back the position he took on the various subjects.

Mr. George A. Hancock has resigned as master mechanic of the Atlantic & Pacific to accept the position of superintendent of machinery of the San Antonio and Arkansas Pass, with headquarters at San Antonio, Tex. Mr Hancock will be missed at Albuquerque and other places on the Atlantic & Pacific, for he had labored zealously to promote the comfort and well being of the men under his charge. By his efforts libraries were lately established at three division points.

Mr. W. W. Thompson has been appointed supervisor of rolling stock of the Chicago South Side Elevated Railway, the position being that of master mechanic under the superintendent. Mr. Thompson was for about ten years on the elevated railroads of New York, the greater part of the time filling the position of road foreman of engines. He left there to be division master mechanic of the New York Central. Col. Hain, speaking of this appointment said. "Mr. Thompson was one of the very best executive officers I ever had."

The report has again reached us that Mr. Theo. N. Ely, general superintendent of motive power, of the Pennsylvania Railroad, has been elected a vice-president and that Mr F. D. Casanave, of the Fort Wayne district, has been appointed general superintendent of motive power Some time ago Mr Casanave received a highly tempting offer from the Philadelphia & Reading, and it has generally been understood that he was retained in the service of the Pennsylvania by a promise of something much better than he had at Port Wayne.

The Society of American Railway Superintendents is an organization that is in a highly prosperous condition. Delegates have been appointed by the Master Car Builders and Mechanics' Associations to attend the next convention of the Superintendents. This action and the sentiment that prompted the sending of the invitations are likely to draw the three associations concerned into closer intimacy. Much of the recent prosperity of the Society of Superintendents is due to the work done by the secretary, Mr. C. A Hammond He holds decided views about the good work that can be done by his society, and labors vigorously to have the work accomplished.

## A Wonder for the World's Fair.

There was one thing at the last Paris Exposition that seemed to overshadow everything else in the eyes of visitors—that was the Eiffel Tower. There were many things at that exposition of greater value from an engineering standpoint, yet the Eiffel Tower received more attention than all the other wonders combined of that great show.

When the Columbian Exposition at Chicago was first spoken of, there were numerous proposals made to build a tower which would eclipse in magnitude that of Paris; but imitation is not one of the views of this nation, and the idea did not receive support. We now learn that it has been decided to build an apparatus at the World's Fair which will be as conspicuous as the Eiffel Tower and a far more wonderful conception from an engineering standpoint. Money has been raised to build of steel a revolving wheel 240 feet in diameter, with a periphery 50 feet wide. This immense wheel will be set on an axle and revolved by two engines of 1000 horse-power each. On the periphery of the wheel will be hung a series of cars capable each of seating fifty persons. The cars will be hung on the same plan as the revolving curtains that are to be seen in store windows for showing small articles that always keep perpendicular as the screen moves round. Passengers will enter these cars at suitable landings and be lifted up into the air round the largest wheel in the world. From the top a view may be had equal to anything seen from the Eiffel Tower.

The whole of the plans of this wonderful conception have been worked out by an eminent engineer down to the minutest detail. The drawings are made, all the money has been raised to defray the entire expense, and the contract is about to be let to parties competent to perform the work of construction within the required time.

## Foreign Railroad Exhibits for the World's Fair.

Mr. Willard A. Smith, commissioner of the transportation department of the World's Fair, has returned from a trip to Europe highly encouraged and elated by the interest displayed in the exposition by railroad and government officials in Europe. The German government will send a large exhibit of locomotives and cars, most of the former being compounds. Several other continental countries will send interesting exhibits. Some of the leading British railway companies will send locomotives and cars, and Mr. Smith has secured the promise of several machines of great historic interest, among them Stephenson's "Locomotion," one of the first engines that was used on the Stockton and Darlington Railway and similar in construction to the "Stourbridge Lion," the first locomotive that turned a wheel on an American railroad.

Mr. F. W. Webb of the London & Northwestern, has promised to send one of his latest compounds.

Mr. Smith is striving to arrange for the making of tests between European and American locomotives during the exhibition. There are few things that could be done to excite greater interest. There are many obstacles in the way of making such tests, but we hope they may be satisfactorily overcome.

## A New High-speed Engine.

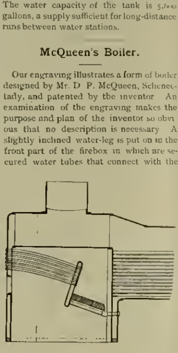
Scranton papers have contained lately some elaborate accounts of a high-speed locomotive built at the Kingston shops under the supervision of Master Mechanic Charles Graham, Jr. The engine has Wooten patent firebox and the intention is to burn anthracite coal.

The cylinders of No. 245 are 19 inches in diameter and 24 stroke, and the driving-wheels are 5 feet 8 inches in diameter. The firebox is 8 feet wide and 10 feet in length, and the cylinder part of the boiler is 54 inches in diameter at the smallest point and contain 220 tubes of 2 inches diameter.

In general beauty of design and mechanical construction it may be said that this engine excels in many points any of its predecessors. It has all the latest improvements, including air-brakes, air-whistle signal, air bell-ringing attachments, steam heat, sight-feed cylinder lubricators, and Leech's patent appliance for feeding sand on the rails by air pressure. It has also two No. 11 injectors, the largest made. The water capacity of the tank is 5,000 gallons, a supply sufficient for long-distance runs between water stations.

## McQueen's Boiler.

Our engraving illustrates a form of boiler designed by Mr. D. P. McQueen, Schenectady, and patented by the inventor. An examination of the engraving makes the purpose and plan of the inventor so obvious that no description is necessary. A slightly inclined water-leg is put on in the front part of the firebox in which are secured water tubes that connect with the



back water space of the firebox. A brick arch is built from the lower part of the water-leg to the front flue sheet. The purpose of the invention is to make a successful spark-arrester that will keep the sparks in the firebox, and also to increase the heating surface. No boiler of this design has yet been built but the inventor is in hopes that it will soon be given a practical trial.

## A Butting Match with Locomotives.

A press dispatch from South Bethlehem, Pa., says: Owing to a dispute as to who should use the switch first, the crews of two trains that met at the Third street crossing of the North Penn Railroad instituted a novel pushing match to-day, which may cost them their situations. Both engines were shifters and each had about a dozen cars attached. They met with a slight bump at the switch, and after an exchange of warm words each opened his throttle, intending to push the other back. Both the engines snorted and puffed, while sparks flew from their rapidly revolving wheels. For several minutes neither budged an inch. Finally the camel-back was forced to give way.

## Power Required to Move Reciprocating Parts.

Mr. Ben. Johnson, writing from Topeka, Kan., says:

"I wish to dissent from the conclusion of Mr. Frank Corbett, in your July number, that of the power developed in the cylinders of a locomotive running 60 miles per hour, 336 horse-power is consumed and lost in getting up the speed of crossheads and connections in the first half of each stroke.

"While it is true that the pistons start from a state of rest at the beginning of each stroke and attain a greater velocity at the middle, it is also true that from a great velocity at the middle of each stroke they come to a state of rest at the end of each stroke, and in so doing give out to be utilized in turning the wheels and moving the train all the enormous amount of power or energy absorbed in the first half of the stroke.

"The failure to recognize this fact is one of the principal reasons for the perennial crop of rotary engines that fill the Patent Office."

## Exporting American Railroad Track Spikes.

The proverbial "carrying of coals to Newcastle" has been again discredited by a transaction lately come to our knowledge.

The remarkable interest manifested in this country of the "Greer" Improved Railroad Track Spike has been met by the same feeling of interest in England and her colonies. A little while ago Morris Sellers & Co., of Chicago, received an order for several lots of "Greer" track spikes from the government of New Zealand for delivery at Auckland, Lyttelton and Dunnedin, New Zealand.

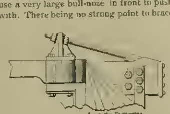
These were shipped via London, being then transhipped for the Pacific, and the remittances duly received in payment for same.

It makes considerable difference what kind of "coal" is sent to Newcastle.

The Greer spike is giving extraordinary results on numerous roads where it has been adopted. Its holding tenacity is nearly twice that of any other spike, and it does not split the tie but cuts its way in. Several roads are using the spike exclusively for curves and places difficult to keep in gauge.

## Drawhead Brace.

The annexed engraving shows a form of drawbar brace used for the front of pilots, by Mr. A. Dolbeer, of the Buffalo, Rochester and Pittsburgh. With the heavy coal traffic done on this road it is necessary to use a very large bull-noze in front to push with. There being no strong point to brace



from beneath, much trouble was experienced from breakage and from the bar dropping down. To give the required strength Mr. Dolbeer designed the brace shown, and it has proved a perfect remedy for the weak point. By its use the repairs to pilots and front drawbars have been greatly reduced.

## Lining Pistons.

In the July issue I see an article from Mr. Hugh R. Crawford in regard to lining by counter-bore of cylinder, in which he says: "To set a line in a cylinder worn the least possible measurement out of truth by the counter-bore is a delusion and a snare. One object in setting a line is to get the center of crosshead directly in line with center of cylinder, and if the crosshead guides are set with a line centered from counter-bore they will be found too high when piston-rod is keyed to crosshead." It seems to me that Mr. Crawford disregards altogether the back cylinder head in his idea of lining from worn part of cylinder. Suppose, for instance, a cylinder is worn an eighth of an inch out of true, and your gland fits both piston and stuffing-box neat, how would it be possible to connect piston to crosshead? A good way to bore a rod brass to fit a crank-pin to keep it from binding top and bottom, is to place a $\frac{1}{16}$-inch liner between each half of brass before boring, and to caliper pin with same thickness of liner allowed. You will find that it works admirably.

ERNEST MARTIN.

*Raleigh, N. C.*

We have received several notices lately that the Pennell Feed-Water Purifier is doing remarkably good service for railroads. M. M. Dunn, of the Idaho Division of the Union Pacific, where one of these purifiers is in use, writes: "You will remember that when you were out here last month I told you that the engines were leaking considerably, and that we were getting a great deal of scale out of the boilers. I think now that we have about all the scale out of the boilers of the two helping engines located there. They have been up to Montpelier to have the boilers washed, and necessary repairs done, twice in the last month, and each time they came in the flues were perfectly tight and we did not have to calk them. Another good indication is that whatever sediment we find in the boilers now is very soft and can be washed out readily. The only trouble we have is that they foam some. Have arranged to put pipes on the blow-off cocks, so that they can be blown off every day, or oftener if necessary, which I think will obviate the trouble of their foaming, and also keep the boilers clean, as it will blow off all the sediment as it collects in the shell of the boiler."

The Illinois Central Railroad officers have been investigating the propriety of ordering some compound locomotives. To help them to a decision they had some comparative tests made with a Baldwin compound and some of their ordinary engines. After weighing the question carefully, they have decided not to have compounded any of the engines they are about to order. The Cooke compound locomotive is built after the pattern of some ten-wheel engines the Illinois Central Railroad have in service, and this engine is now in Chicago to be subjected to tests alongside engines that are in all respects the same except in the cylinders. On the result of these tests will depend the future action of the Illinois Central regarding compounds. Several of the officers are very favorably inclined toward compound locomotives, but they intend to be certain that they are right before making a change.

The Ashton Valve Company of Boston have issued a circular announcing that they have bought the entire plant, material and business of the Boston Steam Gauge Company. They will manufacture all classes of steam pressure, vacuum and other gauges. Mr. H. L. Willard, formerly business manager of the Boston Steam Gauge Company, goes with the Ashton Valve Company.

Various improvements in car trucks have been patented by Arnold Miller, of Medford, Wis. They embrace changes on the diamond truck which put the springs over the axle-box and provide a strong frame for the pedestals, an improved journal bearing, and alterations on the passenger car truck intended to keep it from becoming distorted and to make it more durable.

The N. Y., O. & W. have increased their order for engines with the Dickson Mfg. Co. to ten instead of five, as originally let.

Lake Shore & Michigan Southern have just closed a contract with Brooks for twenty additional engines.

The Florida Central & Peninsula Railroad will contract for three hundred freight cars in the near future.

Specifications for one thousand freight cars for the Illinois Central road are in hands of bidders.

The Mahoning Valley will soon be in the market for three hundred more cars—hopper bottoms.

Baldwins have closed a contract with New York, Chicago & St. Louis for ten engines.

It is rumored that the B. & A. will contract for five hundred additional cars.

## Devotion to Railroad Duty.

By Sam Short

My sympathy and fraternal interest have been greatly moved of late for my old friend, Kurgess. He was the hero of my youth, in the days when hero-worship was one of my weaknesses. It is curious to notice the different kinds of objects that boys take for making heroes of. Boys of railroad proclivities generally fix on an engineer or conductor, or even an imaginative brakeman, as the object of adoration, but my hero was a wrinkle-faced, grease-apparelled machine-shop foreman.

When I was learning the machinist trade by doing chores in the two-stall mechanical headquarters of the Big Mountain Railroad of Illinois, Roger Kurgess was general foreman, and a better man to make things out of nothing there was not in the West, where original creative methods were greatly cultivated. Roger had peculiar views about some things, but a better mechanic never pushed a file. There was a tradition around that nothing had ever been done in the working of metals that Roger could not do better than any other man. He appeared to know more about boilers than any of the boiler makers, and when iron or steel worked badly under the blacksmith's hammer, Roger was the expert who investigated the cause of the metal's shortcomings, and always found them out.

These high accomplishments were in the line of Roger's ordinary duties. To see the ability and ingenuity of the man shine in full splendor, an engine had to come in with something broken that no other man ever thought of mending. To tell of the broken parts that Roger repaired with his own hands would be to enumerate all the parts about a locomotive. His pride and glory, however, was in repairing broken cylinders. The boys used to say that Roger was always uncommonly cheerful when he heard about a collision, and that his greatest pleasure was in seeing an engine come in with the cylinders badly stove up. This was probably a joke, but he took undoubted interest in repairing cylinders, and the harder the job the greater the personal care he bestowed upon it.

It was no wonder that a boy should become a blind admirer of a man so gifted.

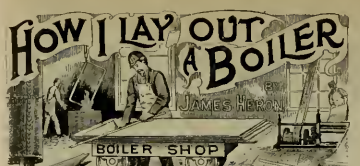
Roger was very careful about my training and took particular pains to see that I did not fall into idle habits for want of something to do. When I was not developing muscle twisting a tap or die lever, pulling at the lever of a screw-jack or operating a pinch bar, the foreman found work for me in packing boxes or cleaning up the place. This latter occupation was the resource when all others failed, and it was never properly begun.

Only one thing came between me and the sunshine of Roger's constant favor. I was fond of reading, and Roger had a particular antipathy to everything that was printed. On rare occasions I had concealed myself in tanks and fireboxes to finish some thrilling story by Mayne Reid or other favorite author. From bliss I would suddenly be dragged to humiliation by a hose stream directed by Roger. Then he would make me shovel out the ash-pit and keep me at roughest drudgery for a week.

About the time that I attained to the honor and dignity of facing valves, the Illinois Transcontinental fell in need of a master mechanic and Roger Kurgess was appointed to the place. At that time the road was small, having only about ten engines and 120 miles of track. But it was one of those ambitious Western railroads that started out with ten miles of scrap rails, an old locomotive, half a dozen second-hand cars and trans-oceanic aspirations. If it did not yet reach the aspirations of its promoters, it has not been for want of trying and boasting.

At the time Kurgess took hold as master

(Continued on page 293.)



### Taper Connection Sheet.

Fig. 10 shows front elevation of taper connection sheet, large and small ends. Radius of large end 2 feet 6¼ inches and 1 feet 2½ inches outside, and of small end 2 feet 4½ inches inside. Note that the large end is not a true circle. The radius for top of boiler is struck 6 inches from center of boiler and radius for side 3¼ inches above and 7¼ inches to one side of perpendicular center line. This is done to avoid having a flat place on side and to strengthen same by getting as near a circle as possible. I am aware that this is a hard problem for amateurs to work out, but if the boiler maker trying to work it out perseveres he will find it simple enough. It was my intention to give something easier for the first, but I have had several requests for the taper connection and I like to supply first what is most in demand.

Now, you must study Fig. 10 well before going to other figures. Fig. 10 shows edges of plate, back and front, after being bent to proper shape. I show but half view, as the other half would be the same. Now suppose you take and divide your small end into eight equal parts, by spacing off on edge of sheet, as at 1 to 0, then do the same with large end, as at *A* to 1. Then strike lines *A* to 1, *B* to 2 and so on; then your front elevation is complete.

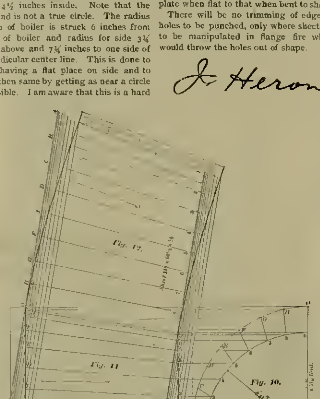
I speak of edges of plate in connection with this figure, to give an idea what these lines are for and why this elevation is required to be laid down in order to lay out flat plate.

Fig. 11 shows side elevation of taper connection. Note that Figs. 1, 2, 3 to 0 are parallel with Figs. 1, 2, 3 to 0, Fig. 10 or small end of taper sheet. The large end is the same, but I have not drawn all the parallel lines as it would not leave side view so clear.

Fig. 12 shows one-half of plate when flat, and taking 0, 0 as center, as shown. Were it of light material that could be bent by drawing same over Fig. 11, all lines and letters, figures and holes would meet the corresponding letters, figures and holes. In my next paper I will give a simpler method, and go into details of laying out plate when flat to that when bent to shape.

There will be no trimming of edges or holes to be punched, only where sheet has to be manipulated in flange fire which would throw the holes out of shape.

J. Heron



### A Separate Engine for Each Car.

A somewhat novel means of propelling railroad cars has been invented and patented by Mr. J. M. Keith, a member of the Railway Master Mechanics' Association, and now in the employ of the Baldwin Locomotive Works. Mr. Keith proposes to put a steam motor under each car and supply steam from a boiler carried in front. His object for this arrangement is stated to be that the full horse-power of the steam boiler may be applied in a manner enabling it to be utilized to the greatest possible advantage and to the utmost extent.

The cylinder to be used under each car transmits power to a gear wheel which engages with a gear wheel on one of the car axles. Means are provided for throwing out the gear connection when desired. Two lines of steam pipes are led through the train, one to supply steam, the other to return the exhaust steam to the smoke-stack of the boiler.

The claims for the invention are in a railway car the combination, with a wheel-axle, of a gear mounted loosely on axle, a clutch for making gear fast with the axle, a crank-shaft having a gear meshing with the axle-gear, a steam cylinder mounted on the car truck and having its piston and valves connected with said crank-shaft, separate live-steam and exhaust pipes connected, respectively, by flexible couplings to the live-steam and exhaust ports of the steam cylinder, said pipes having at their ends flexible couplings to corresponding pipes on the adjacent car or cars, and a common steam-supply to which one of said pipes is connected, substantially as described.

The combination, with a car-axle, of a steam cylinder mounted on the truck-frame, a crank-shaft connected to the piston and valves of said cylinder, a gear fixed to said crank-shaft, a gear loose on the car-axle and meshing with the crank-shaft gear, a clutch splined on the axle, a shipping lever for actuating said clutch, a live-steam pipe and an exhaust pipe carried by said car and connected to the steam cylinder, means for connecting said pipes to similar pipes upon an adjacent car or cars, and a steam-supply common to the steam-cylinders of several cars in a train.

### Master Mechanics' Association Scholarships.

The following circular has been issued by Secretary Sinclair of the American Railway Master Mechanics' Association.

"There will be one scholarship for the four years' course open for competition at the Stevens Institute of Technology next September. The requirements are that the applicants shall be sons of members of the American Railway Master Mechanics' Association in good standing, and they must have at least one year's experience in a machine shop.

"There will also be vacancies for scholars in the second and fourth year classes. Should no candidates pass for these, there will be two scholarships open in the Stevens Preparatory School for persons eligible for the Association scholarships in the Stevens Institute of Technology."

### Locomotives of the War Time.

Mr. Sam Manley, International & Great Northern Railroad, Palestine, Texas, writes us.

"I see in the June issue of your paper an article called 'A Completed History of the Rebel General,' taken up by Mr. W. A. Knight where Mr. W. H. Wesley left off. If you will give me space in your valuable paper, I shall tell what I know about this engine, and give some notes of my experience with locomotives in the South during war time. The hard-looking locomotive illustrated on page 211 of your June number was not called the Rebel General. The only engine named the Rebel General, that I ever heard of, was that belonging to the Western & Atlantic Railroad, captured by Captain Andrews and his company during the war and taken from her crew while they were eating breakfast at Big Shanty. The engine, as is well known, was recaptured by her crew after a very lively chase, and Captain Andrews and his crew were executed for the daring act of trying to run away with the engine.

"To go on with my story, Mr. Knight is entirely clear of his bearings, when he says that, when he took charge of the Tennessee Coal and Railroad Co., as superintendent of motive power, he found the Sewanee out back of the shop, where she had been furnishing steam to run the works. This is a mistake, as I was working for this company at the time as a machinist, and know all about it. My father, Joe Manley, was master mechanic at Tracy City, and I was working for him, and I had the honor, if any there be in it, of rebuilding the engine after her memorable trip down the mountain, though I believe she was brought to Nashville, Tenn., and rebuilt again by Mr. James Cullen, master mechanic of the Nashville & Chattanooga Railroad. When I went out to Tracy I found this engine in the shed, with a coat of white lead on her, where she had been put after being overhauled by my father, previous to his appointment of master mechanic of that road.

"I will always remember this engine coming out of this shed to go into service, as there is a very sad incident connected with the history of the first run. She was called the Colyer. The incident I intend to relate will show how some men have a presentment or forewarning of something going to happen, as I have noticed in different cases, especially among engineers.

"Engineer James Legg was called to go on his run at 5 A. M., with engine No. 3. While getting his engine ready, some staybolts gave out, which caused his engine to leak so badly that she had to be returned to the shop for repairs. It was then that the old Colyer was taken out to be put upon the road. Instead of the engine No. 3, my father had her fired up, and told Engineer Legg to go out on her until he could get the other engine repaired. During the time they were getting up steam on the Colyer, Engineer Legg said to my father, 'Uncle Joe, I do not want to go out on the Colyer. I feel that if I do something is going to happen to me.' My father told him he was foolish to think of such a thing. Engineer Legg then went home, and there is no doubt in my mind but he went there to take the last good-by of his wife and little ones. On his return to the engine he said again, 'I will go out, but I know something is going to happen.' Then my father said, 'If you feel that way do not go out,' and offered to make the trip in his stead, as there was no extra engineer at Tracy, but Engineer Legg replied, 'No, I will go out on it myself.' So out he went, and everything looked as if they would have a good trip and safe return to Tracy; but alas! such was not their good fortune. When they got to Corn Crib crossing, as it was called, the Colyer left the track and turned over on Engineer Legg, scalding him so badly that he died before morning.

"Another thing about this ill-fated engine, which hardly seems creditable, was that she once broke loose from her tender and went down the bank. The tender and eight car-loads of coal and caboose went down the mountain without her until stopped by a train crew. Comptroller Gaines was on the engine when she turned over; he was not hurt, but a worse scared man you never saw, and I guess he will always remember his ride on the old Colyer down the side of the mountain. She was afterward picked up and brought to Tracy. At that time I was overhauling engine No. 4, and our stationary boiler gave out. The Colyer was then made to furnish steam for the shops until the stationary boiler was repaired. After I was done overhauling No. 4, the Colyer was brought into the shop, and the engraving in the June issue of your paper shows how she looked. After I rebuilt her there were considerable changes made. She was an old Danforth & Cook, one of their first build when locomotives were in their infancy. She had no running boards on her until I put them on—nothing but a foot rail running from back end of engine to bumper on front end, made of 4-inch angle iron, and not a very safe thing for the engineer to go out on on a bad night when he imagined that something was going to be wrong. By a look at the engraving you will see I cut this rail off the back end of guide yoke and joined it to back end of cylinder for a brace for the yoke.

"I have started to give you my experience on this engine, and I will not stop until I tell you about her jacket. I did not know before I went to work at Tracy that a machinist had to be up to what the master mechanics now call a handy man. If I had known that before I would not now be writing my experience with the Colyer. When I got her ready to receive her jacket, I asked my father, who was going to put on her jacket? Imagine my surprise when he said, 'You are going to do it.' Well, I told him that if I had to put on that jacket to send off and get a good supply of Russia iron, as I did not want to be limited on material. Well, I got the jacket on, but not until I had lost

all my religion over the job. I never did ask my father how he liked the looks of the jacket, nor did I care to have him express his opinion. Suffice it to say, there was less Russia iron there when I got through than when I commenced.

"This is a true history of my experience with the Colyer, and not the 'Rebel General,' as Mr. Knight says. I know Mr. Knight well, as I worked for him. He relieved my father at Tracy, and not caring to be a handy man any longer, I quit."

## Rod Boring Machine.

Our illustration shows a new tool recently built by the Niles Tool Works, Hamilton, Ohio, for the Grant Locomotive Works at Chicago.

The machine was especially designed for rod work. It has great power and will bore both ends of the rod at the same time, thus allowing the work to be done in duplication with the greatest degree of uniformity.

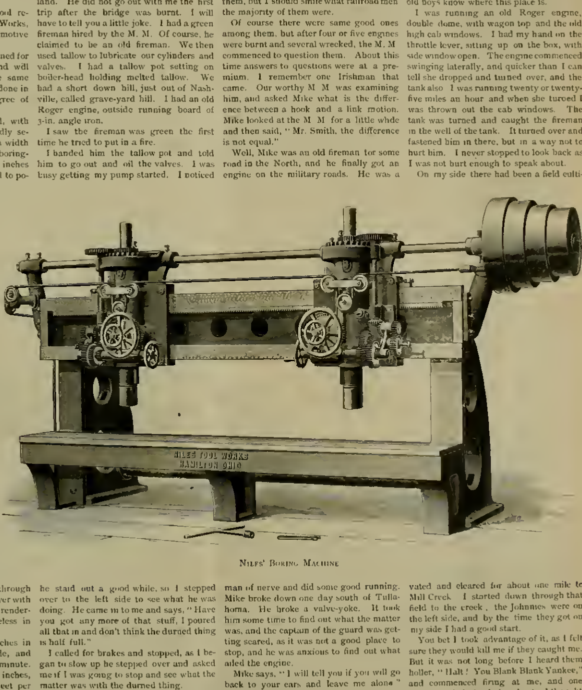
The housings are double-webbed, with the cross-rail and work-table rigidly secured to them. The cross-rail has a width on the face of 20 inches, and the boring-head saddles have bearings on it 26 inches long. Saddles are quickly adjusted to position on rail by means of rack and pinion, operated by a "T" wrench. Their relative positions once being determined for the work to be done, the saddles are firmly clamped in place.

Boring spindles are 3¾ inches in diameter, having a vertical traverse of 14 inches and a range between centers of from 3 feet to 10 feet. Both spindles are counterbalanced by a single weight, in same manner as the tool-bars on boring and turning mills. This device permits an adjustment of the saddles without moving the weight, and does not burden the saddle or rail with additional weight to secure the counterbalance, as must be the case with other methods.

Three changes of feed are available for each spindle without the change of gears, ranging from $\frac{1}{32}$-inch to $\frac{3}{16}$-inch per revolution of spindle. Spindles have rapid hand motion to facilitate setting, and are provided also with slow hand-feed. The spindles are always driven together, but the feed is independent for each.

The machine is designed for boring diameters ranging from 3 inches to 7 inches. Cone has four steps for 5-inch belt, and transmits motion to the spindles through tangent gearing, securing great power with extreme steadiness under cut and rendering the machine practically noiseless in action.

Countershaft pulleys are 23 inches in diameter, for belt, 5 inches wide, and should run 100 revolutions per minute. When operating on a diameter of 7 inches, this gives a cutting speed of 20 feet per minute.



NILES' BORING MACHINE

A smoke burner invented and patented by Theodore Lustig, Chicago, has a box set in the front of the grates with a perforated lid through which the air is admitted to the fire. Steam jets are employed to force a current of air into the box. Yarrow, in his first smoke-consuming firebox, used an arrangement similar to this without the jets and without the box. His was a perforated iron plate. It worked all right while the plate lasted, but it sometimes burned out in a single run.

A correspondent is solicitous that some one would write a good, plain article on laying out shoes and wedges as it is done in the best repair shops.

## Locomotive Running Among the Bushwackers.

By Old Soldier.

[Continued.]

After the bridge was burned and rebuilt we commenced running regular. The Johnnies did not hold the fort long, nor was there enough of them to hold it, so they were sadly disappointed.

Poor Pat, he told me he had enough of the military road, and that if he could raise the money he would go back to old Ireland. He did not go out with me the first trip after the bridge was burnt. I will have to tell you a little joke. I had a green fireman hired by the M. M. Of course, he claimed to be an old fireman. We then used tallow to lubricate our cylinders and valves. I had a tallow pot setting on boiler-head holding melted tallow. We had a short down hill, just out of Nashville, called grave-yard hill. I had an old Roger engine, outside running board of 3-in. angle iron.

I saw the fireman was green the first time he tried to put in a fire.

I handed him the tallow pot and told him to go out and oil the valves. I was busy getting my pump started. I noticed he staid out a good while, so I stepped over to the left side to see what he was doing. He came in to me and says, "Have you got any more of that stuff, I poured all that in and don't think the durned thing is half full."

I called for brakes and stopped, as I began to slow up he stepped over and asked me if I was going to stop and see what the matter was with the durned thing.

About that time I stopped and said to him "Now you get off this engine darned quick and walk back to Nashville." I called back to the captain of the guard and told him to send me over a "blue coat." Well, "blue coat" did pretty well for a greeny; but, oh Lord, how it makes me creep all over every time I think of him! He was covered with "graybacks." All the old soldiers will know what those are if you "tenderfeet" do not, or any old passenger conductor on military roads can tell.

Well, we went on to Winchester and returned without any serious mishap. The first fellow I met on my arrival was my fireman Pat. He could not raise money enough to go back to old Ireland, so he concluded to go back with me on the old six.

Going out we had a couple of cab windows shot out and several shots into the guard car and coaches, but returned to Nashville with the old six and our carcasses O. K.

About this time the soldier boys commenced to kick about pay, and the business commenced to pick up on the roads so fast that we had to get new engines and new men. We got some pretty hard old scraps, and the road that sold them got a good big price for them. The Government sent out men North to hire engineers and firemen and train hands. They got them, but I should smile what railroad men the majority of them were.

Of course there were same good ones among them, but after four or five engines were burnt and several wrecked, the M. M commenced to question them. About this time answers to questions were at a premium. I remember one Irishman that came. Our worthy M M was examining him, and asked Mike what is the difference between a hook and a link motion. Mike looked at the M M for a little while and then said, "Mr. Smith, the difference is not equal."

Well, Mike was an old fireman for some road in the North, and he finally got an engine on the military roads. He was a man of nerve and did some good running. Mike broke down one day south of Tullahoma. He broke a valve-yoke. It took him some time to find out what the matter was, and the captain of the guard was getting scared, as it was not a good place to stop, and he was anxious to find out what ailed the engine.

Mike says, "I will tell you if you will go back to your cars and leave me alone." As this was agreed to, Mike told them that the "doowaddle fell down on the dingus rigging and she came up on center and refused to qualify, but I'll have her ready on one side in about an hour." I think this gag got through the whole army of the Cumberland. The train then backed up to Tullahoma, and the conductor telegraphed back what the matter was, as this was a newfangled breakdown.

As I said before, the army wanted their pay. The road was being pushed on to the Tennessee River as fast as men could do it. I still retained my run. About twelve miles out of Nashville there was at that time a heavy cedar grove. It was to the left of the road after leaving Antioch, going south. Well, as I said in my last article, the Yanks liked revenge, so did the Johnnies, and Dick McCann got his.

He and General Forrest planned the capture of our paymaster. I was the lucky one pulling.

I think Dick and Forrest had 500 or 600 men. Dick was an old thoroughbred railroad man and he knew just how to capture a train. He spread the rail by pulling out the spikes until he got the tracks widened out to let the engine drop. I had just wood enough to build up first rack of wood in tank. The fireman had just about finished his pile when I struck this place. We had about three-fourths of a mile to run to old Mrs. Dows' wood pile. All the old boys know where this place is.

I was running an old Roger engine, double dome, with wagon top and the old high cab windows. I had my hand on the throttle lever, sitting up on the box, with side window open. The engine commenced swinging laterally, and quicker than I can tell she dropped and turned over, and the tank also. I was running twenty or twenty-five miles an hour and when she turned I was thrown out the cab windows. The tank was turned and caught the fireman in the well of the tank. It turned over and fastened him in there, but in a way not to hurt him. I never stopped to look back as I was not hurt enough to speak about.

On my side there had been a field cultivated and cleared for about one mile to Mill Creek. I started down through that field to the creek, the Johnnies were on the left side, and by the time they got on my side I had a good start.

You bet I took advantage of it, as I felt sure they would kill me if they caught me. But it was not long before I heard them holler, "Halt! You Blank Blank Yankee," and commenced firing at me, and one bullet struck the heel of my boot. I thought my ankle was broken but did not stop to investigate. The Johnnies had too much booty to follow me. I kept up running until I came to the creek. I jumped in and swam across. I had to swim the creek three times before I could reach Fort Nagle, but I made it and gave the alarm. Troops were immediately sent out, but too late to save anything. The whole crew and everything on that train were captured except myself.

[To be continued.]

The Fitchburg Railroad will begin work at once on twelve more coaches. Being so well pleased with the twelve just put in service, built by Superintendent Car Department J. W. Marden, they will be duplicated.

## Hold Better Sentiments.

*Editors:*

We see an article in your last issue with our names attached. Gentlemen, those names were signed by Mr. Goffney without our permission, for the letter he wrote in no way speaks our sentiments. To oblige us both will you please publish this in your next issue, to exonerate us from all the criticisms of a thinking public.

J. B. TUCKER,
WM. G. RAY.

*Water Valley, Miss.*

## This Paper is all Right.

*Editors:*

Messrs. J. R. Goffney, W. G. Ray, Jas. B. Tucker, you three old sports, what is the matter with you that this paper does not suit you? Tell me, and I will blow the Editors up.

Now come, boys, do not let your passion get the better of you, as you know this is just what we mechanical men want, and of course they cannot write to suit everybody. Now, just sit down and write the Editors something worth reading and I guarantee it will be published and you will feel better and subscribe for the paper another year, and the Editors will answer any question you may ask them about mechanical matters or on any railroad matters. Now come, boys, do not throw cold water on this paper, as its columns are open to all and it is a good channel of communication for all of us, from the M. M. down to the trackman. Now, Mr. Goffney, come out and retract your notion of this paper, not on account of the Editors, but on account of your fellow shop and roadmen, I for one; and I have been in the road and machinery departments of railroads for thirty-five years, and I find no paper printed so instructive to the engineer and mechanic. I never pick it up without learning something.

Do not imagine I am put up to writing this by the Editor, for he is in New York and I am in Texas, and I am what you might call an independent mechanic. Come, boys, no more of this, but pitch in and give us some new kinks.

E. A. CAMPBELL.

*Houston, Texas.*

[Our correspondent will see that Messrs Ray and Tucker are in line, as their letter in another column testifies. They deserve sympathy for being placed in a false position without their consent.—EDS.]

## "Lining by Counter-bore of Cylinders."

*Editors.*

In the July number of your valuable paper, Mr. Hugh R. Crawford says, in answer to engineers and young mechanics, that the method laid down by R. H. Zwicker for centering line by counter-bore when cylinders are worn is a "delusion and a snare." Now, if we follow out Mr. Crawford's advice, we will set line by the wearing surface of the cylinder, and if cylinder is worn below center $\frac{1}{16}$ inch, the center of crosshead will be just that amount below center of stuffing-box, and the consequence is that the gland will not enter stuffing-box but will bind on bottom. To do this job properly is to center line by front counter-bore and stuffing-box (first see that back cylinder-head is central with back counter-bore), set crosshead to line, put piston and packing in, and line piston up central with front counter-bore. The gland will then enter stuffing-box, the piston will travel central with counter-bore and stuffing-box, while the centers of packing rings are below counter-bore center $\frac{1}{16}$ inch.

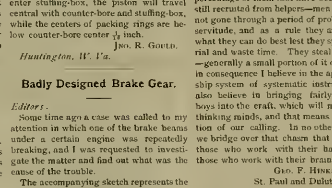
*Huntington, W. Va.*

## Badly Designed Brake Gear.

*Editors.*

Some time ago a case was called to my attention in which one of the brake beams under a certain engine was repeatedly breaking, and I was requested to investigate the matter and find out what was the cause of the trouble.

The accompanying sketch represents the lever arrangement as I found it, and as it



BADLY DESIGNED BRAKE GEAR.

is a regular curiosity in its way it may perhaps be of interest to some of the readers of LOCOMOTIVE ENGINEERING.

If any of them can figure the pressures on the different beams, let us hear from them in the next issue.

The fact that such a mechanical abortion was put on and sent out into service by one of our most prominent locomotive builders shows how badly some of the locomotive supply men are in need of a little instruction on the air-brake, for the road to which it was sent never sent them any such drawing, and if they had I doubt but it would have been good policy on the part of the makers to object.

PAUL SYNNESTVEDT.

*Chicago.*

## The Blacksmith Trade.

*Editors:*

I have read your valuable paper with great interest and benefit; have read therein articles from engineers, firemen, machinists and boilermakers, which have been interesting and instructive.

Now, I thought it would not be amiss to give blacksmiths some recognition. Blacksmithing is a calling, in my opinion, foremost among the mechanical arts, it is the groundwork, in fact, the root, from which the metal arts have sprung, and of all trades it is the most berated and abused. How often we hear the opprobrium, "A blacksmith's hair," deservedly applied in numerous instances. If blacksmiths in general would give that attention, exercise that regard which in the nature of their vocation is required of them, it would be only a question of time when they would occupy a position among the trades second to none.

Forging is to some extent lost sight of as not in keeping with other advances in the mechanical arts, something that is not comprised in the improvements and inventions. Yet there has by no means been a halt in the steady development of new features in this most useful and interesting branch of industry.

There are few branches of industry that present a greater variety in the choice of methods and wherein the judgment of the artisan is oftener called into requisition.

To learn to be a forger requires a considerable length of time, from four to five years being the customary time.

Now a few words relative to the skill and qualifications of blacksmiths (forgers would be a better term). There is quite a large percentage of them that have been and are still recruited from helpers—men that have not gone through a period of probationary servitude, and as a rule they are kept at what they can do best lest they spoil material and waste time. They steal the trade—generally a small portion of it only—and in consequence I believe in the apprenticeship system of systematic instruction. I also believe in bringing fairly-educated boys into the craft, which will mean to it thinking minds, and that means the elevation of our calling. In no other way can we bridge over that chasm that separates those who work with their hands from those who work with their brains.

## Filed Preferred to Scraped Surfaces.

*Editors:*

While looking at the fancy scraped surface on machine tools, the thought suggested itself to the writer that this is one of the few places where a scraped surface is of any good, if at all. Of course the mottled surface can only be produced by a scraper and is all right for appearance sake, but in wearing surface the scraper might be used to advantage in removing tool marks on light bearing surfaces where there is very little friction, but when we get on locomotive repairs, such as rod brasses, shoes and wedges, valves and seats and journal filings, the file is the tool to use unless a driving journal or crank pin is full in the center. In such cases we must resort to the scraper, but where it is possible to use a file in the absence of a machined surface the file makes the best job and one that will give the best results. Scraped surfaces on valve-seats make the contact too severe at the start, as there is no room between the surfaces for oil, while the filed surface leaves a multitude of minute cells or cavities that will retain the lubricant and prevent cutting until the surface glazes over. A valve-seat well filed by a good mechanic seldom blows. How often we see valve-seats faced in the roundhouse where there is little time to resort to a scraper go out and give the very best results; and why is it that driving-boxes, rod brasses, shoes and wedges repaired in the roundhouse give so little trouble? It is for the simple reason that, in nine cases out of ten, they are filed surfaces, and often done at night, in a hurry, by the light of an old smoky torch, and everybody mad and disagreeable.

Now don't understand me as taking the ground that the roundhouse is the best place to have the work done; I am only quoting facts to illustrate my subject. The back shop is the place to rebuild an engine, but we are after the scraper fiends. Driving boxes, shoes and wedges can be planed to fit, and it is the worst kind of practice to scrape the surfaces. How much trouble there was with hot engine and tender-truck brasses when we used to scrape the brass down to a red-lead bearing, and how quick our trouble took wings when we filed the brass out too large for the bearing! My good brother, how often you have cooled off a hot box on the road and put in a brass that had not been fitted, and it would run all right. If you had not enough waste you would jam a lot of weeds or green grass into the oil box, and go on your way rejoicing.

There has been no time in the history of American railroads when our locomotives were doing better and harder work than at the present time, and at no time did they get less care than at the present, except in boiler work, and I say right here, boiler-shop work was never done better than at the present; as for the good or bad design of locomotive boilers, the boiler maker has nothing to do with it. The above remarks are not confined to any one locality, but from tramping up and down through the world, from west to east and from east to west. In these days of push and hurry and sharp competition, we must get rid of old ideas; out of old ruts, and deal with facts.

*Indianapolis, Ind.*

## A Roundhouse that is not Square.

*Editors:*

Will you please give me a chance in your columns to notice the communication of "Roundhouse" in your June issue. In the first place, I desire to say that I never entered the controversy in behalf of the "Over-worked wheel lathe." In taking that view of the case "Roundhouse" has shown himself to be as poor a critic as he makes me to be. In all probability my voice would never have been heard if it had not been that Mr Purves stated the conditions under which "two pairs of driving tires could be turned in one day and by a little extra crowding could get out three pairs if they were not extremely hard." I took this to mean that the man was the party to be crowded, not the lathe. Now, since "Roundhouse" has let his flood of light in on the subject I see my mistake, the man doesn't do any more work than he formerly did, it 's the machine that does it, the man simply watches "the wheels go round." This being the case, Mr. Purves made a serious mistake in increasing the man's pay.

Another point that induced me to take up arms in this unpleasantness was the needless insult Mr. Purves offered to every machinist in the United States (see his article "New and Old Tools" March number, L. E.), and which "Roundhouse" echoes when he says that "my interpretation of a machinist's duty is to do work good and in as long a time as possible." Now, I defy "Roundhouse" to prove this from my article. I stand pat on the proposition, that if you want a *good* job you must allow a *reasonable* time to perform the work in, and I'll venture this, that there are numbers of master mechanics who would not tolerate the kind of work that must result from the limit of time given by Mr. Purves and "Roundhouse Foreman" (for I guess he didn't sign his full name).

Then, again, there are M. M.'s who, on reading Mr. Purves' records, will insist on their men turning off a six-foot tire, worn down ⅜ inch, necessitating a reduction of diameter 1¼ inches, and extremely hard,

in the same time, overlooking the conditions prevailing in Mr. Purves' shop—viz., a 49¼-inch diameter reduced ¼ inch and probably "good tire steel," as "Roundhouse" says; and moreover, the above M. M.'s—most of them, I believe—would want the work as well done as if two days had been consumed in doing it, which is about the length of time it takes to do the kind and quantity of work described according to my observation and the appliances I have seen for doing it. And right here I want to say that I am not an expert at any branch of the business. I never ran a wheel lathe a single revolution in my whole experience, but still I take exceptions to the proposition laid down by "Roundhouse" that "To be a critic a person should be an expert in the work he criticises." "Roundhouse" is dead wrong here; take art matters for instance, the best critics cannot begin to do the work they pass their judgment on; it is so in music, painting, and the drama, it is so in mechanical matters; how often have we observed M. M.'s and foremen "jacking up," *i. e.*, criticising a workman whose performance they never equaled in their circumscribed existences, nor ever could, but they are the proper people, and what they say "goes."

"Roundhouse" indulges in a little flattery when he says (alluding to myself), "He would shine in another field," and is "just the kind of a man that railways are looking for to fill positions at the present time." On reflection I suspect that this is intended to be sarcastic also, but will only pause long enough to say that I *have* shone in the other field, and if considered of sufficient interest, will some day let your readers know to what extent I illumined the firmament made radiant by stars of such magnitude as Mr. Purves, Jr., and "Roundhouse," and the gentleman I described in my criticism, who undertook to show a machinist how to turn a crank-pin. As to his other bit of sarcasm, will say that railways don't have to spend much time in looking for men "to fill positions," the men are tumbling over one another in their mad endeavor to be the one that the lightning will strike next. I know I have not taken the popular and powerful side of this question, and have possibly made a serious error in exposing the cause of the maligned machinist, but I always sympathize with the under dog in a fight even if I own the top dog.

But this is a question of wide scope, and discussion could be prolonged indefinitely, so I will only notice two other suggestions that "Roundhouse" makes and they are both sarcastic to a degree. It seems "R" is nothing, if not ironical. He says, referring to the different methods Mr. Purves may employ in handling driving-wheels, "or by absorption in the body of a laborer," etc. Here is the meat of the nut, there is a class of people (and "Roundhouse" is only watching his chance to step over) who dread work to such an extent that they will resort to any form of oppression of their fellow-men to secure an easy position for themselves. They are only content when they are eating their bread in the sweat of the face of somebody else. These people never realize that they are no better than their less fortunate brothers till misfortune overtakes them, as it sometimes does, and they are rolled in the dust with the common herd. His other suggestion is in regard to "apprentices in his shop." "Roundhouse" certainly went out of his way to bring this matter in. So far as I recollect no whisper of the apprentice matter was broached by either Mr. Purves or myself, so it must have had its birth in the fecund brain of "Roundhouse" himself in one of his most satirical moods, with a deep and fell purpose behind it, which with my usual obtuseness, I fail to fathom. However, I will say that I have an opinion both on the apprentice and the expert, not forgetting that I was once an apprentice and may yet be an expert.

In conclusion it is admitted that "Roundhouse" has proved conclusively that a pair of driving-wheels can be turned off in three hours—on paper.

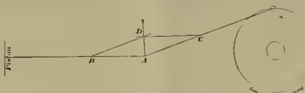
## Lining Guides.

*Editors:*

Under the heading of locomotive running and repairs, of the February paper, there appears an article on guides by L. C. Hitchcock. I consider this a very able article with a few exceptions, which I beg leave to state. The writer says. "That when the guides are level, straight and in line with the cylinder, to remove the line and place the crosshead on them," and then says "that the most particular part of the operation is then to take place in taking the rock out of the crosshead." He previously has stated just how to plane the crosshead perfectly true; so it is impossible for me to see just where that



TO FIND THE PRESSURE ON GUIDES.

rock comes in. I will say, after setting guides for fifteen years, that when my bottom guides and crosshead were as stated by the writer, I never once found that rock that he speaks of.

The writer further states that it is best to place a ⅛-inch liner between top guide and block, as the greatest wear is on the top guides of locomotives running ahead, thus permitting the ⅛-inch liner to be reduced to overcome wear, as the greatest pressure is on the top guides. The writer is correct in stating that the pressure is on the top guides when running ahead, but I say that the greatest wear is on the bottom guides, strange as this may seem to the readers of the article. Nevertheless, it is a fact, and only on examination of a number of crossheads, liners and guides you will agree with me in this statement. The reason for this, I will state, is caused by cinders, sand and dust being pounded in the crosshead at each end of stroke, when the crosshead drops, because the angularity of the main rod is not great enough to hold crosshead to top guides. You can well imagine the effect when the engineer shuts off the throttle coming into cities and running down hill.

I will give a rule to find the pressure on the top guides by the action of the angularity of the main rod. It will be necessary to refer to the cut, in which the engine is supposed to be running ahead. By the pressure on the piston and the angle of rod we obtain the pressure on the guides. For illustration, we will say there is 10 tons pressure on piston, and that each ton's pressure represents 1 inch on the piston line and crank line from the point $A$. Then 10 inches from the point $A$ on the piston line, we mark the point $B$ also on the crank-rod line; we mark the point $C$ 10 inches from $A$, and drawing a parallelogram to $A$, $B$, and $C$; we find the point $D$, and drawing a line from $A$ to $D$ gives the direction of the force, and the length of this line in inches gives the pressure on the guides, each inch representing 1-ton pressure.

C. F. WILLSON.

*St. Paul, Minn.*

## A Standard for Tests.

*Editors:*

There has been much time spent, and it appears that much more will be, in finding out how "*tests* should be conducted" with the locomotive, so that one may find out the merits, or demerits of the different types, kinds and breeds of said machines (and their name is legion). I have seen some very elaborate methods suggested which deserve much credit for their authors, but all such methods require an army of generals, lieutenants, and a few privates to conduct the test referred to in the manner prescribed; also needing a school of technology to explain reports to the ordinary mortal that he may have some understanding of them. It is quite possible that in making these tests as referred to, it gives employment to a certain class that are not of any value to the producing world, and that the time used by them is of little loss; but it should be remembered that *some* are required in the performance that could be useful in other vocotions. It appears to some that about all a test need show is *how much work can be done and what is the cost of doing it?*

To one not up in high science and the arts, it would seem to be only necessary to use a good dynamometer between tender and train, a record of speed, the work that was being done, and the amount of coal used.

Water-meters, pyrometers, calorimeters, indicators, vacuum gauges, etc., etc., are all tip-top things for a dress parade, but when you come right into actual service they are not worth a negative blessing, also the amount of ashes there is left is not a good thing for a railroad company to realize much dividend from.

Should any persons have doubt on this matter let them look over the reports made and published during the past two years on locomotives of different types, and then testify how much the writer is out of his head on this subject.

BILL PAVER.

*Buffalo, N. Y.*

## Single Wheels Slid Flat.

*Editors:*

In your July number I notice a communication in regard to flat wheels. In your case of one wheel being flat and the other wheel all right, I will answer the wheels were slid on a wet rail and the sand from the engine was running on one side; I know of cases of this kind. I saw an engine with four air-brake cars holding a train down a hill 5 miles long. When the brakes were released we found a pair of tank-wheels. One of them had a 3-in. flat spot, while the other one was not marked over ⅛-in. When we looked we found sand running from one sand-pipe. The wheel sliding on the wet rail (especially on an empty car) would not flatten very much. While the sand on the other rail would cut a very large flat spot either on a loaded or empty car. This is a very common occurrence, finding one wheel with a 3 or 4-in. spot and the other wheel only 1 or 2-in. Sliding an empty car on sand will cut flat spots in a very short time, while sliding an empty car on a wet rail will not have very much effect on the wheels; that is for a short distance. I think this will explain to your readers how this can be done.

FRED. F. HAYES.

*Ottumwa, Iowa.*

## Train Resistances.

*Editors:*

The June issue of your very interesting paper has just arrived here, and I have read the article, page 192, relating to train resistances.

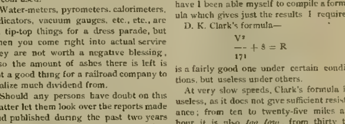
Compilers of text-books, and mathematicians, must have a formula for everything; they maintain that resistance *must* increase as the square of the speed. During the last twenty years the resistance of trains has received my constant attention, with the result that I have never found any formula in any text-book which gives results corresponding to actual practice, nor have I been able myself to compile a formula which gives just the results I require.

D. K. Clark's formula—

$$\frac{V^2}{171} + 8 = R$$

is a fairly good one under certain conditions, but useless under others.

At very slow speeds, Clark's formula is useless, as it does not give sufficient resistance; from ten to twenty-five miles an hour it is also *too low*, from thirty to forty-five miles an hour it is fairly correct; from forty-five to fifty-five miles an hour it is *too high*; from fifty-five or sixty miles an hour to seventy and seventy-five miles



WORK ON THE CYLINDER OF SCHENECTADY COMPOUND LOCOMOTIVE.

an hour it is useless, as it gives the resistance far *too high*.

I know of one special case in which an engine, according to Clark's formula, would just be able to run at sixty miles an hour with a certain train; in a few minutes I timed the speed at seventy-three miles an hour.

My opinion is, that no one formula can ever be made correct for all various speeds.

### Big Driving Wheels.

*Editors :*

For fast running, and economy both in fuel and repairs, there is in my opinion nothing equal to a single pair of 7 feet 6 inch drivers, cylinders 18½ x 26, and a steam pressure of 160 pounds per square inch.

Upon a heavy road where power is required, four coupled 7-foot drivers will give excellent results. Both the above classes are working in England, and giving the greatest satisfaction. I am not aware what is the result of working of "compound" express engines in America, but so far in England they are unsatisfactory. Three sets of motion cost more than two—cost more to maintain. The compounds burn more coal, use more oil, and the engineers have much more trouble than with the "simple" engines.

CLEMENT E. STRETTON,
Consulting Engineer.

*England, June 10.*

### Relyea's Brake Puzzle.

*Editors :*

In answer to W. F. Relyea's brake puzzle I would say the fault may have been in the governor.

I have seen governors that would stop the pump when maximum was reached, and not start it till the pressure had fallen five or ten pounds. With triple valves sensative to slight changes of pressure, and no leakage grooves in the brake cylinders, the brakes would be very apt to go on as he says.

W. E. WATTS.

*West Nanticoke, Pa.*

*Editors :*

In regard to air-brake puzzle on page 243, July number, "brakes settling on train when brake-valve was changed from running position to full release," I think there was a bad leak in main reservoir pipe or the drip-cock in main reservoir worked open. If the pump stopped, the pressure in main reservoir leaked down below train-pipe pressure. This it could do if valve was on running position, as excess pressure valve would stay on its seat, and train-pipe pressure will not raise rotary valve 13 off its seat till there is considerable difference in the pressures. The train pipe probably leaked a very little and set one or two of the brakes; the brake-valve was put on full release, thus letting air from train pipe to main reservoir, lowering the train-pipe pressure and setting all the brakes tight. The governor opened steam valve to pump as soon as pressure dropped in train pipe, and air enough was pumped up to release brake before train was stopped.

Try this experiment on a standing train. Shut off the pump when your train line pressure reaches 70 pounds, place the brake-valve on running position, open the drip-cock in main reservoir, see how many pounds reduction on red hand before black hand begins to drop back, and in how many seconds. When your tender brake begins to go on, turn the handle of brake-valve into full release and the results will surprise you in more ways than one.

Why is there no leakage groove in driver brake cylinders the same as for tender brakes? The same kind of triple valve is used for both brakes.

I notice in the list of questions and answers on the automatic brake, which has been under discussion by the railroad clubs and associations for months back, the statement that on freight cars the engineer may set the air-brake when the brakemen are setting the same brakes by hand, but on passenger coaches never. The Pennsylvania Company run a line of freight cars equipped with air brakes which can be set by hand from either end of the car. One end has the brake worked from the end of car for tunnel use, the other is operated from the roof of car. When the brake is being set from the top of car by hand, and air is applied, it will set the brake *against* the brakeman *same as a coach*. There is another feature about this arrangement; if the slack is taken up some on brake chain at that end it changes the leverage on that truck by moving the fulcrum 7¾ inches farther away from the power, so the braking strain is increased from 8,500 pounds to 14,000 pounds, in round numbers. There is a fulcrum pin working in a slot in a bracket between the power and coupling to hand brake; as long as this pin rests at the end of the slot the braking strain is the same on each truck, take up the slack with the hand brake, it is changed. Why is this? See P. R. R. car No. 75,942 or the Union Line cars.

On page 243 of the July issue there is a lubricator puzzle, also one in March issue—one not answered yet. Was the pipe which brings the condensed water down to bottom of oil tank of full length, and not loose or leaking at the top end? When this pipe breaks off the oil will go up into the condensation chamber or ball at the top of lubricator and from there through steam supply pipe into boiler. It will also do the same if this pipe does not come clear down to the bottom of oil tank. Of course this cannot take place if globe valve at bottom of condensation chamber is shut tight, but lots of them have got dirt on the seat and leak. In the small air-pump lubricators all this oil goes over into the air-pump, but it feeds out too fast when first started, or won't feed at all through the sight-feed sometimes, if this water-pipe does not come clear down to the bottom of the cup so the open end will be below the oil. Keep a good gasket in the joint at the bottom of sight-feed glass, and this glass as far down through the gasket as possible, that stops feeding when sight-feed valve is shut off.

C. B. CONGER.

### Relyea's Air-Brake Puzzles.

*Editors :*

In answering my last air-brake puzzle, will say that the pump governor caused the brake to set. The ⅜-inch copper pipe from governor is connected direct to train pipe. The air passed through ⅜-inch pipe to governor, thence past diaphragm-valve 17, thence past piston 5, and out at waste pipe connected at bottom of cylinder 3; this caused the brake to set when the handle of engineer's valve was in running notch or on lap.

See pump governor, plate D 9, of Reference Book of 1890.

I have one more puzzle, and will send a good 25 cent cigar to the man who guesses it.

An air-pump was reported to me as being worn out, so I had men called (it being midnight when the engine got into the house) to take it off and put on one that I had just overhauled but had not tested. When steam was turned on the pump would not work without the aid of a hammer; so they sent the caller after me. Well, when I got over to the engine-house and saw how the pump acted, I said to myself, it won't take long to fix that "thing." So I went at it, first like one of those fellows who thinks he knows it all, but don't. Well, it didn't take me long to find out that I was one of those fellows. Here is the way the pump acted: the piston would not move without tapping on the reversing cylinder cap, and then it would only go up and down once and stop. My first thought was that the reversing piston was too loose and would not press the main steam-valve down to open receiving ports in lower bush. I examined the reversing piston and it seemed to be all right, so did the reversing cylinder, but to satisfy myself I put in another reversing piston and plenty of valve-oil; but this did no good. Then I concluded that the main steam-valve was too tight, so I took off the head and found that the valve was as good and worked as free as I could make it. The supply port, leading from main-valve chamber up into the head and over to the reversing valve bush, was all clear. In fact, all steam ports were clear and the piston traveled its full stroke. But to make sure that the trouble was not in the top head, I put on a new one and gave her steam. The piston "went up and then went down again" and stopped as before. Not having examined the new head thoroughly, I thought, perhaps, in shifting, something might have got in some of the ports, especially the one mentioned above; so I took the head off again and found all ports open. My body had now attained a temperature of about 212 degrees and my mind was about ready to leave me, when I discovered the difficulty, and with a small hammer and chisel removed it, and the pump went to work all right. I omitted to say that there was a hole in the gasket to accommodate the port leading from main-valve chamber to reversing valve-bush.

In answer to Paul Synnestvedt, will say that if the engine was equipped like those on the N. Y. C. & H. R. R. R., the cause of brake-setting was this. There was a leakage that reduced the pressure in the main drum below that of train pipe, and in putting handle in release notch, the air went from train pipe back to drum. This reduction of pressure in train pipe allowed the governor to open and start the pump, and in a short time gaining pressure enough to release brakes.

I have another "nut" for next month, and it's no "chestnut," either, but something entirely new; look out for it.

W. F. RELYEA.

### Remedies for Air-Brake Troubles.

*Editors :*

Before attempting to solve some of the air-brake puzzles published in your July number, by stating how troubles resembling these have been remedied, I wish to echo the sentiments of Brother Wood in regard to correspondents making obscure statements of difficulties overcome by them. It is almost impossible to give a correct answer to a general description (although I believe the practice will ultimately be of great benefit to all who are interested in these matters), and as an illustration, will mention our friend from the Empire State whom we are all glad to hear from again. It will be remembered that last year he gave a case where the stop to main-valve was broken, but did not say that main piston was held against the upper head when steam was turned on and stayed there, if piston-rod packing was tight enough to hold it up when steam was shut off, which must have been the case. It is also my experience, that the investigator, to be successful, should usually, in person, examine the one who has met with the difficulty, as there is in such cases often a statement made in which everything is shown but the clew to the whole affair, this not being thought of sufficient importance to be mentioned.

As for brakes not going on, in Brother Wood's puzzle, on the front part of train, when it broke in two, there must have been some obstruction in train-pipe or hose on back part of last car on front section of train; perhaps sparks in coupling, lining of hose stripped down, or waste, scale or other matter sufficient to plug train pipe anywhere from strainer to rear end of last car.

If the train mentioned by friend Synnestvedt was all Westinghouse air, did not the engineer tell him that the brake-valve kept blowing from service exhaust longer than it ought when handle was put in release position, and in that case was not piston No. 17, plate D 8, or the port above it partially stuck or closed, giving way, finally, enough to let the piston seat itself?

Now for the tender brake, as this trouble has developed here. The first real tough case of tender brakes sticking on was not tough at all when located. It was caused by the tender brake beam-hangers bearing directly on wood, and being outside breaks, the rear hangers finally knocked holes in tender frame and brake-beam, and when the brakes were applied rear beam would carry up on wheels and top of lever would catch on a projection that was not in the way when brake was at its normal position. It would only release when engine was backed or dead rod disconnected, and as I had no chance to watch the engine while it was in motion, it ran two or three trips before the right remedy was given. Next brakes were found going on as described in paper, and a number of tests showed that the driver brakes, having 12 x 33-inch reservoirs and 12-inch brake-cylinders, had 50 lbs. in emergency stop, while tender brake with 12 x 33-inch reservoir and 8-inch brake-cylinder had 60 to 63 lbs. Of course when the brakes were applied there would be an emergency application on the tender brakes with only 7 lbs. reduction, and at 20 lbs. reduction the driver-brake reservoir would have 50 lbs. while the tender reservoir would contain 60 or more lbs., and would have a tendency to creep on again while the reservoirs were recharging or if pump governor was slow to act. We now let out tender-brake cylinder pistons in this condition as much as possible in order to expand the air more and make valve graduate better. We also found that working tallow in piston packing ring space was an improvement. The amendment to Schedule B[1], page 60, 1890, W. A. B. catalogue, will help explain. There is but or more cause easily detected, this is a lea above piston 17, plate D 8, or at the bo tom of piston; either will leak at servic exhaust and can be told by stopping th hole with the finger to see if pressure a cumulates.

GEORGE HOLMES.

### "Oil Can's" Break-Dowo.

I will try to explain the break-do puzzle which I gave in the July numl It was the go-ahead eccentric that bound, and what I did was this. I t down the strap on same and then pu it over on the shaft almost to the side, so as to get it out of my way, b careful to tighten it enough to prev turning around on the shaft. Then I took the back-up eccentric and slipped it enough to make it in a position to go ahead. I then knocked out the middle bolt or what was now the go-ahead, and took one of the long bolts that came out of the disabled strap and bolted both the rods securely together to the single eccentric, at the same time putting a piece of wood between both rods to prevent the link pins from rubbing. This done, I was ready to go on, and I can assure you it is better than to disconnect and take chances of stopping on center with no slack in a train, making it necessary to pinch the entire train back, one coach at a time, or cut off the engine. Those of us who have had a trial of this plan will resort to it rather than disconnect and run on one side.

OIL CAN.

---

A quick acting triple valve for air-brakes has been patented by Jesse F. Carpenter, Washington. The inventor of this valve is the carpenter who had a combined air and electric brake at the famous Burlington tests.

---

A station agent on a road in Kansas, tells a story of a German tramp who wanted to pay his fare for walking along the railroad track. That tramp ought to be found and exhibited at the World's Fair, as the greatest curiosity of the age, or the Ananias Club might invite the station master to enroll himself as an honorary life member.

---

A Grand Trunk engine and the express and baggage cars took a fearful plunge of forty feet down a deep cut, when half way between Hilburst and Conticook, Canada, one day last month. The two cars were piled on top of the engine. When the frightened passengers left the train and went to the assistance of those who had been carried down with the engine and cars, they looked upon a scene of death. Every one of the men who took the plunge into the cut was killed.

## Train Running for the Confederacy.

By Carter S. Anderson.

Taking up the narrative of the part performed in the summer of 1862, by the Virginia Central, now Chesapeake and Ohio Railroad, in transferring General Jackson's army from the Valley of Virginia, and placing them in a position to attack General McClellan's rear, while the Johnson-Lee army attacked McClellan in front, I will now proceed. My last letter left us at Louisa C. H., Sunday night, with not even a rumor of any movement. It was so quiet and peaceful that we forgot it was the time of war. On Monday morning, though, the scene changed. If any of General Jackson's officers knew where the General was going, they were extremely true and prudent in keeping secret his plans. I have no idea of attempting war history, neither does General Jackson's character need anything from my humble pen; but I will make one remark which is as applicable to success in business as to success in war. General Jackson undoubtedly used the enemy's spies. He was glad for them to go and tell everything that he was doing, and then he always did the opposite to what most people would consider advisable and likely. This was certainly true of him in this movement, for on Monday morning he had everybody, citizens and all, figuring out the nearest and best roads to Washington. The railroad men felt confident that we would haul no more soldiers, soon. Before noon, however, the lumbering of heavy artillery could be heard along the country roads toward Richmond, and everything wore a serious and sober aspect. Pretty soon we were ordered to prepare immediately every train. "Load them to their fullest capacity and let each train give to the preceding train thirty minutes' time. Keep trains well in hand; sound no whistle; ring no bell. Brakemen, keep a sharp look-out for trains in front and rear. *Death* to the whole crew who cause a collision!" This was indeed what might be termed a limited time card.

Locomotives used by Chicago, Milwaukee & St. Paul in Making Tests of Simple and Compound Locomotives for Master Mechanics' Committee.

Our superintendent, acting under instructions from President Edmund Fontaine, who then resided at Richmond, would not assume the responsibility of running his trains any further into our unoccupied territory, but was perfectly willing to allow the Government to use the trains on its own responsibility. Since McClellan had removed the line of battle from Manassas to the Peninsula, beautiful Piedmont had been unoccupied by either army. Anywhere from the Potomac to the James, and east of the Blue Ridge to the vicinity of Richmond, the citizens would just as soon have expected a Southern army as a Northern one, and vice versa. The Southern as well as the Northern officers in approaching a farm house, would note that awful stillness around, and the apparent absence of every living being from this once nice and happy home. "Halloo" would sink so deep into the souls of the unprotected women and children, and cowardly men concealed within, that in many cases death resulted. For once the rich and poor met together, and sweet life, heretofore so unappreciated, was now all they asked for, and happy were they to retain "only that and nothing more."

No wonder then that our engineers hesitated to plunge their trains into such a country. The rain was pouring and it was nearly night. They did not fear for their own lives as much as for the responsibility of 2,000 soldiers, which was the average of each of the ten trains. The officers acted very nicely, and assured us that our cavalry had gone all through the country, as low as the South Anna river, and that there was not a Northern soldier west of Hanover C. H. Furthermore, they gave us two Confederate officers who rode on the pilot of the front engine.

Our ten trains of 18 to 20 cars per train, were soon placed for loading. I wish our passengers nowadays could have seen how quickly (about ten minutes) 1,500 to 2,000 men, with their heavy muskets, clumsy boots and haversacks, crawled into and on top of 20 box cars and work train flats. There is wisdom in letting every man taste a little of war, as the German Government does. It's the finest *peace tonic* I know that I ever used. You know how it is up there, but down here our old veterans are the best American citizens. They have seen a plenty.

Conductor John H. Richardson and Engineer Martin Alley took the lead of the ten trains in this momentous occasion, and two safer men never pulled a bell cord or stepped upon a footboard. Martin looked quite serene on the "Westward Ho!" engine, with a Confederate Brigadier on either wing of his pilot. It was a war picture indeed, and as he quietly and carefully pulled his engine pin and drew his train into the curve east of Louisa, there went up a yell which seemed to fill the whole air around us. Our train came next and the signal was given to my engineer, John Whalley, to pull down in place to load. To my horror, I then discovered that John was pretty drunk, and my fireman, John Wesley, dead drunk! We needed but little steam, however, as it was mostly down grade all the way.

I hope I may never again experience such feelings as I then had. I had on board 2,000 soldiers; a train just ahead, one just in rear, overloaded; pouring rain; nearly night, engineer very much in liquor, no fireman; not a whistle allowed to be sounded; not a bell allowed to be rung!

I at once, held an earnest conversation with Conductor Joshua Finks and Engineer Fendal Ragland, who were immediately behind us. No kinder-hearted man ever lived than Josh Finks. He was much older than I, and putting his arms around my trembling shoulders, said: "Carter, get on your engine and keep John from running into Richardson, and Ragland and I will keep from running into you." I gratefully acted as he suggested, and slipping upon the "Monroe" in front, tied a knot in his whistle cord. Cautioning my brakeman to keep a sharp look-out for my signals from my lamp on the engine and to use the brake on Whalley if he wanted to run too fast, I then informed Mr. Whalley that we were ready. He stepped upon the Monroe's footboard, and stooping a little to enter his cab, he tapped her open gently with his characteristic way.

I sat on the box opposite him and watched anxiously the curves as we rolled gently along toward Mineral City. Mr. Whalley told fireman John Wesley to fill her up, at the same time opening the firebox door with the toe of his boot. Wesley was so drunk that he thought the wood piled up in the tender was the firebox, and began cramming wood back and *firing the tender*. We were now approaching the 65-foot per mile down grade east of Mineral City, and as we had gotten into a pretty good swing on the level, I knew there was great danger, and asked Whalley to shut her off and get the train well in hand before he struck the grade. His eye flashed fire. He snatched the Monroe's throttle wide open and as she struck the down grade we dashed through "Rock Cut" at a desperate speed. Physically I was nothing to Whalley, but fear left my timid frame and left me strength instead. I felt I could do anything. I snatched the stick of wood out of Whalley's hand and told Mr. Whalley to shut her off. He saw that what I had made up my mind to do I would do, and reached immediately for the whistle cord, forgetting that it was *death* to pull it. The knot I had tied, however, saved his life. He at once drew her in back gear and as soon as he could possibly do so, nearly stopped the train. Looking ahead as we entered the reverse curve, I exclaimed, "Great God, Whalley, just look!" There, just ahead of us on the curve near Frederick's Hall, was what I had dreaded for the last few minutes—the *red lights on the rear of Richardson's train*, as he cautiously rolled down the grade!

Mr. Whalley realized now the situation, it sobered him. With tears rapidly rolling out of his great eyes he beckoned to me to come out to him, and drawing me close to his side, told me that when he shut off the Monroe and reversed her, it was with the full determination to throw me into the firebox, and the only thing

that stopped him was the ruby glare from the rear of Richardson's train

This very narrow escape from such an awful and wholesale massacre as would inevitably have soon followed had Whalley not shut off when he did, sobered him completely, and well it might. We crept along to Frederick's Hall, and putting a brakeman to firing, I assumed his place on top of rear car, and we reached the end of our trip in good order, though drenched with rain.

General Jackson did not take the train at all, but generally kept ahead of us. He stopped over night at Frederick's Hall, at the hospitable home of Mr. N. W. Harris. Mrs. Harris assigned him her best room, and the family retiring at the usual hour, General Jackson slipped out and rode to *Richmond*, about 45 miles, the nearest route; held a council of war with President Davis, General Lee and others, and returned to Mrs. Harris to breakfast. *Being a little late*, he apologized for it, remarking that he often took moderate horseback exercise before breakfast. Mrs Harris' housemaid was much bewildered to find that the bed had not been touched in the General's room, and ran down to tell Mrs. Harris that "De general either slep' on de flo' or made up de bed hisself." Mrs. Harris was curious to know how it so happened, but the silent old war-horse was gone.

I had intended concluding the narrative in this letter, but my superintendent, Mr. C. E. Doyle, must have my "record abstract" to-morrow. So I must try for a little corner in your next issue, and I will try to condense into it something to interest your readers

*Richmond, Va.*

## Reciprocating Parts of Locomotives.

A. Farmer, Youngstown, O., writes us

I have just finished reading my July copy of Locomotive Engineering, and while the subject is fresh in my memory I will beg the privilege of criticising the letter from Mr. Corbett appearing on page 241.

The importance that Mr. C. attributes to the weight of reciprocating parts of an engine will no doubt astonish engineers and locomotive builders, and on the other hand will be read with pleasure by those who favor electric motors for railroad locomotion, showing as it does at high speeds an unprecedented improvement of tractive efficiency. I am sure Mr. C. has made an error in his calculations, as well as in his philosophy, for theory ought not to be at variance with practice, and practice has proven many times over that Newton's third law of motion ("to every action there is always an equal and contrary reaction") is correct.

Some of our best builders of high-speed stationary engines make the crossheads very heavy in order to equalize the pressure on the crank-pin. These engines give excellent results in practice and will be sufficient evidence that Mr. C. is in error. It may not be amiss to add, however, that the force that brings the crosshead, etc., to a standstill at the end of the forward stroke, helps to pull the train along an equal amount, and that the force that stops the crosshead at the end of the backward stroke, retards the train an equal amount One balances the other, and no force is lost or gained thereby.

There is no part of a locomotive that may be studied with more interest than its reciprocating parts, and I hope Mr. Corbett will either conclusively prove the assertions he has made or else give us some that he can prove. This is written in a kindly spirit, and I trust it will be so received.

An improved form of car seat has been patented by Mr. Edward L. Bushnell, of Poughkeepsie, N. Y. The improvement consists of the mechanism for turning the back, and makes a combination that provides strength and simplicity that are likely to insure durability.

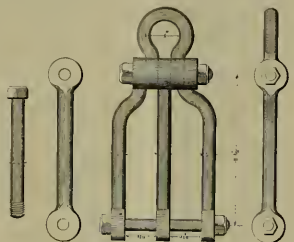
## A Big Steel Smoke-Stack.

One of the most notable achievements in the rapidly multiplying applications of steel to structural purposes is the new chimney of that material in Chicago, the dimensions as given being a height of 350 feet, with an outside diameter of 9 feet 5 inches, while the steel varies in thickness from $\frac{5}{32}$ at the top to $\frac{3}{8}$ of an inch at the bottom. The lower 75 feet of the chimney is lined with fire-brick 8 inches deep, formed to fit the shell compactly all around, and above this is lined with hollow tile. This lining is supported at intervals of 25 feet by an angle-iron riveted to the steel shell, that is, the chimney is lined in a manner similar to blast furnaces and foundry cupolas, no expansion by heat being able to lessen its strength, and the joints are all hot-riveted. The steel shell is carefully protected from corrosion and from any attacks by the weather, by painting inside and out. The weight of the chimney is spread to the foundations in the same manner or general way as that of the columns of the building, the base or foundation on which it rests being constructed similarly; the ground first is covered with a layer of cement, then two layers of steel rails in cement and one layer of I-beams, on which the cast-iron shoe, which takes the shell of the stack, rests. The capacity of the chimney is twelve 60-inch boilers, 20 feet in length. The outside diameter of this chimney is 9 feet 5 inches, while were it constructed of brick it would be 16 feet 6 inches.

You will never find a competent mechanic forcing a piece of work together with an idea that it may prove all right. The nicely adjusted bearings, fitted at all points with an idea of accommodating opposing parts, will go in direction of successful work, while all haphazard work will eventually return to condemn the loose methods of those responsible for them. In mechanic, or fireman, or engineer, the principle is the same. Honest methods insure honest work—honest effort gains its ultimate reward as surely as night follows day.

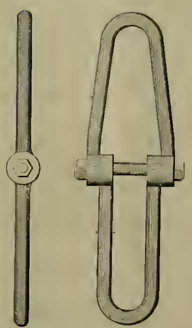
## Foster's Wrecking Pulleys.

The annexed engravings illustrate a form of single and double pulley blocks used by Mr. W. A. Foster, superintendent of motive power of the Fall Brook Railroad, for wrecking purposes. With this rig worked by a wire rope he can lift his heaviest locomotives. The device is so clearly shown in the cut that no description is necessary.



*Frame for Double Pulley*

*Pulley Wheel Sections*



*Frame for Single Pulley*

*Pulley Wheel*

Foster's Wrecking Pulleys.

The express messenger of a train on the Chicago, St. Paul, Minneapolis & Omaha road saved the money of his employers by a cool act in a recent interview with a train robber. The train was stopped by robbers in a lonely part of the road. While one man armed with shooting-irons looked after the welfare of the engineer and fireman, another thief went to the express car and interviewed the messenger. In answer to a knock, the messenger opened the door and found himself looking down the barrel of a rifle. He was ordered to open the safe and deeming it not safe to refuse he complied, but at the same time he whipped out the money package and slipped it out of sight. The train robber finding the safe empty departed in an angry mood without any booty. This was a very smart act on the part of the express messenger and he is receiving much praise for it, but we are inclined to ask why he was so ready opening the door of his car? The rules against this practice are pronounced enough. In the case of express messengers, it is a good plan to lock the door before the horse is stolen and keep it locked.

The car wheel loose upon the axle which is regularly pressed upon the attention of railroad men has again been patented, this time by Abner Johnston, of Jersey City The invention this time has a rather practical look about it. The wheel is held in place by two collars, and provisions are made to supply the wheel seat with lubricants.

The activity of train robbers is setting inventors at work to provide the means of frustrating the designs of thieves upon express cars Several patents have lately been granted on methods for protecting express cars, the most elaborate of them being the invention of John Beermaker, Wahoe, Neb. He proposes to make the inside of the car a bullet proof fort, with means for opening or closing the doors at the will of the man inside.

## Steel Plates, Old and New.

During the discussion at the Master Mechanics' Convention on tests of steel and iron, Mr. Lauder said:

"One statement made by Mr. Smith brings out a fact that we should all dwell upon, and that is that he has got, even with his extremely bad water, boilers that have given him from 400,000 to 600,000 miles service, covering a period of nearly twenty years. I think that it is a very remarkable fact that a firebox on the Chicago & Northwestern road, with their extremely bad water should give a service of twenty years, while he produces before us here samples taken from a furnace that has run less than one year and is absolutely worthless, being cracked from some cause or other. Now, to a layman like myself, it seems that if twenty years ago the manufacturers of steel in this country could make a plate that would give us twenty years' service, they ought to be doing the same thing to-day. (Applause.) In fact they ought to be giving us a better plate, because they ought to be progressing in their business, as we hope we are in ours, and to know more about the manufacture of steel to-day than they did twenty years ago. Possibly some of the fault lies with us. The average purchasing agent wants the steel that he can buy for the lowest price. Manufacturers well understand that, and if they cannot produce a steel to sell as cheap as the other man, on many roads they cannot sell any.

"Now, I do not suppose there is a railroad in this country on which the mechanical man would not consider the question of price of secondary importance and the question of quality of the first importance. But, unfortunately, on many of these roads the matter is not settled entirely by the mechanical man. It is settled by some one who wants to make a good showing in his particular department without regard to the machinery department, and if some fellow comes along with a glib story to tell and a lot of scientific tests formulated in a table and offers steel for a quarter of a cent a pound lower than some well-known manufacturer offers it, he gets the trade. What is the consequence of all this? It forces the man who has been making an honest article, and making it intelligently, to come down to the methods of those who sell the steel cheaper than it can be made. Now, I believe, that instead of the price of steel for fireboxes of locomotives dropping all the time, it would be largely for the interests of the railroads if it were increased, if the increase meant a better product.

"I think the facts produced here in this discussion should be scattered broadcast amongst the railroads of this country and amongst the general managers and the men who are responsible for the financial results of the operation of our railroads. Just think of it for a moment; a new boiler costing from $1,500 to $2,000 is put into service, and in ten months torn all to pieces at a cost, I don't know how much, because some one has chosen to put in plate that is improper, while the neighboring engine, doing precisely the same work, has caused no expense to the owners. I tell you these facts have a broad bearing on the future prosperity of our railroads, and in the West especially, where they are cursed with bad water. This question of firebox steel is one of the questions that is probably as serious a one as they have to contend with—by far the most serious, perhaps. In my country almost any of the steels sold would give us good results, because if we take out a furnace in less than twenty years we think there is something radically wrong. I speak warmly about this thing for my neighbors; I am not troubled myself, but I know the difficulty of operating boilers in the western country with this extremely bad water, and I tell you the steel manufacturers and the railroads in combination ought to do something to eliminate this terribly destructive effect that the bad water has on the firebox of the locomotive, if it can be done."

## The Oldest Steel Converter.

The vessel shown in the annexed engraving is of great historic interest to every one interested in the development of the manufacture of iron. This is a converter for making steel direct, by what is known as the Bessemer process, and the vessel shown was made and operated years before Henry Bessemer astonished the world with his great discovery. This Kelly converter, as it is called, is to be seen in the Cambria Works at Johnstown, Pa. It was made in 1853 under the direction of a metallurgist named Kelly, and he and friends experimented at great length to convert pig iron directly into steel. The theory of the process was that by blowing hot air through the molten metal in the converter, the excess of carbon and silicon could be burned out (oxidized), and that the blowing could be stopped at the point where the necessary amount of carbon was still left in the charge. The stopping at the right point was the great difficulty encountered by Kelly and his associates. If the blow was kept going a few seconds too long, or if it was stopped too soon the charge was worthless. Bessemer overcome the difficulty in 1856 by blowing out all the carbon and silicon and then recharging with spiegeleisen or ferro manganese metals that contain the required quantity of carbon. By this simple expedient Bessemer made himself the most famous metallurgical engineer in the world and accumulated a colossal fortune. Although Kelly did not achieve success he was working in the right direction, for his converter is essentially the same as that employed by Bessemer several years later. We know of few articles that are more worthy of a place in the Nation's Museum of Industrial Curiosities than the Kelly converter. It is going to be exhibited at the World's Fair.

KELLY'S CONVERTER.

## In the Grant Locomotive Works.

When a visitor goes through a great manufacturing establishment and sees all the machinery at rest, he must call upon his imagination to picture the possibilities of production within the power of these silent tools. Such an experience does not offer good matter for description, and it is not altogether inspiring, but it gives a mechanic a good opportunity to study the plan of operations. This idea struck me during a recent visit to the Grant Locomotive works of Chicago.

The shops have not been built on the plan of any other locomotive works, but it is evident that much thought has been devoted to making them models of convenience and perfect in arrangement. The designers of shops like these have an enviable problem to work out, compared to those who are left to struggle to enlarge an old establishment, and keep it in harmonious shape. They had an open prairie to plan on, and they have worked to the end of building shops where material can be converted into locomotives, with the lowest possible amount of handling and where the work shall be done on tools that are the best of their kind.

The main building, consisting of the machine shop and erecting shop is built in the ┘-form, the long leg being the machine shop, which is a fine lighted building, with galleries upstairs for light tools. The floor is traversed by a heavy traveling crane, which takes the work to and from the heavy tools that are purposely set so that they can be reached by the cranes. The wheel lathes and some of the heavier tools, are set in the erecting shop wing, the overhead crane that serves that part being used to handle the work for the wheel lathes. All the tools are set so that work will be finished with as little movement as possible, all the tools for the finishing of cylinders for instance, being grouped together, and the same with frames and other parts that require to be worked on by different machines.

The machine tools moved from the Grant Works at Paterson, appear to cut little figure in the new works, for all the most important machines are new. They have a good supply of tools for special operations, milling, and grinding evidently receiving prominent attention. A separate shop is provided for grinding tools and the intention is to have everything of the most approved kind therein. Portable appliances for drilling, tapping and such light work, where it is not convenient to reach a foundation tool, is quite a feature of these shops.

The separate-power plan has been adopted, independent engines being used to drive the principal lines of shafting and separate engines for the machinery in the various shops.

The erecting shop is arranged with pits set at right angles to the shop, a transfer table being employed to take the engines out. A careful study was made of the leading erecting shops in this country, both of builders and railroad establishments, and it was concluded that the stall plan was more convenient than the longitudinal floor plan, where engines must be lifted by a crane. The cranes in this erecting shop are powerful enough to lift an engine, but they will not be used much for that purpose. The machine shop and erecting shop are ready for business, but the other shops are scarcely in working order yet. The firm has already done some repairing and have engaged to do a great deal more. Those in charge think that the works can be conveniently organized and put gradually in operation while doing repair work. Mr. Edwin M. Herr, the very energetic superintendent of the works, is working things into shape very rapidly. He has an able lieutenant in Mr. P. Arnot, master mechanic of the shops, who was long superintendent of the Grant Works at Paterson. I missed seeing President Fenner during my visit to Chicago, but I understand that he has adopted the policy of having the best appliances possible to equip the shops.

The original purpose was to start the boiler shop with an ancient steam riveting plant, but Mr. Fenner has ordered an entire outfit of Wood's hydraulic machinery for this shop. When this plant is in, nearly all operations in the boiler shop will be performed by hydraulic worked tools.

The blacksmith shop has the most approved form of forges, with down draft leading to pipes under the floor, the gases being drawn in by an exhaust-fan. This shop is well provided with furnaces, hammers and all kinds of tools used to facilitate blacksmith's work.

The foundry appears to be particularly well designed and equipped. There are two Collau furnaces that are supplied with material by an elevated railroad outside. A traveling crane traverses the whole shop and handles everything for the cone ovens, besides the ordinary floor work. The only familiar thing we found absent here was the molding machine, which will no doubt get there in due time.

The management of these works are to be congratulated on the progress they are making to produce a model locomotive building plant.

A. S.

## South Harrisburg Accident.

A correspondent in Mount Savage, Md., writes us:

I wish to say something about the brakes on the second section of the train that caused the fatal accident at South Harrisburg on June 25th. Engineer Kelly says that he was running about thirty miles per hour when he saw red signals, and had about one hundred yards to stop in; that he whistled, reversed, and applied the air-brakes, but on account of the wet rails the brakes did little good. Now, out of seven cars, five were Pullmans; the other two were baggage cars. In traveling I find that a great many Pullman cars are not braked on the middle wheels of the six-wheel trucks, and the brake rigging for the other wheels is by no means perfect. With the great weight of the train and the small portion of it braked, it is no wonder that the engineer reported that applying brakes did little good. The miserable form of the cam arrangement for driver brakes is also very objectionable and reduces the chances still further for a quick stop in case of emergency. The whole of this brake question wants overhauling. It is not long since that a report was published to the effect that the Chicago limited, when suddenly flagged, running at a speed of fifty miles an hour, ran over two thousand feet before stopping. This state of affairs is an invitation to the killing of people in collisions. It appears to me to be the duty of railroad companies to see that all the cars on the train are properly braked, and while six-wheel trucks are running with two-thirds of the wheels braked, this duty cannot be said to be done.

(Continued from page 276.)

mechanic, Mr. Simeon Hailbreth was superintendent and representative of the principal bondholder, a New York financier. Mr. Hailbreth was a fortunate roadmaster who rose through a well earned reputation as a hustler. He was reported to be capable of putting more emphatic language into a common order than any man in Indiana, where the headquarters were located. His policy as a manager was very simple. Run the road with as little expense as possible and beat competitors out of all the business that can be taken from them.

When Kurgess took charge, a construction company was extending the road at the rate of a mile a day, which was kept up, with brief interruptions, for several years. During the construction period there was no difficulty in getting all the machinery and tools necessary for operating the road. First class locomotives and cars were purchased and shops were built calculated to take care of fifty engines and two thousand cars.

Before the gala days of illusory prosperity ended, the company owned nearly one hundred locomotives and five thousand cars, and the shops that were built to take care of half that volume of rolling stock were promised material additions in the way of buildings and tools. But a succession of adversity blizzards put their chilling influence upon the Illinois Transcontinental. In the first place the stock market was overtaken with an epidemic of skepticism concerning the value of securities founded on streaks of iron oxide starting from nowhere in particular and striving to reach a similar objective point. This suddenly put an end to the flow of joy that had for a few years streamed from the Construction Company, and the road was forced to fall back upon earnings to defray operating and other expenses. This was a new and bitter experience to the management, but there were still other griefs in store, for the management of a rival trunk line with many potential advantages in the form of size and connections was moved to enter into aggressive competition. There were numerous debts outstanding among the connections that believed in returning to the Transcontinental an equivalent for meanness rendered, and not a few of them were returned with interest when adversity dawned upon the road. Mr. Hailbreth was a very successful maker of enemies, and his ability in this direction helped the road to make rapid headway down the financial grade when once it was started in that direction. It is not surprising, then, that the road made startling progress from reputed prosperity into the hands of a receiver.

About the time this event happened things were looking remarkably blue for the property. Business seemed to have dropped out of sight. There were long stretches of the road that yielded neither passengers nor freight. It was for some time a serious question with the receiver how he could find money to pay operating expenses. Like many another man put in control of a business he did not understand, this receiver conceived that a change of operating officers was the first movement toward bringing back prosperity to the property, so he appointed a new general superintendent, and he, in turn, removed most of the other officers, including my friend Kurgess.

The men on top now fell into an error which has cost the owners of railroads untold sums of money. They encouraged a clean sweep of the employés high and low as far as the policy could be carried out. Good men who were familiar with the working of the road were turned off to make place for men whose only recommendation was that they had previously been acquainted with some of the new officials or with the friends of the officials. Officers who go to a railroad with a tail of followers behind them trail a powerful means for creating failure. Men acquainted with all the details of a railroad's operating appliances must be ridiculously inefficient if they cannot do the work more satisfactorily than strangers. The wise man who takes hold of a prominent position on a strange road makes the best of the material he finds there, and he soon has every man helping to contribute to his success; the man of the long-eared kind finding himself newly in power on a railroad proceeds to show his authority by making numerous changes. Every change brings him some enemies and rouses opposition to the new incumbents. Open hostility may not be practicable, but there is covert opposition in all directions and a prevailing tendency toward carelessness which soon brings woful fruits in railroading.

Mr. Winter, the new general superintendent, was a better railroad man in many respects than Mr. Hailbreth, but he began by demoralizing the army that was going to help him to business victory or defeat. There was no *esprit de corps* on the road. The energy that on a well-managed road is devoted to hearty performance of duty was spent in endless bickering among individuals and in the settling of personal animosities. By the time that the road had been in the hands of the receiver for nine months the property ran down so badly that a sale was forced and it was bought up for the bondholders.

This brought back Hailbreth as general manager, and he called Kurgess to his old position. The road and all its belongings were in a ruinous condition, and the problem to be worked out was the paying of fixed charges and operating expenses. A prolonged struggle was engaged in to put the track and the machinery in decent running order. Patch and scheme and mend were the watchwords of the mechanical department as they were of all others. Kurgess worked early and late. Wherever there was a difficulty encountered, he was there to help and encourage. When breakages of worn-out appliances took all the persistence and hopefulness out of others, Kurgess came to the front with directions and patient, stimulating aid that shamed failure out of the field. He appeared to have no thought but for the interests of the company. Self was entirely immolated in devotion to what were considered duties and which by degrees became sources of pleasure.

Good or bad habits are apt to grow upon us, and with Kurgess the habit of making his worn-out engines and antiquated cars last a few years longer became a passion. This taste was strongly encouraged by the general manager, who made it a leading article of his business faith to refuse renewals till the road began to suffer. So Kurgess became noted in the West as a wonderful patcher. Nothing pleased him better than to take his friends into the engine house and point out fearful patches to cylinders and other parts. It was frequently difficult to identify the original parts of engines and cars after they had gone through the shops under the supervision of Kurgess. The boys used to say that he would jack up a bell and build an engine under it for the sake of saving the bell. But the men did not forget that they still had an old engine made at an outlay which would have bought a new one.

Under the fostering penurious care it received on all sides, the road gradually emerged from its financial difficulties and of late years it has been considered in a prosperous condition. A few months ago the management appeared to become aware of the fact that the practices of the mechanical department were antiquated. The diamond stack and small familiar engines suddenly became an eye-sore to the man

WESTERN FLOODS.—C. & N. W. RAILWAY, AT GALENA, ILL.

DESTRUCTION OF ILLINOIS CENTRAL BRIDGE, AT GALENA, ILL.

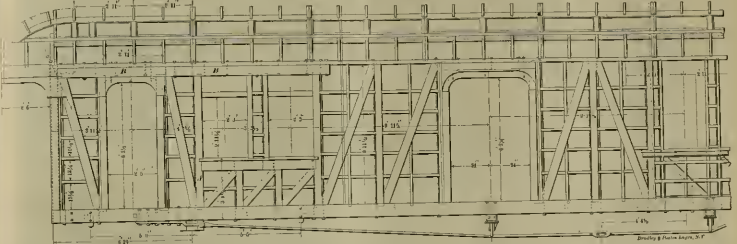
who had turned his face for years against any suggestion of change or improvement that involved the spending of a cent. The shops, the engines, the cars and everything under the master mechanic were declared to be out of line with modern ideas and the only remedy within sight was the relegating of Kurgess to the street. He was a back number, and back numbers were no longer in favor on the Transcontinental.

No hint that a change of policy was desirable was given. General fault-finding was indulged in for a few weeks and then the intimation was given that Mr. Kurgess' resignation would be acceptable.

Here is a man whose work was the object of devotion approaching adoration. His thoughts were even more bent in serving the company than in looking after his own interests. Sunday and week-day and holiday always found him attending to business. He never took a single holiday and never attended a meeting where railroad men assemble to talk on questions that interest the craft. Yet he was turned adrift on two weeks' warning. Verily there is a striking reward in store for men who devote heart and soul to the interests of some railroad companies.

## The Cantilever in Car Framing.

The framing of the combination baggage, passenger and express car, shown in the annexed engraving, embraces a novelty that probably never was before introduced in the construction of railroad cars. The car is one of the New York, Lake Erie & Western, and is throughout a good specimen of designing with the end of getting the greatest possible strength out of the least material. In putting in the side door toward the end of the car it was found that with ordinary methods of framing the vertical strength of the car would be very much reduced. To overcome this Mr. A. E. Mitchell, superintendent of motive power, resorted to the cantilever principle so well known in connection with bridge work, and applied the timber B B. The middle of the beam rests on a post which is immediately above the body bolster and transfers the load direct to that strong point. The strengthening timber thus becomes a cantilever with the body bolster for a support



FRAMING OF NEW YORK, LAKE ERIE & WESTERN COMPOSITE CAR.

## Make the M. C. B. Coupler Automatic.

An esteemed correspondent who has performed an important part in the improving of railroad rolling stock writes us as follows:

I notice the indorsement of the M. C. B. type of draw-bar is reported, which if correct, will confine that type in use, as I think. The point now should be to make it so far automatic as to be manipulated by switchmen and trainmen without the necessity of going between the cars. This point is what must be reached in the successful bar, as I understand the action of Congress may follow the action of the Master Mechanics' Association on this point, and in some direction ought it not to be so shaped as to bring out the point of necessity for automatic action in the bar? Is it not a fact that the interest of the men using the bar, as also of the roads, calls for this as the first consideration? The only objection to the type from the first has been on this point, and now that indorsement of the Master Mechanics' Association is had for it, why cannot the defect be emphasized so as to reach a correction of it? I think the interest of the men should be recognized and urged in all proper ways. The roads are able to, and doubtless will, as usual, take care of their side, but there is room for others to work on the other side.

A tragic incident happened lately on the New York, Ontario and Western. A helping engine was pushing a train and a signal was given to the engineer to slow down, but he did not respond and kept the engine working full steam. A brakeman climbed back from the train to see what was the matter and found the engineer dead, leaning with his head out of the cab window. He had been struck by some projection in a rock cutting. The fireman was attending to his duties in the hind cab unconscious of the accident. The engine was of the Wootten type which keeps engineer and fireman apart. The tragedy was sad enough but it carried the possibilities of one much greater. A dead engineer in the front cab and the fireman in another part of the engine with no means of finding out that anything was wrong make a startling situation. When these men are so widely separated it raises the necessity for another man being on the engine.

## Merits of Simple and Compound Locomotives.

Considering the large number of compound locomotives now in service all over the world, it appears strange that there still exists so much diversity of opinion concerning the merits of the compound as compared with the plain locomotive. The advocates of the compound locomotive have no patience with the conservative tendencies of those who cling to old forms, and simple-engine advocates consider the views of those who favor compounds as being nothing short of temporary lunacy. We think that considerable arguments have been adduced on both sides, although we think the weight of evidence appears to be in favor of compounds being so economical as to be worthy of introduction where coal is expensive. There is always a conflict of opinion when an important change is proposed in machinery matters, and the opposition to the compound locomotive is certainly not nearly so vindictive and aggressive as was the opposition to the compound marine engine in times within the memory of men who are not yet very old.

At the Master Mechanics' Convention, when there was talk going on about a committee to investigate compound locomotives, considerable amusement was excited by Mr. Forney when he suggested that a committee be appointed to investigate plain locomotives. The question when properly considered is not as funny as it seemed to be. We do not recall any question that might have offered better subject for investigation than, "how can the simple engine be made more economical?" The ordinary locomotive has been one of the worst neglected machines that we know of so far as its possibilities for securing improved economy are concerned. In connection with this subject we consider the remarks that Mr. Forney made at the Master Mechanics' Convention while the discussion on compound locomotives was going on as being worthy of the most careful consideration. He said:

"Supposing a railroad company wishes to have a certain number of locomotives, those locomotives to weigh, we will say, 100,000 pounds. Suppose under that condition of things that the general manager of the railroad should go to a builder of compound engines and say to him, 'We want you to build engines weighing 100,000 pounds for such and such traffic,' and suppose that same general manager should go to some other builder of engines and say 'We want you to build us some simple engines, weighing 100,000 pounds for such and such traffic,' and that he were to tell each builder that he would not be obliged to conform to any conditions except those he saw proper, what he had to do was to put 100,000 pounds of iron and steel into the form of a locomotive to give the best service; whatever advantage the simple system gave, the builder of simple engines could avail himself of. Under those conditions we have two locomotives in which we may imagine we have the highest degree of efficiency of the two systems.

"What do we find under these conditions? In the first place it is generally acknowledged that compounding increases the weight of the locomotive considerably. Now, to the extent to which we increase the weight of the engine it is a disadvantage. The simple engine man, under those circumstances, might take that extra weight and put it into the boiler and get a larger boiler on his simple engine so as to get greater efficiency from that larger boiler. A trial made with engines of that character would, I think, reveal what are the relative advantages of the two systems. If the system of simple engines has an advantage in weighing less, why surely you have a right to avail yourself of that. In the comparisons and tests and discussions that have been made, it seems to me that in nearly every instance the compound engines have asked for odds in their favor. They have asked to make the engines heavier.

"One of the most important things in locomotive engineering, or in building locomotives, is to get locomotives that will do the work. It is not a question of getting locomotives that will make a good indicator diagram. It is not a question of getting locomotives which will show good results from very careful tests when all these variables are brought into consideration. The business of a locomotive is not to burn variables; it is to burn coal. The important and overwhelming question, the one which your general manager, your directors, everybody, asks you, is, How long can you keep your engine in service? The most important question is the number of miles you can run in the course of a year and the number of cars you can haul. The question of hauling cars is of infinitely more importance than the saving of coal. Now, is it probable that we can get an amount of service out of the compound engine which is equal to that of the simple engine? If the compound engine is not able to give as many miles service in the course of a year as the simple engine, it will condemn the system.

"A good plan would be to appoint two committees on this subject, one consisting of the advocates of the compound system, to get up a compound engine of the very best character they can find, and the other consisting of gentlemen like Mr. Barr, who are agnostics on the subject, and let them get up the very best simple engine that can be found, and then have a competition of these two engines, and let the advocates of the two systems have charge of those tests. It is unfair to try a man for his life without giving him counsel. It is unfair to try the simple engine before the public without giving it counsel. Therefore I think there should be a committee to stand up for the simple engine. It may be that the simple engine can be improved still more than it is."

## Will be Wiser Next Time.

"The Master Mechanics' Convention was a great disappointment to me this year," remarked our funny editor, as he masticated the last piece of pie left at the lunch counter.

"What was the matter with the convention?" inquired Tom Purves. "I thought it was the best I had ever attended. I am sure the members attended to business closely enough."

"That's just the grievance," was the reply; "it was not business I wanted, it was stories. Why, I did not hear but one funny story at the convention. Why man, when they were sitting on the piazza in the evening, instead of telling funny stories as they used to do, they talked about compound locomotives. I got more sick of that word than I was of the compound of salts and cream of tartar that my mother used to dose me with when I was a boy."

"Was the solitary funny story you heard worth repeating?"

"It scarcely comes up to the mark of the Ananias Club. It was told by E. S. Marshall, who is now superintendent of the Madison Car Works. Mr. Marshall is a Southern man, having been superintendent of motive power of different Southern roads. The story as he told it went something like this

"Some of your Northern people used to come South in winter and many of them were always wanting to regenerate the natives down there. One of your effusive goody-goody preachers came to our place and he had a letter of introduction to me from a friend in Boston. I showed him all the courtesies I could, and on his expressing a wish to see the way prisoners were treated in the State Prison, I obtained a permit of admission and accompanied him through the place He would persist in talking to the prisoners and giving them what he called seasonable advice.

"There was a big nigger in one cell whom he seemed particularly anxious to convert. He entered into conversation with the convict, and spoke of the power of grace in sustaining a man in that unhappy position. Then he inquired.

"'For what crime were you convicted that led to your deplorable incarceration in this place?'

"'Fo' de stealin ob a hog, Sah.'

"'I am sure you will know better than steal again when you are released.'

"'Yes, Sah, I'll know better next time. Will neber steal nuffin again dat can squeal.'"

## A Misleading Change of a Word.

We owe our correspondent, Mr. W. F. Relyea, an abject apology. It is well known that Mr. Relyea is one of the steadiest and most respected citizens in Western New York. Those acquainted with him personally know that Mr. Relyea has always been a steady man, with no inclinations toward convivial habits, yet we have unconsciously implied that passing the ruby was once in his line In our last issue, while writing on a brake question, Mr. Relyea attempted to say that he had "resumed business at the old stand after a satisfactory trial of dispatching." Imagine our horror on finding after the paper was all mailed that the printer had perverted dispatching into "dissipating" We offer our regrets and sympathy.

The incident reminds us of an incident that happened in a rather pretentious literary society that the writer belonged to some years ago in a Western city They had a series of literary entertainments and among them an amateur theatrical performance. The intention was to send out circulars intimating that the most accomplished amateur actors in the city had been engaged as performers. The wicked printer got in his work, it was said with malice aforethought, and the circulars first sent out read "amateur asses."

The wicked printer does not have a complete monopoly of making mortifying blunders. The typewriter is now coming in for a share. A friend writing lately from Scotland mentions a curious blunder caused by a careless typewriter. A station master had been teasing the superintendent to give him a change to a more important station. The man was not entirely satisfactory and the applications generally called forth reproaches for shortcomings In one letter, after berating the applicant, the superintendent intimated that he had given orders for the man to be changed to Auchterarder. The typewriter missed the c in changed and the aspirant for a better position received notice to his amazement that orders had been given that he should be hanged to Auchterarder.

## Paid for Change of Opinion.

"Dutch Frank," who used to run old 161 on the Union Pacific in the sixties, had for a fireman a Milesian named Patsy Lahey. 'Twas during the French and Prussian war and Frank was eating lunch and talking war with Pat who had no lunch and would have to wait until they arrived at Sydney for his dinner. Frank remarked, "Patsy, vot do you tink, de Prussians git away mit de French, eh?" "Yes," said Pat, "I think so." "Here," said Frank, "took a nudder piece of pie, Pat" Pat ate the pie, and the conversation continued. Finally, Pat said, "Well now, Frank, come to think it all over those Frenchmen are pretty smart and may get away with the Dutch yet" "Ugh! Shuffel in some more coal," said Frank. "Da ol angine vorkin in de corner vill gif you some sings to do breddy soon."

## Another Railroad Man Who Tried Farming.

It is sad to reflect on the number of railroad men of saving habits who have accumulated enough to buy a farm and taken that way of spending their hard-earned money. Train men seem to be especially prone to hanker after the charms of rural retirement, and they are the last men in the world to be satisfied with the uneventful, dull existence that most farmers lead We can recall the names of scores of men who had good runs as engineers or conductors and left them to turn farmers. After a few tailsome years they would return to railroad life sadder and wiser men, ready to begin life again at the bottom.

The last dreadful example that we have to relate of this form of madness was gone through by one of the last men in our acquaintance whom we would have suspected of hankering after rustic simplicity

A year ago W. W. Thompson, who had long been road foreman of engines of the Manhattan Elevated Railroad of New York, accepted a position as division master mechanic of the New York Central at Mott Haven, New York. The new place did not suit him and he resigned, and intimated that he was going to California to turn farmer. A month ago Mr. Thompson went running an engine on the Elevated Railroad of Chicago.

We recently gleaned a few particulars about the experience of Mr Thompson as a farmer. Having friends on the Pacific Coast, William was persuaded to try his hand on a rented place before purchasing, which he fortunately consented to do. A good farm was selected and all appeared to go merry as a marriage bell when the looking round period was on. Then he got a few necessaries together and took possession of the house

"Now," he said to Mrs. Thompson, the morning after arrival at the place, "the first thing to do is to get a garden ready. I'll spade you up a fine plot and you can get all the seeds you want put in it right away."

"Had'nt you better wait till the plow comes and have the ground plowed," suggested Mrs. T

"Oh, no," said William, "I cannot wait for that. My motto is strike while the iron is hot"

He measured off about half an acre and proceeded to turn over the soil as if his life depended on the work being done in one day The hot sun poured down and the hot moist air rose from the baked ground, but William toiled at his determined task and finished it in good style Next day he was laid up with an attack of muscular rheumatism. Lying in bed in a solitary farm house is not an exhilarating experience to a man accustomed to the bustle and turmoil of cities, but the neighbors, who were not more than four or five miles away, would make visits of condolence every four or five days and do their best to cheer the sick man. Several of them were very careful to assure William that he had their regards and they would not fail to attend his funeral if he died.

He did not die, however, but after two or three weeks got round, painfully leaning on a cane. Mr. Thompson had an idea that he would pull California farming out of the rut of grain-raising that it had fallen into. The way to make money in farming, he told his neighbors, was by raising stock. To show the way, he began by buying a thoroughbred bull. The animal was delivered and was kept in the pasture, secured by a long rope and stake. William was proud of the bull, and during his convalescence spent considerable time visiting with the bull and admiring its various good points. One day he thought it would be a good plan to change the bull to another part of the farm, so he pulled the stake, and as he was still very lame, fastened the rope round his waist as an aid to locomotion. As he drove along something frightened the bull and he began to run William shouted and held back, but the more he shouted the faster the bull ran. He was like the innocent tender stuck to a runaway engine. He was anxious to let go but couldn't Failing to let go he tried to keep up, and soon was running with steps that took about three to the acre. He held bravely on through a thick piece of brush and a muddy creek, and was still right end up when the bull reached the barn.

Next day he could walk without a cane. The incident that brought about his sudden cure of lameness, however, broke his confidence in farming. As he was tearing along like a rocket, attached to the bull, he reflected about the mortifying end it would be to get killed in that tame way, after passing through all the perils of running locomotives in three continents. The thought was too much From that moment William turned his thoughts eastward, and a few months later found him speeding toward the restful haven of Chicago.

## Stack-base Damper.

The Rogers Locomotive Works have lately delivered to the New York & Northern Railroad a passenger engine, cylinders 18 x 24, 62-inch drivers and a double-ender rapid transit engine, cylinders 14 x 22, 54-inch drivers, fitted with the usual appliances of first-class engines, and with the Luttgens' stack-base damper, this being the third lot of engines furnished to this company so fitted.

Howe, Brown & Co., Limited, of Pittsburgh, have sent out a circular to railroad men, intimating that they are prepared to supply crucible steel cast-steel suitable for fireboxes. It is said that some fireboxes recently taken out of engines on the Chicago & Northwestern Railway, that made extraordinary mileage, were made of crucible steel, and this is evidently why the makers offer to resume the manufacture of this article.

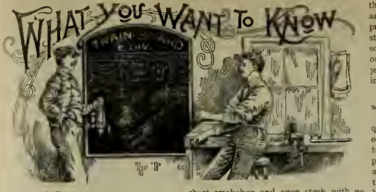
A very simple form of brake slack adjuster has been patented by George L. Harvey, Chicago. A ratchet is attached to the brake-rod which connects with a clutch by a sliding-rod. When the brake piston travels beyond the limit, the clutch moves a catch along the ratchet one notch, thereby taking up the slack. It is one of the simplest devices we have seen for the purpose

Messrs. Spon & Chamberlain, of Cortlandt street, New York City, have sent out a circular intimating that the Standard Electrical Dictionary, by Professor T. O'Conor Sloane, will soon be ready This book will be of great service to the many men who are trying to post themselves on electrical matters.

Jackson, Sharp & Co. have contract for thirteen coaches and two chair cars for Jacksonville, St. Augustine & Halifax River Railroad

## Burdette on the Drummer.

"He looks over my shoulder as I register after him, and hands me a card with a shout of recognition; he peeps over the register again, and watches the clerk assign me to ninety-three. 'Ninety nothing!' he shouts 'Who's in fifteen?' The clerk says he is saving fifteen for Judge Dryasdust. 'Well, he be blowed,' said my cheery friend. 'Give him the attic, and put this gentleman in fifteen.' And, if the clerk hesitates, he seizes the pen and gives me fifteen himself, and then he calls the porter and orders him to carry up my baggage and put a fire in fifteen, and in the same breath adds 'What time will you be down to supper, Mr Burdette?' And he waits for me, and seeing that I am a stranger in the town, he sees that I am cared for, that the waiters do not neglect me, he tells me about the town, the people and the business, he is breezy, sociable, full of good stories, always good-natured, he frisks with cigars, and overflows with 1000-mile tickets, he knows all the best rooms at the hotel, he always has a key for the car seats, and turns a seat for himself and friends without troubling the brakeman, but he will ride on the woodbox or stand outside to accommodate a lady, and he will give up his seat to an old man. I know him pretty well. For three years I have been traveling with him, and I have seen the worst, and I know the best far outweighs the worst. I could hardly get along without him. I am glad he is so numerous"



(73) H. T. F. says:

Why does not an injector, say the Monitor of '88, or Seller's of '87, waste water at overflow while working? *A.*—Because the injectors are so constructed that the stream of water is carried over without any escaping.

(74) C. W. W Stovall, N. C., says

The Westinghouse Instruction Book says the pressure on top and bottom of valve 17 is equalized. I think there is a greater pressure on the top on account of the valve stem on bottom of valve, which gives the top the greatest area, consequently the greatest pressure. Am I right? *A.*—Yes. The difference is very little, however.

(75) E. F. B., New Orleans, La., asks:

Why do locomotives have brass or copper throttle-stems while others have iron or steel? *A.*—Because copper or brass is not so liable to corrosion as iron. 2. I was on an engine that had her pop set to blow off at 132 pounds pressure. When pulling on a hill she did not pop when she had 145 pounds Please tell me the cause. *A.*—The safety-valve was badly adjusted, or was out of order.

(76) E P., Montreal, Que., writes:

We were talking about the crystallization of metal, and a man whose opinion is considered of value said that the talk of metal becoming crystallized by use is an old-fashioned fallacy. How is that? *A.*—The theory that metal becomes crystallized by vibration, shock or constant stress is no fallacy. In tests where metal is vibrated till it breaks, it is seen that a change to crystalline structure has taken place.

(77) C. H. K., Tucson, Ariz., writes:

What is the difference between a high-pressure and low-pressure engine? *A.*—The difference usually has been that a low-pressure engine exhausts its steam into a condenser. In early days engines of that type worked very low steam pressure. Condensing engines nowadays often use as high steam as engines that are called high-pressure engines. The original distinction between high-pressure and low-pressure engines was that one exhausted into atmosphere and the other into the condenser.

(78) Subscriber, Ennis, Tex., writes:

We have some ten-wheeled engines with eccentric blades about eight feet long. When you get one of them running about 30 or 35 miles an hour you cannot drop the reverse lever down. Some of them have caused a clean sweep of all the motion when the attempt was made to hook them up What is the matter? *A.*—The eccentric rods are too long and heavy. They get vibrating from the movement of the engine in a manner that puts the link beyond control. The trouble is a common one.

(79) P. W., Atlanta, Ga., asks:

What is understood by the expression, "An American engine," when applied to a locomotive? *A.*—An ordinary eight-wheel engine with a four-wheel truck. 2. What is the leading difference between an American engine and an English engine? *A.*—American engines have outside cylinders and bar frame with provisions for arresting sparks. English engines generally have inside cylinders and slab framing with short smokebox and open stack, with no provisions for spark-arresting. There are other minor differences

(80) S. P. R., Cincinnati, O., writes:

Why is it that they put thicker steel in the shell of a large boiler than in a small one? *A.*—Because there is greater surface to receive pressure, and greater strength is necessary to resist the tendency to burst open the boiler. This will be understood better by imagining you see a ring of the boiler one inch wide. If this ring is 66 inches diameter it will have a surface of 207 square inches. With 100 pounds of pressure to the square inch there will be 20,700 pounds pressure on this ring. If the ring is only 50 inches diameter, the square inches exposed to pressure will be 157, and with 100 pounds of steam the total pressure will be 15,700 pounds.

(81) J. M., Kansas City, Mo., writes

What is cylinder condensation and re-evaporation? I have several times seen the expressions together, but do not understand them. *A.*—When the steam enters the cylinder it generally goes into contact with metal colder than itself. As ordinary steam has only sufficient heat to keep it in the gaseous form, the least abstraction of heat causes some of the steam to turn into water. At the end of the stroke, when the pressure is released from the steam, the water that has been condensed at the beginning of the stroke is liable to turn back into steam. This practice of steam condensing at the beginning of the stroke and re-evaporating at the end inclines to make an engine wasteful of steam.

(82) Foreman, Omaha, Neb., writes;

In reading your paper I see that you say in speaking of the big wheeled locomotives on the New York Central that the increase of wheel has made the engines easier on fuel. I cannot see why it should. It is contrary to the law of mechanics, which says that increase of speed is obtained by decrease of power. The same horse power must be exerted to pull the trains, whether the wheel be large or small. *A.*—There is a certain piston speed that is the most economical in the use of steam. When an engine with a small wheel has to run very fast the piston speed is so great that the steam is not used to good advantage. The comparatively slow piston speed is what gives a big wheeled engine the advantage.

(83) D. A. G., Pittsburgh, writes.

In answering a question in the July number you say that compression is back-pressure. If I understand the thing properly you are away out. If compression is back-pressure, why make two names for one thing? *A.*—We suspect that you do not understand the action of steam in the cylinders very well. Compression is back-pressure in the piston, yet back-pressure is not necessarily compression. When a piston begins to move on its return stroke it is obstructed by steam generally of low-pressure, that has not had time to escape through the open valve. That is generally known as back-pressure. When the valve advances to the point where the valve closes, the steam left in the cylinder gets squeezed into smaller bulk, and the pressure rises sometimes so high that it raises the valve off the seat. That is called compression, because it represents the time that the steam is closed in the cylinder and compressed. Although being compressed it is still back-pressure, as it obstructs the movement of the piston. Persons interested in questions of this kind ought to study books bearing on the subject or the current articles by Harris Tabor in this paper.

(84) Chequamegon, Ashland, Wisconsin, writes:

Will you kindly answer the following question to settle a dispute With a train of thirty cars of air we turn up fifteen retaining-valves, make a reduction of fifteen pounds, recharge train and make a second application of ten pounds. Now, does this second application apply to the rear brakes only, or to all, and if so have the forward brakes with retaining-valves turned up twenty-five pounds pressure? Our retaining-valves are weighted to fifteen pounds. *A.*—When you first release brakes the forward cars will retain fifteen pounds, then when you reduce train-pipe pressure ten pounds there will about eighteen pounds flow into the cylinders instead of ten, after air has passed the triple and gone to the cylinder it has no influence on the movement of the valve; when the second reduction is made about eighteen pounds will flow into the rear cylinders and about the same into the forward ones; this is *added* to the fifteen already there, but probably loses a little from the resistance of the pressure already there. The Westinghouse people say the pressure on the brakes with retaining-valve will be practically about twenty-five pounds; the *exact* figures are hard to arrive at.

## Air-Brake Disorders.

By Paul Synnestvedt.

Permit me to hazard a few more guesses on some of your air-brake puzzles.

The flattening of one wheel without the other showing any damage is not an infrequent occurrence, and is probably due to the fact that when the pair slid one rail was slippery from moisture or oil, and the other dry or possibly sanded. Many air-brake men know that a wheel can slide quite a long distance on a wet or greasy rail without doing it any perceptible damage, for it does not begin to flatten until it is so heated that the chill is taken out, and then it wears away very rapidly. Of course heating takes place on a dry or sanded rail much more rapidly than on a wet slippery one. Another condition that may have entered into the case is that there is quite a difference in the chills of different wheels, especially in the depth of the chill, and the deeper one would take longer to heat up to the softening point.

Though the statement is made that the chill seemed to be all right, I think it would be found on very close examination that the metal was damaged immediately around the flat spot, for I have known many cases where, though examination revealed no defect in the metal and the wheel would run ordinarily till the spot was worn away, a very cold day would cause it to shell out so badly as to make the wheel dangerous to run.

Mr. Woods' puzzle looks to me very like the case that excited so much discussion a short time ago, in which the inside of one of the hose was damaged in such a manner as to prevent all the brakes from setting from one end, while they worked all right from the other end. From some defect in hose or piping on the box car the forcible separation of the coupling back of it closed the communication, preventing the escape of air from the forward section, but of course not interfering with the operation of the brakes from the head end. Possibly when stretched the internal lining of the hose gave way and rolled up in such a manner as to close the opening.

Mr. Relyea's brake-puzzle is one that is encountered in actual practice probably more than any other one in the whole list of air-brake difficulties. The engineer's constant complaint is "my tender-brake sticks," and he generally wants the triple-valve cleaned, quite naturally supposing that that is the seat of the difficulty.

I think that out of ten such cases there is seldom more than one in which any of the trouble is due to the triple-valve. Some times the cylinder needs oiling, or it is full of dirt, and the leakage groove is not performing its proper functions because it is stopped with gum. Generally, however, such trouble arises on the engine, which, when first equipped with the driver-brake, were supplied with an auxiliary reservoir under the tender of sufficient capacity to supply both the tender and driver-brake cylinders. Afterward a separate reservoir was provided for the driver brake, leaving the large reservoir under the tender with only one 8-in. cylinder to supply, and resulting, on an application of the brakes, in a much higher equalized pressure under the tender than in either the driver or the car-brake cylinders, and this necessarily causes the brakes to reset after a release when the pressure in the train-pipe becomes reduced by feeding into the reservoirs under the train in which the pressure is not so high. I know of many engines on which "tender-brake sticking" has been permanently cured by simply putting on a smaller auxiliary reservoir.

Although well satisfied with Mr. Holmes explanation of the reason why one engineer's valve can be handled successfully in the service-stop position with the little drum cut out, while another cannot, I am much surprised at his statement that it is possible to stop a train in a shorter distance in service application than in emergency. It seems to me it would be very poor policy to suggest to the men anything other than the instruction that they must never hesitate to use the full emergency in any case where there is a question of danger, for although I am well aware that with all the air exhausted out of the train-pipe there is considerable back leakage through the triple valves, and that a wheel loses braking power when it begins to slide, the back leakage can be prevented by putting the handle back on the lap after making the application, and there is little danger of much damage being done in the way of flat spots, provided the pressure carried be not excessive, as a wheel rarely or never slides at a high rate of speed.

There is no question but that some men are recklessly free with their use of the emergency action of the valve, and all reasonable measures should be taken to remedy this evil, but I cannot help saying in behalf of those whose lives and limbs may be in danger, that considering the fast time made by the trains of the present day, the large number of trains run on the same track, many of them only a few minutes apart, and in general the many dangers that threaten the passenger as well as the railway employé, it is best that too many restrictions should not be put on the actions of our locomotive engineers else they may hesitate in case of doubt, and it is assuredly true that when running at a speed of 60 miles an hour "he who hesitates is lost."

*Chicago, Ill.*

"Speaking of the inability of compound locomotives to burn the same coal as common locomotives," said M. N. Forney, "reminds me of a little story There was a young doctor who was called upon to attend a patient who was in the last stages of consumption and who desired very much to have some corned beef and cabbage. The doctor thought the patient would die very soon, and perhaps it would hasten his death, so he allowed him corned beef and cabbage. The patient began to improve, and finally got well. Soon afterward the doctor had another patient, of the German persuasion, who was suffering from stomach trouble, and who, in the absence of the doctor, ate corned beef and cabbage and died. Thereupon the doctor made this entry in his book 'Corned beef and cabbage cures consumptive shoemakers and kills dyspeptic Dutchmen.'"

RADIUS LINK PLANER ATTACHMENT.

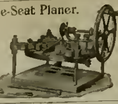
—FOR—

Planing Links, Blocks and Circular Work on ordinary Planer.

Quickly Attached.
Easily Operated.
Does Accurate Work.

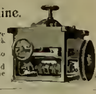
Valve-Seat Planer.

Over 300 in use.



—DAVIS—

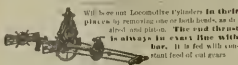
Valve Port Milling Machine.



This machine will mill out ports in valve faces of steam cylinders, duplicating work exactly and in the shortest possible time. It is operated by a rope belt similar to that used for driving drills, etc. It is much lighter than the cylinder and can be readily placed in position using the stud-holes to attach to for that purpose.

PATENT PORTABLE

Locomotive Cylinder Boring Machine.



Will bore out Locomotive Cylinders **in their places** by removing one or both heads, as desired, and piston. **The end thrust is always in exact line with bar.** It is fed with constant feed of cut gears

PEDRICK & AYER,
MANUFACTURERS
Special Railway Tools
1001 Hamilton St.
PHILADELPHIA, PA.

—LEED'S—

Horizontal & Radial Drilling Machine.

Designed to work on or from a Drill Press. Is useful in drilling ends and diagonal parts of frames. Can also be mounted on the work and driven by a sliding shaft and universal joints. Drilling in all directions can be done

—LEED'S—

LINK MILLER & SLOTTER.

For rapidly and accurately Milling out Links to any desired radius. Can be used on Drill Press or as an attachment to our Heavy Universal Milling Machine.

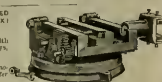
*A link 20 inches long can be finished in four hours.*

Greenwood's Universal Planer Chuck.

FOR STRAIGHT, CURVED (CONCAVE OR CONVEX) OR ANGLE WORK.

Used on any planer with cross-feeds for Hubs, keys, wedges, etc.

*Indispensable for Locomotive Builders and Master Mechanics*



—JOINTER—

FOR

Facing Locomotive Brasses.

Will hold any size brass same as held by strap when in use.
No more time required to place brass than screw up an ordinary vise.
Any desired thickness of cut can be taken, jointing the faces perfectly true.
No files required.

CRANK-PIN MACHINE.

For turning off Crank Pins in position, keeping the original centers of the Pin

PORTABLE DRILLING MACHINE.

For Fitting New or Old Cylinders to Locomotive Boilers.

It will drill all the holes in smoke boxes and cylinder flanges necessary to hang one pair of cylinders at one setting of the machine

Quickly set and operated
Driven by hand or belt power.

## A Tortuous Climb.

The engineering difficulties encountered by the Canadian Pacific Railway in crossing the Selkirk Mountains are strikingly illustrated in the annexed engraving. Four tracks are shown from the point where the photograph was taken, three of them being almost parallel, each working upward to attain the elevation necessary for climbing over the upper pass

The scene represents "The Loops in the Selkirk," situated immediately west of the summit of the Selkirk range of the Rocky Mountains and a short distance beyond the great glacier of the same range. By means of these loops, which show four portions of the main line, the road is brought down from a considerable elevation to a lower level and the apparent paradox of two trains rushing past one another on the same pair of rails not unfrequently occurs. The loops occur in the midst of some of the most magnificent scenery of the Rocky Mountain ranges and in the immediate vicinity of the peak known as Sir Donald, and the highest in that range on the line of the Canadian Pacific Railway. A few miles east of the loops is the Glacier House, one of the picturesque and luxuriant chalet hotels erected by the C P. R. Co., about a mile and a half from the great glacier at the foot of Sir Donald; a favorite stopping-place for tourists and hunters of the mountain sheep and mountain goat. The river in the valley fed by the glacier is the Illecillwaet.

This is one of a variety of most striking views which we have of this region. For those who are fond of mountain scenery or of examining difficult engineering works, we know of few places that would give greater satisfaction than a trip over the Selkirk Mountains, on the Canadian Pacific Railway.

The trip can be made from Montreal to Vancouver in about six days, and the splendid accommodation provided by the Canadian Pacific Railway makes the trip a luxury

CANADIAN PACIFIC CROSSING THE SELKIRK MOUNTAINS

## Notes on the German Railroads.

[EDITORIAL CORRESPONDENCE.]

It seemed to me as if I got into Germany on stepping on board the Norddeutscher Lloyd steamer *Ems* at Hoboken. She was manned from bridge to forecastle by Germans, many of them unable to speak a word of English, the signs and notices were printed in German and the cooking was German, while charges were all in marks instead of dollars.

Of course I went into the engine room and stoke hole—they couldn't have kept me out with a gun. The *Ems* is eight years old and is fitted with compound engines [illegible] high-pressure cylinder in the center and two low-pressure cylinders, one on [illegible] I did know the diameter of the [illegible] cylinders in meters, but cannot [illegible] I should say the high-press-

The pressure gauges were numbered 1, 2, 3, 4, 5, 6, 7, and pressure was at 6, which meant 90 pounds, the gauges being figured for atmospheres, 14.7 pounds, practically 15.

had covered about 390 miles a day—which in going eastward is less than twenty-four hours by some thirty-six minutes, as you go toward the sun.

I shall not attempt to describe the engine

The engineers do not get half as good pay as locomotive runners and the firemen get about half what men on locomotives in the United States do.

But, I started to tell you something

Railway Station, Frankfort-on-the-Main.

[illegible] about 40 inches in diameter and the [illegible] 60 and 70 respectively, all with [illegible] of 42 inches.

[illegible] were four boilers about 18 feet in diameter, but very short, with three furnaces in each end.

The engines were started at Hoboken on Saturday morning at 7.30 o'clock and were not slowed down or stopped until we reached Southampton, England, a week from the next Sunday. They had made over 700,000 revolutions and the *Ems*

room, it is simply a labyrinth of machinery for almost every conceivable service, water works, lights, fire, drainage, hoisting, cooling, etc. An ocean steamship can only be likened to a village afloat—a village of 1,500 inhabitants.

about the German roads. Well, there a[illegible] some things to admire and others tha[illegible] wouldn't suit the restless American pub[illegible] at all.

In the first place the most of them a[illegible] owned by the government and they a[illegible]

Railway Bridge at Cologne.

conducted in military style, every last man wears a uniform, even the section men, you won't find any enginemen there with overclothes on. There are about three times as many men around as you will find in America. There are no baggage checks and large numbers of "grip packers," as the Americans call them, are suits trimmed with red, with the brass insignia of railway service, two wings and a wheel, on the collar and cap.

The cars are compartment affairs with the doors on the sides. There are four classes, first for blooded people and tourists, 33⅓ per cent. higher than second class and little better. The best German distinguished from the crew by a red leather bag, with a shoulder strap of the same material.

You have bought your ticket, tipped your porter and got into a compartment marked "Nicht Rauche," which means no smoking. The gafter has punched your ticket and closed the door, all the others railroad. Every street and road-crossing, no matter how remote, has a gate and a guard in uniform, and as the train passes each man comes to a salute position with his flagstaff used as a gun.

The section buildings are very much superior to the best of ours. They are far longer and have facilities for getting from

Roman Gate, Cologne. Railway passes through

around to lug baggage, for which you are expected to *tip*, in fact tipping is the principal exercise foreigners are expected to indulge in.

The station-master wears a red cap and a blue suit with red trimmings, gorgeous shoulder straps, braid, etc.; the train crews, engineers and firemen as well, wear blue people ride second class—I went with the best. The third class is cheaper but has seats without cushions, while the fourth class cars have no seats, and fifteen to twenty persons are crowded into a section, yet they are always full.

The train crew—brakemen—collect the tickets before you start. The conductor is are closed, the trainmen salute the conductor, he salutes the station-master, a porter rings a bell on the platform, the station-master swells out his chest and whistles on a little dingus hanging to his uniform, the conductor whistles on a similar concern, the engine gives a sharp little screech and you are off—on a German [illegible] platform [illegible] without crossing any tracks.

The platforms are spacious, the waiting rooms large and all accommodations clean and good, the buildings are of stone or brick, handsomely ornamented and are built to stay, all the permanent way is the same, heavy and substantial.

Across the Rhine at Coblentz.

The photographic reproduction of the station at Frankfort-on-the-Main shows one of these buildings for a moderate sized city. There are three immense train sheds of iron and glass, with an elegant station in front of them. On all station platforms in Germany clocks are placed to face each way, and on many of them the difference between official, or railroad time, and local time is given. Thu at Bremen, where we landed, the station clocks were marked on the face + 24 m., which means that the railroad time is twenty-four minutes ahead of local time. The picture of the Frankfort station was taken before the carriage drive in front was finished.

The railroad bridge at Cologne is a sample of this permanent kind of work. The noted cathedral is shown in the background. This bridge crosses the Rhine. Another handsome piece of steel is the Rhine bridge at Coblenz, while the bridge at Mainz is fully as good.

Cologne was once a walled city, the original walls having been built by the Romans in the twelfth century. These walls have been taken down and parks made in their places, but the historic old gates have been left as monuments. Through one of these, the

"Hahnen Thor," a railroad enters the city. I couldn't get a picture with a locomotive in it, but here is the gate.

As I sat looking at it I dreamily imagined it peopled and guarded again by Cæsar's soldiers, with their zinc undershirts, wire socks, battle-axes and two-handed swords, and I wondered how many of 'em would shed their tin overclothes and try to climb those little trees if one of these modern Dutch locomotives made a dive for that gate with her pop up and whistle open.

It is seldom that passenger trains are late in Germany; they run only about twenty-five miles per hour, but they are very regular. On top and at the ends of the coaches there are little coops for the train crew, where they can see over the [illegible]. These little houses are found perched [illegible] ends of cars, even four-wheeled [illegible] cars having brakes [illegible] freight cars have brakes, [illegible] entirely unprotected in this [illegible] large cars you will find [illegible] employes in stopping [illegible] setting the club in front of [illegible]

[illegible] and six-wheeled, [illegible] American [illegible] wheeled [illegible] cars are being introduced [illegible] have [illegible] heavy iron trucks and [illegible] side beams.

All cars have an immense spring buffer at each corner and are coupled together by a couple of links on hooks. Between these links there is an inch and a-half square threaded bolt, one end right, the other left, and from the center of it projects a handle with a weight on it; the slack is taken up with this before starting.

About ten six-wheeled carriages seems to be an average passenger train. These cars seat thirty four passengers and weigh nearly 800 pounds per passenger.

The car wheels are always of wrought iron, 38 and 40 inches, and the pedestal jaws are long and light, the bearing on each side of the box being but 1 inch wide.

The Carpenter air-brake, which has been applied to upward of 2,500 engines and 10,000 cars, is now being taken off, and the Westinghouse applied. It is claimed that the Carpenter brake was not reliable and produced destructive shocks.

The engines are generally four coupled with a single pair of leading wheels. They are not large engines and seem to have rather an easy job of it—I did not see a thirty-car train of freight in Germany.

The cabs are short iron ones without side windows. The injectors are on the boiler-head and the door handle is on the hinge side of the door and is placed on an extension of the hinge-pin so that it is about twelve inches above the door and can be reached without stooping down.

Screw reverse is used, and the throttle is a grindstone crank that is opened by shoving it from you. This has one advantage over the American plug, and that is that it is handled easily and will stay where you put it without a latch.

There is no provision at all for the crew to sit down, but on one engine I was on the engineer had a little iron three-legged stool with a round seat of wood; he sat on this *in the tank gangway*.

The tenders have iron boxes in each head and the water space is *under* the coal pit, so that coal is shoveled from about knee high.

There are no bells used on German engines but they have two whistles.

Great care is taken of oil; the fireman does the oiling, and when a long stop or lay-over is reached he pulls the wool feeders out of all the truck and driving-wheel boxes and those on the tank; when they start he goes around and sticks them all in again. Truck and car boxes are small. The top of the box is but large enough to hold the brass and carry the spring above it. The cellar is the largest part of the box and can be taken off, exposing the lower half of the journal, without any trouble, generally by loosening one screw.

Every freight car is marked with its weight, length between end axles, load capacity in kilos, age, etc., and has in addition the number of horses and the number of men it can carry in case of war—usually six horses or forty men.

Perhaps two-thirds of the goods shipped are loaded in open cars with sides about three feet high. This car is piled full of some commodity and then a large tarpaulin is tied over it. This canvas is numbered the same as the car. This variation in load makes it impossible to get over a freight train and calls for a load gauge. These are frames built over the tracks at all important stations with iron pieces hanging down from the top and hinged from the sides. If a load touches one of these irons it is too big and can't go. The largest cars carry fifteen tons and from that down to six tons.

The engines carry the clumsiest looking jacks I ever saw, they have wooden sides and the bar has teeth instead of a screw; the head is lifted by a crank.

Copper fireboxes and brick arches are universally used, while open stacks, short fronts and high nozzles are the rule.

Machinists in the shops get about 4½ marks a day, a mark being equal to 24 cents of our money. Engineers get 1,800 marks the first year, which is increased to 2,100 the third; this is the highest pay, but the men make premium money on oil and fuel, which amounts to considerable—one engineer told me that he made 3,400 marks last year on a favorable run. They have free doctor, hospital service and a pension when disabled or old, the same as soldiers, and there is a permanence to their positions that is at least encouraging.

There are very many details of the engines and shops that I have gathered, with the camera and otherwise, which I shall give to the readers of LOCOMOTIVE ENGINEERING when I get back to the land of the stars and stripes. J. A. H.

AT MAINZ, GERMANY.

A letter from Geo L. Beckwith, of Pacific Junction, Ia., takes up the proposal made by a correspondent of running trains with the baggage car behind so that there would be lessened loss of life in case of a collision. Mr. Beckwith looks upon this as a barbarous proposal and holds that the life of a baggageman is of as much value as that of a passenger, and is deserving of as much protection.

## Master Mechanics' and Car Builders' Meeting at Galveston.

A Galveston, Texas, correspondent, who signs himself J. McD., sends us the following notes of the above meeting.

There was a meeting of Master Mechanics, Master Car Builders and Joint Inspectors held in this city on the 20th and 21st instant, with representatives from the following railways: G. C. & S. F., I. & G. N., S. A. & A. P., H. & T. C., So. P., T. & P., M. K. & T., Ft. W. & Rio Gr., A. T. & S. F., St. L. & S. W., 'Frisco, Mo. P., St. L., I. M. & S., H. E. & W. T.

Mr. F. Reardon, master mechanic of the Mo. P. Ry., was chosen chairman and Mr. Cain, of the A. T. & S. Fé, secretary; both were good selections. After complimenting the meeting for large attendance, the chair called on Mr. Douglas, master mechanic of the T. & P. Ry., to explain the purpose for which the meeting was called. Mr. Douglas, in a few well-chosen words, said the principal object of this convention was to see if some uniform understanding could not be agreed upon to get rid of the present annoying and unsatisfactory manner of carding cars. The friction caused by the too rigid inspection of cars at local and interstate points was so disagreeable that this meeting was called with a view of more friendly relations and uniformity of inspection and carding.

The matter was discussed in an intelligent and friendly manner, and it was decided to have a representative from each road present form a committee to draft resolutions, and submit them to the meeting later for adoption. The following gentlemen composed the committee:

John Player, A. T. & S. F.; Jos. Billingham, G. C. & S. F.; F. Reardon, St. L., I. M. & S.; W. P. Siddons, I. & G. N. Ry., Jas. McGee, H. & T. C., Jas. Doyle, M. K. & T., J. R. Cade, So. Pac., G. A. Hancock, S. A. & A. P.; J. R. Groves, 'Frisco, R. N. Galbraith, St. L. & So. W., F. McGee, Ft. W. & D.; C. H. Burke, Ft. W. & Rio G.; E. A. Campbell, H. E. & W. T.

The committee not being ready to report at 4 P. M., they accepted, through the courtesy of Mr. Farrell, of the Sante Fé, an excursion on the bay, that they might have a good view of the harbor improvements of the deep-water port of Texas. The sail was delightful, but on the return trip there was not enough wind to fill the ship's sails, and, as a sailing craft cannot "compound" in a calm, the party had to disembark and walk over the Jetty Railway. On arrival at the beach they disported in the surf until, wearied with the day's work and pleasure, they retired.

Promptly at 9 A. M., next morning, Chairman Reardon called the meeting to order and announced readiness for the report of the committee. Secretary Cain read the report, as follows:

"Your committee, appointed to devise a uniform system of inspection and carding of cars on the railroads of Texas and connecting lines, recommend that inspectors be instructed to receive all foreign cars having old defects which do not render them unsafe to run or unsafe for trainmen; that a record of the condition of such cars be kept, and that each company be responsible and card only for new defects of foreign cars that may be brought about while the cars are on its lines. Inspectors are requested to dispense with the use of indelible pencils, and use pen and ink when making out defect cards. A copy of these resolutions shall be furnished the representatives of Texas and connecting railways."

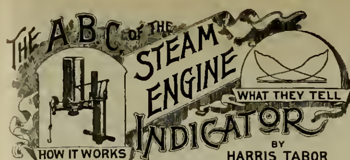
The report of the committee was unanimously adopted.

Mr. Adrien, of the Westinghouse Brake Company, being present, extended an invitation to all to go fishing, promising that he would furnish enough air to fill the ship's sails for the return trip. The invitation was accepted, and many availed themselves of the pleasure.

After adopting resolutions thanking the Galveston *News*, Houston *Post* and citizens of Galveston and managers of the Beach Hotel, also the Pullman Palace Car Company, for use of a special car, and Mr. Billingham and Mr. Farrel, for courtesies, the meeting adjourned.

---

The New York Central Railway, in its exhibit at the World's Fair, will strikingly illustrate the wonderful improvements that have been made in railway transportation by showing a magnificent, complete vestibuled train and alongside of it a reproduction of the first train of cars used in this country, the cars of which resemble old-fashioned stage coaches.



Probably no recent change in the construction of locomotives has had so great an influence on the motive department as compounding is bound to exert; and as this influence will touch the traffic manager as well, in the way of cheaper haulage, it is only fair to assume that *all* railway executive officers must soon give this question serious thought. The gains from compounding involve so small a cost and risk, and so little change in existing plans, that we may expect to see this system tested very soon on all important roads. Where tests have been made, with rare exceptions, the results have been largely in favor of expanding steam in two cylinders. In many cases the gains reported have been so absurdly large that conservative railroad men have regarded them with skepticism. It is an argument with radical reformers that advocates of a cause can never hope for all they ask, and for this reason claims are made looking away beyond possible realization. It is possible the more enthusiastic advocates of the compound locomotive are influenced by the reformer's argument when they claim a gain of from 40 to 60 per cent. over a simple engine in ordinarily good condition. Such gains are simply impossible, and must be so considered in discussing the compound and simple engine.

It is a general belief that the source of gain from compounding lies in the fact that expansion of steam may be carried farther, with less condensation, in two or more cylinders than in one. If steam at an initial pressure of 100 pounds be expanded to the atmosphere, the range of temperature will be from 327.9 degrees at 100 pounds, to 212 degrees at atmosphere, or $14\frac{7}{10}$ pounds, a range of 115.9 degrees. To a certain extent the walls of the cylinder respond to this change in temperature. The low temperature of the exhaust steam cools the cylinder, which is again warmed by the incoming steam from the boiler; this transfer of heat from the steam to the cylinder causes initial condensation, which is a serious loss. When the temperature of the expanding steam in the cylinder falls below the temperature of the walls, a portion of the heat stored in the iron is returned, causing re-evaporation, unfortunately too late in the stroke to be of value. If steam at an initial pressure of 100 pounds be expanded through the same range in two cylinders, each cylinder will be subject to a smaller range of temperature, and less condensation will occur. Where high steam pressure is used the gain from condensation, as a result of compounding, is considerable. But this is not the only gain from compounding, nor is it the greatest gain. Clearance is always wasteful, and especially so when it equals one-eighth of the piston displacement, which is not unusual in many simple engines running in competition with compounds.

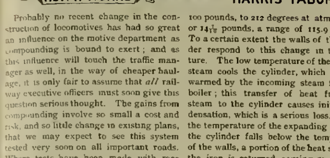
There are two ways in which clearance may be lessened: 1, by reducing the space between the valve face and piston, when it is at the end of the stroke, 2, by filling this space with steam of less weight. The best designers of compound locomotives have done both. It may be claimed with safety that the loss due to leakage is greatly reduced by compounding. In the simple engine the conditions (high-pressure on one side of piston and valve and low-pressure on opposite side) that indure leakage exist; in the compound the pressure is divided between two cylinders, and the extremes in opposite pressures are less. In the simple engine all steam that leaks past the piston goes to the atmosphere, and is wasted; any leak by the high-pressure in the compound engine must exert its expansive force on the low-pressure piston before it is released.

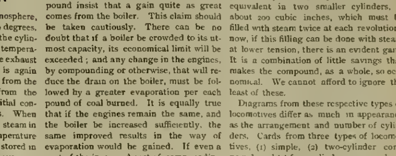
The sources of gain from compounding, thus far considered, are independent of the boiler. The advocates of the compound insist that a gain quite as great comes from the boiler. This claim should be taken cautiously. There can be no doubt that if a boiler be crowded to its utmost capacity, its economical limit will be exceeded; and any change in the engines, by compounding or otherwise, that will reduce the drain on the boiler, must be followed by a greater evaporation per each pound of coal burned. It is equally true that if the engines remain the same, and the boiler be increased sufficiently, the same improved results in the way of evaporation would be gained. If even a part of the increased cost of compounding a locomotive would be put in additional heating surface of the simple engine's boiler, it is probable that its evaporative qualities would be equal to the compound.

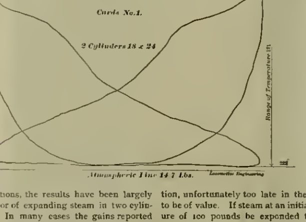
In the preceding paper attention was called to two distinct types of compound locomotives which have been thoroughly tested in this country, these have become standardized as commercial machines, under the names of two and four-cylinder compounds. These only will be considered comparatively. There is a greater difference in these types than the number and location of cylinders would indicate. They should be classed as receiver and non-receiver. Each has its advocates. The friends of the four-cylinder system make two strong claims, and with some show of reason. (1) A better steam distribution, because a full-sized pipe is used to supply cylinders containing only half the contents, (2) an equal distribution of power to the drivers, same as with a simple engine. The first claim is well supported by the cards recently published in LOCOMOTIVE ENGINEERING, from No. "385," at the wonderful speed of more than ninety-one miles per hour. The believers in the two-cylinder system also make strong claims, which are well grounded. Their principal gains, from their standpoint, are: (1) the use of the receiver which allows a cut-off in the low-pressure cylinder, which is adjustable by the link, (2) superheat by means of the hot gases in the smokebox, by which the receiver is surrounded. The amount of heat absorbed from the smokebox is probably small; but a small amount has its value because it checks condensation in the low-pressure cylinder. There are other gains from the use of the receiver which its friends have ignored, viz., a farther reduction in the range of temperatures, and a reduced clearance by means of filling this space with steam at a lower tension. The clearance space in a low-pressure cylinder 30 by 26 inches, or its equivalent in two smaller cylinders, is about 200 cubic inches, which must be filled with steam twice at each revolution, now, if this filling can be done with steam at lower tension, there is an evident gain. It is a combination of little savings that makes the compound, as a whole, so economical. We cannot afford to ignore the least of these.

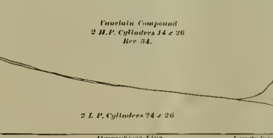
Diagrams from these respective types of locomotives differ as much in appearance as the arrangement and number of cylinders. Cards from three types of locomotives, (1) simple, (2) two-cylinder compound, and (3) four-cylinder compound are introduced for the purpose of illustrating the effect compounding has in reducing the range of cylinder temperatures and clearance. On each card is marked the highest and lowest temperature of the steam, and on each low-pressure card is marked the initial pressure which fills the clearance space.

The two-cylinder compound from which these cards were taken is the "Pitkin," built by the Schenectady Locomotive Works. Nos. 3 *A* and 3 *B* are from the "Vauclain," built by the Baldwin Locomotive Works. The Pitkin cards represent a full revolution for each cylinder, and the Vauclain a high-pressure card in one direction and a low-pressure in the opposite, the two making one revolution.









Card No. 1, from the simple engine, with much lower initial pressure, shows a decidedly greater range of temperature than either from the compounds. With 160 pounds initial pressure, this would be increased to 143 degrees. No 2 from Pitkin compound, with an initial pressure of 175 pounds, gives a range of temperature in the high-pressure cylinder of 79 degrees; and in the low-pressure cylinder a range of 78 degrees, a difference of only 1 degree. No. 3 *A*, from a Vauclain compound, with an initial pressure of 160 pounds, has a range of temperature in the high-pressure cylinder of 86 degrees, and in the low-pressure cylinder the extremes cover 118 degrees This is not a fair case, however, for an increase in speed to running conditions would raise the back-pressure line, and consequently the temperature, which would reduce the temperature range in proportion No 3*B*, from the same type of engine, represents more nearly the average running conditions Here we find a difference of only 3 degrees in the two cylinders But with the same initial pressure, as shown on the two-cylinder card, the range in the high-pressure cylinder would be increased 2 degrees, and with the same back-pressure in low-pressure cylinder, the range in that cylinder would be increased 14 degrees. If we consider these cards with a view to filling the clearance space, we find that in No 1 it takes steam at 125 pounds, in No 2 at 60 pounds, in No. 3*A* at 58 pounds and in No. 3*B* at 75 pounds

Harry Tobey

## A Practical View of Compound Locomotives.

Mr. F D. Casanave, superintendent of motive power of the Western lines of the Pennsylvania system, is recognized as being one of the ablest and most progressive railroad officers in the country. He has given careful study to the subject of compound locomotives, and his views on the question are well worthy of consideration. At the Master Mechanics' Convention he said

"We have had no experience with compound locomotives on our road so far, having had only four or five, which are scattered over a large territory, and we have very few figures to show the economy From somewhat imperfect trials which we have made of one compound of one type we have found an economy of about 5 per cent. in fuel. There is no doubt, from all the figures shown, that there is economy in compounding and that the economy will be greater where the price of coal is larger, but it seems to me that one of the essentials is to confine the compound locomotive to the simplest form That matter of repairs is one that must be looked to in order to ascertain whether any saving in fuel will not be absorbed by it. The compounding of locomotives is certainly in its infancy. If I were to take the money out of my pocket to equip a railroad I hardly think I would go very extensively into compounding I would wait for a year or two until it is clearly shown where the range of economy lies "

## Improvements on Fitchburg Railroad

On a recent trip East one of the many things we found to interest us, and which indicates progress of the most gratifying character, is the management of the operating department of the Fitchburg road In the adoption by this company—virtually the first New England road to do it—of the standard code, with some slight modifications where changes are made, the departures strongly indicate improvement The effort made to secure more rapid movement of freight, that is a fixed determination to deliver all freight received to destination, whether local or through, within 24 hours of its receipt, is most commendable. That the *shipshod* manner in which the average road handles its freight business is open to the harshest criticism, there is no doubt whatever in our minds, and this effort on the part of the Fitchburg road cannot help but meet with the most substantial encouragement on the part of shippers The senseless practice, so commonly in vogue all over the country, of hauling half-filled cars for hundreds of miles and returning them entirely empty, is receiving attention and great savings are effected. That other roads will sooner or later give this matter the attention it deserves there can be no question of doubt.

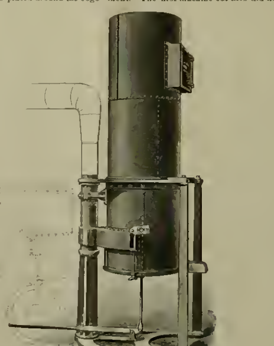
President Marcy is to be highly complimented for bringing about these numerous reformations. They reflect very creditably upon his management and his selection of men to bring them about.

## Long's Swinging Cupola.

The accompanying illustration represents a cupola furnace having a hinged movable section which moves both horizontally and vertically from under the upper or stationary portion of the furnace.

The advantage gained over the ordinary stationary furnace is the ease and convenience with which the necessary cleaning and lining process is performed. This improvement is not found in any other furnace manufactured.

The dotted lines represent the hinged section in position for picking and lining, which is performed by the operator from the outside with the same ease and convenience as an ordinary foundry ladle. The bottom of sand or clay can be placed more securely, and the kindling and bed of coke may be charged, after which a daubing of clay is placed around the edge



LONG'S SWINGING CUPOLA.

of the hinged section to insure a tight joint when closed.

In an open position, the hinged section is somewhat lower, to allow it to pass under the plate When in a closed position, as shown, a lifting jack is placed under the bottom, which elevates and holds the section in position and insures a tight joint as the process of melting is carried on, after which the jack is removed, allowing the section to drop to the collar, on the supporting column The clay joint is broken by the drop, the section opens out, and the bottom drops in the usual way.

Mr. A Beckert, master mechanic of the Louisville & Nashville Railroad, at Decatur, Ala , and several other experts examined the working of the cupola and testify very strongly about its convenience and efficiency. It is recommended as a good furnace for melting brass and other metals in crucibles instead of a regular brass furnace The furnace effects great saving of time and labor, and ought to be valuable in railroad shop foundries. It is made by Long & Jervis Co., Decatur, Ala

One cannot go about the shops of European roads without noting the absence of machinery and the presence of extra men to what we are accustomed to in America. Men are cheap there and machinery dear. In a large shop that we visited in Germany the machine shop proper occupied about one-fifth of the space it would in our country, and while there were pits for thirty-five engines in the shops they kept each one in for about six weeks and employed 900 hands, there being more than 150 vises in the erecting shop alone. The locksmith seems to be the ideal, and tools and devices are exhibited as good, because "made by hand."

## To Prevent a Rose-Reamer from Chattering.

"I wish that seating tool would cut smooth ; it chatters fearfully," was the tail-end of a remark overheard in a shop recently. The seating tool or rose-reamer was liberally supplied with soap and paper to fill the teeth and prevent chattering, but was not entirely satisfactory. The paper and soap will help, but the best help is in cutting the teeth correctly. By correctly I do not mean *evenly*, for that is probably the way they are cut at present, but space them as irregularly as convenient, and see if there is not an improvement. The first machine-cut files did not give satisfaction, from the fact that they chattered badly, due to the teeth being cut evenly, while the hand-cut files were spaced by the eye, and consequently not exactly even ; this is remedied now, so that a man can hardly pick out a hand-cut from a machine-cut file, and the trouble has disappeared also. Try cutting the teeth unevenly, and not having them too sharp, and see if it isn't an improvement —*F. H. Colvin, in Am. Machinist.*

One thing that the Germans excel us in is their method of lighting the locomotive. All the lamps on a passenger engine are lighted by Pintsch gas. They have no headlight, but their two forward signals are reflector lamps set on the forward buffer, and are 12-inch reflector lamps. Even the gauge lamps and tail lights have gas jets. The supply is carried in the regulation sized receiver placed at the rear of the tender. It is better, cleaner, safer and a better light than oil

Things seem to be coming to a pretty pass in some countries in Europe where steam boilers are used. There was a disastrous explosion on Lake Geneva some time ago through a worn-out boiler blowing up. Instead of censuring some petty official or arresting the engineer the Juge d'Instruction caused the arrest of the leading director of the company.

## Locomotive-Running Among the Bushwhackers.

By OLD SOLDIER.

(*Continued*)

I got to Nashville O. K. with my mind made up to get back North and join a regiment, as a common soldier had ten chances for his life that engineers and firemen had on the road, but after talking with some of my friends I concluded to try it again, so I reported for duty and got another good old Roger engine and pulled out again.

Obstructions were thicker on a military road than cattle are on Texas roads. That is, such as putting cross-ties and old rails across the tracks , they did not put any fish-plates on, for we did not have any on the Nashville and Chattanooga road. I have often thought if the road had been laid with fish-plates how handy it would have been for the Johnnies. We had the U rail. This rail was made in England and, by-the-by, you seldom see as good iron as it was. About this time the business was picking up fast on the Nashville & Chattanooga road, and the management was pushing the road to Stevenson, Alabama, and then seven or eight miles further to Bridgeport on the Tennessee River. Here at Bridgeport we had quite a siege.

The two armies lay here for about fifty or sixty days and at this time we had a large army of men, and so did the Johnnies The Johnnies laid on the south side of the river and the Yanks on the north side Now, dear reader, just imagine what a sight that must have been to an eye witness viewing the great hostile armies divided by the river, both sides throwing up breastworks and expecting every day and night to come together, neither one knowing the strength of the other, both armies being re-enforced every day Now, remember this was before any of the battles were fought at Chattanooga, but the Yanks played the Johnnies a pretty sharp trick and made them believe we had a much larger army than we had. Whenever a freight train arrived at Bridgeport you would see the tops of the box-cars just lined with blue coats, with their bayonets and swords shining in the open air. They were unloaded on the brink of the river so the Johnnies could see them leave the trains. Well, every day they laid there, they thought the Yanks were being re-enforced, but they were not ; at night you would see the same men loaded in the box-cars and sent back. Of course the Johnnies would not see them going back. This was kept up all the time the armies lay there, and the Johnnies certainly thought we had a great army, but all the same we did not.

Now I will relate a little story here that a good many young men would hardly credit, and it will perhaps astonish a good many old ones . About the middle of the Tennessee River there was an island just below the bridge, and every day the army laid there you could see at least fifty or a hundred men naked on that island playing cards, shaking dice and pitching quarters and dimes and other games. Now, this was a mixed crowd, about half Yanks and Rebs. The Rebs would give the Yanks four or five pounds of tobacco for a pound of coffee. Well, this thing was carried on to such an extent that it had to be stopped by the officers of both armies, as it was getting demoralizing to both sides. It took considerable trouble to enforce those orders, but it was finally stopped, but Rebs and Yanks would converse and trade while on picket duty, but when the Yanks got ready they crossed the river and made the Johnnies fly.

Dear readers, you must not expect to be given a history of the war, but I am compelled to give you a little so you can form some idea of how we proceeded with the railroad.

Well after the army moved across the river we proceeded with the road on to Chattanooga The bushwhackers kept falling in the rear of our army and keeping the train men lively. I think about five or six engineers and firemen were picked off in one week. About this time all engines on the road had from one to fifty bullet holes in her cab and jackets.

All around Chattanooga is high and mountainous. After the Rebs got there they had a little the advantage of us in the way of those mountains but we were too many for them and we soon got the mountains from them.

About this time there was a hospital train put on. Engineers and firemen were rolling iron to Nashville by the wholesale, but you bet after they heard of what train crews had to go through with we would only average about one out of every three that would venture out. I have seen lots of men sneaking over the L. & N. R. R., especially at Nashville, making their way back to the North, and I must confess I often wished I was one of them, but I made up my mind I would stay until the war ended or until death finished me.

As I was saying, the hospital train was put on and double crewed. I was assigned to it with old Charley Benteworth for a partner. It will be necessary to give you a slight description of this train so you may understand it. It consisted of three passenger coaches and a baggage car, but this baggage car was used by the doctor in charge as a kitchen and dining room car for the doctor and crew. Of course the doctor had several nurses and he also had part of the car for a drug store. The train crews stood a watch eight hours on and eight hours off.

I suppose a good many of my readers have heard how the Mississippi steamboat crews lived before the war. Well, I assure you they were not a comparison to the way we lived.

Our living consisted of sundry goods sent down for sick and wounded soldiers, and that consisted of the best that the North, East and West could provide.

Well, now boys, this hospital train was what we call a safety train. We carried the yellow flag. No soldier—neither Rebel nor Yank dared to fire into it, but bushwhackers did not respect any flag. We carried a good many sick and wounded Rebs in those cars. I remember one night I was out of Chattanooga, I was on watch. The same day our army had a little skirmish a few miles from Chattanooga and we were loaded down with wounded men. The night was very dark. About five miles from Chattanooga I was flagged down by a small squad of men. When first flagged I could not tell whether Yanks, or Rebs, or bushwhackers, but I soon found out. It was the bushwhackers, and the first thing I knew there were a lot of them up on my engine; they told me if I offered to move they would kill me. Well, I was pretty nervous, but I managed to keep right still. By-and-bye some of them came up to the engine and asked me what kind of a darned train I called that. I told them it was a hospital train, for all soldiers—Rebel or Yank. One of them asked about the yellow flag and wanted to know if the Yanks had hired some other nation to help them. I explained the flag to their satisfaction and they concluded they could not make much by taking such a train, so they told me to pull out. Well, you bet that throttle flew out, and away I went. Of course they had a talk with the conductor and brakemen, but as I am only writing my part, you will have to put up with it. When I got to the telegraph station I reported it to the operator, but the wires were down. He reported it to the post commander and men were sent out to rout them, which I learned afterward was done.

That night, after I went off watch, I went through the train to see the wounded. I heard one fellow in one of the berths making more noise than all the rest of the wounded. I thought he was some fellow slightly wounded and filled up on whisky, but when I got up to him and saw his condition, my eyes met a sight I shall never forget; he had both arms and both legs shot off. I asked if he thought he would get well, and he said, yes, certainly he would. I asked him how he would navigate without arms or legs; he said he would get around like a tumble-bug.

I never heard whether he got well or not, but hope he did. I arrived in Nashville O. K. We lay there a couple of days and then—you will here from me again.

*(To be continued.)*

## Swedish Locomotive Smoke-Boxes.

Railroad men who read engineering papers are often struck with the stability of the established rules about locomotive smokebox arrangements and exhaust nozzles in foreign countries. Here nearly every railroad has its own practice about the arrangement of draft appliances, and those most familiar with the subject are strongly impressed with the belief that there is still a great deal to be learned about the proper size and form of exhaust-pipes, smoke-stacks, and of all the parts that affect the generation of steam. In England most of the railway companies have settled down to a forked exhaust-pipe with single nozzle. D. K. Clark established a rule for exhaust-pipes, and English engineers have been contented to follow without question as to its utility.

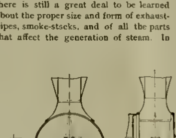


FIG. 1.

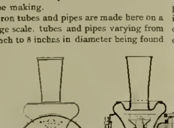

Section A B

FIG. 2.

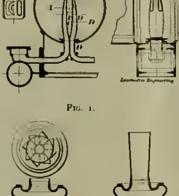

FIG. 3.

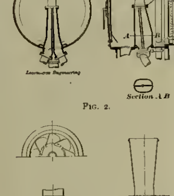

FIG. 4.

SWEDISH LOCOMOTIVE SMOKE-BOXES.

On the continent of Europe there is much more individual inquiry than there is in England, and we find in the reports of engineering societies considerable discussion respecting improved forms of draft appliances. The annexed engravings of smokebox and exhaust-pipe arrangements are taken from the *Bulletin de la Commission Internationale du Congres des Chemins de Fer* and illustrate appliances used on the State Railways of Sweden. As will be seen, they embrace annular, cylindrical and conical nozzles. The exhaust-pipes are of diverse forms, that with an enlarged body so successfully employed by Mr. McCrum on the Kansas City, Fort Scott & Memphis being represented. Some notes are given of experiments made with the forms of nozzles *C*, *A*, *B*, shown in Figure 3. The nozzle *C* was most successful. The enlargement of the smoke-box at the stack base appears to be a favorite form, but no information is given of advantages claimed.

## The Making of Boiler Tubes.

On the west side of the Schuylkill River, in Philadelphia, there are very extensive works that cover two or three large blocks with buildings. They are the works of the Allison Manufacturing Company, and are devoted to the business of car building and flue making.

In the course of a ramble through the shops I found them building a large number of hopper cars for the Pennsylvania Railroad. These cars are models of good design and have all modern improvements, including air-brakes and Janney couplers. The works are remarkably well arranged for doing the business at the least expense, the best of tools being employed in every department. Railroad men wishing to watch the operation of well-managed car works can have their desires satisfied by a visit to this establishment. To me the most attractive part was that devoted to tube making.

Iron tubes and pipes are made here on a large scale, tubes and pipes varying from 1 inch to 8 inches in diameter being found in course of manufacture. Nothing but the best of wrought-iron is employed for the making of the tubes turned out in these works. The company have made steel tubes repeatedly, by special order, for parties wishing to try tubes of this material, but they do not hold themselves responsible for anything but iron.

To a mechanic who has never seen a tube made there is something difficult to comprehend in the long uniform weld which is generally as strong as the rest of the tube. I had long experienced a curiosity as to how this skillful mechanical operation was performed, and I watched the work here with very much interest. Beginning with the first operation, I found that to be the cutting of sheet-iron into strips that were wide enough to form the circumference of the tubes to be made. These strips were then taken to a scarfing machine and the edges scarfed for welding. The scarfing machine is a special tool that takes hold of the strip of iron and pulls it rapidly through a set of jaws that cut the edges as clean as a lathe tool turns down a shaft. After being scarified the strips go to a long furnace where they are heated a cherry red heat. They are drawn out at one end and passed through a machine which bends them into tubular form. Then they are passed into another furnace and raised to a welding heat. As the hot tube emerges from the furnace an iron conical plug, drawn by a mandrel is forced through the inside, and the outside shell is firmly held by the clamps of a machine. By this means the scarified edges are squeezed together by a prolonged draw and the welding is effected. Some of the tubes go through this operation two or three times.

The next thing done is the cutting off the ends. In connection with this there is a very rigid inspection by an expert in search of defective welds. When any indication of a defective weld is found the tube is rejected, or if the defect is merely at the end that part is cut off.

When the tube passes the physical inspection it is taken to a hydrostatic testing machine and pressure applied to it. Ordinary locomotive tubes are tested under a pressure of about 400 pounds to the square inch. Pipes for ammonia, hydraulic and oil carrying purposes must sometimes be capable of enduring enormous pressure, and these are subjected to very severe tests. I saw some pipes tested with a pressure of 1,600 pounds to the square inch.

The Allison Company do a large business in the making of high-pressure pipes, and they have devised several improved forms of joints which do not reduce the strength of the pipe where the thread is cut. In one form the pipe is thickened at the ends, and in another what is called a "vanishing" thread is employed. The latter is cut so that the thread runs out from the center, gradually decreasing in depth, till at the shoulder there is no cut to cause the beginning of a fracture. This joint is reported to be as strong and as free from failure as the body of the pipe.

Any railroad man visiting Philadelphia can spend a half-day very profitably in visiting the works of the Allison Manufacturing Co.

A. S.

## Railroading in Costa Rica.

A railroad man writing from Costa Rica says: There is a main line here 117 miles long and a branch 20 miles long, all narrow gauge. The railroad is owned by English capitalists and operated by English rolling stock in the most miserable condition that could be imagined. They have twelve or thirteen English locomotives that are the most awkward and badly proportioned engines I have ever seen. About half the weight of some of them is on the forward truck, and they all have stationary grates set lengthwise of the fire-box, the same as in our old wood-burning locomotives. They go puffing up the mountain for two or three miles with a big Jamaica negro poking at the furnace every few minutes. Then they stall for want of steam and start the blower and injector. They never put water in the boiler when the engine is working. Sometimes this stop consumes half an hour. They have to stop about every fifteen or twenty miles to clean the fire, and this is done by pulling up some of the grate-bars and knocking the dirt through.

No running is done with freight trains after night. There are only three stations on the main line between Limon and San José. It is a miserable country for a white man to live in, and I advise all your readers to keep away from it.

A patent has been granted in this country to Robert Lindner, of Chemnitz, for an improvement in starting gear for compound locomotives. The Lindner starting gear is already in use on several compound locomotives built in the U. S., and recent improvements will make it still more popular.

LOCOMOTIVE ENGINEERING.

## Keep to Standard Screw Threads.

A highly important resolution was adopted by the Railway Master Mechanics' Association at the Saratoga convention which cannot be too strongly impressed upon the minds of all railroad men who are in any way influential in the ordering of railroad machinery. The resolution reads—"This association commends and emphasizes the United States standards, and urges upon all a rigid adherence to the same, and deprecates the use of over or under-sized bolts and nuts, and urges all railroad officers to discontinue the use of screws which are not of standard size."

We know of no subject concerning expense of maintaining rolling stock that is of more vital importance to railroad interests than this one. It is the key to that system of interchangeability which has done so much to reduce the expense of repairs and to facilitate the work of repairing foreign cars. Before the United States standards were adopted railroad companies were put to great inconvenience, expense and delay on account of the variety of screw threads in use. The men in charge of our railroad rolling stock twenty-five years ago were readily brought to see the importance and advantage of adopting standard threads, and they did so with remarkable unanimity, considering the prevailing tendency of railroad men to try and have something different from that of their neighbors. For years it became the practice to specify United States standard screws and nuts, and there was evidently no inclination to depart from the standard, and the only trouble experienced was with iron rolled too large for the standard sizes. The obedience to the standard may have resulted from the men ordering rolling stock not being familiar enough with the subject to venture on putting their own ideas of improvement upon the dimensions. Be this as it may, the standard sizes rapidly came into almost general use, and the railroad companies were great gainers by the improvement.

Of late years a change has been gradually creeping over the land. Many master car builders and superintendents of motive power have been specifying screw threads and nuts that are not standard. It has become a common practice to specify screw threads from $\frac{1}{32}$ to $\frac{1}{16}$-inch above the United States standard sizes, and taps and dies have to be made to suit. It is needless to say that these sizes are not standard at all, and that it is a misnomer to speak of oversize standards. If this practice is not arrested soon it is going to introduce hopeless confusion at points where cars with bastard screw threads have to be repaired away from home. The men who are encouraging the practice of leading railroad rolling stock again into the wilderness of strange-sized screw threads are performing evil service for the companies employing them. The head of the mechanical department often deceives the management by misrepresentations as to supposed advantages to be derived from "improvements" on established standards. We believe that every time this is done the railroad company is directly the loser. Railroad managers ought to examine very rigidly into every proposed change that specifies details which entail a departure from standard forms or dimensions.

It is passing strange that while all other lines of mechanical engineering are every year making decided progress toward the use of standard screw threads, bolts and nuts, railroad companies are wandering away from uniformity. There is every reason why it should be the other way, for no interests are so closely bound together for good or evil as the mechanical details of different railroads. In nearly all other lines of mechanical industry, except railroads, the taps, dies, bolts and nuts, made to standard sizes by manufacturers, are purchased in preference to being made by the users. A great many railroad companies, however, persist in making these things for themselves, and by doing so enjoy the expensive luxury of paying much more than the market price for an inferior article. It is safe to say that were the men who follow their own whims in making these things a little more directly interested in paying the bills there would be a greater tendency to work closer on business principles.

When criticisms have been sent home to the mechanical heads of railroads for ordering taps and dies that depart from standards, the excuse has repeatedly been offered that it was done to suit over-sizes of commercial iron. The Master Car Builders and the Master Mechanics' Associations both have standard limit gauges for iron, and if a purchaser accepts material of the wrong size he is demonstrating thereby that his business methods are bad. The vigilant and competent man gets the bar-iron of the proper size every time. There is no excuse for departing from standards, and every man who does it is certainly leading his company into trouble.

## Faults of Long Eccentric Rods.

In a letter published in our correspondence pages, Mr. E. A. Campbell, superintendent of motive power and machinery of the Houston & East and West Texas, raises questions about the utility of 10-wheel locomotives that have long eccentric rods spanning the forward axle. He sees no reason why the old stationary link should not be employed, and gives particulars of design by which that link could be used to make a simple form of valve motion.

In this connection we would say that the 10-wheel engine appears to be a necessity to cope with the growth of passenger traffic, but we have long favored a design of the valve motion that would dispense with the long eccentric rods. Seven or eight years ago while taking indicator diagrams from a 10-wheel engine with long eccentric rods we met with a curious distortion of the diagrams that we did not understand at the time. Later we found out that it was caused by the springing of the valve-rods when the valves got a little dry. The distribution of steam was made so bad as to afford a good reason for a change of design. The dreadful shaking and vibration set up in the long rods when an engine is running fast is proof that the design is mechanically defective.

Objections have been raised to a link motion made with short eccentric-rods on the grounds that the lead is very rapidly increased when the links are hooked up and that the motion wears badly. We believe that these objections rest on defects due to bad designing and that a skillful draughtsman can produce a motion with short eccentric-rods that distributes the steam satisfactorily and wears very well. Some 10-wheel locomotives built by the Brooks Locomotive Works for the Lake Shore & Michigan Southern have very short eccentric-blades and yet the engines are said to be successful in every respect.

With a view of eliminating the objectionable features of long eccentric-rods the Pennsylvania Railroad Company have adopted in a 10-wheel locomotive, built lately at Fort Wayne, stationary links, and the engine is reported to be working very well indeed. It appears to us that the use of the stationary link would overcome many of the difficulties experienced in scheming a good valve motion for a 10-wheel engine. The stationary link with short rods would certainly be a better arrangement than the shifting link and rods spanning the forward axle. As there is no increase of lead when a stationary link is pulled up, there is no objection to the use of short eccentric-rods. The steam distribution can be adjusted without difficulty and a good wearing motion can readily be designed.

## Rolling Stock of the Chicago Elevated Railroad.

We understand that an application was made by the officers of the Chicago South Side Rapid Transit Railroad to Col. Hain, general manager of the Manhattan Elevated Railroad of New York for the loan of one of the locomotives recently built by the Pittsburgh Locomotive Works for the latter company. The intention was to make a comparative test of a good simple Forney engine with the compound locomotives in use on the Chicago road. Col. Hain was anxious to oblige the Chicago people, but there is so much business to do on his own roads that he could not see his way to spare one of the engines.

There are good reasons for believing that the experiment of equipping the Chicago elevated railroad with nothing but compound locomotives is going to prove very expensive. It is the kind of an experiment that no sensible engineer would have recommended. A progressive man of good judgment might have recommended a small proportion of the locomotives to be compound so that their merits and shortcomings could be tested by comparison with simple engines. That is as far as a man had a right to go with a type of engine that had not been a recognized success on the peculiar service of handling elevated railroad trains. In starting out an entirely new enterprise like an elevated railroad there is always certain to be more or less difficulty with everything strange to the men doing the work. Ordinary business sagacity would in a case of this character dictate the use of appliances as well known as possible.

The compound locomotives on the Chicago elevated road have been extremely unpopular with the men, and to a great extent they have been opposed by everybody except those immediately interested in ordering them. The engines have caused considerable trouble, much of it no doubt arising from prejudice and from the fact that the enginemen did not understand the machines they were working.

The performance of the engines that were most skillfully handled leads us to fear that the service of elevated railroads where stoppages have to be made at brief intervals is not adapted to compound locomotives. Cylinder condensation wastes more steam than the saving effected by increased expansion can balance. The cylinder area exposed to chilling influences is so large that serious annoyance has arisen from the volume of condensed water that has to be carried to the terminal points. The engine starts out with the cylinders cold. The runs are so short that the cylinder metal is scarcely heated when it is time to shut off steam. The cylinders keep cooling again and are ready to act as condensers when steam is applied for the brief period it is continuously in use. If the engines had long runs between stations they would probably give economical service under the peculiar conditions of very frequent stoppages they appear to use more coal than simple engines would consume in doing the same work.

We could find no feature in which these engines are superior to simple engines for suburban railroad purposes. The exhaust makes quite as much noise as that of the New York elevated engines, and the engines do not start more quickly or with less jerking.

There has been considerable difficulty with the driver-brakes on the engines. It was said that they were not applied properly, and the leverage was so great that wheel-sliding resulted. The Westinghouse automatic air-brake is not an unmixed success on these elevated trains. It releases very well, but causes more surging in stopping than the vacuum-brake. The vacuum-brake is so successful for this kind of service, handles the trains so smoothly, releases so promptly and costs so little for repairs, that the question of merit could not have been considered when another brake was specified for the rolling stock of the Chicago elevated road.

## Wanting Longer Hours.

For years there has been steady agitation in labor circles for reduction in working hours. The general tendency has been to demand a reduction of the time to eight hours a day. In view of this it is strange to tell that the machinists of the Union Pacific system have asked an increase of the working hours from fifty hours to fifty-four hours a week. The men making this request intimated that they were willing to submit to a reduction in the force sufficient to equalize the increase of working hours. It may safely be asserted that the men agitating the change expected that the other fellows were the men who must go if the request were granted.

A movement of this kind on the Union Pacific is the more surprising since the Knights of Labor are very strong on that road and their policy has been in the opposite direction. The request was not granted. The reply given by the management of the Union Pacific was that under an agreement with the Knights of Labor reductions could be made only in hours and not in the number of men employed. This seems to us a very just arrangement. It was said that to increase the hours as requested it would be necessary to discharge between 500 and 600 men on the Union Pacific system. A move of that kind would be granted only by unanimous consent of the men. As the depression of business that keeps the working hours on the Union Pacific so short is not likely to last long, it would be a great hardship all round to send so many men adrift.

## To Prohibit the Employment of Plug Operators.

There is a very sensible movement among railroad trainmen in Pennsylvania, led by the Brotherhood of Locomotive Engineers, that calls for the enactment of a State law prohibiting inexperienced telegraph operators from having charge of the movement of trains. The collision at Harrisburg in the end of June, when twelve persons were killed, is the immediate cause of the agitation, for an inexperienced telegraph operator in charge of the signal tower was really the cause of the accident, although the blame was pushed on to other shoulders. A bill has been drawn up which provides that all operators employed on railroads in the State of Pennsylvania shall have at least one year's experience and shall not be under 20 years of age. Where block signals are employed the operators are required to become familiar with the system before being put in charge. The railroad companies will do all in their power to prevent this bill from becoming a law, and it will require extraordinary efforts on the part of trainmen to get it pushed through. The Legislature of Pennsylvania is dominated by railroad companies, and few of the leaders are liberal enough to perceive that a law to promote the safety of travelers is for the best interests of railroad companies even when it makes the employment of efficient help compulsory.

## To Make Station Agents Meek.

We are informed that the Railway Agents' Association of America has inaugurated a new plan of operations. Letters have been sent to officials everywhere, asking approval of this plan. They are signed by the Secretary, R. W. Wright, of Cleveland. The new scheme is to take the control and direction of agents out of the hands of the operating superintendents, and place them under the direction of the traffic managers. Mr. Wright says: "We feel that it is the duty of every official to encourage a movement which will keep the station service from the dominance of radical labor agitators." This, he thinks, can be done by placing the freight and ticket agents under control of the traffic department. He believes that neither the appointment nor the removal of an agent should be made without consulting with these officials, and that the jurisdiction of the operating department should be confined entirely to the duties which fall to an agent's lot in this direction. In other words, this is a movement on the part of the agents to be taken from under the authority of general and division superintendents.

We suppose that the Railway Agents' Association think that an underpaid station agent will be happy under control of the traffic officers, no matter how little he may be paid for responsible services. We think the scheme will fail. The proper way to make station agents contented is to treat them as they deserve, and this is seldom done.

## Crucible Steel for Boiler Plates.

Since the discussion at the Master Mechanics' Convention on boiler steel and the impression given out that some crucible steel sheets had given extraordinary mileage in fireboxes, there has been a tendency to regard crucible steel as being particularly valuable for boiler purposes. We believe that this impression is at best a fallacy and that there is no kind of steel so well adapted for fireboxes as the open hearth steel that is commonly in use. It seems certain that the tendency to break down prices has brought into the market steel of inferior quality, which is not well adapted for use in fireboxes. Many railroad officers are now saying that they are prepared to pay any reasonable price for good boiler steel and their eyes are turned toward crucible steel as the material that is going to realize all their expectations. We would caution our friends not to be precipitant in patronizing this material for fireboxes. Those who are considering the merits of crucible steel will do well to study a report that was submitted to the Master Mechanics' Convention in 1888. In that report the following points were made about crucible steel

"The crucible process of making steel is the oldest, commercially speaking, and for some purposes the best—that is, when steel is wanted in small quantities of considerable purity. It is a failure when large masses of homogeneous character are required, as is the case in boiler plate. Its shortcomings in this respect are due to the process of manufacture, which, as is well known, consists in melting wrought-iron, etc., in a crucible holding generally from 80 to 125 pounds. To obtain a mass large enough to make boiler plate, it is necessary to pour the contents of from 20 to 50 crucibles into one mold to form an ingot. As the 'steel' is made in each crucible, it follows that in 30 crucibles we have 30 different kinds and grades of steel in the one sheet. The result, when subjected to the trying conditions found in a locomotive firebox is, of course, disastrous in the majority of cases, as homogeneity or absolute uniformity of the metal in this service is one of the most important elements found in long-lived fireboxes."

## Railroad Business Last Year.

From "Poor's Manual," received this month, we find that in 1891 there were 167,845 main track miles of railroad in the United States, an increase of 4,487 miles over that reported for the previous year. The number of locomotives in use was 33,563, an increase of 1,751 in one year. The number of passenger cars was 23,083, baggage, mail, etc., 7,368. Of freight cars there was reported to be 1,140,737 owned by railroad companies.

The figures presented in the various statistical tables of the Manual show that the business of railroads during 1891 was exceptionally good, and they also indicate that there has been great improvement made on the physical condition of railroad properties. The passenger mileage, which represents individuals carried one mile, reaches the enormous figures of 13,316,925,239, and this does not include the Elevated Railroads of New York. It may give a better idea of what great travelers Americans are, to say that over thirteen millions of our people traveled above 240 miles by rail last year on surface railroads. The average fare paid was 2.184 cents per mile. The passenger mileage increased 6.4 per cent. over that of the previous year.

The tons of freight carried during the year was 81,210,154,523, being an increase of 2.6 per cent. over the business done in 1890. Considering the number of cars in use to do the amount of hauling performed, there was a rather small average mileage got for each car. If we reckon each car capable of hauling 15 tons of freight, the average mileage per car would be 4,800 during the year, or 16 miles per day. The average freight-train load was 164½ tons. The average charge made per mile for each ton of freight hauled was 0.929 cent.

The total earnings for passenger, freight and other business was $1,125,534,815, and the net earnings was $350,807,370, so that close on 68.8 per cent was spent in operating expenses. This is a high ratio of operating expenses considering the efforts that have been going on to reduce the expenses of moving trains. The train loads have steadily gone on increasing and the expense of power every year gets less according to the amount of work done. It is then an interesting question to investigate why the operating expenses keep so high in proportion to the gross receipts? The answer is found very readily. The general freight agents, in their scramble for business, take freight at rates which leave no margin for profit. When a ton of freight is hauled at less than 1 cent per mile, the business will be done at a loss on many lines. If the average charges for freight had been raised from .929 of 1 cent to 1 cent, this small advance would have reduced the ratio of operating expenses about 2 per cent. The owners of railway property do not make big returns on their investments, for the average interest paid on bonds was $4.25 and on stock $1.85 per cent. We do not see that there is much inducement for people who have saved money to put it into railroad securities.

In another column, our correspondent, Mr. Wood, directs attention to a very detailed and interesting style to certain various forms of brake-levers that cause great inconvenience and annoyance in the handling of trains, and cause serious damage to wheels. The subject deserves to be thoroughly ventilated. No railroad company can afford to retain in use inferior brake-gear, and we trust that the criticisms made by this and other correspondents will have the effect of consigning all bad forms of brake-gear to the scrap heap. It is very short-sighted policy for a master mechanic or master car builder to keep in use brake-gear that has been demonstrated to be defective. If enginemen who are annoyed with the brakes on their tenders not working properly will read the letter from Mr. W. W. Wood, in this paper, and that from Mr. Synnestvedt, in our August number, they will probably get information that will enable them to understand what is wrong. If the facts are then laid before the proper authorities we feel certain that in nearly every case the proper remedy will be applied.

The question raised by a correspondent about one wheel being slid flat has excited much attention, for, besides the letters which have appeared, there are five or six that we cannot find room for. The points made in most of the letters that do not appear, refer to flattening of a single wheel being caused by sand running out at only one pipe. While thanking correspondents for the attention they have given to this subject, we would prefer to let it drop now unless something novel comes up, like the explanation given by one writer in this issue, where through the defects of truck and brake gear, one wheel was raised entirely off the rail when the brake was applied.

## NEW BOOKS.

STREET RAILWAYS, their construction, operation and maintenance, a practical hand-book for street railway men. By C. B. Fairchild, New York, Street Railway Publishing Co.

This book deserves to become a manual on street railways, for it is the best and most comprehensive work that we have seen on a subject about which there is not much reliable literature. While the book contains a great deal of technical detail, it has been so skillfully written that an ordinary reader interested in the wonderful development of the street railway system of transportation follows on, chapter after chapter, with keen interest. The author says that he has "endeavored to treat each topic in a simple manner, having in mind the needs of men who may engage in the service, and who must necessarily learn the business by first studying the alphabet." We confess that the alphabet of street railway operation is made very simple, and will, no doubt, meet with the deserved appreciation. The first part of the book is devoted to chapters on electric traction; cable traction; horse traction; steam, air and gas motors; inclined planes, elevated roads, car building; and track construction. The remainder of the book is taken up with executive matters. Each part of the book has features peculiarly valuable, but we think that on electric traction will be found of most use by the many men who are trying to learn something about this part of street railways. This chapter gives an elementary treatise on the development of the dynamo, and then works along to the application of this power transmitter to the operating of street cars, giving numerous illustrations of dynamo construction and of all the minor parts connected therewith. We think it would be a good plan to make a hand-book of this chapter for the benefit of men engaged on operating electric cars.

STANDARDS OF LENGTH and their practical application. By George M. Bond. Pratt & Whitney Co., Hartford, Conn.

This is not a new book, but it has lately reached our desk by the courtesy of the author. It contains a resumé, covering the methods employed for the production of standard gauges to insure uniformity and interchangeability in every department of manufacture. There are also the reports of Professor Rogers, that of the committee on standards and gauges of the American Society of Mechanical Engineers, that of the Master Car Builders' Association, also the report of the special committee appointed by the Franklin Institute. Besides these very valuable reports there are lectures on measurements, by George M. Bond, who is the most accomplished expert living on this subject. The book appears to contain nearly everything of value that has been done or said concerning accurate measurements. It would be good for railroad companies if all the men in charge of the designing or repairing of machinery were familiar with the leading facts concerning measurements and interchangeability that are to be found in this book.

EXPERIMENTAL ENGINEERING for engineers and for students in engineering laboratories. By Rolla C. Carpenter, Associate Professor of Experimental Engineering, Cornell University. John Wiley & Sons, New York. Cloth $6.00.

This is a somewhat ambitious book of over 700 pages, devoted in a great measure to the describing of methods followed in making all sorts of tests required in engineering. The work has been done with considerable care, but yet it has the stamp of a compilation of papers contributed to technical societies. For persons engaged in testing departments the book is likely to become a manual, for it contains information relating to all branches of experimental work in convenient form. Being the work of a college professor the book is naturally bristling with mathematical formulæ. The subjects treated are as varied as the ramifications of engineering science. There are several chapters devoted to the testing of material, which will be read with interest and profit by railroad men, and the parts relating to testing of lubricants, heating value of coals, the steam-engine indicator, and the injector present good material for study. The book as a whole is not made for reading. It is profusely illustrated.

SYSTEMS OF CAR LIGHTING. By A. M. Wellington, W. B. D. Penniman and Charles Whiting Baker. Profusely illustroted. *Engineering News*, New York.

This book consists of a reprint of a series of articles that appeared in the *Engineering News*, and deals very extensively with all the systems of car lighting employed in this country and in Europe. It deals with oil lamps, gasoline carburetters, compressed gas and electric lighting, showing the merits and disadvantages of the various systems. Every person who has any influence in deciding what system of lighting shall be used on railroad cars, ought to study this treatise. It is certain to throw a clear light on a subject that is indifferently understood by many who ought to be familiar with all the systems that are offered for adoption. All the articles are clear, sensible and practical, and good illustrations are used to make the text easily understood.

DYNAMOMETERS AND THE MEASUREMENT OF POWER. A treatise on the construction and application of dynamometers, by John Flather, Professor of Mechanical Engineering, Purdue University. John Wiley & Sons, New York.

This book, from beginning to end, is devoted to describing the construction, performance and purpose of power measuring apparatus. It is intended for the use of students, and like most books written by college professors, it is not of consuming interest to a reader. Students are not likely to be allured away from their pillows to finish reading the book, but nevertheless, they will learn a good deal by carefully studying its pages.

The Master Car and Locomotive Painters' Association will hold their annual convention at Detroit, Mich., beginning on September 10. The programme of work to be done indicates that a valuable convention will be held. Much of the work of this association falls upon the secretory, Mr. Robert McKeon of Kent, O. The work is a labor of love and is done with remarkable zeal and efficiency.

## Master Mechanics' Report.

The report of the proceedings of the twenty-fifth annual convention of the American Railway Master Mechanics' Association has been received. It is a volume of over 250 pages and contains a large number of illustrations, the reports on compound locomotives and on boilers for high pressure being profusely illustrated. An exceptionally good opportunity for judging of the merits of the various annual reports of this association leads us to the conclusion that the report for 1892 is far ahead of any previous ones in the engineering value of papers and discussions presented. The report on compound locomotives and the long discussion thereon form a highly important addition to the literature on this important subject. The reports are all so good that it seems invidious to select any for special commendation. The discussion on tests of steel and iron is scarcely second in interest or value to that on compound locomotives. The report is got out in a very attractive style, on excellent paper, is well printed and has a good index. It is for sale by the secretary at this office. Price $1.50.

We have received an illustrated catalogue of Norton's improved ball-bearing railway and bridge jacks. It shows this valuable jack in all the variety of forms for which it is constructed. We understand that the business has been very much extended of late and that numerous railways are using the jack with marked success. The West End Street Railway of Boston has made this jack their standard and have a large number in use, the order being to carry one on each car. This is one of the largest street railway corporations in the country, and they are very careful in making thorough tests of all the appliances they adopt.

"Well Worth Reading," is the title of a pamphlet issued by B. F. Mahler, of the Lodge & Davis Machine Company, Cincinnati, Ohio. The good words consist of the report made by LOCOMOTIVE ENGINEERING, of the paper read by Mr. B. E. Davis, M. M., of the Boston and Maine, at the New England Railway Club, on tools and machinery for railroad work. They are certainly words that will stand reading a good many times to advantage.

The Field Water Purifier Company have recently added to the list of railroads on which they have their device the Grand Trunk and Chicago and Alton, and have also fitted up one of the large new iron steamers lately launched by the Detroit Dry Dock Company. The business is rapidly increasing on the roads where their device is at work.

Persons interested in engineering books should apply to Spon & Chamberlain, New York, for their monthly catalogue, which embraces every month books that engineers ought to keep the run of. One of the latest books issued by the firm is "Electricity, its Theory, Sources and Application," by John T. Sprague.

We have received a copy of a letter written by Mr. McConnell, superintendent of motive power of the Union Pacific system, regarding Falls Hollow staybolt, which he has been using with much success for locomotive boilers. This form of staybolt seems to be making rapid progress into favor with railroad men.

We have received from the Forrest Silver Bronze Packing Co., a voluminous list of copies of testimonial letters concerning this excellent packing for stuffing-boxes. We have personally examined some of the high speed locomotives which are using this kind of packing and obtained the very best impression of its utility.

## PERSONAL.

Mr. James Cunningham has been appointed master mechanic of the Buffalo division of the Philadelphia & Reading.

Colonel F. J. Hecker, president of the Peninsular Car Works of Detroit, is also president of the Police Commission of Detroit and a member of the Board of Health. He wields great influence in municipal affairs.

We have received several pleasant calls from Professor Alexander D. Romanoff, of the Institute of Engineers, St. Petersburg. Professor Romanoff is on a visit to this country as a government officer for the purpose of inspecting all our systems of inter-communication.

Some of our California exchanges have discovered on the Pacific Coast a lady blacksmith, and, of course, they want her to show off at the World's Fair. Her name is Miss Ray Beveridge, and she is reported to have more than a smattering of the blacksmith trade. We doubt it.

Mr. J. O. Pattee, who has for some years been at the head of the mechanical department of the Great Northern Railway, with the title of master mechanic, has been given the title of superintendent of motive power, his jurisdiction extending over the entire Great Northern system.

Mr. Henry C. Gould has been elected vice-president and general manager of the Gould Coupler Co., and Mr. F. P. Huntley, for many years employed in a confidential capacity by Mr. Chas. A. Gould, in his various manufacturing enterprises, has been elected secretary of the Gould Coupler Co.

Mr. S. W. Huston has been appointed superintendent and master mechanic of the South Side Rapid Transit Railway, Chicago. He was previously master mechanic of the Cornwall Railroad, and went there from the Pennsylvania shops at Altoona, where he went through the improver training.

A Chicago paper publishes a portrait of John F. Enright, a fireman on the Chicago & Eastern Illinois, and a picture showing him rescuing a child from the front of the pilot of his engine. Mr. Enright displayed extraordinary nerve and coolness and deserves all the credit newspaper attention can bestow.

We notice by a paragraph in the New York *Tribune* that $37.50 has been received for the Fresh Air Fund from Mr. F. W. Coolbaugh on behalf of the Railway Master Mechanics' Association. This money was collected at the Saratoga Convention and represents half the fund; the other half going to Chicago.

Mr. M. M. Reid, general foreman of the Norfolk Southern road at Berkeley, Va., is a near relative of Joseph Hume the celebrated British statesman. Mr. Reid is a man of strong personality and is a worthy member of an illustrious race. He is a cousin several times removed of Mr. Balfour, late Secretary for Ireland.

We understand that Professor A. T. Woods, of Washington University, St. Louis, has accepted an editorial position with the *Railroad Gazette*, with headquarters in Chicago. Professor Woods is author of a book on compound locomotives, and is particularly well informed on matters connected with railroad rolling stock.

W. H. Doane, the well-known president of J. A. Fay & Co., wood-working machinery manufacturers at Cincinnati, Ohio, recently presented $25,000 to the Denison University to be used in building an academy hall for that institution. Mr. Doane is a public-spirited and progressive business man as well as a philanthropist, and he is constantly performing benefactions that will make his name live long after he shall have passed away.—*The Timberman.*

Mr. E. T. Silvius, master mechanic of the Jacksonville, St. Augustine & Halifax River Railway, was a printer in his youth. He still takes a lively interest in matters connected with the printer's art. When he and John A. Hill, who was also a printer, get together they make their hearers believe that there must be great art and mystery connected with the slinging of letter type.

Dr. Webb, president of the Adirondacks and St. Lawrence Railroad, has a small inspection locomotive that he rides over the road on. He is ambitious to know how to handle a locomotive and runs the engine a great part of the time. The Doctor has taken instructions in the art of locomotive engine running from William Buchanan, James Macbeth and Nat Sawyer and it is reported that he is likely to excel all his sponsors, especially on speed.

Stephen Pratt, one of the oldest locomotive engineers on the Chicago, Milwaukee & St. Paul, is said to have died of the heat last month. How more enginemen do not die from heat exhaustion during heated terms, like what the country has experienced lately, is something wonderful. Scores of people were prostrated daily of the heat in every large city, yet enginemen who have the heat of the boiler added to that of the sun, are very seldom reported to be injuriously affected.

A report is in circulation that the N. Y. & N. E. will employ girls as waiters on its dining cars instead of colored men. It will be a novel experiment, but if it enables the traveler to get meals without hiring the waiters to bring them to him, it will be a popular departure. We are inclined to doubt the accuracy of the report, however, since Nicholls has ceased to be superintendent. If he was still there it would be a likely experiment.

It has been suggested to us that a very readable and amusing article might be written on deep-sea fishing, and Mr. R. C. Blackall, vice-president of the Master Mechanics' Association, has been mentioned as one who could describe the sensations with the accuracy of one who has been there. A party of railroad men went out fishing on the New England coast last month, and several of them obtained experience that was more novel than agreeable.

A great many master mechanics are running over with theories about the necessity for improving and training enginemen, and they theorise so much about it that they have no time to reduce any of the principles to practice. Mr. John Bean, master mechanic of the Cleveland & Canton road, does not theorize a great deal, but he is a host in practice for good works. He has lately got up a large club of readers of LOCOMOTIVE ENGINEERING among his men and has raised enough money to buy the valve-motion model for the instruction of engineers and firemen.

Mr. Joseph Whitlock, who used to be master mechanic of the Housatonic Railroad, was taken ill last fall with some sort of lung trouble. He went to Florida and hired a house boat, and went to live on one of the rivers, spending all his time fishing, hunting and sleeping. He returned North in the spring entirely recovered. When Mr. Whitlock took mechanical charge of the road which he served for so many years it was in a semi-insolvent condition. Power was badly needed at one time, and locomotive builders would not trust the company with engines. They were, however, ready to take Mr. Whitlock's indorsement, and he became security for the engines that were required. The management treated him shabbily afterward.

When the combination was effected by which the Philadelphia & Reading Company secured control of the Central of New Jersey and the Lehigh Valley roads, it was rumored that President Roberts, of the Pennsylvania road, had opposed the deal so vigorously as to give offense to Drexel, Morgan & Co., and that these capitalists were likely to use their influence to effect Mr. Roberts' removal. These rumors are again revived. It is reported that Mr. Roberts is willing to retire if he is permitted to name a successor satisfactory to himself. The gossip has been stimulated afresh by the sudden departure recently of A. J. Cassatt for Europe. He had arranged to take his family to Long Branch and Saratoga for the season, but it is said that he came home and directed preparations for a departure for Europe in three days. This has given rise to the report that the foreign stockholders of the Pennsylvania had selected Mr. Cassatt as the successor to Mr. Roberts. The natural choice of Mr. Roberts for his successor would be Frank Thomson, first vice-president. It is said that Drexel, Morgan & Co. are working to effect a combination between the Pennsylvania and the Philadelphia & Reading systems, and that the removal of President Roberts is necessary to the working out of the contemplated changes.

## George M. Pullman.

We often hear it said that American business men keep the fires of their energy burning so fiercely that they become physical wrecks while still young. There may be a fraction of truth in this, but it is certain that some of the men who have done the most stupendous work connected with the building up of our railroad system, display little diminished vigor after long years of ceaseless devotion to business. We were forcibly struck with this lately on meeting Mr. George M. Pullman in Chicago. The detail work of building up the vast sleeping-car business has fallen in a great measure on the President of the Pullman Palace Car Company, yet, with sixty odd years, he looks as fresh and healthy as an English squire with nothing to do but amuse himself. Mr. Pullman raised himself from the position of a workman, as many others of our most successful business men have done. What he has accomplished is within the possibilities for every American boy gifted in the same way.

Mr. George M. Pullman was born in Chautauqua County, New York, in 1831. When a boy he learned the cabinet-making trade, and remembers with pride that he was a first-class workman. When he was twenty-two years old, a change in the Erie Canal called for the moving of a great many houses and Mr. Pullman saw there was money in the business and undertook the work. When this was finished, in 1859, he removed to Chicago to follow the business of house-moving. Before this time his attention had been directed to the discomforts of night travel, and he revolved in his mind a variety of plans for providing sleeping accommodation to passengers. Shortly after going to Chicago he arranged with the Chicago & Alton Railroad Company to convert two of their day coaches into sleeping cars. This work was successfully carried out and Mr. Pullman personally attended to the operating of the cars, doing much to make them popular with the traveling public. They slowly worked their way into favor. In 1863 he began building the first new sleeping car, the "Pioneer," that comprised all his ideas of what a car of this character ought to be. It cost $18,000, an enormous sum for those days, but it proved a success and really was the pioneer of the comfortable sleeping-car service that has taken away the dread and discomforts of night travel, turning transportation into pleasure and luxury.

The Pullman Palace Car Company was organized in 1867, and has been one of the most successful companies in the country. The company now operates about 2,000 sleeping, palace and dining cars and builds a large proportion of passenger and freight cars used by railroads. The village and shops of Pullman were built in 1867. The town has about 12,000 inhabitants, of whom over 5,000 work in the car shops.

In talking about the success achieved, Mr. Pullman said his motto had been "have the best of everything." His early aim was to have a sleeping car that in every respect would be far ahead of anything else. In that he succeeded and its reward came. As the business increased he followed the same policy and aimed to keep in front with the best cars and the best service. This is the policy that still actuates the company.

## F. D. Adams.

When we were preparing the group of portraits of the elder members of the Master Car Builders' and Master Mechanics' Associations for our June number, one of the first persons to be thought of was Mr. F. D. Adams, master car builder of the Boston & Albany Railroad. By some misunderstanding our request for a photograph was not received. We regretted this sincerely, for a group representing the master car builders without Mr. Adams

being in it was conspicuously incomplete, and numerous friends promptly informed us about the prominence of the omission.

We are now pleased to present the portrait of Mr. Adams to our readers. To those who are familiar with the work done by the Master Car Builders' Association, Mr. Adams requires no introduction. He has been one of the most zealous workers in the improvements effected on railroad rolling-stock by the Master Car Builders' Association, and he was for long years a member of the Executive Committee. The Interstate Commerce Commissioners credit Mr. Adams with much of the work performed in the adoption of a standard car-coupler by the Master Car Builders' Association. Throughout his whole connection with the association he has been a firm and consistent advocate of the adoption of appliances calculated to reduce the dangers to the men handling cars.

Mr. Adams is a native of Connecticut and was born in 1822. In spite of his seventy years he is hale and hearty and unlike most old men he is still in the van of those pushing forward improvements in car construction. At nine years of age on the death of his father, he was bound out until he reach the age of twenty-one to a citizen of the town who was both a farmer and carpenter. Seven or eight years of this servitude were devoted to learning the builders' trade, his renumeration being $20 per year. Several years before this apprenticeship expired, he was put in charge of the business. When he was twenty-five years of age, he went to work as carpenter in the Norwich Car Company's Works. This was one of the first car works in New England. After spending some three years working at the bench here and having worked himself up to the very high pay of $2 a day, he and a fellow workman determined to strike out into the unknown. They started to look for work and landed after a weary pilgrimage by boat and foot in Philadelphia. Mr. Adams failed to obtain work in that city and walked back to Norwich and after a time returned to work in the car shops there.

Shortly afterward, Mr. Pierce, who was the owner of the Norwich Works, determined to launch out in a branch establishment which he located at Ramapo, New York. Mr. Adams was detailed to design and build these works, including a dozen dwellings for the workmen. This was the beginning of the present Ramapo Foundry Company's Works. Passengers on the Erie Railroad passing through the mountains of Rockland County, near Ramapo, can obtain a glimpse in the woods of a large frame building that may readily be mistaken for an overgrown barn. This was once the Ramapo Car Works, and was built under Mr. Adams' supervision.

The enterprise did not prove successful and when failure came, Mr. Adams moved to Buffalo and engaged himself as subcontractor with the Buffalo Car Company. This company failed in 1857 and Mr. Adams lost about $3,000 which the company held belonging to him. He then struck out for the Western wilds and settled at a place called Wayne, near Detroit. Here in company with a friend he chartered a small steam saw mill, and half starved trying to make a living with this for a year. He then loaded his earthly possessions on a single ox-cart and drove it some twelve miles through almost a trackless wilderness to a railway station, from which he returned to Buffalo. Shortly afterward, he took charge of the Buffalo and Erie Railroad Car Shops. On returning from the West the train he was on met with the memorable accident near Hamilton on the Grand Trunk Railway, where fourteen lives were lost and scores injured. Mrs. Adams was seriously injured in the wreck and for many months was a great sufferer. Mr. Adams was the last person taken from the wreck and he too was dangerously injured.

In 1870 Mr. Adams became superintendent of the Ohio Falls Car Works, where he remained two years. In 1872 he left there to become master car builder of the Boston & Albany, a position he still holds. The cars of his road are the best monument of Mr. Adams' ability. His shops at Allston, Mass., are models of convenience and neatness, and everywhere display indications of excellent management. His success in his department is attributable to his sympathy with the men's interests and welfare; firmness of purpose; progressive ideas, and promptness in recognizing merit in devices for the betterment of his equipment.

---

Mr. Arthur Pennell has just closed a contract with the Union Pacific Railroad to erect, maintain and operate a plant for treating the water at Bitter Creek, Wyoming, and guarantees that the water shall be free from scale, corrosive matter or a tendency to foam. The Bitter Creek water contains per U. S. gallon, sulphate of soda, 25.05 grains, carbonate of soda, 48.90 grains. The plant is to be capable of furnishing water at the rate of 50,000 gallons for each twenty-four hours.

---

The report has reached us that sixty-five engineers, brakemen and fireman have been discharged from the Mexican Central Railroad because they were Brotherhood men and that more will be let out.

## An Unwelcome Visitor.

We are indebted to the *Railway Age* for the striking picture that illustrates an exciting phase of railroad life in some parts of India. Our enterprising contemporary says that the picture is from a drawing by R. P. W. Strong in the

AN UNWELCOME VISITOR.

London *Graphic*, illustrating a disagreeable incident to which railway men in India are occasionally exposed. It was at a small "up-country" station that the tiger appeared one day and for a while made things very lively, until help came (in the shape of white men with rifles) from headquarters. The telegram of the native station agent summoning help was delightful in its conciseness. He wired, "Tiger jumping about platform. Please arrange."

---

Railroad managers do business with a much higher hand in the British Isles than their peers are permitted to assume in this country. We learn from an English exchange that Mr. Conacher, general manager of the North British Railway Company, has consented to receive a Linlithgow deputation in connection with the application of the Council for cheap summer fares and better train arrangements for Linlithgow. Now, if the members of a City Council in this country wanted an interview with a railroad manager in relation to giving him a few hints about how to conduct his business, they would demand a pass for the party and intimate beforehand that they intended making it particularly sultry for the railroad magnate if he did not display a spirit properly toned to grant all the concessions asked for.

---

An improved iron brake-beam has been patented by D. L. Barnes, Chicago. The novelty is in the method of securing the truss-strap to the compression member of a brake-beam, which consists in bending the ends of such strap entirely around the ends of the member and passing the brake-heads over both strap and member.

## A Great Educator.

We clip the following from a late issue of the *Catoctin* (Md.) *Clarion*, and are gratified to find that this is only one of many Southern papers that have very kind words to say of LOCOMOTIVE ENGINEERING.

"A GREAT EDUCATOR.—Few even of those given to thinking of the practical problems of the present scurrying age, have a measurably accurate idea of the numberless and complicated problems that grow out of the immense railroad interests in this country. Not least among them all is that by which the wonderful motive power of the myriads of giant motors, the steam engines, are developed, cared for and improved. If one would gain an intelligent idea of the amount of thought and careful research that is bestowed upon the locomotive engine, he should read that great publication, LOCOMOTIVE ENGINEERING, a monthly published in New York city, a copy of which now lies before us. It contains not only the latest developments in this branch of steam engineering and scientific discussions of the thousands of practical questions that arise, but interesting and instructive accounts of real happenings in the life of these reckless phaetons of the iron ecliptic. It is the very best stranger that has visited us in years and we shall be pleased to see more of it."

---

The July number of LOCOMOTIVE ENGINEERING has reached us. It is an admirably illustrated monthly, and its value to engineers must be incalculable. The contents are varied and interesting, but more particularly to those in whose interest it is published. How so large and expensively illustrated a monthly can be furnished subscribers at $2.00 a year we do not know, but it is done. Among the articles we notice two that relate to scenes of the late war. The first is "Locomotive Running Among the Bushwhackers," and the other is "Train Running for the Confederacy." Thus, both sides are represented. Besides these there are other articles in the number that will be found interesting to the general reader.—*Southern Reporter*.

## ALL KINDS OF WANTS.

*The [illegible] using this column is 25 cents for each insertion.*

WANTED—Position as salesman for railway supplies. Large acquaintance with general managers, superintendents of motive power, master mechanics, master car builders, purchasing agents, and railroad men generally. I am a hustler and can give good references. Address, F. C., LOCOMOTIVE ENGINEERING, 5 Beekman Street, New York.

WANTED—Position in stores department of a railroad. Have had long experience in charge of store department. Best of references. Apply to W. G., 912 Temple Court, New York.

WANTED—Copy of third annual report of Master Mechanics' Association. Will pay good price. Send to C. E. R., 9 N. Munn Avenue, East Orange, N. J.

WANTED—Agents on every railroad in the country to solicit subscribers for LOCOMOTIVE ENGINEERING. Send for rates to 912 Temple Court, New York.

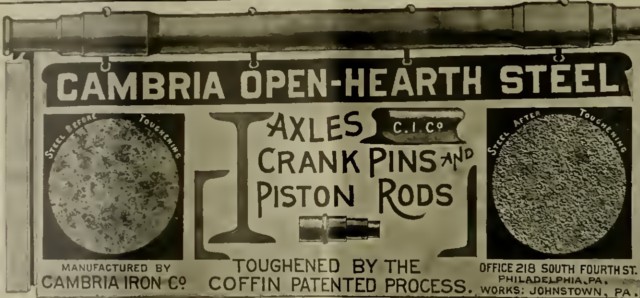
A FIRST-CLASS draughtsman and mechanical engineer wants a position. Is thoroughly familiar with car and locomotive designing. Accustomed to working out and putting in form designing ideas of superintendent of motive power. Apply to F. S. C., office of this paper.

A LOCOMOTIVE engineer who is well posted on air-brakes, combustion and locomotive mechanism wants position as traveling engineer. Good references. Address, No. 912 Temple Court, New York.

WANTED—A master car builder with long and valuable experience wants position. Apply to C. B., office of this paper.

A RELIABLE man who has been assistant superintendent of locomotive works wants a position. Is thoroughly familiar with piece-work and the prices. Would take position as inspector. Apply to B. A. Y., office of this paper.

WANTED—Persons interested in reading good mechanical literature to send for bound volumes of *The Locomotive Engineer*. Four years in one volume. Price $5.00.



Kalamein Boiler Tubes not affected by alkali water.

# National Tube Works Co.,

FRANKLIN, PA.

MANUFACTURERS OF

SIBLEY'S Perfection VALVE OIL,

The only perfect Locomotive Valve Lubricant.

J. C. SIBLEY, Prest.

## GALENA OIL WORKS,

LIMITED.

**Galena Engine, Coach and Car Oils, the Standard Lubricating Oils of America.**

SAFETY, SPEED and ECONOMY are the results of the use of Galena Oils. COLD TEST, 10 to 15 BELOW ZERO. These oils do not freeze in the coldest weather, while they are adaptable to the hottest climates.

In the use of Galena Oils there is an entire freedom from hot boxes, except when these are caused by mechanical defects.

The adoption of Galena Oils as standard railway lubricants by a large majority of the leading railways of this country is an evidence of their superiority, while the fact that the same roads use these oils to-day that used them more than 20 years ago, is an evidence of their uniformity from year to year and year in and out.

Galena Oils are in exclusive use upon three continuous lines from Boston and New York to the Pacific coast, and upon one continuous line from the City of Mexico to New York, thus demonstrating their adaptability to all temperatures and climates. Being entirely free from gum, these oils are not affected by dust and sand as other oils are.

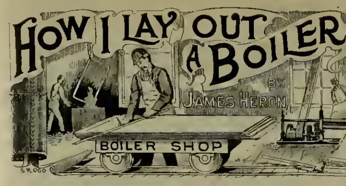
We also furnish our customers SIBLEY'S PERFECTION VALVE OIL, which is also used exclusively upon a majority of the leading railways of America.

**GALENA OIL WORKS, Limited,**

CHARLES MILLER, President,

CHICAGO BRANCH OFFICE, Phenix Building, 138 Jackson St.

Franklin, Pa.



## Laying Out Boiler Sheets.

Figs. 13 and 14 are the same as Figs. 11 and 12, last paper, but made more plain for benefit of student. Fig. 15 will show why we require a sheet the shape of Fig. 16 when flat, to form Fig. 13. Suppose we take a sheet and roll it up to radius required without cutting to shape, which has been and is still done in many places, while others make templates by using light iron and getting shape from boiler and marking plate from template so made. Fig. 15 shows this plate in place. You will see by lines you have too much stock at back end and not enough at front. My object in giving this figure is to help you to more clearly see through Figs. 13 and 14. *A, B, C, D, O*, and 1, 2, 3, 4, o, Fig. 15, shows the same view as Fig. 13, but I made sectional view of boiler, and lined the same off back and front and divided into four parts instead of eight, as Fig. 13, to simplify matters. This view also gives you the method of finding width of sheet required when ordering material.

Now, if you follow perpendicular lines of opening in boiler, where taper sheet should be, also lines of square sheet placed in opening where horizontal lines cross, it will give the amount of material to be cut off or added at each point.

I think I explained fully in last paper the object of drawing views 13 and 14, so I will now go on to Fig. 16. Our plate required to make this taper sheet or gusset sheet must be $118 \times 60\frac{1}{2} \times \frac{1}{2}$ in. Draw a line $4\frac{3}{8}$ in. from edge of sheet lengthwise. This is for your flange or lap. Find center of sheet and draw center line by squaring from line at edge. This will be back end of sheet. Plan of boiler shows double row of rivet holes in this sheet, so that the first thing one must do is to allow $4\frac{3}{8}$-in. for flange at this edge, as we require that much for lap of inner and outer sheet and space between centers of holes. As at *K*, Figs. 14 and 16, measure distance from *O* to *A*, Fig. 13, and measure off same distance along center line, Fig. 16, as at *A, O*. Draw line full length of sheet. At this point do not draw line $4\frac{3}{8}$ in. from edge full length. A short line or center mark is sufficient. I should have told you to take measurement at *O* to *A*, and strike that line the full length of sheet, and square your center line from that, as the other line would confuse you at ends of plate, and is of no use, as you can see by engraving. Mark your line *A O*, as on sketch. Make distance *O O*, Fig. 16, the same as *O O*, Fig. 14. This means the full length of line on slope, not including lap or space added for flanging.

Get distance from 1 to *O*, as at *N*, Fig. 14, mark off along center line. Make center marks at all points you have measured off. Strike or draw line full length of sheet at last center found. This will give you points *K, O, A*, 1, o on center line.

Now we want length of sheet. We find radius of small end, $28\frac{1}{2}$ inches inside or 59 inches diameter, to which we must add thickness of plate $\frac{1}{2}$-inch, making diameter $59\frac{1}{2}$ inches or $59.50 \times 3.1416 = 186.92 \div 2$. We only require length of half the circumference, which is 93.46, or $93\frac{1}{2}$ inches nearly. The length of large end can be found in a similar manner, but we have two radii to figure on and have to find the area of a circular sector, which is too lengthy to go into at present. The method I use is quicker and simpler and just as accurate. This plate when rolled and flanged is same size and shape as back sheet from center of boiler up. When I lay down view of back sheet, as at Fig. 4, March, 1892, paper, I run distance from center to center of boiler around circular part, and this gives me the size required, assuming we have lengths required. Measure off same on flat plate on lines marked *P* equal distance each side from center of sheet.

Now space off sheet back and front as at Fig. 13, *A B C D* and so on, and 1, 2, 3, 4. By setting your dividers where spaced off at Fig. 13, you will come out nearly right, but may vary a little on account of thickness of material, but you must have the same number of spaces on view laid down on flat plate. You must space off along lines marked *P*. I take a piece of letter paper and mark lines *A* to *O* and o to 1 as at *N*, Fig. 14, and carry paper to flat plate as at N, Fig. 16. Take paper to other end of plate and do the same. Mark letters *A O* and o 1 on your plate and paper so that your paper letters, or letters on paper will correspond with letters on sheet, and not get your paper wrong way about. Now draw your lines from marks you transferred from paper parallel with sheet, and where your lines cross make center marks. This will give you the regular line of curvature. Draw your line of curvature by holding flexible straight-edge at center marks. Now you must get your lengths of sheet along this line of curvature then draw end lines, which will be your center of boiler and top row of rivet holes in lap. The row of holes shown above is for welt-strip as shown in plan of boiler. Those still above that are for crow-feet, to brace irregular circle.

Note hole back and front on center line of flat plate. These holes correspond with holes on center line on top of wagon top and cylinder of boiler. This must bring every part to fit accurately. Having done my best to make this matter as clear and simple as possible I left half of view of flat plate without curvature line, so that it would be more easily understood. I will take up dome sheet next paper.

J. Heron

## Iron Better than Steel for Tubes.

There seems to be no clear reason why steel should not make as good stay-bolts and tubes for boilers as iron, but there is nothing more certain than the fact that it does not. Steel tubes are more or less used in this country but the parties using them would probably consult the interests of their employers by selecting good iron tubes instead.

Those interested in this subject will find edifying reading in the report of experiments made by an English engineer who took a practical way for satisfying himself of the relative merits of steel and iron for the material of tubes. The most conclusive experiment was made by putting two tubes in a pair of plates bolted together, the tubes and the fittings in each case being the same. The structure was heated in a furnace to a dull red heat, and dropped into water of a temperature about 100 degrees F. After cooling, it was found that the steel tube was so slack in the hole that when water was poured upon the joint it ran between the plate and the tube. The iron tube was tight.

On Irish railways women are much employed as booking clerks, and in Dublin tickets are given almost entirely by women.

## Making Solid Cast-Steel Wheels.

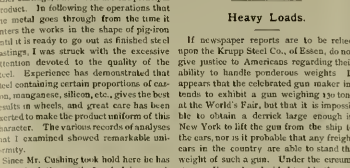
During a recent visit to Boston I called upon my old friend, Mr. G. W. Cushing, who is now manager of the American Steel Wheel Co., and in the course of the visit learned a good deal about the making of solid cast-steel wheels.

I found a regular Bessemer steel plant in operation, producing metal for a great variety of purposes. For railroad work there are draw-bars, knuckles, gearing, buffers, levers, crossheads and numerous other castings, but wheels are the principal product. In following the operations that the metal goes through from the time it enters the works in the shape of pig-iron until it is ready to go out as finished steel castings, I was struck with the excessive attention devoted to the quality of the steel. Experience has demonstrated that steel containing certain proportions of carbon, manganese, silicon, etc., gives the best results in wheels, and great care has been exerted to make the product uniform of this character. The various records of analyses that I examined showed remarkable uniformity.

Since Mr. Cushing took hold here he has reorganized the methods of doing work and effected great improvements in the pouring of castings, more particularly in the casting of wheels. The steel wheel patterns were formerly for single-plate wheels, but after studying out the matter thoroughly Mr. Cushing designed the double-plate pattern shown in the annexed engraving and that is now the standard form of wheel. The mold for this wheel is so formed that the metal runs directly into the tread of the wheel and extraordinary measures are taken to facilitate the escape of the gases from the steel. The improved methods of casting have resulted in producing wheels that are entirely free from the defects of piping and blow-holes that have done so much to retard the success of steel castings. A very exhaustive series of experiments were carried on under Mr. Cushing's supervision to find out means of producing more reliable castings, and the discoveries made are said to have led to the most satisfactory results in practice.

The wheels are cast in chills which appear to solidify the casting, although it is not chill-hardened like a cast-iron wheel. After being taken out of the sand the wheel is placed in an annealing furnace and kept there at a very high heat. This annealing operation appears to have a material effect upon the nature of the metal, for the fracture of pieces that were examined before and after annealing showed as great structural change as that of steel before and after treatment with the Coffin toughening process.

The works of the American Steel Wheel Co. are at present at South Boston, in an inconvenient location. The company are building first class works at Garwood, N. J., about fifteen miles from Jersey City. The plant to be put up there will embrace the latest improvements in furnaces and in all the apparatus necessary for doing the work of making steel castings. A. S.



AMERICAN SOLID STEEL WHEEL.

## Heavy Loads.

If newspaper reports are to be relied upon the Krupp Steel Co., of Essen, do not give justice to Americans regarding their ability to handle ponderous weights. It appears that the celebrated gun maker intends to exhibit a gun weighing 130 tons at the World's Fair, but that it is impossible to obtain a derrick large enough in New York to lift the gun from the ship to the cars, nor is it probable that any freight cars in the country are able to stand the weight of such a gun. Under the circumstances Krupp has decided to ship the gun on his own cars loading the gun on the largest freight steamer.

We regret the difficulties that beset Mr. Krupp in his endeavors to exhibit at Chicago, but are inclined to doubt the fact that a crane to do such work could not be procured. We also feel certain that the bringing over of the cars is another case of "shipping coals to Newcastle." Some machine tools lately shipped from Philadelphia were as heavy as the Krupp guns and there was no difficulty experienced in handling them.

## A Startling Brake Test.

The late Emperor Dom Pedro, of Brazil, once gave audience to a young engineer who came to show him a new appliance for stopping railway engines. The Emperor was pleased with the thing and said:

"We will put it at once to a practical test. The day after to-morrow have your engine ready; we will have it coupled to my saloon carriage, and then fire away. When going at full speed I will unexpectedly give the signal to stop, and then we will see how the apparatus works."

At the appointed time the Emperor entered his carriage and the engineer mounted his engine, and on they went for a considerable distance; indeed, the young engineer began to suspect that the Emperor had fallen asleep, when the train suddenly came to a sharp curve round the edge of a cliff, on turning which the driver saw, to his horror, an immense bowlder lying on the rails.

He had just sufficient presence of mind to turn the crank of his brake and pull up the engine within a couple of yards of the fatal block.

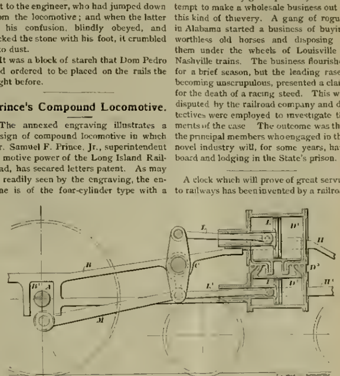
Here the Emperor put his head out of the window and asked what they were stopping for. The engineer pointed to the piece of rock, on seeing which Dom Pedro burst into a merry laugh.

"Push the thing on one side!" he called out to the engineer, who had jumped down from the locomotive; and when the latter in his confusion, blindly obeyed, and kicked the stone with his foot, it crumbled into dust.

It was a block of starch that Dom Pedro had ordered to be placed on the rails the night before.

## Prince's Compound Locomotive.

The annexed engraving illustrates a design of compound locomotive in which Mr. Samuel F. Prince, Jr., superintendent of motive power of the Long Island Railroad, has secured letters patent. As may be readily seen by the engraving, the engine is of the four-cylinder type with a rocking shaft as a means of transmitting the power from the pistons to the crankpin. Trunk pistons are employed and no crosshead is necessary. The arrangement is, to say the least of it, novel as applied to a locomotive, and it strikes us as having several commendable features.



PRINCE'S COMPOUND LOCOMOTIVE.

## Advantage of a Tests Department.

The advantage of a railroad company having a good department of tests was lately illustrated in a curious way. A new car remarkable for its cleanliness, was recently adopted by the Pennsylvania for the transportation of butter. The first car load, delivered in New England, was refused by the consignee on the ground that the butter was spoiled. The shipper positively asserted that the butter was in first-class condition when it left Chicago, and the Pennsylvania saw no recourse but to make good the loss. Before paying the shipper, however, numerous samples of the butter were shipped to the Pennsylvania's extensive laboratory for analysis. The chemists promptly reported that the butter had absorbed the odor of the shellac on the new car until it was unfit for use. The Pennsylvania promptly changed the painting on the car and suffered no further loss, where almost any other railroad would have lost car after car without discovering the cause. The Pennsylvania watches over details with the exactitude of a bank.

## Systematic Stock Killing.

A great many farmers are extremely willing to sell poor stock at high prices to railroad companies under the pretense that they have been struck by trains. A great many animals that have died from natural causes have been paid for by railroad companies. In districts where the railroads are not fenced no cattle or horses die of any complaint except that of the pilot, and railroad companies quietly submit to the imposition.

The most disgusted farmer we ever met was one who led an old dilapidated mare into a cattle guard to be slaughtered, and the train stopped and the crew jerked the animal out with a switch rope. The owner tried again and the same thing was repeated with the addition that he was landed in jail the next day.

These kinds of tricks are to be looked for among poor but dishonest people. The courts have lately given publicity to an attempt to make a wholesale business out of this kind of thievery. A gang of rogues in Alabama started a business of buying worthless old horses and disposing of them under the wheels of Louisville & Nashville trains. The business flourished for a brief season, but the leading rascal becoming unscrupulous, presented a claim for the death of a racing steed. This was disputed by the railroad company and detectives were employed to investigate the merits of the case. The outcome was that the principal members who engaged in this novel industry will, for some years, have board and lodging in the State's prison.

---

A clock which will prove of great service to railways has been invented by a railroad man. As a train rushes through a station the hour and minute hands whirl around like a flash to the correct moment, and a red bull's-eye flashes into the dial. Five minutes later the red light turns green, and in five minutes more the green light disappears. The engineer on the next train can tell exactly to the moment how many minutes ahead is the train that precedes him. The clock is a perfect timekeeper, and when the train passes drops the signal light.

---

The Patent Office has issued three patents on valves for automatic air-brakes to the Boyden Brake Company of Baltimore. The application for one of these patents has been pending since September, 1889. The patents relate to improvements in triple-valves and have been pending for some time. The Boyden triple-valve is a very simple and efficient device and has the merit of being original.

---

The Pintsch Gas Lighting Company have sent out a card with a map of the United States, showing the places where Pintsch gas works have been established. They also make some points respecting the advantage of using this form for car lighting. It is said to be safe, economical, effective and simple in operation.

---

We have received from the National Machinery Company of Tiffin, Ohio, a new illustrated catalogue of the machinery which they make. It is got up in first-class style and will be a convenient reference for the class of railway men who have to deal with the purchasing of bolt, nut and forging machinery.

The Q. & C. Company of Chicago, have issued a very handsome souvenir of the World's Columbian Exposition, giving excellent wood cuts of all the buildings.

## Iron vs. Steel for Fireboxes.

*Editors:*

Having read a discussion between the agents of the Low Moor Iron Company and steel manufacturers, in the June issue of the LOCOMOTIVE ENGINEERING, I beg to submit a few items of interest, which are doubtless known to many master mechanics.

Steel certainly has the advantage over iron in flanging. It is worked much easier and far less heat is required than in good strong iron. During the many years that steel has been made, it does not yet appear that the manufacturers understand it thoroughly. We put a first-class flange-steel into a firebox, which may stand all the requirements of a first-class article, and in a little while it cracks from one end to the other. There is no warning given for such crackings; to all outward appearances it is a perfect plate when put in. The magnitude of this evil is well known, alike to users of the best and highest grade steels, as well as to those using the cheapest.

Charcoal hammered iron has not this tendency, but sometimes shows blisters. These blisters are the results of imperfect welding, for which the manufacturers have no excuse except carelessness in manufacturing.

The intimation that the Low Moor brand is the only good iron made is not well founded. The Tennessee Charcoal Bloom Iron made in Kentucky is equally as reliable as the imported Low Moor. This brand of iron has been made into firebox plates for many years, and is still in use. This high grade charcoal iron when properly made (though more difficult to work) makes a more reliable firebox, and will outlast steel a number of times over.

A WESTERN MASTER MECHANIC.

## Power Absorbed by Locomotive Machinery.

*Editors:*

I notice that a communication has been criticised by Mr. Johnson, of Topeka, and a Youngstown gentleman. I am undoubtedly to blame for not explaining the matter clearer. I intended showing that one of the difficulties of high speed was the great proportion of power absorbed by the engine itself, and as a detail of this the power required to keep the pistons, crossheads, etc., in motion. That there is no loss of power by the use of the crank, which is the point, I take it, that Mr. Johnson calls attention to, will certainly not be questioned, and I have no remembrance of saying there was, nor that it is possible to destroy a force once created, which I believe he also calls attention to, nor that action can exist without an equal reaction. But before the work stored up in the piston, etc. during the first half of the stroke can be delivered in the last half, it must be created and made to exist, and it was this that I intended calling attention to, that is, that high speed is difficult because of the large amount of power required to keep the engine, alone in motion. If my memory serves me correctly, I indicated a light engine at a little over sixty miles per hour, which showed a horse-power of nearly 500.

Because stored-up force is returned it is of little value if there is no surplus to put into a train. As the Youngstown gentleman says, heavy reciprocating parts are used in automatic high-speed stationary engines, forming a reciprocating fly-wheel, that is, a mass to absorb the force put into the piston during the first part of the stroke before the valve is closed, and shortly afterward, when the pressure is high in the cylinder, which force will be given out at the latter part of the stroke when the cylinder pressure is low, due to expansion. This has been a recognized necessity for years, and its value, I believe, first appeared in pumping engines known as "bull engines," which were supplied with a weight, because of the absence of a fly-wheel for this purpose.

But my Youngstown critic is wrong if he believes that heavy reciprocating parts are "the thing" on the locomotive where the mass of the engine itself serves as a fly-wheel.

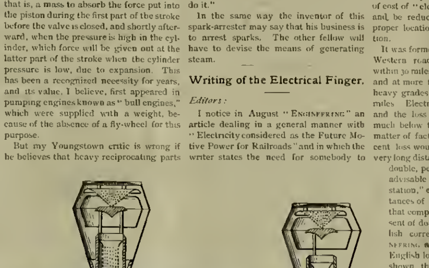
High speed requires a well counterbalanced engine, and heavy reciprocating parts are in the way of good counterbalancing, as any one is aware who has had this work to do for the locomotive. While it is quite possible to counter-balance a stationary engine perfectly, it is impossible to do the same for the locomotive, as the conditions are not similar, and the heavy reciprocating parts favored by the Youngstown gentleman would prove the destruction of the locomotive and the track.

FRANK CORBETT.

## An Effectual Spark-Arrester.

The annexed engravings show a spark-arrester which is about the latest invention in this line, and was got out by J. W Curran, Marshall, Tex. The invention appears to combine nearly all the devices that have been employed for spark-arresting. It has the diamond stack with provision for carrying the sparks back to the firebox, a perforated lift-pipe like what is used in the Smith spark-arrester, and an extension front with diaphragm and netting. The device ought certainly to prevent spark-throwing, but a man familiar with the running of locomotives naturally asks, how is draft obtained for the generation of steam? The invention reminds us of an anecdote about a testy old gentleman in England who was tortured with a gouty toe. The family doctor failed to give relief, and the sufferer eventually ordered him out of the house and talked of giving a big reward to any one who would cure the troublesome toe. A man called on him one day and offered to make a contract on the no-cure-no-pay principle. An agreement was made and the man appeared next day with a set of surgical instruments and told the 'squire that he was ready to perform the cure. The foot was laid bare and the 'squire asked, "Now, what are you going to do?" "Why," replied the man, "I am going to cut off your foot." "Cut off my foot!" exclaimed the sufferer, "you are mad! How can I walk without my foot?" "That is no business of mine," replied the man, "my business is to cure your toe and I can do it."

In the same way the inventor of this spark-arrester may say that his business is to arrest sparks. The other fellow will have to devise the means of generating steam.



NEWEST THING IN SPARK-ARRESTERS.

## Writing of the Electrical Finger.

*Editors:*

I notice in August "ENGINEERING" an article dealing in a general manner with "Electricity considered as the Future Motive Power for Railroads" and in which the writer states the need for somebody to "rise up" and present the problem of electrical railroading understandingly to the "railroad army," as "Sinclair has presented the problem of train resistance; in an understandable way."

Doubtless we may wait, as in the case of steam railroading, before the electrical problem will be *clearly presented* to the "army," but the "train resistance problem" applies to each.

The electrical system as applied to railroads will doubtless become familiar in the near future, but in the meantime it may be far more troublesome to officials than is now the compound locomotive matter. We will need to prepare to meet the electrical power question and to deal with it in a progressive spirit, settling the troublesome details as they appear. Electricity will not wait for leaders, those who take hold in earnest and work out practical points, as has been done in steam railroading, will, by their determination to overcome difficulties at the start, win one-half the battle, and doubtless as many paths will open to the active workers as in the former instance. Conditions of service will change, requirements will change to meet the new conditions, and in general there is likely to be an adaptation to the new power in all mechanical plans and arrangements. Hence, it seems less necessary to consider in experimental talk or practice a preservation of the old system. Something better *will* appear and that is the thing to consider and apply to use

Those who, in the past, have been through the "old mill" will, as a consequence of their experience, take a conservative view of the new order of machinery and be most likely to look and work with unprejudiced minds for results in the new field.

To my view a most important change will result in the adoption of the central station system and the *concentration of power* at difficult places on railroads, as for instance, near heavy grades or where traffic may be centered for useful or any convenient purpose; and the adoption at all the stations of the proper form of compound condensing engines in which the best possible results may be reached in the use of steam power; the result of which will *more* than compensate for the loss which is at present considered in the sum of cost of "electrical power transmission," and be reduced in amount also by the proper location of the central power station.

It was formerly considered necessary on Western roads to place water stations within 30 miles distances at the maximum, and at more frequent intervals in case of heavy grades or of bad water within 20 miles. Electrical stations may be placed and the loss of power transmission be much below the present estimates. As a matter of fact, I am informed that 30 per cent loss would now be experienced in a very long distance transmission, more than double, perhaps, what might be found advisable in the actual use of "power station," except on roads with long distances of level track. It may be said that compound locomotives are at present of doubtful utility, and your English correspondent in August ENGINEERING appears to have this view of English locomotives, but it cannot be shown that compound, stationary or steamer engines are unsatisfactory when properly designed for the service. They are used the world over in all sorts of service as compound and compound-condensing engines, and it is folly to regard them at all in an experimental light. They long since passed that stage; as they doubtless may on steam railroads for special service, and certainly have done in electrical station service all over this country.

Mistakes in electrical power stations undoubtedly have been made in the selection of suitable engines, and may be again, but there being given a fair understanding of various requirements, power can be supplied to meet the probable minimum and maximum duty under best conditions with compound condensing engines, or a number of small compound engines, where these seem desirable in a central station, as is now often the case in electric lighting and power plants.

The Thomson-Houston Co., at their Lynn works, which, by the way, employs 4,000 men, have a locomotive department, and are there planning and constructing the electric-power locomotive frequently referred to in the newspapers for use by the B. & O. Railroad. While the exact tonnage is not made public, they are designed to displace the "steam locomotive" at present used in local service at a point near Baltimore.

A recent *Electrical World* notes that a project is on foot for an electric line between Brussels and Antwerp, and which proposes to run trains of one car, each holding 60 people, at a speed of 66 miles per hour, time 20 minutes and at intervals of 10 minutes. The present steam roads make up 16 trains daily each way. The conditions are said to be favorable and the only notable point is the proposed speed.

St Paul and Minneapolis are served by an electrical railway at more frequent intervals at a less speed, because mainly of its being entirely a suburban road, running and discharging passengers at all points along the distance of 11 miles. Omaha is supplied with a very complete and nice-

working electric system, which doubtless will extend as required. In Boston there are motor cars throughout the city reaching well into the suburbs, and considering the crowded conditions of the streets of Boston, this system is wonderfully well managed and accommodating. Here are modern motor cars, seating 34 and taking on 80 passengers; and they may well be styled the people's carriages, as a Yankee girl was heard to remark of them. These roads are destined to extend beyond the suburbs to *25 miles or more*.

In the progress above referred to and in the near prospect, it seems to point to a favorite method in the new transportation system, but it is practicable, of course, to add one or more cars to the motor car to make up the "electric train," as is now done on cable roads, wherever used. Fast time within the limits of a city like Boston will not be practicable on surface roads, but in the long stretches of suburban districts, even now satisfactory speed is obtained, and high speed may be made with no material *damage to track or road bed*.

The "army" of workers on the present steam roads may not soon be affected by the certain advance of electricity, as the natural expansion of the country constantly going on makes room for a new order of things without any apparent disagreement between the two systems; but eventually it will affect them seriously and they should note the signs of the time and prepare to *accept results*, or possibly to control and profit by them. "Hitch your wagon to a star," is an Emersonian maxim, but it is well nigh a reality by reason of the adoption of electricity to carriages, which is being done in Boston, and it may be practicable for the ordinary person to own his own electrical carriage, and even the "army" may do so yet, as freely as in the case of the bicycle. When this happy time comes, the writer may be able to invite his friend, your correspondent, J. E. F., to ride, provided he "gets there" in advance of the young man.

G. W. Cushing.

## A Way to Reface Roughed Tracing.

*Editors:*

Until, lately, when obliged to alter a tracing, I have first removed the ink with a steel scraper, so far as could be done without injuring the cloth, completing the erasure with a sand rubber, and restoring the surface as well as possible by rubbing hard with a piece of white paper until the cloth again appeared glazed.

This gives fairly good results, but takes much time, and the new surface is apt to become soiled.

A short time ago I learned of a better method, as follows:

After the erasure is complete scrape some French chalk on the tracing cloth and rub it in lightly until the cloth will retain no more. This will produce a surface nearly equal in every respect to the original.

Of course it is premised that the erasure has been made without injury to the texture of the cloth, as no surface can repair any damage to that.

I have tried this method on both new and old tracings and always with success.

French chalk is commonly used by tailors, and can be obtained in small sticks at any drug store.

Frank M. James.

*Haverhill, Mass.*

## Ten-Wheel Engines. Stationary Links.

*Editors:*

Now that the different railroads are catering to large ten-wheel locomotives for passenger trains, will you state for the benefit of myself and readers of your paper, if there is any economy in the use of such locomotives to the railroad company, or are they used on account of having heavy trains to pull on heavy grades? I have been a M. M. for many years and am getting old in the machinery department. It has long been a question in my mind if there exists any economy in locomotives of that class. I see one or two great faults, to wit

Those long eccentric blades crossing forward axle. I tell you when those long blades get to vibrating I imagine you are in danger of losing your motion.

Now, will you tell me why we could not go back to the old-time stationary link with movable blocks? Then we could have an arm running over the top of forward axle and get our clevis-rods back of forward axle. Now, is there any reason why this would not work? You would only have two more joints than you have now.

You all know, who understand this link, that it was a good motion for fast engines. You remember this link was the first link adopted to take the place of the old V and drop-hook motion.

Now, the second I should think would be the clevis end of parallel rod end, the rod reaching from middle or main driving-wheel to back-wheel. Now, I think when sizes are worn down, one smaller than the other, the slip of wheel must make a tremendous strain on those rods and hammer the main pin. Now, please answer this through your paper and tell all the boys to join in.

Supt. M. P. & Mach'y.

*Houston, Tex.*

The Result of a Collision Between Trains on a Foggy Day.

## Frost Lighting and Westinghouse Air Get Mixed.

*Editors:*

For the benefit of all interested in air-brakes, we will relate a circumstance that happened on the E. T., V. & G. An engine and four cars are running on a short run. The cars are kept in the run and are not changed. Engineer reported brakes would release in 10 seconds after being applied, and handle put on lap. Equalizing and discharge-valve was overhauled, with no relief. The engine was then coupled to other cars and brakes held perfectly on lap, demonstrating defect was not on engine. The original cars were equipped with the Haberkorn triples and governor attachment. The engine was then coupled to its own train, same result; brake would release on lap. Then commenced a chasing up one side and down the other. The M. C. B. and road foreman of engines, both experts, rendered frantic by the guying of the S. M. P., who happened along that way. This would make a good puzzle. But as few roads use the Frost Dry Carburetter system of lighting, it would be unfair to put it as a puzzle. This system of lighting is done by a light air pressure passing into large cavities, where gasoline is held in cotton wicking and vaporized into illuminating gas by air and heat. A large reservoir is suspended under car and connected to train-pipe with a check. This reservoir is four times as large as an auxiliary reservoir. This is charged to full train-pipe pressure, and then air is fed to carburetters by a diaphragm regulator set to 2½ pounds. The check is supposed to hold all it gets from train-pipe, thus cutting it off when train-pipe pressure is reduced in application. Two gauges were applied; one to auxiliary reservoir and one to train-pipe. Brakes were applied, and as soon as auxiliary reservoir-pressure and train-pipe pressure had equalized, the gauge on train-pipe was observed to increase slowly till it released brakes. The trouble was then located. The check between train-pipe and Frost lighting reservoir was found to have been broken—a small piece broken from valve. The reservoir being so much larger and containing a much larger volume of air than auxiliary reservoir, it fed its pressure very fast through the small opening in broken check-valve, releasing train-pipe pressure and releasing brakes. The Haberkorn triples were removed and Westinghouse triples substituted. The result was precisely the same. The Haberkorn governor attachment is a fine move in the direction of instantaneous release. It is as quick as vacuum.

## One Wheel Slid Flat

*Editors:*

I notice in your July number on page 231 a query in relation to *one flat wheel*, which seems to bring forth several comments as to cause. Although I do not often care to discuss a great many questions that come before us, but as this has attracted my attention several times and I have not found one answer that I think correct, I will state my views for the benefit of those who may have more time and better opportunity to experiment than I. I had a tank truck on my engine with a wheel flat on one side, and I could not at first account for it. But I made up my mind to solve the mystery, which did not take long. I watched the wheel when I applied the brake, and found that when the brake-shoe clamped the wheel it would raise it clear from the rail and it would slide in this way and not drop down until the break was released. In another instance I noticed a similar working of a brake on a gondola coal car, that when the brake was applied one wheel came up clear off the rail at least one-half inch, and did not drop down until the brake was off. I examined the car, but could not see why it should do this, unless it being a very rigid brake and one brake-hanger some shorter than the opposite one, and the metal in the brake-shoe was very soft, so when it became a little warm, would stick or hang so as to raise the wheel when the brake was set. Perhaps some one else has noticed similar actions of brake which may be of help to others.

## Lining Guides by Counter-bore.

*Editors:*

In the July issue of your paper I see an article about lining guides by the counter-bore of cylinder, where Hugh R. Crawford says the method laid down by P. H. Zwicker, in his "Revised Practical Instructor," is a delusion and a snare, and also says he has been asked by engineers and young mechanics several times in the past few months if the method is correct. Well, let me say as far as the engineer is concerned, it is all right if he knows these things, as they are good things to know, but the average engineer does not trouble himself to know. If the guides on his engine are lined by cylinder or counter-bore he gets there all the same.

But I must say Mr. Crawford's way of learning the young idea how to shoot is a bad one, and if my boy was going to learn to be a machinist I would take care and not place him under such an instructor as Mr. Crawford seems to be.

I say, Mr. P. H. Zwicker is right, I don't care how much the cylinder is worn on the bottom, which every good machinist knows is caused by the bull-ring dragging the bottom of cylinder, I will venture to say that he never found a cylinder worn as much in the back end as in the front. If he has, he has found more than I have, and I have run a few lines through cylinders myself. Another thing, he does not say whether he sets his line in center of cylinder in front end and stuffing-box on

back end If he does take this for example Take a pair of dividers and make a circle sixteen inches, then make another one, say five feet. Then draw a line from center to center, then take and drop down one-eighth of an inch from center of one and then draw another line. I would like to know if that is the center of cylinder? I guess not. Then, on the other hand, set the line to the cylinder worn out in the bottom one-eighth of an inch. He says Put up your guides, put in your piston and key it in crosshead. Now, Mr. Crawford, how about that neck-ring and gland, and how about the center of that back cylinder-head? If the neck-ring fits like it should for what it is intended, you could not get it in because your guides are an eighth out of line. I have seen guides lined up this way, and I have seen the wool pulled over the foreman's eyes about that unruly neck-ring, and I will tell you how it was done. Take care, Mr Crawford, I have been all along there It was this way Piston shoved in, neck-ring was put in its place, then piston was keyed in crosshead (great care taken to keep its neck-ring in place) until packing was put in stuffing-box and gland screwed up. You can get your cylinder packing in; no trouble about that (but oh, what a job). Now, is this the right way to line up guides? I think not. This is a delusion and a snare. If the line had been set by the counter-bore in front end and stuffing-box in back end, as center of stuffing is the center of counter-bore, there would be no trouble of cross-head and piston not working all right. Let me say right here, such works as P. H Zwicker, or any other mechanical works, you can bank on them being right They are not got up to gull the young mechanic. They are out on their merits, but my advice to the young mechanic is if the shop foreman tells you to line up guides by Mr Crawford's method, do it. They are responsible for the job. If not, be governed by the counter-bore and you will have no trouble. I have seen so many articles in the LOCOMOTIVE ENGINEERING about guide lining, and when I saw this one by Mr Crawford I could not keep from chipping in. The article written by Mr. Hitchcock is a good one, and shows he knows his business in the manner he handles Mr. Dolbeer's method of putting up guides without a line, which is one of the slimmest methods I ever heard of.

I got hold of a set of guides once to take down and line up that had been put up by Mr. Dolbeer's method, and I will here tell the readers of your paper about them. I lined up my guides with a line. When I got them done I found guide too high for pump one-fourth of an inch. This engine had two pumps on her which were not taken down.

Now, if these guides had been put up in the first place with a line, the very fact of taking down the guides and then putting them up would not put the pump out of line as it was Well, I run over my work again to be sure I was right before I told the foreman of the trouble, and he was like some more foremen I know of, who know it all themselves and do not allow the men to know anything He laughed at me and I heard him mutter something about a chump, and went so far as to run my work over before he would be convinced that such was the case, but it was there Therefore the pump had to be raised up and branch-pipe shortened, but before doing this we tried to work a hollow plunger, but pump was too much out to admit of it. These guides were lined up the first time by the Dolbeer method.

SAM MASLEY.

*Palestine, Tex.*

## Faults of the Link Motion.

*Editors:*

In your issue for August, I observed a communication on link motion which seemed somewhat vague, but still I seemed to comprehend its meaning, at least, I thought so

It seems to be the desire of most engineers to pull their trains with reverse lever as near the center notch as possible, in fact, if the engine could not pull her train in the first notch, it was not uncommon to have the reach-rod lengthened out until she did, which gave her a later cut-off.

We have a class of 17 x 24-in. engines in passenger service which will pull their trains with from 6 to 7-in. cut-off, valves have $\frac{3}{4}$-in. outside and $\frac{1}{64}$-in. inside lap, and $5\frac{1}{4}$-in. travel and $\frac{1}{16}$-in. lead.

Now, beginning with forward dead centers, forward motion and reverse lever in first notch out of center, we find front port open to extent of lead, which in this case is $\frac{1}{16}$ in.; and, proceeding, we find that the port is open to its fullest, which is ½ in at 2 in. of piston travel, and cut-off at 6 in., when the valve closes, port moving ahead, leaving the steam to work expansively until released by the exhaust cavity at 15 in. of piston stroke. You have now had 6 in. of boiler-pressure steam, supposing throttle to be wide open and 9 in. of expansive steam. But, now, when we consider that the moment the steam is released from the front end of cylinder (yes, and before) the back port is closed, with piston moving back for the remaining 9 inches, which causes a back pressure which is sufficient to lift the valve, and must be more than the boiler pressure until back port begins to open, which it does at 22 in. of piston stroke, and we are ready to proceed with the back end in the same way. Now, it hardly seems reasonable to me to think that these 9 inches of compression are necessary to cushion the reciprocating parts of an engine which does not run faster than it would when reverse lever is in the corner notch, when compression does not begin until more than 23 in. of piston stroke.

Of course, the throttle is not open so far when in the corner, but it seems to me that it would be a greater economy if the engine was worked at, say, $\frac{2}{3}$-in. stroke, or, at the most, at about 15-in. cut-off, when compression begins at about 21 inches.

I hardly think it possible to get results from a link motion to compare with a Corliss engine, where they keep the steam working expansively for nearly the whole stroke, and employ an extra valve to control the exhaust. In the modern marine engine an adjustable cut-off valve is employed, which is worked independently from the main valve by the cut-off eccentric, main valve being always at full stroke. This appears to be the only way to get desirable results from an engine where it is wished to use boiler-pressure steam, and the engine works too strong at an advantageous stroke.

But the link motion will never be discarded until something decidedly superior is designed, which is hardly probable; but to see a good cut-off valve introduced on the American locomotive is the hope of

*Green Bay, Wis.* S. P.

FIRST RAILROAD STATION IN AMERICA

## The Oldest Station in America.

The house shown in the annexed engraving stands on the brow of a hill overlooking Schenectady, N. Y. It is in the midst of a quiet rural scene that savors more of stillness and repose than the stirring surroundings of noisy railroad life yet it was once the scene of the most active railroad life on this continent, having been the principal station house and operating headquarters of the Mohawk and Hudson Railroad, the first railroad chartered in America and the first one built in New York State. There is no doubt that this is the oldest station building in the country It is a very modest structure compared with the pretentious buildings now dotted over every line in America, but it possesses historic interest second to none in this line.

The charter for the building of the Mohawk & Hudson Railroad was granted in 1826. The Erie Canal had been opened the previous year and the Empire State was enjoying extraordinary prosperity, the improved means of transportation contributing in no small measure to the growing welfare of the community The whole country was unusually prosperous under the beneficent policy of the Adams administration, and New York State had a particularly enterprising executive in Governor Clinton. The time was propitious for promoting improved means of intercommunication and courageous capitalists cheerfully risked means in the building of the railroad that was to unite in more than fraternal bonds the waters of the Mohawk and Hudson Rivers.

There were untold difficulties in the way of pushing this enterprise, for when it was undertaken there was not a railroad in the world in the sense that the Mohawk & Hudson was intended—that is a railroad for general transportation of passengers and freight.

In 1831 part of the line was opened for traffic and a portion of it near Schenectady was operated by inclined planes and cables The building shown in our engraving was erected on the part operated by locomotives The window that was used for the issuing of tickets is still there, the glass marked with a diamond ring. Around the house are pavements made of the stone blocks first used as ties for laying the rails upon.

For those who are inclined to look up the railroad scenes possessing historical interest there are few places now more worthy than this one A pilgrimage to the spot would be a day agreeably spent.

It is sixty-two years ago this month since a wonderful train passed here drawn by the De Witt Clinton, the first locomotive built in America. The locomotive was about the size of a modern fire engine, and was run by David Matthews, who helped to build the machine and who is still alive. The running of the train was a great event, for the passengers were the leading men of the State who had come to take ceremonial part in an event which was of greater importance to mankind than anything that had ever happened before.

### Bad Brake-Levers.

*Editors:*

A few years ago, many of the railroads in this country used a standard tender brake-gear almost identical with Mr. Synnestvedt's sketch in the August number, differing sometimes in detail but possessing the absurd features of a *dead* brake-lever.

Brake-levers have a double or compound fulcrum and are connected directly with the source of power. With the Hodge and Stevens systems of leverage adopted by Westinghouse and the railroads generally, a "floating" brake-lever is used, that is, the lever has no fixed fulcrum, the brake-rod connections forming compensating fulcrums. The push-rod from brake-cylinder piston is attached to one extreme end of brake-lever, one of the brake pull-rods connects at the opposite end and the other pull-rod is connected to the lever at an intermediate point and when power is applied one rod pulls out to its limit and becomes a fulcrum for the other rod.

The pull-rod nearest the connection to power has the greatest leverage and develops greatest braking force. The weight on both trucks of a passenger or freight car is about the same and means are employed to equalize the unequal leverage, but with a locomotive in service, the weight on forward tender truck is continually lessened as the fuel is used and the standard car brake-gear may be simplified to advantage when used under a tender by connecting the pull-rod from forward truck to the end of brake-lever opposite the power and the rod from rear truck to the proper point on the lever and nearer the connection with piston power, thus throwing the greater braking force to the wheels bearing the greatest load.

A lever can have but two general fulcruming points. With a *dead* brake-lever there is a fixed, immovable fulcrum-pin about the center of the lever and when the brake is applied the pull-rod having the least slack forms the other fulcrum, while the other pull-rod may not have sufficient power to draw its shoes against the wheels.

Whenever one of those ancient forms of leverage is discovered, it is claimed that it is a relic of a previous administration and most generally is, but it would be in the line of economy to remove them. I knew of a passenger train which stopped for a crossing when within a mile of the terminal station, and when brakes were released the tender-brake failed to let off, it had an independent auxiliary and triple; a dead brake-lever was used and the forward pull-rod fulcruming gave the entire braking power to its shoes. The front end of tender was light of coal and the front four wheels skidded the mile without giving a resistance noticeable to the enginemen. When the train stopped at the station the brake was still "stuck," while the shoes on the wheels of the rear truck could be moved laterally with the foot. The resisting power of this brake was so slight that the men on the engine didn't know that it was set when pulling a nine-car vestibule train, but I was informed that on the return trip those four forward wheels developed flat spots.

This tender brake-gear differed slightly from Mr. Synnestvedt's "frightful example." A 36-inch *dead* brake-lever had the pull-rods connected to each extreme end with the push-rod attached twelve inches from the fixed central fulcrum, and with very little slack in the gear, it can be figured just about how short the piston travel was and how great the auxiliary pressure that the releasing pressure had to overcome.

Another bad feature is that closing up the slack in brake-gear and getting a shorter piston travel decreases the effectiveness of this kind of brake, and when both driver and tender-brakes are supplied from a single auxiliary, the driving wheel tires suffer from the effect. Put an engine thus equipped on a fast scheduled local passenger run. The engineer must make the time, but after running past several stations, he gets suspicious of the tender-brake and has the slack taken up. The brake holds better for about one single trip and then is as bad as before, will only hold on one truck, and in his desire to make the tender-brake efficient, the engineer will often have its piston travel so shortened as to give a greatly increased force to the driver-brakes and when he shortens their piston travel he makes the stops all right, but after a short while is requested to give an explanation of why he ground off his driving wheel tires so soon and also as to why he has so many flat wheels under his tender, and usually he can't give it.

WILL W WOOD.

### Air-Brake that Set in Full Release.

*Editors:*

You request, in the last issue of your paper, that all puzzles be accompanied by the solution, written on a separate sheet, for insertion in the number following the publication of the problem. The reasons are obvious, so I beg leave to send the following explanation of the peculiar case cited in a communication I sent you last month (July.)

As is frequently the case the difficulty lay in a combination of circumstances or conditions, no one of which by itself would have been sufficient to cause the trouble encountered. The engine was equipped with all the latest improvements in the air line, including a bell-ringer operated by compressed air from the main drum.

The governor stopped the pump at 70 lbs. train-pipe pressure, but partly on account of the small brass packing ring being a very tight fit, would not allow the pump to start again until quite a reduction had been made in the train pipe. The follower-plate in the bell-ringer was loose, causing a large loss of air from the main drum through the leakage around it. With the valve handle in the working position the excess pressure remained practically constant (that is about 20 lbs. above train-pipe pressure), until the train-pipe accumulated about 70 lbs., when the governor stopped the pump.

The leakage from the main drum through the bell-ringer reduced the pressure in the main drum to a few pounds less than there was in the train-pipe, when that pressure began to reduce also by back leakage into the drum through the engineer's valve. This caused the brakes to drag slightly, and of course, when the engineer pushed the valve handle to full release position, the higher pressure in the train-pipe equalized with the air in the main drum, reducing the train-pipe pressure sufficiently to cause quite a heavy application of the brakes and at the same time start the pump, which by rapid action soon released them again.

After this experience I made some experiments to see how far the main-drum pressure could be reduced with the valve handle in the running position, before the rotary valve would raise and allow the train-pipe pressure to flow back into the drum, and I found that while there was considerable variation with different valves, with some this did not occur until there was nearly 10 lbs. difference in the pressures.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

### Relyea's Brake Puzzles.

*Editors:*

In explaining my last air-brake puzzle will say that the cause of trouble was in main steam-valve bush. If you refer to Plate D. C. you will see that the main steam-valve bush, 25, has a collar just above the exhaust-ports which projects into the bore of cylinder far enough to strike the shoulder on the cylinder-head, that enters the bore of cylinder. In putting in the new bush, I did not file off enough of the collar to clear the shoulder on the head, and withal, I filed it a little beveling, so that when I put on the head the shoulder pressed against the collar just enough to spring the bush and hold the valve when it moved up. I chipped off the collar a little more, put on the head and the pump worked all right.

Here is the "nut" I promised last month. The engine on which I found this "new" difficulty is equipped with train signal apparatus, as well as all the latest Westinghouse equipment. I got on the engine to examine the brake-valve, and found the handle on lap, and red pointer which indicates drum pressure was down to 10 pounds and the black pointer stood at about 50 pounds train line pressure. Thinking perhaps the gauge might be out of order, I hit it with my hand to see if the black pointer would fall back to the red one, but it did not. I then put the handle in the release and the brakes went on; the pointers came together and the signal whistle began to blow and kept blowing at short intervals until I started the pump and got up a good pressure; the pointers both went up evenly. I then put the handle on lap and stopped the pump, and watched the gauge and saw the pointer indicating drum pressure slowly falling back. I started the pump again to keep up the pressure, and began looking around the drum for a leak but found none. I then examined the pipe from brake-valve to drum, also every part of whistle-pipe and whistle-valve (Fig. 4, Plate 3 of instruction book) and found no leak. I next examined the pressure reducing-valve (Fig. 5, Plate 3 of instruction book) and found the difficulty. What was it? As it requires a reduction of pressure in chamber A of whistle-valve to blow the whistle, and the engine having stood in the house two hours, and the whistle not blowing once in all that time, while the air was leaking off why was this thus?

W. F. RELYEA.

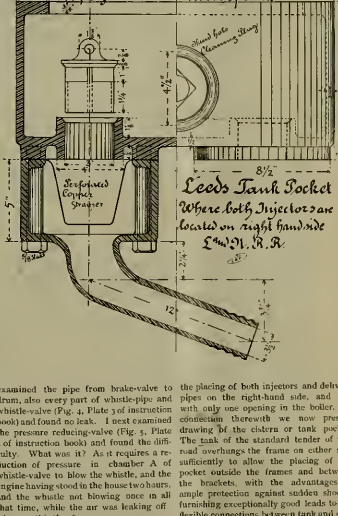
*Editors:*

In regard to Mr. Relyea's air-brake puzzle in the August number of your paper, I believe the trouble was with the hole in the gasket not being exactly in line with the port leading from the main-valve chamber to the port in the top head, which did not allow enough of steam to enter the reversing-valve chamber. There may have been a bad joint on the steam cylinder of the pump, which would let the steam in the small part blow into the cylinder or to the exhaust, and with the port partly closed with hole in gasket being out of line. This would not let the full pressure go into the reversing-valve bushing, and when admitted by the reversing valve into the reversing cylinder the steam would not be able to overcome the main valve. As it seems, the piston would go up and down with the aid of the hammer. I believe when reversing piston was up against its cap the area was somewhat reduced, so it was nearly on a balance, and with the help of a hammer it was able to overcome the main valve. I expect the gasket was a home-made one, which would account for the hole being partly out of place, and when Mr. Relyea cut it out to the proper place it would give plenty of steam to the valves on the top head, and would make the pump work all right.

*Galveston, Texas.* TEXAS

### Louisville & Nashville Tank Pocket.

In the March issue of LOCOMOTIVE ENGINEERING was shown a double check valve designed by Mr. Pulaski Leeds, superintendent of machinery of the Louisville & Nashville system, which permits



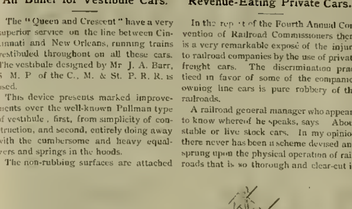
the placing of both injectors and delivery pipes on the right-hand side, and this with only one opening in the boiler. In connection therewith we now present drawing of the cistern or tank pocket. The tank of the standard tender of this road overhangs the frame on either side sufficiently to allow the placing of the pocket outside the frames and between the brackets, with the advantages of ample protection against sudden shocks, furnishing exceptionally good leads to the flexible connections between tank and suction pipes, plainly in sight at all times for inspection, and being entirely out of the way of the running gear. The drawing shows plainly the arrangement of the pocket-valve for shutting off the water, provision for keeping out sediment, the strainer and the hand-hole plug for cleaning. The nozzles are placed at an angle of about thirty degrees to the center line, drawn lengthwise through the pocket, thereby keeping the hose pipes sufficiently apart to prevent chafing. This pocket is made of brass, and rounded off on the outside at the front, to conform to the shape of the deck at the point where fixed. These pockets have been in use for some time, and are entirely meeting the expectation of the designer.

## Air Buffer for Vestibule Cars.

The "Queen and Crescent" have a very superior service on the line between Cincinnati and New Orleans, running trains vestibuled throughout on all these cars. The vestibule designed by Mr J. A. Barr, S. M. P. of the C., M. & St. P. R. R. is used.

This device presents marked improvements over the well-known Pullman type of vestibule, first, from simplicity of construction, and second, entirely doing away with the cumbersome and heavy equalizers and springs in the hoods.

The non-rubbing surfaces are attached



BARR'S VESTIBULE AND MEEHAN'S BUFFER.

to the cars by means of a simple parallel motion similar to the familiar parallel ruler, but in this device the motion from the platform buffers is transmitted to the upper portion by means of rods and in order to have these rods stiff enough to keep the tops always together without springing apart, they would have to be quite large and heavy

Mr. Meehan, S. M. P. of the Q. & C., got over this difficulty by putting on these air buffers. They are a little larger than the well-known Norton door-check The cylinders are suitably connected to the air-brake pipe of the car and are giving excellent results, always keeping the tops in contact, and absolutely keeping out the weather, which a good many of the other vestibules now in service do not do, and at the same time is sufficiently flexible to meet all requirements. The drawing is sufficiently plain to require no further explanation.

Since the first application, the device has been very much simplified, doing away with the two angles in the pipe. The pipe will enter the side duct and a passage will be cased in the side of the cylinder to the back end of the piston, which will admit of the unscrewing of backhead and taking out the piston without taking down the pipe.

## Revenue-Eating Private Cars.

In the report of the Fourth Annual Convention of Railroad Commissioners there is a very remarkable exposé of the injury to railroad companies by the use of private freight cars. The discrimination practiced in favor of some of the companies owning line cars is pure robbery of the railroads.

A railroad general manager who appears to know whereof he speaks, says "About stable or live stock cars. In my opinion there never has been a scheme devised and sprung upon the physical operation of railroads that is so thorough and clear-cut in its effect in the way of depleting legitimate revenue, and such a rigorous leech upon the earnings of railways, as the use of these cars. There were, in the early days of railroads, schemes by which the earnings of certain roads were divided with what is known as "fast-freight lines," but in the majority of such cases there was some slight benefit This cannot be said of the palace stock cars. I have never been able to see wherein the railway companies derive any benefit, either directly or indirectly by their use I consider that every dollar paid by the railway companies for the use of these private cars is absolutely sunk or thrown away, as they do not in any manner increase the traffic to the roads to the amount of one dollar. There is, I understand, now in use about 20,000 palace stock cars that are not owned by railroad companies. If the run of these cars will average fifty miles per day each, they will earn per day $7,500 or $2,700,000 per year If my theory is correct, this amount represents the increased net earnings the railroads would derive from the use of their own cars. The use of the private stock cars is still a further burden, inasmuch as they are, in my opinion, largely responsible for a more or less demoralized condition of rates, also for the increased expense in the handling or moving of the live stock traffic. Before these cars came into use, thirty-seven hours—Missouri River to Chicago—was about the average schedule time, allowing five hours for stop-off, for feed and rest. But this reasonable time would not do for the cars of private corporations or individuals, and, as many large shippers are interested in the property, it is easy, by using one road against the other, to bring about faster or special schedules, and as a result increased mileage for the cars. Now, something from the standpoint of the shipper Until within the last four or five years railroad companies furnished, and live stock shippers were perfectly satisfied with, the improved common stock car then and now in use, and this would be the condition to-day if the so-called palace stock cars had not been introduced. Further, my experience is that there are but two classes of shippers that prefer the palace to the common car first, the shippers that own stock in the car company; second, those that have long runs (that is, runs that exceed thirty hours), in which event they can, if they so desire, evade the twenty-eight hour law, and thus run their stock into market famishing for food and drink to an extent that insures an extraordinary fill before weighing to the buyers. It is true that most of the so-called palace cars possess facilities for watering and feeding, but, to quote the language of the writers of the inclosed clipping (two large cattle shippers). "They are simply to make a bluff at complying with the law. The troughs are seldom used; it is impossible to use them practically." "The poor cattle, instead of drinking water every twenty-eight hours, as intended by the law, are in luck if they see water once in seventy-five or eighty hours."

## Making Good Cast-Iron Wheels.

To the ordinary observer or even mechanic the making of cast-iron car wheels is not an operation that excites consuming interest; yet a visit, which the writer made some time ago to the New York Car Wheel Works at Buffalo, is remembered as one of the pleasantest and most interesting hours spent in a manufacturing establishment. Here the fact was very forcibly brought home that there are car wheel works and car wheel works. Some of these places excite a keen desire to be somewhere else; this one made me regret not having a whole day to devote to watching the work done.

The New York Car Wheel Works, of which Mr P. H. Griffin is president, follow a specialty of making machined car wheels, and the appliances in use for handling and grinding the wheels make the establishment peculiarly attractive to a mechanic.

There are a number of grinding machines in use and they are of a pattern entirely different from the car grinding machines that are on the market. Car grinding machines have generally been made so that wheels might be ground after they were on the axle. As the greater part of wheels sold are not mounted on axles, it was necessary here to devise means of grinding the wheel true without the aid of an axle. This was not a simple problem, but it was worked out with consummate skill.

They first bore the wheel. This is done with a chilled reamer that has six cutting edges, with 24 inches of cutting face. This is certain to make the hole true. This tool deserves to be better known among those who handle many wheels It is pushed through the iron about as fast as a power-driven auger is pushed through a pine stick

After the wheel is bored it is slipped upon an expending mandrel and secured on the face-plate of a very strong lathe specially designed for this work. Emery wheels that move radial to the center of the lathe are advanced together to the tread of the revolving wheel, and it is trued up in a few minutes.

This company appears to have devoted very intelligent attention to the selecting and mixing of iron with a view of obtaining great strength combined with chilling qualities. Mr. Griffin remarked that there is as great difference in chilled iron as there is in the various unchilled grades, although this fact is not generally understood. I was shown samples that were harder than the hardest tool steel. They have succeeded here in making test bars that had a strength of 90,000 pounds to the square inch, a strength exceeding that of any other metal within the elastic limit.

Their method of cleaning the wheels after they come out of the annealing pit is unique. Each wheel is placed in a box and subjected to a tremendous sand blast which cleans it thoroughly in a few seconds

The statistics furnished by several railroad companies of the mileage made by wheels turned out of these works, show three or four times the mileage usually credited to cast-iron wheels. This result is evidently obtained through several causes. First, the iron employed in making the wheels is properly adapted for the purpose. Then the grinding of the wheel makes it perfectly round and not so liable to have its life shortened by sliding or flange cutting as a wheel out of round The wheels are perfectly balanced, which is another point in their favor, and they are bored true, which saves them from several destructive agencies

The additional cost of these properly made and correctly finished wheels is very little more than that paid for the commonest kind of cast-iron wheels. Why railroad officers prefer the poor article to the good one is one of the mysteries that the ordinary mind cannot grasp The finished wheel gives a longer service than the poor one and is much the cheaper in the end. It makes the cars ride much more smoothly and reduces the repairs of running gear, besides being much easier on the track Yet for a dollar or two in first cost the cheap wheel is generally preferred.

A S

## World's Fair Passenger Cars.

The problem of building temporary passenger cars to carry the crowds of people during the World's Fair has been very well worked out by the Illinois Central people. They are preparing to build 245 cars that have framing and trucks the same as the standard freight car of the road. They will be arranged with seats like the summer street cars that have the seats crosswise. The cars of course will be entered from the sides The length of each car is 35 feet over sills There are 16 seats, the whole capable of holding 96 persons. It is estimated that there will be less than 300 pounds of dead weight required to accommodate each passenger, which is extraordinary low. It will be done, too, with perfect safety, for the cars are of a very strong design.

The sills are the same as the ordinary box car, and they are strongly trussed to give vertical stiffness. The posts are so arranged that windows can be placed opposite each seat The cars will of course have Westinghouse air-brakes and Janney couplers.

When the necessity for using these cars for passenger service is over, they will be converted with very little work into express cars for the large Southern fruit and vegetable trade done by the company

A number of new sleeping cars were put in service last month by the Chicago, Milwaukee & St. Paul. The cars are handsome and their looks convey ideas of comfort, although they are not so ornate as some of the other sleeping cars in use. The drawing-room seats are covered with dove-colored broadcloth.

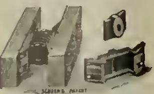
## Articles in Pressed Steel for Railways and Car Construction.

Made to Interchange with any Standard.

**Offices & Works, PITTSBURGH, Pa.**
Western Office, 523 Phenix Building, Chicago.
Eastern Office, 909 Drexel Building, Philadelphia, Pa.

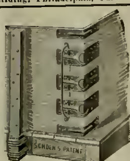


**Pressed Steel Drawbar Attachment.**
Our Pressed Steel Drawbar Attachment commends itself to all for its simplicity and strength.

**Pressed Steel Stake Pockets.**
*For Gondola, Flat and Coal Cars.*
No change whatever is necessary in substituting steel pockets for cast iron, as we make them to interchange in bolt-hole centers and inside dimensions.

**Pressed Steel Corner Bands.**
*For Gondola and Box Cars.*

Our Pressed Steel Corner Bands, as shown in cut, are heavily embossed. The inside corner bands are ribbed the opposite way so that they may lay flat against the timber. Besides being very strong, they add materially to the appearance of the car. At about the same cost as common wrought-iron bands.

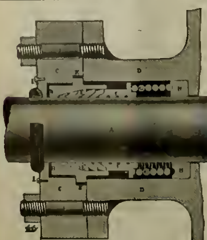


**Pressed Steel Center Plates.**
Made to interchange with present standard

By the use of our articles the weight of your car will be decreased from 800 to 1,200 lbs. The cost of repairs reduced to a minimum. All without material increase in cost of construction. We will be pleased to give full information and quote prices upon application.

---

# JEROME METALLIC PACKING.



STANDARD.

This Packing is the Standard Metallic Packing all over the world and is now more generally adopted and in use on more Locomotives than any Metallic Packing in use. Give the JEROME a trial and be convinced. Put it in competition with any other Packing and be convinced of its superior merits.

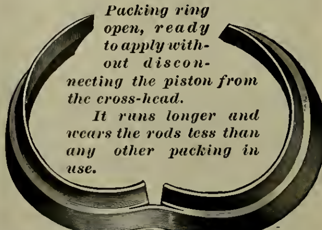
OFFICE AND WORKS:

**Nos. 35 & 37 South Canal St., Chicago, Ill.**

## C. C. JEROME,

**Inventor and Proprietor.**

SEND FOR CATALOGUE.



*Packing ring open, ready to apply without disconnecting the piston from the cross-head.*

*It runs longer and wears the rods less than any other packing in use.*

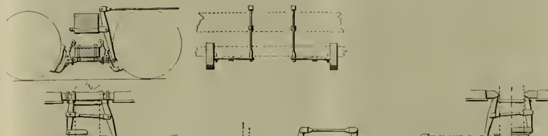
## Brake Rigging Without Beam.

In connection with the novel brake rigging shown in the annexed engravings, Mr. James McGee, of the Houston & Texas Central, writes · I will endeavor to explain the object of this brake as far as possible and its working. A brake-beam of any kind on a car has always been a source of annoyance and always in danger of being broken or torn off by obstructions on the track, whether hung inside, between the wheels, or outside, and up to this time there has never been anything offered as a substitute for the brake-beam, this being the only one that seems to fill the place of the brake-beam and doing away with all the objections to same, and furnishing a more reliable brake in its place.

By referring to the cut it will be seen that it is simply a system of levers so con-



Novel Brake Gear

structed as to equalize the power applied to each wheel perfectly. Any amount of power can be had by this system of brakes that is necessary, according to the weight of the car. The power exerted on these levers by the application of the Westinghouse air-brakes is figured out for the light weight of a car weighing 24,000 lbs. As the wooden brake-beam even when trussed has been deemed not sufficiently rigid for the application of air, metallic trussed brake-beams of different patterns have been gotten up for the purpose, which are sufficiently rigid to meet the demands made necessary by the application of air, but they do away with none of the objections had to the brake-beam. It is claimed that this brake meets all the requirements in the way of rigidity, there being no deflection, the levers being made sufficiently strong to have no deflection whatever, and will perform all that any pattern of metallic trussed brake-beam will, and is less liable to get out of order, being close and compact, and there is no danger of its being injured by any obstructions on the track. The parts are so adjusted that there is very little slack from the wear of the shoes. It is found that the actual cost is no more than the ordinary wooden brake-beam without the truss, when connected with the Westinghouse air-brake. This being the case there is no reason why it should not take the place of the brake-beam on all cars.

---

The Washburn Car Wheel Company of Hartford, Conn., are now filling an order from the Chicago & North-Western for the equipment of 120 passenger coaches. They filled an order from the same company of about the same size last year. These wheels are made of cast-iron centers with crucible steel tires which are welded to the cast iron centers by pouring the molten steel around the centers when hot, making a solid wheel. Mr. Adams of the Boston & Albany has had them in service for many years, and his reports show an increasing mileage each year, the average mileage in passenger service in 1889 reaching over 200,000. After being condemned for passenger service they go under freight cars.

## Electric Car Triumphs.

The operating of electric cars appears to be making rapid headway in New England notwithstanding the popular opposition of the trolley system, which certainly is dangerous. An item in a late Boston paper says:

A man can now sit in a trolley car and ride through a delightful country from North Attleboro to Providence, covering over one-third of the distance from Boston to the Rhode Island metropolis.

That this is only the beginning of an enterprise which will yet connect Boston and Providence through electric cars over a distance of 44 miles, almost goes without saying.

Thus do inventions and enterprise gradually make it possible for the poor as well as the rich to enjoy a summer day's outing on wheels for a comparatively small expenditure.

---

The Mexican railway, says the *Railway Age*, has had some metal box cars built for it by the Ashbury Railway Carriage & Iron Company of England. The cars are entirely of iron and steel. All sills are of steel channels and the cross ties and transoms of steel I beams. The flooring is of iron plate, the body framing of steel angles and ties and the siding and roofing of corrugated galvanized iron. The trucks —with rigid bolsters—are of Fox solid pressed steel. The truss-rods extend only from transom to transom. A spring side bearing is used. Link and pin draw-bars with double conical draft springs are used. The cars are fitted with the Westinghouse automatic brake.

---

Secretary Arthurs, of the Mt. Vernon Car Manufacturing Company, writing to this office, says. "We are very busy in our works, as we have been all the time since starting. We just recently turned out an order of Mobile & Ohio box-cars, Paducah, Tennessee & Alabama coal cars, and have just recently completed an order for 500 Louisville & Nashville box-cars. We are at present working on orders for Evansville & Terre Haute flat and coal cars 36 feet long, of 70,000 lbs. capacity, frost-proof refrigerator cars for Union Refrigerator Transit Company, St. Louis, Chicago & St. Paul box-cars. We have recently built an addition to our foundry 50 x 125 feet, largely increasing our wheel capacity. We are now making this one of the special features of our business, and are furnishing such roads as the Louisville & Nashville, Illinois Central, Mackey system and others with their supply of car wheels."

---

A fireman on the Southern Pacific, writing from California, says that the practice is rigidly followed there of promoting firemen by seniority and that there is no inclination among the men to learn anything about the locomotive or its attachments to make themselves efficient when called upon to take charge of an engine. He cites several anecdotes illustrating the ridiculous ignorance about the business of men who were put in charge of locomotives. If the letter is true the most ignorant man has as good a prospect for advancement on the Southern Pacific as the man who labors to acquire information about the business. The supreme power for promotion is the determination to wait. This is not the only road where staying qualities are the most valuable.

---

In the course of an article on tungsten steel the *Iron Age* says: "Mushet's special" has been on the market for so many years that it is probable there are but few users of tool steel who are not familiar with its peculiar qualities. The majority, however, are not aware that it owes its property of becoming and remaining hard when cold, without the necessity for any hardening process, to the fact that it is an alloy of tungsten and ordinary carbon steel. Its extreme strength and hardness are due, principally, to the large percentage of tungsten, which it is possible to incorporate as a perfect alloy.

---

According to a recent letter from Japan, there is a fair chance for American locomotives in that country. The engines now in use are, with two exceptions, of English make, but the correspondent attaches great importance to a competitive test made with American engineers in the cab. It is well known that foreigners deem the American locomotive a powerful rival, and strive to check its steadily-growing popularity.

---

An incident of train service that attracted wide attention last month was the running of a train from San Francisco to Washington loaded with $30,000,000 of gold coin. As a gold dollar weighs 25.8 grains troy, the sum of money carried by the train would weigh 110,571 pounds, or a little over 50 tons. That would have been a heavy haul for train robbers.

---

The Cooke compound arrived in Chicago over the Pittsburgh, Port Wayne & Chicago August 3. It made a fine run from Crestline to Chicago, hauling the Columbian Express, a train of fifteen heavy passenger and sleeping cars, and making up thirty-five minutes on the running time. For this train a double header is necessary to make running time when it is as heavy as the one just noticed. The engine is now running on the Illinois Central. It has been placed in freight service for a few days, and will then be put into passenger service.

---

The Richmond Locomotive Works are busy with a variety of orders, mostly for Southern roads. Among the engines in course of construction are some for the Chesapeake & Ohio, and two for the South Bound road.

## A Bow-Wheeled Railroad.

In a recent issue, the *Railway Age*, which is devoting a great deal of attention to the illustration of railway machinery, gives a very striking picture of the Meigs elevated railway system in operation. There is a fearful-looking train which resembles five overgrown oil tanks with windows at the sides, rushing along on a sort of single-beam elevated structure. The way the wheels are arranged put one strongly in mind of a badly bow-legged man. We are afraid that this style of elevated railroad will never progress far beyond the pictorial stage. Yet it is just the kind of a scheme that will strongly appeal to a certain class of capitalists. The more absurd a thing may seem to an engineer the more certain is it to receive financial support from a speculative class of capitalists, who are numerous.

---

The Brooks Locomotive Works have received another order for locomotives from the Great Northern. Seventeen consolidation and eight six-wheel switchers will be built. These works have also received an order for one consolidation engine for the Duluth, Mississippi River & Northern.

---

The Baldwin Locomotive Works have received orders from the Brainerd & North Minnesota for five passenger engines; from the Clarion River road one double-ended bojie engine weighing 100,000 lbs., and from the Great Northern five freight and two passenger Vauclain compounds.

---

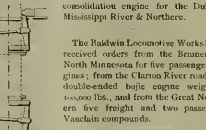
The Illinois Central are in the market for two compound suburban locomotives, to be of the same power as the 18 x 24 double-ender Hudson engines now operating the suburban business. They are going to try the Cooke compound on their famous heavy suburban trains.

## Connelly's Axle Lubricator.

The annexed engraving illustrates a form of car axle and crank pin lubricator invented and patented by Mr. J. T. Connelly, Milton, Pa. The form of the lubricator can readily be understood by a glance at the cut. The patent claims made for the invention are.

The combination, with a journal provided

Fig 1.



Connelly's Axle Lubricator.

with a central longitudinal bore and with one or more transverse bores extending from said longitudinal bore to the periphery of the journal, of a plug secured in the open end of the longitudinal bore and provided with a central longitudinal bore of less diameter than the main bore of the journal, and with one or more transverse bores coinciding with the corresponding bores of the journal.

---

The Chicago & Northwestern about August 1st ordered from the Schenectady Works 15 more 10-wheel engines similar to the 35 received during last spring.

---

The Rhode Island Locomotive Works have delivered two compound locomotives for the Minneapolis, St. Paul & Sault Ste. Marie

The Wisconsin Central are in the market for 30 passenger cars.

In accordance with a law passed by Congress the famous ocean steamers, the *City of Paris* and the *City of New York*, will soon begin flying the American flag. There appears to be an unpatriotic sentiment among a certain class of Americans to employ foreigners in every responsible position connected with our mercantile marine and, of course, an attempt has been made to permit the British officers who now handle the ships referred to, to retain their positions when the vessels begin running under the American flag. We are now pleased to notice that Mr. Egbert P. Watson, proprietor of the *Engineer*, New York, has elicited the information from our government officials that neither engineers nor other officers of the ships will be permitted to hold their positions unless they are American citizens.

The Midland Railway of England has adopted the Pintsch light as the standard method of illuminating their passenger cars. They have already caused the erection of three gas plants at various points along their line, and have ordered lighting equipment for 886 cars. This railway has abandoned the use of the electric system of lighting which they have had in use for a number of years as they found it both too expensive and unreliable for service, and after due consideration have taken up the Pintsch system as being the cleanest, safest and most economical method of car lighting.

A correspondent writing to the Joseph Dixon Crucible Company, Jersey City, about the use of graphite, says "I have used handhole and manhole gaskets eight to ten times by carefully smearing the surface next boiler shell, taken out at periods of three to four weeks, using steam pressure as high as 100 lbs. In packing water glasses, by putting a little graphite and oil in the gasket they would vulcanize as soft as lamp wick and retain their elasticity until the glass was changed, when the old rubber could be removed without trouble, while by the old way, I have spent much time in digging out the rubber baked hard as vulcanite. Another thing I used it for was, after putting back my handhole plate or plugs in back connection, I carefully brush away all the soot and ashes; then with a small brush paint a good coat of graphite over flange, stud and nuts. After running boiler from three to six months, and using coke for fuel, with forced draft, the nuts can be removed without trouble, as the heat has not been great enough to burn the head."

Everything on the German railroads is regulated in military style. There is a time and place for everything. Even the cars must go into the shop after running 160,000 kilometers, whether they need it or not.

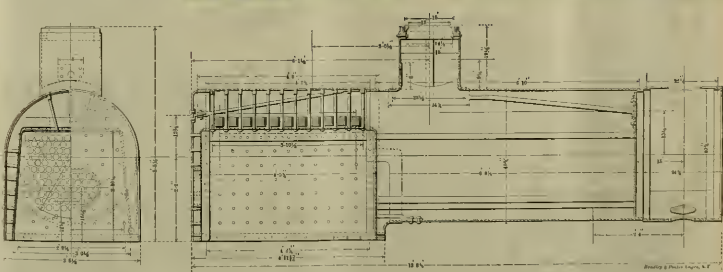
## Coxe Locomotive.

The annexed engravings give a perspective view of the finished engine and a sectional view of the boiler of a dome locomotive designed and built for the Delaware, Susquehanna & Schuylkill Railroad. The engine was designed by Mr. Daniel Coxe, superintendent of motive power, assisted by Mr. William J. Goyne, chief draughtsman for Coxe Brothers & Co., who made the drawings. In the designing, the leading idea was to get as much power as possible in a wheel base of 66 inches.

These engines were built to take the place of four-wheel engines that were formerly employed hauling cars to the coal breakers from distant workings, and they are a decided success. Among improvements effected on the new engines are the use of high nozzles without an extension smoke-box. This is a success, the engine throwing practically no fire even when working in the corner on a heavy grade. The cinders are removed daily through a small hand-hole in the front. Solid-end bushed rods, main as well as side rods are used, with very large wearing surface. The straight shoes are without adjustable wedges.

There is such a disposition among the engineers to "monkey" with and improve their machines that it seems the only way to stop it is to make things so they cannot be adjusted at all. The actual tractive power of the engine has been merely guessed at as yet; but in pulling cars it is just about 50 per cent. more than the four-wheel mine engines.

The firebox is a peculiar combination of crown-bars and radial stays. It is a particularly strong boiler and unusually convenient for a small engine. The saddle tank has a capacity of 425 gallons. The engine is equipped with two No. 6 Rue injectors and Nathan's double-sight lubricators.



Coxe Locomotive Boiler.

A curious case concerning the duty of railroad companies in relation to intoxicated passengers, has just been decided by a court in Ireland. A passenger came to a station in a helpless condition of intoxication, and in that condition was helped into a carriage by the railway employés. During the journey that followed, the intoxicated man got out of the carriage while the train was in motion and was killed. His wife sued the company for damages for the loss of her husband and a verdict was given in her favor. The decision appears to be that railroad companies have no right to help intoxicated persons into trains, where they are in danger of losing their lives. The Irish court appears to have great consideration for people who make themselves helpless by the use of intoxicating liquors.

Train robbers sometimes make mistakes with the people they expect to fleece with impunity in cars. A recent dispatch from Denver says: Last night, as the Denver & Cheyenne train on the Union Pacific stopped at the coal chutes at La Salle, two masked men entered one of the cars, and with loaded revolvers ordered the passengers to hold up their hands. Hands in profusion went up instanter, and the fellows were on the point of collecting toll from the astonished passengers when one of the latter opened fire upon the "hold-ups." The latter returned the fire, but one of them getting hit, both jumped from the cars and fled. As near as could be ascertained, the man on the train who opened fire on the "hold-ups" is a member of one of the Wild West shows that have been exhibiting at Denver the last two weeks, and with the show was going to Kansas City.

The editor of *Industry* has a way of making difficult questions plain which we admire. In regard to the Free Coinage of Silver problem he says: "The present ery of free coinage divested of its sophistry, means a privilege of taking 90 cents worth of silver to the mint, and by coining, have it converted to $1.29, in other words, adding a fictitious value of about 39 cents, less seigniorage, if any, to every dollar, or to state it still more plainly, to raise the price of silver 33 per cent by Act of Congress.

A runaway engine on the Chicago, Milwaukee & St. Paul road, on August 5th, caused great consternation near Williamsburg, Iowa. An engine and caboose collided with a dirt train, and the engineer and fireman, seeing disaster, reversed the engine and jumped. The reversed engine piled up the cars of the dirt train and then started backward wild. After killing a horse and a cow it was stopped at Conroy, ten miles north.

## A Test of Constancy.

By Sam Short.

Perhaps it was to answer in season for some of my sins, or perhaps it was the result of a rambling disposition, that shortly after the war I found myself running a locomotive on a poverty-stricken railroad in Georgia. At its best the place was a quarter of natural banishment for a man with any taste for social enjoyments; for sectional prejudices were then at their height and it was made particularly disagreeable to the hated Yankees, of whom I was a representative. After I became a little acquainted the days and nights of my season of isolation from social joys were cheered by the acquaintance of a Scotchman named Donald Fraser, who was boarding at the same hotel. This man was manager of a cotton mill and had been once a railroad man, which attracted him toward brothers of the craft.

Mr. Fraser had been all over the world and carried with him the graces that travel gives to the right kind of people. Some people who travel appear to gain nothing by the experience beyond learning the names of the places where they have been. They would not lose anything by going round blindfolded. Their eyes do not appear to convey impressions to the brain. They bow to the fashion of travel, and their description of every place and country is, "Oh, it was lovely."

Donald Fraser was a different kind of traveler. He belonged to the class that have the gift of seeing—a gift that appears strongly developed among the natives of mountainous countries. Mr. Fraser possessed another rare gift, that of describing what he had seen and of story telling. In early life he had been an engine-driver on a Scotch railway. From there he went to India, as many of his countrymen did, when railways were opening up in Asia. Then he went to sea as a marine engineer, and left that to go railroading in South America. Eventually he found a more restful haven in that Mecca of ambitious workmen, the United States He was a great reader, and took in every department of literature, from mechanics to theology. What he read always seemed to remain within the grasp of his retentive memory. A keen observer of men and things, his mind was loaded with reminiscences drawn from every quarter of the globe.

A man of this sort was a treasure in a region where excess of leisure was cruel oppression to men who found no pastime to while the weary hours away. Fraser appealed to my sympathies on the first evening of our acquaintance by telling me that no country on the globe gave privileges to workmen equal to those enjoyed in the United States. He was an enthusiastic admirer of our country, its institutions and the ways of the people; and was ever ready to give free expression of his views.

One evening as we were all seated around Fraser in the smoking room of the hotel, waiting to get him into the story telling mood, one of the boys asked:

"Why did you come to leave Scotland, Mr Fraser? It's said to be a grand country, and its history makes fine reading for people who like poetry and romance."

"Aye, aye, lad, it's a fine country to read about," he answered, "and it's a noble country to think of as your native land, but it's a better country for a poor man to leave if he is ambitious to be more than a workman all his days, and fears to face the winter of life with penury as his companion."

"Was that why you went away to seek your fortune?" persisted the questioner.

"Yes, and no," said Fraser. "I had sometimes thought that there were better countries than Scotland for a steady industrious man, but I had worked into a pretty good job, and might have remained in it all my working days as many others do, if it had not been that something happened which switched me off the well-beaten path."

"What happened? Tell us the story," came from several voices.

"It's not much of a story, and the motive power that 'sent me over the sea' has been in active force ever since the world began.

"More years ago than I care to count I reached what appeared to be the height of my ambition when I was promoted to drive a locomotive on the Scottish Midland. Few men of my years had seen less care or had fewer misgivings as to the future. Before entering railway life I had been three years at the blacksmith trade Indoor life was daily punishment, for I inherited rambling habits from a Highland ancestry. It is hard to curb in three generations the habits that never have been restrained since the race began.

"In passing, I may say that the Highlanders have been greatly given to following the callings that lead them moving about. As trainmen and sailors and steamboatmen they have made a mark for their race.

"The change from the shop to the foot plate was to me as gladsome as the escape from a cage must be to a soaring lark. A good mother had brought me up to look upon hard work as my natural birthright and a thing that was a blessing to those who learned to enjoy it. Perhaps it was this inspiration that made me the happiest and most contented trainman who ran through the great Valley of Strathmore. That was before the something happened which I spoke about at first.

"The Valley of Strathmore, as people familiar with the geography of Scotland know, extends northward from Perth for 60 miles and embraces some of the finest farming country in the British Isles, besides some of the noblest scenery. Like every naturally rich region it led to much strife for possession in early days, and scenes of strife make stamps on the earth that the sons of man hanker to look upon. The Valley of Strathmore is rich in scenes of historical interest and dotted with buildings that are land-marks in the history of the country I shall not impose upon you a talk on Scottish antiquities, although in my youth I contracted the fad of Burns' friend, Captain Grose, and spent many an hour—

"'By some auld howlet-haunted biggin'
Or kirk deserted by its riggin'.'

"My 'shop' days were often devoted to looking up the ancient relics within reach. The Sedlaw hills form one bank of the valley. Here we have the wood-clad hill of Dunsinane where Macbeth had his stronghold and which was invaded by soldiers carrying Birnam wood. To railroad men there is a more interesting object on the Sedlaw hills than the scene made famous by Shakespeare. The Dundee & Newtyle Railway, the first line built in Scotland, crosses this natural obstacle to transportation. It was in the early days a mixed railway, for part of it was operated by locomotives and part by cables. There was no twisting round to get up and down the hills. The early British engineers believed in going direct to the terminus, and this road was the best illustration of what their policy led to. The cars were pulled up the hill side by a cable operated by stationary engines. On reaching the top a locomotive was hitched on, which pulled the cars to the next 'bank' and handed them over to the cable again.

"I had looked forward to a ride over this line, partly to watch the way it was worked and at the same time to examine an ancient tower in the neighborhood. A bright August day found me enjoying the pleasure anticipated.

"I had spent a delightful day. There were many novelties to be seen in the operating of the road. The old tower exceeded my expectation and I set it down as dating back from the days of the Roman invasion. To settle any question of this kind is naturally a great satisfaction to a youth with a hobby, and I felt that I might yet find something worthy of putting before the Antiquarian Society—an ambitious thought scarcely to be cherished without awe.

"Full of ambitious communings I wended my way to the train that was to take me back to Perth. In the carriage sitting on the opposite seat was a girl whose face quickly distracted my thoughts from the glories of antiquarian research. A man seated on my side of the car was drunk and noisy, and he persisted in addressing his conversation to the girl She had a mobile, speaking face that seemed to express eloquently the emotions of amusement, disgust, shame, resentment and appeal, that were at different times aroused by the words and actions of the drunken man. While in repose there seemed nothing striking about the face, but the excitement roused it into animation and beauty.

"Offering myself as a protector of suffering beauty was a little out of my line, and bashfulness for a time kept me from interfering. To cause a scene in a small car compartment by trying to restrain drunken revelry is generally more painful to those you want to protect than to the offender. We had stopped at one of the inclines and the excitement outside took the man's attention out of the carriage for the time being. But I had made up my mind that should he become offensive again I would try to quiet him. As a preliminary, I motioned to the girl to change seats with me, which she readily did, as the change took her away from facing the man. In the act of changing seats I stopped at the window to watch the process of attaching the cable to the train. As I stood looking the train was pushed to the brink of the inclined plane and by some blunder the cable connection was missed The train had scarcely begun to move when I realized like a flash that the cars were running away. I threw open the door, pulled the girl after me and jumped off The train was 'falling' down the hill side and had gained considerable velocity before we got out.

"A railroad train is going very fast when a nimble trainman cannot jump off without injury. Jumping off a train is something like swimming—easy for one but hard for a pair. In getting off I tried to save the girl from a hard fall and she landed very well, although we did not come to the ground in a dignified fashion. I was not so fortunate, for my arm was broken in the fall. Even with that injury I had reason to be thankful that I did not share the experience of the people who went down with the train.

"The accident was a nine-day talk and I came in for more attention than my retiring disposition relished For ten days I was in Dundee infirmary with others who had been multilated in the wreck. At the end of that time I went home.

"The day after my return to Perth I received a note intimating that Mrs. Clementina Urquhart would be pleased to have me call upon her. The missive was of a particularly stiff and dignified character. I learned that the writer was the mother of the girl I had helped out of the carriage, and that she was one of the proudest and poorest ladies recognized as belonging to the Perth gentry.

"I called on Mrs. Urquhart next morning, feeling more like a criminal than like one worthy of thanks. She received me in a most impressive and ceremonious fashion, and made her daughter, who was no worse of the jump out of the carriage, express formal thanks for the service I had rendered I was abashed and confused with the interview and stammered my regrets at having done anything, at which the girl laughed and the mother looked severe. But that did not prevent her from taking out her purse and offering to pay me for the service I had done to her daughter.

"I had not been reared among the gentry of my native town, but I had enough innate refinement to be shocked and offended at the offer made me by Mrs. Urquhart, and rose quickly to go, full of rage. The lady made some sort of apology and managed to detain me long enough to let me know that I must never presume on acquaintance with Miss Urquhart on account of the unfortunate occurrence that had brought us together. I answered that such a thing had never entered my mind, and took an abrupt departure. I was pleased to see that the girl appeared mortified at the shabby way her mother acknowledged the service I had rendered

"Paying attention to girls was entirely out of my line, and I was far from being so foolishly ambitious as to aspire to a girl away above my social position. But somehow the treatment I had received from Mrs. Urquhart, and being forbidden to see the girl, made me think about her. While I was still idle with my broken arm and rambling round, I accidentally met the girl and she stopped and apologized for what had been said, and expressed the hope that I would believe her to be grateful for what I had done. We chatted pleasantly together for a few minutes and the offense of the mother was forgotten in the sweet appeals made by the daughter's blue eyes.

"This might have ended my connection with Miss Urquhart and saved no end of heart aching and unsatisfied longings had it not been that she lived in a cottage close to the railway. When I began running again I naturally looked for the girl as I was passing At first I seldom saw her but one day she recognized me and smiled. After that I rarely passed in daytime without receiving a nod or smile from the girl, and we gradually came to have that kind of acquaintance. There came to be a dangerous element of secrecy about the acquaintance, for when the mother was about I was not recognized. This nettled me at first, but like every element of opposition it egged me on to think about the girl.

"I found that something new had come into my life. Six months ago my work and my antiquarian studies filled the measure of my existence, and I longed for nothing out of reach. Now my work and my hobby palled. Even reading failed to satisfy. My whole heart appeared to be centered into the brief glances I would have of this girl. I felt oppressed and humiliated at not being better able to restrain my thoughts and feelings, and from day to day kept making resolutions to conquer myself again by a vigorous effort. But day after day passed and the nod and smile from the girl dispelled all my efforts at mental control. One day it suddenly dawned upon me that I was in love with Madge Urquhart.

"It seemed like insanity. I might as well be in love with one of the Queen's daughters. Our social positions were so different that the hope of stepping over the society barriers that lay between us seemed pure madness. All this I understood, but like the moth to the candle I was drawn irresistibly toward the light that was to scorch me.

"I continued to meet the girl after a time. The meetings were repeated secretly. We vowed love and constancy to each other and closed our eyes to the future. Some busy mischief-maker found out that a sooty engine-driver was clandestinely walking in the woods with the only daughter of one of Perth's proudest mothers, and carried the news to where it would cause most excitement. It did raise a storm.

"There are certain quiet, weak-like persons whom everybody is ready to abuse and bully with impunity. They are deficient in self-assertion and appear to fall before every form of aggression, but they are not conquered or suppressed, they have only bowed before the storm, and came up again as serenely as if no tempest had passed.

"Madge Urquhart was that kind of a girl. Her willow-like nature seemed to settle down before the tempest of her mother's coarse wrath, but an hour afterward she was perfectly serene and stand-

ing in the same position she was in before the storm began.

"She would promise nothing to her mother, but when she met me again it was to let me know that we must meet no more. She was willing to wait until I should be in a position to marry her and give her the home of a lady, but she would meet me no more secretly.

"The prospect of an engine-driver ever reaching a position to make what in Scotland is considered a home for a lady, was so remote that I gave it up. I resolved to try something else. At this time the government of India was building railways and giving golden inducements for British railway men to go there. I determined to go to India in hopes of attaining a position that would enable me to offer a suitable home to the girl I loved. She agreed with me that it was the right thing to do, and promised to wait until I should send for her.

"I went out to India in 1856 and had not got settled there when the mutiny broke out. It would be a long story to tell of the horrible experiences I went through in that dreadful country. Nearly all the Europeans in the place where I was were murdered, and word went home that I was one of the unfortunates. Two years passed before I had the opportunity to write home, and I received no answer to letters written to Madge. I concluded that the will of the mother had triumphed and that the girl had given me up.

"A man does not lose his life, or his senses even, when in a strange land he is forced to believe that the girl he loves has jilted him. It is needless to tell of the looked-for letters that never came, the deferred hope that brought no comfort and the constant longing that found no response.

"I remained in India five years and then returned to my native land. My first search was for news of the girl I left behind me, but my quest was in vain. Mrs. Urquhart had left Perth a few months after I went to India, and I could find no tidings of where she had gone. She appeared to have no relatives in the place, and I searched a long time without a clew, but eventually learned that she had moved to Edinburgh. Thither I went, and after another search I discovered that she remained in Edinburgh but a few months and that she had gone to England, to what part I could not find out. I went to several of the larger cities and inquired among the Urquharts, a name that is not common, but without success. The family had vanished as completely from me as if the earth had opened and swallowed them. One day while I was discouraged with disappointment, I met an old acquaintance who was chief engineer of a tramp steamer. He was about to ship a crew and I went with him. That led me to rambling, and since that day I have seen many countries, but I have never seen or heard a word of Madge Urquhart."

That was Fraser's story. He received the only tribute his hearers could bestow, sighs of sympathy. However unwilling we may be to give voice to romance, we all heartily admire those whose lives show examples of devotion and constancy.

The Georgia Central did not come up to my ideas of what a comfortable road to run on should be. A few months' experience running on kinked rails, with engines that were very poor scrap, convinced me that a change of climate would help the shakes that were beginning to make my life a burden.

I started North and to my surprise and vexation found that the malaria went with me. For several years I kept moving from place to place, bent on finding a locality where the chills and fever did not thrive. I was like Christian in the "Pilgrim's Progress," toiling along with the malarial burden on my back, and it seemed for a time that the celestial or some other gates would be reached while I was still shaking.

During this season of unrest I had been advised that Quebec was the place to cure ague, and to Quebec I went. I would have gone to Alaska if it had been recommended. Well, people laugh at the irrational things those who are sick will do in trying to get themselves cured. It is like a drowning man grasping at a straw. I was a good subject for the cranks who have a cure for every disease. I tried them all and was grateful. In the same spirit I went to Quebec and did not get cured.

One evening I was sitting in the boarding-house, debating with myself where I should go next when a fellow-boarder came in and began talking about a dreadful runaway accident he had seen. The driver of a carriage had lost control of the horses in descending one of the precipitous streets. The carriage had been dashed over a ledge of rocks and two ladies instantly killed.

We were naturally on the look-out next morning to learn from the papers particulars of the accident. My interest in the case was suddenly intensified on reading that the ladies were Mrs. Urquhart and her daughter, a music teacher in the city; that the mother was dead, but that the daughter was alive with some prospects that she might recover.

On making inquiries my hopes were suddenly chilled by the information that Urquhart was a common name in Quebec. I was, however, determined to find out if this was not the Miss Urquhart in whom I was interested on account of my friend Fraser.

The ladies had been taken to a hospital and the survivor was in no condition to answer questions. But I set to work with zeal; found out where they had lived and learned that the name of the mother was Mrs. C. Urquhart. By skillful use of a few of Her Majesty's coins, and pretending that I was a newspaper man, I prevailed upon the servants in the house to permit me to visit Miss Urquhart's room. On a quaint-looking dressing-case there was a pocket Bible. On opening it I read the words "Madge Urquhart, Perth, 1855."

The servant appeared astonished at the small amount of curiosity I displayed concerning the room. Half a minute after entering it I was hurrying to the telegraph office. I wired Fraser that his long lost girl was found.

Next morning I regretted having revived the hopes of my friend, for it was reported that Miss Urquhart was dying. Second thoughts convinced me that I had done the right thing in sending for Fraser, if he should only have the melancholy satisfaction of following the lady to her last resting place. Day after day I haunted the hospital gates torn with suspense about the condition of the sufferer. Morning after morning I learned that she was still alive, and encouraged to hope that she would survive at least long enough to see her old lover. It was nearly a week after the accident before Fraser arrived. The girl was still alive.

I need not protract the story. Two months afterward my friend carried Miss Urquhart to the Sunny South to recuperate, but she had changed her name.

Since that time a native of the South named Sam Short Fraser has grown to manhood. His name is testimony that his parents were grateful.

PASSENGER TRAIN RAN INTO A FREIGHT TRAIN THAT WAS BACKING INTO SIDING

During a recent visit of President Van Horn of the Canadian Pacific Railway to a place on the New Brunswick Division, his special train was run a distance of 127 miles in two hours and thirty-three minutes, that being the quickest time ever made over the division. The train was pulled by a locomotive recently built by M. M. Haggerty, at McAdam Junction. The Canadian papers have had a great deal of commendation to make about the run.

## Failed to Inspect the Road.

The Railroad Commissioners of Vermont had a curious experience lately. They went out to make the annual inspection of the Bennington & Glastonbury road, which is about nine miles in length, and runs up into one of the world's "end places" in the Green Mountains. It was built twenty years ago for the purpose of getting off an immense track of timber lying in the several townships. No regular trains have run over the railroad during the last year and a half, and it is probable that the line will be abandoned in time. A large portion of the timber has been cut off, and as a consequence it does not pay to operate the road. The rails are badly bent and worn and many of the ties are so rotten that they will not hold a spike.

When the party got about half way along this interesting railroad the engine jumped the track, and for a time it appeared as if the remainder of the trip must be made by walking. The incident happened on a steep ascending grade, and the car was uncoupled and ran back by gravity. The commissioners have for the present deferred inspecting the whole of the line. The locomotive is supposed to be still in the ditch.

## Short of Rails.

Section Foreman Mike, of the —— Railroad, had begged frequently for supplies. He was especially short of rails for repair work. Matters ran along for some time, track not improving and supplies growing scarcer and scarcer. One day the superintendent was out on the road, and while on Foreman Mike's section the train was suddenly brought to a standstill by a flag. On inquiry as to the cause, the superintendent was quietly informed that there was a bad rail just ahead, and that the train would have to be held until the section gang could take out a good one from just behind the train and make the track safe. This settled it. A car load of new rail was sent to that foreman at once.

A very convenient and satisfactory device for displaying placards which show the destination of trains or cars, has been adopted by the Fitchburg Railroad at their Boston passenger station. They stretch a piece of telegraph wire alongside of the track at about 10 feet and 2 inches from top of the rail, so it will stand about 2 feet from the side of the coaches. Intermediate guy wires or supports are used as necessary. Placards are then furnished with hooks that will hold the cards at right angles to the coaches. This arrangement enables the station master to place his cards in the most conspicuous position possible, without in the least interfering with the movement of the passengers, and where they can remain until the train has departed. The advantages of this plan are certainly obvious, as they overcome the objections to placing cards in any manner on the coaches or upon a movable stand, which is always in the way. If properly stretched and guyed the wires, it is claimed, are not unsightly, and a card for each coach can be hung upon them without causing them to sag.

The best handles of small tools are made from the wood of the apple tree, which is extremely hard when dry and possesses a fine grain. Moreover, it does not check easily after it has been dressed. In the case of a plane, while the handle proper will be of this wood, the best wood for the block in which the cutting part of the plane is fastened has been found to be second-growth beech which has grown in a clearing. The trunk of such a tree below where the branches start is used for this purpose with the best results.

1 2 CASES.

# BUTLER
# DRAW-BAR ATTACHMENT.

This Company guarantees its device for One Year from application against breakages. If the Yoke or Strap Style is used, we guarantee against Spring breakages and Pulling out of Drawheads or Couplers.

*No other device offers as many good features as the Butler.*

**IT HAS THE FEWEST NUMBER OF PARTS.**

**IT HOLDS THE DRAFT TIMBERS TOGETHER.**

**Simplicity and Strength are thoroughly combined in this attachment.**

These Elements reduce breakage to the lowest point and make repairing easy.

**It requires the least number of bolts and costs less to apply.**

Is being applied to more CARS than any other device on the market.

**Butler Draw-Bar Attachment Co., Cleveland, O.**

(85) H. P., Hillsdale, New Jersey, writes

We have an engine equipped with air-brake, the driving-wheels being 60 inches diameter. If we reduce the driving-wheels to 48 inches how will it affect the power of the brakes? *A.*—Not any.

(86) R. B., St. John, N. B., says

Our climate here is very damp and there is much difficulty experienced in preventing the tin car and cab roofing from rusting out. Can you suggest a remedy? *A.*—The best coating for tin roofs that we have heard of is the Lee composite paint.

(87) A. C., Trotwood, O., writes

How much of the revolution does the crank-pin of a locomotive make while the piston is traveling half-stroke, the full stroke being 24 inches, and the length of main rod 66½ inches. *A.*—The means of finding this out will be found in Sinclair's Engine-Running, page 211.

(88) O. C., Wymore, Neb., says.

My engine has an equalizing discharge valve that does not show over-pressure at all times when handle is in running position. Again the red hand will show 140 pounds, with train line at 80 pounds. It is either no over-pressure at all or it is all excess. What is wrong? *A.*—We suspect that our correspondent gets the handle on lap instead of on running position.

Apprentice, Huntington, Ind., says.

(89) I have an engine running 400 revolutions per minute. I desire to have shaft run 120 revolutions. Please give rule to find size of pulleys. *A.*—Multiply the diameter of the driver pulley by the number of its revolutions per minute and divide this product by the revolutions per minute of the driven pulley. The quotient will be the size of the driven pulley.

(90) B. E., Sydney, N. S. W., asks

1. What is the highest temperature at which the Sellers new injector will work water. *A.*—About 125 degrees Fah. 2. How should a boiler of a locomotive that is to be laid up for temporary repairs be left. A. states that water should be run off and all plugs left out, B. states that boiler should be dried with small fire and plugs replaced. As A. and B. have equal votes we allow you to decide. *A.*—We vote in favor of taking out the plugs and leaving them out. A very good plan is to put some oil into the boiler before running off the water.

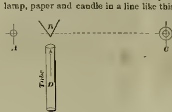
(91) Engineer, Chicago, writes:

What is there in the claim I sometimes hear made that the watches of engineers are liable to be damaged by the magnetism generated in the locomotive machinery unless they are protected? *A.*—The best answer we can make to this question is a statement made by Mr. E. M. Herr, an electrical expert, in a paper read before the Western Railway Club. He said "I have examined for magnetism the different parts of a number of locomotives in actual service, and although they were found in general to be magnetic they were so slightly charged as to render it almost certain they could have no influence upon the rate of a watch."

(92) P. R. L., New York, says

Can you give me an easy method for finding out the candle-power of a gas-jet or lamp?—*A.* Roll a piece of writing or other stiff paper so as to make a tube an inch in diameter and say one foot long.

Take a sheet of stiff white note paper folded once. Open it partly and stand it on end near the lamp to be measured. Light a common wax candle and place lamp, paper and candle in a line like this:



*A* is the position of candle, *B* the sheet of note paper, *C* gas or lamp to be tested, *D* the tube.

When these are in line, close one eye and look through the tube with the other at the projecting edge of the sheet of paper. The two parts of the sheet will appear unequally illuminated and the projection of the paper toward the tube will be readily seen. By moving the candle to the right or left, a point will be found where both sides of the sheet will be equally lighted and then the sense of the projection will disappear and the note paper will appear flat when examined through the tube. Next carefully measure the distance from *A* to *B* and from *B* to *C*. Divide the large sum by the smaller and the result will express the candle-power of the lamp *C*. For example, if it is 3 inches from *A* to *B* and 9 inches from *B* to *C*, the lamp at *C* has a photometric value of 3 candles.

## Air-Brake Lever Arrangements.

By Paul Synnestvedt.

On pages 44 to 55 inclusive, of the Westinghouse instruction book, will be found considerable instruction on this subject, but the writer has found in his somewhat limited experience that there are but very few men who have anything like a clear understanding of the principles involved, and some of them know absolutely nothing about it. Many are able to figure out a leverage of the standard Hodge or Stevens system, as the numerous formulæ given in different books all apply to that class, but when they are confronted with anything that is a little out of the common run of design they are at a loss to know how to proceed, and finally have to get some technical man to do the figuring for them, or else, not wanting to acknowledge ignorance, they "guess" at it, and the result is, as might have been expected, a design that is a disgrace to the community and a menace to the safety of the traveling public.

To find confirmation of this we need but to look around us at the different cars running on some of our most prominent roads, especially those belonging to private corporations or shippers. A few of the cases that have come under the notice of the writer may be of interest. One was a whole train of circus cars that were equipped with air-brakes, but only applied to one end of truck, there being no brake at all on the other end, the one equipped having a leverage of more than 100 per cent. of the weight carried by it, and this unevenly distributed on account of there being no dead lever, the lower tie-rod being attached directly to the beam. Another case was of some passenger cars that belonged to a road that had been troubled with flat wheels and remedied (?) the difficulty by gradually reducing the leverage until there was only about half of a brake left.

There seems to have been, however, the greatest amount of originality exercised on the tender-brakes, and some of them are indeed veritable wonders, fearful to behold, when we think of the amount of brain work that must have been expended in formulating the design.

There are some roads that have the rest of their equipment in very good shape; that have, I was going to say, dozens of different lever arrangements under their tenders, and still the writer has never been able satisfactorily to determine whence comes the existence of so great a variety. Some of them are wonderful combinations of wheels, chains, pulleys and yokes, and others again are so simple as to have no equalizing features at all; but as the adjustment of the slack is tighter or looser on one truck or the other, all of the power is thrown on sometimes one side and sometimes the other, resulting in the breaking of beams, sliding of wheels, and various other difficulties, cited as very peculiar by the expert in charge.

Probably the best way to get a good brake arrangement is to get the air-brake company to make it, but even then there is much more certainty of securing just the thing needed if the parties making the request are sufficiently well posted to understand what data are required, so that the designer will not have to guess at some conditions that may be very essential. For instance, when he is furnished with a drawing from which to work, he should also be told for what kind of service the car or engine is intended, what is the nature of the road over which it is to run, what proportion the load is of the light weight, whether it is to be used only on a line where the apparatus is such as to make it tolerably certain that the train-pipe pressure will be kept accurately within the limit prescribed, or whether it is likely to be used on one road having 70 pounds as a standard, and the next week on a road that has a standard of 90 pounds or possibly no standard at all except the watchful care of the engineer.

Finally, although generally this is not given much consideration, whether the wheels are cast or steel, and the kind of shoes that are used ought to be noted, for as is well known there is a great difference in the holding capacities of different shoes, and this again varies greatly with the kind of wheel used.

The proper method of procedure in laying out a design for a brake arrangement on a new car is, first, to put in the size and style of brake-beam lever that seems to best fit the construction of truck, then locate the reservoir and cylinder in the most convenient place, not forgetting the very important fact that the cylinder must be oiled occasionally and the triple-valve cleaned, and making due allowance of space so that they can be readily reached for that purpose, then proportion the cylinder levers so as to secure the proper amount of braking power on the car, tender or whatever it may be.

It is sometimes found that the construction of the car is such that an odd arrangement or proportion of brake-beam levers must be used on account of limited space, but it is preferable whenever possible, to make changes in braking power by alterations in the cylinder levers, and this should be done after having first located the cylinder and mapped out the general design. The fact that the brake-shoes wear must not be forgotten, and the piston must be given room for full travel and not as we found to be the case on one car, let it strike a beam at 7 inches stroke.

Finally the standards of the Master Car Builders' Association should be followed just as closely as possible, not only as regards general proportions of rods and levers but also in all minor details, in order to facilitate repair work and decrease the amount of stock necessary to be kept on hand.

## Recovery of Steel Rails from a Wreck.

Attempts to find treasure hid in the depths of the sea have often been costly failures. The Pacific Coast is, however, the scene of a very business-like transaction. An enterprising citizen of Spokane purchased a wreck and its cargo of steel rails. Thirty-five men are employed in the work of recovering property; four of the employés being professional divers, who receive $10 per day for four hours work, and $4 per day when not occupied, and whose suits cost $5 per day. When the tide is low the wreck lies in twelve feet of water, as against twenty-four feet at high tide. The men prefer working during high tide, as the lower portion of the water is then less agitated. Four rails, amounting to a ton in weight, are raised at one time, two engines doing the lifting, and in good weather from fifty to one hundred tons can be raised in a day. After the rails have been taken from the wreck, they are loaded in wagons, and hauled along the bank for five miles, after which they are placed on a private railway and conveyed for another mile to a harbor where they can be transferred either to railways or vessel. It is estimated that the cost of transportation from the wreck to Portland is $5 per ton, and the selling price from $50 to $60 per ton. As the cargo amounts to 2,300 tons, it will be a comfortable business transaction, provided all the rails are safely removed. It is stated that the rails have not been at all injured. Before being loaded on the ship they were covered with coal tar, and when this is removed the red sand of the blast remains attached to the steel.—*Railway World.*

After fifteen years' experimenting, the Pennsylvania Railroad Company has decided to discontinue the use of steel ties. The steel ties are found to be too light, and they cannot be kept in line or made to take hold of the ballast firmly. The company has placed an order with the Pennsylvania Steel Company for 2,000 tons of steel rails, weighing 100 lbs. to the yard. The heaviest rail now in use on the tracks of the Pennsylvania Railroad weighs but 85 lbs. The new 100-lb rails will be laid as an experiment on the mountain division of the main line.

A polite colored man in Orange, N. J., recently became possessed of a desire to sneeze while riding on a street car. To avoid offence, this sensitive individual thrust his head out of a window and came in contact with a center pole, during which connection his skull was seriously injured. This is not casting reflections on politeness. It would rather imply that trolley companies with center poles stuck with three inches of clearance ought to make certain that passengers will not be able to push their heads into danger.

A correspondent who says he is a fireman on the Pennsylvania Railroad sends some alleged data of water and fuel used by two-cylinder and four-cylinder compound locomotives, at work on the road, and asks us to explain the cause of the difference. The letter does not give name or address of the writer which we require as evidence of good faith, consequently we have to decline discussing the subject.

It is stated that secret instructions have recently been sent to the managers of all the Russian railways not to enter into contracts with foreign firms, nor to admit foreigners into their service.

## A London Railway Station.

The handsome photo-engraving on this page represents a corner of one of the train sheds of Charing Cross Station, at the outgoing end, showing a South Eastern express engine ready for her run with the boat train to Dover, and a suburban engine on the left.

An excellent specimen of English bull's-head rails, with their cast chairs, can be seen in the foreground; observe the wooden wedge that holds the rail in the chair.

These are the outgoing tracks for two of several platforms and the signals, seen over the suburban engine are for these two tracks alone; in front of where the engines padded stalls for two horses, a place for a carriage, harness and a compartment for the groom or coachman.

It is no uncommon thing for people of means, even moderate means, to take their horses with them if they go visiting in the country; surely, if they spend Sunday or a week at the sea shore.

By giving notice the day before you can torias, traps or dog carts into these special cars, the like of which there is not one in all America.

Horse-boxes are hauled on local passenger trains or fast goods trains, and a fixed fare per mile is asked.

The carriage having a cupola and a bay window, immediately behind the express engine, is a mail car.

At Charing Cross Station, London.

Charing Cross Station is just in the center of London, only a few blocks from the Houses of Parliament and Westminster Abbey on the one side and Somerset House on the other.

The station is reached by an elevated structure for a few squares to the approach of the bridge over the Thames.

stand there are numerous bridges, posts and targets with signals on them.

One peculiar thing seen in all these English stations is the horse-box platform At one platform at the inner end of the station, a track is given up to the loading and unloading of horses and carriages.

A horse-box is a four-wheeled car, with have a horse-box placed at any remote station for you, and at large ones they are always ready.

The writer had a room in the Charing Cross Station Hotel for a week, where he could see the outgoing trains, and remarked every morning from one to half a dozen coachmen loading carriages, vic-

The double ejector on the side of the arch of the express engine is the vacuum producing jets for the automatic brakes.

There is one thing about this kind of a mill, the engineer can't kick about the fireman's being too lazy to clean the paint on ceiling of the cab roof.

## The Underground Railroad of London--A Comparison.

*Editorial Correspondence.*

There has of late been no end of talk in America, and especially in New York, about the underground system of rapid transit, and thousands of articles written against the elevated system—Jay Gould's spider, Hain's alleged railroad on stilts, etc., etc.

While in London, I rode over all the underground system of the Metropolitan road, both on the engines, to study the road, and on the trains, to study the accommodations.

In the first place, the underground system starts off with the advantage over the elevated that it does not disfigure the streets. If you did not run across its stations now and then you would never suspect its presence under you. Stations are usually on corners and the train is often at one side of the street there, and in the open daylight, but it soon hunts a hole.

But its being off the streets is not an unmixed blessing, the elevated roads of New York can be seen from any cross street in the city, and a stranger in any locality knows that by walking to the structure he cannot get more than two blocks from a station as they are on an average, but five blocks apart. This is a great convenience.

The underground roads use condensing engines and the enginemen are all experts on smoke prevention, yet the trains are always close, dark, damp and muggy. It is practically impossible to ventilate them, while our elevated trains are the lightest and best ventilated that can be found.

The underground road charges per mile and has first, second and third class. A very large per cent. of their passengers ride third class and are charged the parliamentary fixed fare of one penny per mile—two cents American money; therefore, to ride ten miles, third class, on the underground, would cost 20 cents, while the same ride on the "L" can be had for 5 cents. The "L" is cheaper for long rides, yet the average fare per passenger on the underground is 3.40 cents, showing that a large proportion of the passengers travel but short distances.

The average speed on both roads is about 15 miles per hour, the average stops on the "L" are but 15 seconds each. I have no figures of those on the underground, but I venture the assertion that they are much longer. It takes a long time to close thirty or forty doors on the side of a train, and, the people having no one to hold a gate half open and yell "step lively, please," take their time.

The underground station is hard to ventilate, to keep clean and light, dust and dirt blow into it—it blows *off* the elevated station. The stations are not as clean as ours, and are the sole instance of the kind I saw in Europe, the surface roads have far superior and better kept stations, as a rule, than can be found in our country.

The underground brakeman (guard) can pronounce the name of a station just as vaguely as can the average Third avenue man—either of them give the password of some Chinese lodge, and both have forgotten the English language. The underground man is on the station platform and hard to hear. The advertising is worse there than here, and all stations are named "Sunlight Soap"—you can't find the name half the time.

The underground operates 34.15 miles of track, the "L" 36.21, but the underground has branches out into the country, mostly on the surface.

The underground employs 71 locomotives and 152 passenger cars of all classes, besides over 100 freight, horse and other cars. The "L" employs 243 locomotives and 950 passenger cars, using only enough freight cars to collect the ashes and dirt from the stations.

Trains on the "L" are much more frequent and less time is put in in waiting at stations.

The London road has great opposition in another underground system operated by electricity, in numerous tram car lines and omnibus routes, to say nothing of the suburban business of all the big roads, most of them coming into the heart of the city underground or elevated.

THE POWER.

The engraving on this page will give our readers an idea of the engines employed on the underground system. These machines are heavy, four-coupled, eight-wheeled tank engines, having cylinders 18 x 24 inches, with 5½-foot wheels. They have inside chests, as can be seen, and are arranged to exhaust up the stack, or into the water tanks, thus becoming condensing engines.

The large pipe seen extending back to the tender is one of the exhaust pipes, and just over the cylinder is shown the valve that controls the direction of the exhaust steam. This is operated from the foot-plate—one cannot say cab, all there is is the little sheet-metal board standing up on the boiler-head with two round glasses in it, called the "spectacle plate."

Where the exhaust pipe enters the tank can be seen an oval cast-iron pipe a couple of feet high. This is the final exhaust into the air and out of the one on either side comes a clearly defined puff of steam at each exhaust. This makes it very warm, damp and cloudy for the crew who are right in the steam.

The two arched steam pipes just ahead of the spectacle plate are those to the vacuum brake-jets.

Hot-water pumps are employed to feed the boiler, as the water gets too hot to be handled with the injector.

The engine can make but a few miles (one trip around the circle) before the water in the tanks becomes too hot to anywhere near condense the exhaust steam, then it is let out and a new supply taken from a crane. There used to be a great valve under these tanks, two feet in diameter, to drop the water quickly, but these were awfully heavy and clumsy, now they have an arrangement to drop the water in smaller volume all the way between two stations, so that they reach the plug with an empty tank.

These engines weigh 46 tons (of 2,240 pounds) or 103,040 pounds, which is more than twice as heavy as the power of the elevated, the biggest engine on the latter having but a 12 x 16-inch cylinder, weighing 47,000 pounds, and the great majority weigh less than 45,000.

The name on the buffer is the destination of the train, and there is a large number of combination signal lights on the buffers and at the end of the tanks that tell the destination of trains and distinguish the trains of other roads entering the city over these lines or running to connect with them.

The quarters of the crew are very cramped and hard. They are in an iron box having two gangways less than 18 inches in width, without roof, seats or cushions. The "driver" is on the left side and the fireman goes at his work left handed.

The fireboxes have large brick arches and a deflector-plate over the door. This is a sheet of ¼-inch iron about 2 feet long, bent to fit the upper half of the firedoor hole, and having on one end a ½-inch flange that prevents its dropping into the firebox. On this end is riveted a short iron handle. The firedoors slide from the center each way and are operated by a lever on the engineer's side. The fireman takes out the deflector-plate at each fire and sets it aside, replacing it after he gets his fire in. The engines steam pretty well, and great care is taken to prevent smoke. Coal and coke are both used, coke usually.

One curious thing I noticed about the exhaust pipe up the stack, and that was the absence of division between the exhaust pipes of the two cylinders. There is a copper pipe straight across the arch from one of the large valves in outside pipe to the other, and in the center, under the stack, there is a T with its open end four or five inches above the cross-pipe and nothing to prevent the exhaust from one cylinder from showing a back-pressure "hump" on the card of the opposite cylinder; but the wheel is so large for the speed run that it is said that no bad results can be seen, as each exhaust has plenty of time to get out of the way, but of course this is not used continuously. On the cylinder can be seen a small oil cup, used almost universally in Great Britain. This cup has a valve in its stem that is closed by the steam pressure and opened by the partial vacuum caused by the pistons after steam is shut off. Above this valve there is a very small cavity and above that a hollow stem extending up into the cup and filled with a woolen feeder. When the engine is using steam the feeder quietly gets in its work and fills the little cavity below the spindle, and this dose is drawn directly into the cylinder as soon as steam is shut off. There are usually other lubricators, often on the chests and often in the steam-pipes. A flat-valve throttle being used it is hard to handle unless means are provided to oil it.

Like other roads in the same country, they use short fronts, open stacks and no netting of any kind, this allows the use of a larger nozzle, and no fire is thrown.

Some of the engines have a steam-reverse gear that looks for all the world like a Westinghouse air pump but these are not popular either with the men or the management.

THE SHOPS

are located at Neasden, N. W., a station on one of the branch lines and out of the heart of the city. The buildings are good and pretty well supplied with tools.

Mr. John J. Hanbury is the locomotive and carriage superintendent, and a very pleasant gentleman I found him. I noticed in the shops that the valve-yokes had a horn on the front of them to run in a bush in forward end of chest and act as a guide the same as often used in this country, but as the chest is cast on to the cylinder this style of yoke could not be gotten in and out if made solid, the horn is keyed into a taper hole in the front of the yoke, and as this can be uncoupled in the chest the yoke proper comes out easily.

Many of the engines have wrought-iron eccentric straps but inside of these there are cast-iron half circles with brass distance pieces between their ends and the lugs of the strap. These wearing pieces are recessed into the strap and have no other fastening.

Like all English roads they do extra nice wrought-iron and boiler work, the stacks are wrought-iron with the base flange welded and as smooth as glass. The domes are welded up, the lower flange turned out and the upper one turned in and thickened a third in the process.

The cars carry sixty and eighty people and weigh 31,000 pounds. The elevated cars weigh 30,000 pounds and seat forty-eight persons, while forty more can stand in them. Both roads pull about the same number of cars.

Most of the passenger stock has six wheels, each pair set in jaws solid on the

LOCOMOTIVE OF THE LONDON UNDERGROUND RAILROAD.

frame, some have eight wheels, using what they call a Bissell truck, the end pair of wheels having a radius bar something like our pony engine truck, with the back end fulcrumed over the center of the other axle. This pair of wheels carries a portion of the load, but I could not see how it did any guiding, and the rigid pair generally proved that they did most of this work by the condition of their flanges.

Wrought-iron wheels can be found under

| | MET. | MAN. |
|---|---|---|
| Train miles made in 6 months by passenger trains... | 1,030,132 | 4,268,548 02 |
| No. of passengers carried | 43,816,342 | 105,753,101 |

| Coal burned per mile (6 mos ending Dec., 1891)... | 35 91 lbs | 42 05 lbs |
| Cost of operating per train mile ...... | $0 26 18/100 | $0 64 |

These figures go to show the immense volume of business done on the elevated, and at the same time show the extra ex-

WRECK OF THE "CITY OF CHICAGO"—FIRST DAY.

all the old stock, but the new has the now very popular wood wheels. These have iron hubs and rims, and are a plate wheel made up of triangular pieces of four-inch hard wood with the grain running radially from the center of the wheel.

All car boxes have an oil cup above the brass with a wick feeder, and three oil pads in the cellar, a great deal of pains being taken to insure oiling with certainty and economy.

Wood brake-blocks are used and automatic vacuum-brakes. There are no heating arrangements on the cars of any kind.

Half of the space taken up by the enormous buffers is now saved by making cars with buffers on one end only and letting the buffer of one car rest directly against the frame of the next, but these trains have to be run solid and not mixed up with other stock.

All the trains and most of the stations are now lighted with Pintsch gas, and some of the stations are supplied from large holders permanently located on flat cars which are taken to the works to be re-charged, some fourteen of these cars are in service.

The permanent way is good, and the block signal system up to the high English standard. Bull's-head rails are used, but these are not reversible, as is almost usually supposed to be the case in this country; the lower part of the rail is smaller than the top. I was told that a turned rail was the "jiggliest" thing ever discovered in Europe and some years ago abandoned. The ties are farther apart than ours, and the cast chairs held down by spikes, screws or a combination of either with a wooden pin, the rail being held in the chair by a huge wooden wedge; rail joints are usually of the suspended order—between the ties—and the fish plates inclose the whole base of the rail.

I noticed several large stacks of hay near the shop, and found on inquiry that it had been gathered along the grade of the open country branches and sent into the shops for sale—an economy that American roads, with ten thousand times as much hay to burn, never think of.

When I was in London the directors of the Metropolitan had just made their semi-annual report to the Board of Trade; this was for the six months ending June 30, 1892, a copy of which was furnished me. The Manhattan made a report for the Interstate Commerce Commission covering the same period exactly, and a comparison will readily show how much more work is done by the elevated over the same length of road as the underground.

pense of "forcing" power. The elevated concentrate a great deal in a little engine weighing less than one-half what the underground machine does, give it about the same load, and, are therefore, obliged to burn fuel fast, which is always more or less wasteful. The underground engine has a comparatively big boiler, a large wheel and cylinder and is very economical of fuel, running as it does most of the time with natural draft.

Another item is that for six months per year the little boiler of the "L" engine is called upon to heat a five-car train, while the underground train is not heated.

Whatever the difference in cost of operating the two systems, the fact remains that for the convenience, cleanliness, comfort and health of its patrons, the elevated of New York is far ahead of the underground of London; the trains are more comfortable, the service much more frequent and the cost nominal—less for long rides and more for short ones. The difference in expense of operating is largely due to better wages paid here than there. Engineers there get from seven to eight shillings ($1.75 and $2) as against $3 to $3.50 on the elevated; this, however, is not all to the advantage of the men, as I took considerable pains to see how these men lived and how much it cost them, and I found a big difference between the purchasing power of a dollar in that country and this, rents and clothing being far cheaper—but more of this at another time.

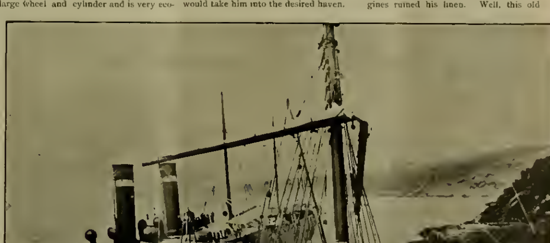
On another page will be found some interesting figures of the business of the elevated road, that could not be used as a comparison in this article. JOHN A. HILL.

## A Wreck—Mistaken Signals.

I came home from Britain on the *City of Berlin*, of the Inman Line, and had the satisfaction—I could hardly say pleasure—of seeing a first-class wreck at sea.

Sometime in July, the sister ship to ours, the *City of Chicago*, was wrecked on the Irish coast at the Old Head of Kinsale, an hour's sail from Queenstown harbor. We went close by her and I had a good view of the fallen queen.

The small picture shows the ship the morning after she struck. The night before was black with fog, and the captain of the *Chicago* was on the bridge, he saw a signal-light on the shore, and decided that it was a well-known light to the east of Queenstown harbor, which he was trying to make, and accordingly steered a course which to the best of his judgment would take him into the desired haven.



WRECK OF THE "CITY OF CHICAGO"—SIXTH DAY

The ship was driven into a sort of cave in the rocks almost up to her foremast, and there she stuck.

All the passengers were taken off safely, some climbing a rope ladder over the rocks and others going in open boats to a small village some miles down the coast.

The photograph taken the day after the wreck shows the boat in a calm, almost uninjured, apparently; but unlike a railroad wreck, which lays still after the first crash unless fire breaks out, a wreck at sea is never let alone. The tide lifts and lowers her, grinding her weight against her wounds, and tons of water in wave after wave beat her against the rocks.

The large picture shows the unfortunate boat as she appeared the sixth day after the wreck. The mountainous waves had actually broken her in two and thrown her stern around against the shore. In this position, with the waves washing her decks, I saw the *City of Chicago* on August 25th, as her sister ship bore myself and 1,200 other passengers away toward New York, the cholera scare, and—home. J. A. H.

## The English Spotter.

"Do you hevver 'ave watchers in America?" asked the old English engine-driver, as we stood up behind him on the footplate of his baldheaded, bell-less and cab-less mill, bowling along at fifty miles an hour.

"Watchers, did you say?"

"Aye, lad, tellers."

"Tellers, you mean in banks?"

"No, no, lad; blooming rascals who are set to watch you and report something, carrying a man on the engine, making black smoke, throwing fire, or leaving the dampers open."

"Oh, yes, we call 'em spotters."

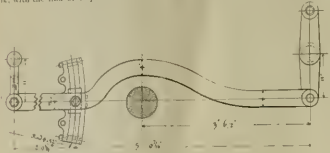
"Spotters, a good name for a rum set of brass rascals. We just had a rare good case. One of 'em, a noted old poacher, too, was sent out to a certain place on the road to report all engines that threw smoke—some fine haired gent had writ a letter to the paper saying as how the engines ruined his linen. Well, this old poachin' teller 'unted rabbits all day and then sent in—by guess—the number for several engines that were bad for smoke. 'E warnt a good guesser, and put down the numbers of two engines that were in the shop, and when they fined one of the men ten shillin's an' tried to get it out of his pay they found he'd been dead for six weeks. The liar is livin' with his wife's relations now."

## McConnell's Plan for Hanging Motion Bar for 10-Wheeler.

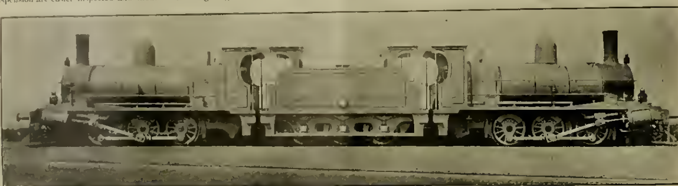
The accompanying sketch shows the plan adopted on the U. P. road for hanging the motion rod for 10-wheelers.

Instead of a short hanger in front of the link, with the link block pin in the end of the bar, they run the bar past the link and suspend it by a hanger that is just the length of the lower rocker arm.

This makes a much steadier motion, admits of larger bearings on the suspension pins and keeps the bar paralleled with the frame of the engine, while the points of suspension are easier inspected and oiled.



MOTION BAR, U. P. TEN-WHEELER.



TWIN ENGINES FOR INDIA.

## An Indian Monstrosity—Siamese Twins.

The engraving shown on this page was made from a photograph of a double-barreled affair recently turned out to order by Neilson & Co., of Glasgow, Scotland, for the Government of India.

These are monstrous engines, the gauge of track being 5 feet 6 inches and the cylinders being 19x26 inches.

Twin engines have often been made with the evident idea of having one crew handle both, but here are two freight engines tied up to one tender which is none too big for either of them for ordinary work. If they are pushing on an incline there would be economy in the single tender, but the man running the mill with her head down hill would have more or less grief in carrying water enough to cover the rafters and at the same time keep out of the dome.

## The Unwritten Laws of Travel on European Railways.

In all compartment cars there are, of course, two long seats across the car, each seat usually holds four in first-class compartments, five in second-class and six in third—all the same length.

At either end of both seats there are located small windows but these are not movable at all; there are two doors in each compartment, one at either end, and in these are sliding windows just like those in hacks, the sash slides down into the door and can be raised by a strap and stopped part way up by slipping one of several holes in the strap over a pin, or held entirely up by pushing the bottom out on to a stop.

It is one of the unwritten laws that the person who sits next to the window and facing the way the train runs has absolute control of the window—he sits in the draft. If so disposed he can shut or open the window without consulting the other passengers. Often the two persons at the ends of the seat will consult one another but seldom the other passengers. The one who is on the side from which the wind is blowing will ask the other to open his window wide while he closes his, and *vice versa*.

If one of those fellows who sweat ice water gets next to the window and persists in keeping it sealed a passenger on the interior may ask him to change seats with him so that the others may breathe without endangering his health. This is often done, but whether the man next to the window moves or not is optional with him.

Another law is that "luggage"—to say baggage is to brand yourself an American, over for the first time—will hold seats. A man going out to get a sandwich or to the closets will take down a young trunk with valise handles, a hat box and an umbrella and leave them on the seat as evidence that the claim is preempted. This plan is universal and pretty well respected.

One of the unwritten laws is for each and every person that gets into a pen to try any and every means to keep others out—stand in the door, strew the seats with bundles, assume partial intoxication or insanity—anything to get a compartment as nearly to one's self as possible, the easiest and surest plan being to tip the train conductor or a guard.

In all trains and in almost all cars there is a smoking compartment and one for ladies where smoking is not allowed, but in the others smoking is permitted by consent of the passengers—"one black ball rejects."

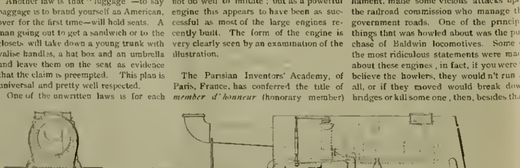
This rule is posted in the compartments of some roads while on others it is the unwritten law. The first experience of the writer on the subject occurred on a Scotch road. The only other being in the compartment was a rough-looking man who eyed me sharply for a few minutes after the train started—much to my uneasiness. At last he came over to me, put his hand in his hip pocket, and said:

"Kin I heve a dhraw at th' poipe?"

In most of the countries the people in a compartment will glare at intruders and try in every way to discourage them about entering the compartment, but on leaving will usually bid each one good-bye very pleasantly.

## French Double-ended Locomotive.

There is an impression in this country that the principal work toward developing extremely wonderful locomotives has been performed in the United States. When we trace the history of locomotive construction in engineering works, we find that America takes a little more credit in this department than what it is entitled to. The locomotive illustrated in the annexed engraving is a case in point. This is a French engine designed and built in 1874. It was used on heavy freight service and was reputed to be very efficient for that kind of work. There are many oddities about the design which our people would not do well to imitate; but as a powerful engine this appears to have been as successful as most of the large engines recently built. The form of the engine is very clearly seen by an examination of the illustration.



A DOUBLE-BARRELED FRENCHMAN.

The Parisian Inventors' Academy, of Paris, France, has conferred the title of *member d'honneur* (honorary member) with the award of the first-class diploma and the great gold medal upon John A Hill, one of the editors of this paper, for his invention of educational valve-models. As the great gilded medal has a string to it that the Academy will let go of only on the payment of $10, Hill will have to struggle along without it for some time to come. The long list of Americans who have put up $10 (names and addresses given in circular) indicate a right smart sprinkling of fools in these United States of America. This society makes a business of selling medals to alleged inventors who have more money than sense and ape after foreign honors (?)—with tinsel on them.

## Causes of Failure.

Few men come up to their highest measure of success. Some fail through timidity, or lack of nerve. They are unwilling to take the risks incident to life, and fail through fear in venturing on ordinary duties. They lack pluck. Others fail through imprudence, lack of discretion, care or sound judgment. They overestimate the future, and build air castles, and venture beyond their depth, and fail and fall. Others, again, fail through lack of application and perseverance. They begin with good resolves, but soon get tired of that, and want a change, thinking they can do much better at something else. Thus they fritter life away, and succeed at nothing. Others waste time and money, and fail for want of economy. Many fail through ruinous habits; tobacco, whisky and beer spoil them for business, drive their best customers from them, and scatter their prospects of success. Some fail for want of brains, education and fitness for their calling; they lack knowledge of human nature and the motives that actuate men. They have not qualified themselves for their work by practical education.—*E.*

Some time ago a labor leader, who had been elected to the New South Wales Parliament, made some vicious attacks upon the railroad commission who manage the government roads. One of the principal things that was howled about was the purchase of Baldwin locomotives. Some of the most ridiculous statements were made about these engines; in fact, if you were to believe the howlers, they would n't run at all, or if they moved would break down bridges or kill some one; then, besides that, there was a "job" somewhere. An investigation has recently been held and the howlers asked to prove their statements, with the result that they were unable to do so and Chief Commissioner Eddy and his colleagues have been entirely exonerated. The Baldwins are running all right enough.

The Eastern Railway of Canada have lately equipped all their rolling stock with the Westinghouse air-brake. They used the hand-brake before.

## A Prize Winning English Engine.

Engine 240 of the SouthEastern Railway, of England, captured the prize in the tests for speed made during the Paris Exposition.

The illustration here shown was made direct from a photograph taken this summer.

The 240 is a typical English eight-wheeler, she has 18x24 cylinders, 6½-foot drivers and 42-inch truck wheels, inside connected.

The affair that looks so much like an air pump on the side of the boiler is a steam reverse device.

The engine is a very fine piece of machine work, she is painted black all over, boiler and all, and all trimming, handles, etc., are polished iron, no brass finish is used.

At the Samuel Moore & Sons manufacturing establishment, at Elizabethport, N. J., we recently observed a very convenient method of transferring power to work by means of an electric motor and the Stow flexible shaft. A great deal of heavy work is done here that is too cumbersome to put to a machine, and they follow the practice of bringing Mohamet to the mountain, since they cannot bring the mountain to Mohamet. By means of this motor, which is light and convenient to carry around, and the flexible shaft, they do drilling, tapping and a great many other operations. One of the most noteworthy improvements in shop practice to be seen at present is the tendency to transmit power by means of flexible shafting. At the Moore Works, the officer in charge said that the drilling of one large cast-iron cylinder of the motor, which it was at work on, saved enough expense to pay for the cost of the motor and shafting.

## How to Tell When Steel is the Proper Heat for Flanging—A Rule.

It is now a pretty well understood fact in this country that steel plate, at a black-hot heat, is almost sure to fracture in flanging, even though it can be flanged cold without showing a flaw.

At the works of Sampson Fox, at Leeds, England, flanging is one of the principal branches of its business. More intricate and better flanging is not done in the world, and they have a simple, easily followed rule for insuring the proper heat.

A hard-wood hammer handle is placed on the sheet, and if it does not blaze instantly on contact, the sheet is heated until it will, if it sparks only, it is not hot enough. The shape of a sheet is never allowed to be changed until this heat is shown.

This is a simple test. Try it.

## Railroad Blacksmithing.

By W. G. Lottes.

I see that nearly all the mechanical branches of railroads are represented in your paper but the blacksmiths, and I think the cause for that is not for the want of argument, or the necessity of information on the subject, but for the want of time, that I have not done more writing in this line, and suppose there is a great many of my brothers in the profession in the same boat.

It must be remembered that there is a tremendous large field to be cultivated in this line, and the cause for not having more of it done is the ten hours' hard labor that is connected with the blacksmith's trade. The blacksmith's trade is not like most other trades; they have not got a minute to study during the ten hours that they stand in the shop.

The fire is ready for the blacksmith before the whistle blows in the morning, and as soon as it blows he puts in his iron and stands patiently over a hot coal fire, watching it every second, which is certainly a strain on a man; and when he has got the proper heat on it, or what he believes to be the proper heat, he puts it under the hammer or on the anvil, grasping the tongs in one hand and the hammer in the other, with a strain on every nerve and muscle in his body; this he is expected to do for ten long hours every day, and six days in the week.

It would be unreasonable to expect writing from this craft or a great deal of reading. Stop and think of it! During the hot summer months we stand over a blazing coal fire, where the thermometer registers from 100 to 130°. After we put in ten hours of this work we have little ambition, or none, to sit down to write or read a great deal about our own trade, which is certainly necessary in any trade in order to keep abreast of the times—more especially in ours.

In the first place we ought to know what the material is composed of that we have got to work up. In order to know this we must read the mechanical papers and writings, or else analyze the material.

When you undertake to convince the average railroad blacksmith of the necessity of this knowledge, the answer is "What benefit will I derive from it? It's liable to get me out of a job." This is true in some cases where you have a jealous-minded foreman, but they are not all that way. There are some, I will admit, that it would be bad policy for any man under them to know any more than they do. I think you will find more of that in railroad shops than others. We all know that railroad shops are run a good deal on the standing plan, more so in the mechanical department than any other. When I say mechanical department I mean the shops. If every man was paid according to the knowledge he possessed of his trade there would be a wonderful change in a large percentage of these shops, especially in the blacksmith trade.

There has been many a railroad accident caused by the ignorance and incompetency of blacksmiths—this may be a strong statement but it is susceptible of proof. How often do we read of some poor fellow meeting with almost an instant death by the giving way of a brake-rod or lever, or step of a ladder, or a draft-iron pulling out, or a switch-rod breaking? They are common occurrences, in fact so common that there is no attention paid to them, not even in the shop where they are made. How often when an accident occurs are they examined, or how many railroad officials have we got, if they do examine them, could give a fair decision? How often do we hear of a side-rod breaking in the weld or a rod-strap in the corner, or valve-stem, or rocker-arm, and it is called an accident and cannot be helped, and nine times out of ten you could blame the material or the man that did the forging.

In the first place the man that purchased the material ought to thoroughly understand both iron and steel, so that when one of these breaks he ought to know whether it was the fault of the material or not. And the blacksmith should know if he was furnished the proper material or not, so that he can work it accordingly, and protect himself in case they blame him.

We see a blacksmith welding two pieces of iron, at what we call a borax heat, and it looks as nice and smooth as any when finished, and may give satisfaction for certain classes of work; but the practice is a poor one, no matter how common or rough the work may be. But when it does give way, the most important part is then to know who is to blame, the blacksmith or the material.

If the material is not what it ought to have been, the blacksmith should be able to tell by looking at the grain of it, and inform his foreman or M. M. that it is not the proper material for the forging, and if he is not furnished the proper material then he ought not to be held responsible.

In fact, it is the blacksmith's duty, when he gets expensive iron or steel, to test it before he works it up. You cannot make a success of tool work unless you test every bar before working it up into tools, and also see that you have the proper grade for the tool you are going to make, as a grade of steel that was made for lathe and planer tools is unfit to use for a chisel or hammer, nor is that which was made for drills and taps fit to use for lathe or planer tools.

If you test every bar as you get it, you will soon discover that there are often poor bars among the best of it.

Very often you will find bars that have been overheated, while others have been spoiled under the hammer by using too heavy a blow for the size bar you are making, which has a tendency to put seams in your bar which cannot be detected until you start forging it or harden it, and then very often they cannot be seen with the naked eye—it is necessary to use a microscope to detect them, and sometimes we find in expensive tool steel some of the impurities of cheap ore, which can only be seen under a microscope, and I will say that you are as apt to find them in expensive English tool steel as in American steel that you pay the same price for you are paying for English steel.

The same rule will to a certain extent apply to iron, as a rule you will find blacksmiths favor a fine, close-grained iron, which is all right for certain classes of work, such as valve stems, rocker arms, guide yokes and links, which are largely made of steel now, and for side-rods and main-rods, but for frame and rod bolts, in fact, all engine bolts except stay-bolts, a loose-grained iron should be preferred, but it should be uniform all through, a pure and clear grain, and the heating should be done in a furnace or hollow fire, as the open fire has a tendency to burn and spoil the grain, especially if the forging is such that a great deal of hammering cannot be done on it while it is at a welding heat. In forging steel more pains should be taken in the first place to get the proper grade and see that it is what it was represented

Gold Medal Engine of the Paris Exposition.

as being not to do as a great many do, simply look for a square, hexagon or octagon bar and then, not knowing what per cent of carbon it contains, use the argument that square, hexagon or octagon steel is better than round because it is finished under the hammer, or perhaps the hexagon or octagon is not as liable to crack in hardening, and the cause for this is that it is generally a milder grade of steel, intended for chisels or similar tools, and will stand more abuse than the round steel, because the round is generally intended for taps, reamers, drills, etc., and contains a larger percentage of carbon, and is more liable to crack in hardening, especially if heated the same as hexagonal or octagonal, and that is one of the greatest difficulties to overcome in hardening, especially in expensive tools, such as large and irregular-shaped milling cutters, reamers, taps and dies.

But when some of our steel manufacturers will put what they call temper marks on every bar of steel they send out, for toolsmiths to be guided by, for instance, "No. 3, suitable for dies, large taps, reamers, punches, hammers, cold sets, track chisels, smith's tools, large shear blades, etc., welds easily and hardens at a cherry red."

"No. 3½, suitable for punches, shear blades, plane irons, large circular cutters, etc., welds easily and hardens at a cherry red."

"No. 4, suitable for cold chisels, small punches, taps, reamers, stamps, mining drills, etc.; weldable; harden at a cherry red."

Now, some of our steel makers ought to ask the different nurserymen to sell only such cherry trees as will bear a certain color of cherries, and that ought to be a very dark color. As it is now, the Minnesota toolsmith has the advantage of the California man, for it is principally choke cherries that are raised there.

Or else ask the California fruit raiser to stop shipping his cherries to Western States, or else send a sample of cherries with your steel, but I don't know how that would work in the month of January.

I would like to have somebody, in the near future, explain how to get at that cherry red. For this same steel company sends out the following instructions.

"We beg to call special attention of the user of steel to the importance of studying its different tempers, with relation to the various purposes for which it is required. Temper means percentage of carbon combined with the iron to produce steel, and has no relation to price.

"The quality of steel means the absence of phosphorus, sulphur, silicon and other impurities, and can only be secured by the selection of the purest ores, which are costly in proportion to their purity. For the convenience of our customers, every bar of our steel bears a label showing purpose for which that particular temper is suitable.

"This temper is signified by number on the label, and for additional security stamped on the bar in the center, so whenever a customer requires the same temper again he can have it by simply giving the number. By this means we put it in the power of every user of steel to select that temper which suits him best. The lowest number is the mildest steel, the percentage of carbon increasing as the numbers advance."

*(To be continued.)*

The Eugene V. Debs Publishing Co., of Terre Haute, Ind., publishers and sellers of books on railroad subjects, are already doing a thriving business. Several new works are in press, and the demand for standard works has taken a spurt, owing to the advertising put out by Mr. Debs.

## To Take Lime or Other Scales Out of an Injector.

When an injector becomes scaled up it often does more harm than good to attempt to remove the deposits with tools.

Scale can be removed very thoroughly by immersing the entire injector in a liquid compound of one part muriatic acid to eight parts of water.

Leave the instrument in the bath as long as it boils; when the scale is dissolved this boiling action will cease. In time the acid would injure the brass, but it will not hurt to leave an injector in over night; two hours, however, is usually long enough to do the work. Should the scale dissolve too slowly, a stronger solution, say one part acid to six of water may be used.

This receipt is worth remembering and may save lots of trouble where injectors, checks or other valves and cocks are partially filled with lime.

The acid solution must be kept in a stone, glass, or lead vessel.

## A Hard Tire.

On the C. B. & N. they had an engine that broke a pin on one side twice within a few weeks. The last time they found a twisted axle and other evidences of severe strains; this was somewhat of a mystery until they came to turn the tires, when it was found that one of them was so hard it could not be turned.

General Foreman Allan McDuff had the tire taken off, well heated and laid on the ground with a band of iron both inside and outside of it. Here it was carefully covered with ashes and left over night and put on the wheel-center next day without cooling. Subsequent wear proved that they had got what the men call "a good scald" on it; it was as soft as the others.

This instance may point out the trouble in other similar cases; this tire was so hard it had less adhesion than the others, and when it let go threw its proportion of the strain upon the other wheel, and its pin was not strong enough to stand it.

Many a slipping engine has been "caught" on one pipe of sand and the slipping side twisted its axles, or bent or broke its pins.

## Tiled Secrets of the Tank Shop.

In only one instance was the philosopher of the L. E. refused admission to a shop in Europe, and that was at the works of Byer, Peacock & Co., at Manchester.

None of the firm were at the works, and after three or four men had come into the waiting room and pumped him a little and then went outside and held a whispered consultation, they decided that they could not, singly or collectively, take the fearful responsibility of admitting a blooming foreigner into the sacred works.

The philosopher knew that the place was mighty little different from other works of their kind and was doing very little just then, and so went away just as happy as if he had been allowed to see the wheels go 'round and sleep with the shop secrets. When going away in the rain, and a tram car, the philosopher could not help thinking of Bobby Burns, the Scotch poet, and the Carron works. At Carron, Scotland, there is an iron works once famous for making a short, heavy, cast cannon, much used on shipboard up to half a century ago. Burns on visiting Carron was refused admittance to the works, and in humorous revenge wrote the following verses on the window of the inn:

> "We came na here to view your warks
> In hopes to be mair wise,
> But only, lest we gang to hell,
> It may be nae surprise.
> But when we tirled at your door
> Your porter dought na hear us;
> Sae may, shou'd we to hell's yetts come,
> Your billy Satan sair us."

## A Boy's Locomotive.

Many a boy with a mechanical turn of mind has started to build a locomotive, but very few have ever finished one that would work and that looked anything like an ordinary every-day locomotive.

An exception to this rule is shown in our illustration, the boy and his work.

Stephen L. Pagenhardt is now 19 years of age and works with his father, who is a gunsmith. Three years ago young Stephen started to build his little engine and has worked at it during his spare moments ever since, having been a little over 3 years in completing it.

The principal dimensions are as follows:

Gauge of track 7¼ inches.

Cylinders 2 x 2½ inches.

Steam port 1 1/8 x 1/8 inch.

Exhaust 1 1/4 x 3/16 inches.

Travel of valve 5/16 inches.

Throw of eccentric 5/16 inches.

Diameter of drivers 6¼ inches.

Total wheel base 26 inches.

Top of rail to top of stack 17½ inches.

Total length of engine and tender 64 inches.

Diameter of smallest boiler ring 5¼ inches.

Firebox 6½ inches long by 4¼ inches wide.

Twenty-three ½-inch tubes 1[illegible] inches long.

Tender holds 3 gallons of water.

Total weight of engine and tender, ready for road, 1[illegible] pounds.

Young Pagenhardt has 2[illegible] feet of track at his home in Westernport, Md., and over this line the little engine has carried four persons. Coal is used as fuel.

The builder expects to exhibit his engine at the World's Fair in Chicago next year.

"Little Maryland."

## Too Much Comfort.

Stepping upon an English passenger engine in the Charing Cross station, London, we took a survey of the footplate and its attachments, and, with a view to striking up an acquaintance with the grizzly old runner, we ventured to remark:

"That cab would hardly do us in America."

It was merely an iron sheet, straight up, with two hinged glasses set in, and called the "spectacle plate."

"They tell me it's a bit colder there than 'ere; they 'ave ye boxed up like,—aint that un'andy?"

"Oh, no, we are as used to it as you are to being out of doors. I dare say we *could* get used to your cab, but every man in America would strike if he couldn't sit down. Are there no seats at all?"

"Seat? Sit down! Why, man, I never 'eard of the like; don't you get drowsy?"

"No, it rests us."

"Seat? Sit down! Well, I just wish my chief could 'ear you talk.

"Why, do you see 'ow far it is from the deck h'over that wheel cover to the side of the engine? Well, no man can see h'over it, I step back into the gangway to see signals and often stand there for miles. Well, sir, I made a bit of a stool like, a board on two blocks, so I could see over and at the same time be out of the stoker's way. But one day the Chief comes up and spies it and says he to me, says he: 'Why the blooming 'ell don't you bring your bloody bed h'on the engine? Take that blasted girl-baby plaything off the foot-plate h'and stand h'up to your work like a man.'"

## A Strong Cylinder.

A curious accident happened last month to one of the Vauclain compound locomotives running the express trains on the Philadelphia & Reading, between New York and Philadelphia. Owing to the jerking caused by the suction of the pistons when steam was shut off, a relief-valve was put into the main valves. One of these relief-valves broke or worked out when the engine was running and dropped into the port holding the main valve in a position that covered the exhaust port. As the steam inside the cylinder could not get out something had to break. The steam was bottled up in the cylinder, and the advancing piston had either to squeeze the whole volume of steam into the clearance spaces or force relief by bursting the cylinder or breaking the piston connections. The weakest point proved to be the great main rod that looks as if it would easily stand ten times the strain that could be put upon it. The rod doubled up, however, and smashed things pretty badly, taking off guides and crosshead.

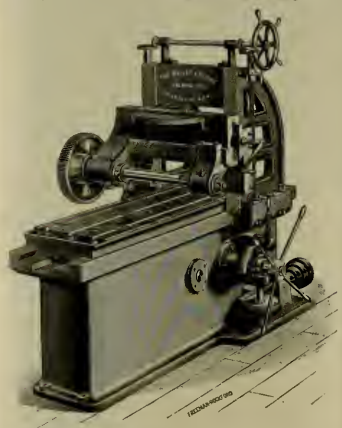
The accident gave very decided testimony in favor of the strength of the cylinders of these compound locomotives. In order to keep down the weight the amount of metal put in the cylinders has to be made as small as possible consistent with strength, but there still appears to be a good wide margin.

## The Ingersoll Milling Machine.

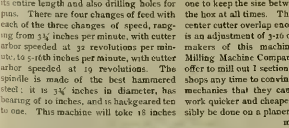
The engravings shown herewith will give any mechanic a pretty fair description of the machine, which the makers call a slab milling machine. It is built more on the planer principle than other millers, and is intended to do much work now done on planers. The makers' circular describes the tool as follows:

"The table is 20 inches wide; mills 5 feet long, is driven by a gear 24 inches in diameter, 3 pitch and 4-inch face, running into a cut rack. By this means we obtain a very steady movement of table. We have arranged for clamping or keying work to the table, by milling three T slots its entire length and also drilling holes for pins. There are four changes of feed with each of the three changes of speed, ranging from 3¼ inches per minute, with cutter arbor speeded at 32 revolutions per minute, to 5-16th inches per minute, with cutter arbor speeded at 19 revolutions. The spindle is made of the best hammered steel; it is 3¼ inches in diameter, has bearing of 10 inches, and is backgeared ten to one. This machine will take 18 inches under a cutter 4½ inches in diameter. We would call your special attention to the means we have provided for cross adjustment of cutter. This is of the greatest advantage, especially in key-setting, or milling work of any special form, such as rod-boxes, crossheads, shoes, etc., as the work can be set on the table at any place and the cover set over to suit the work. There is a dial on the elevating screw reading in thousands. With this machine and our patent cutter we can mill a surface 20 inches wide (either straight or angular face) at the rate of 2 inches per minute and do a finished job. On a large variety of work we have been able to do the work of three, and sometimes four, planers, with one of our millers. The weight is 10,000 pounds."

The third illustration represents the Ingersoll milling cutters, inserted steel teeth that can be changed and ground the same as a standard milling cutter. The particular one shown is intended for milling crank-pin boxes. The center cutter is made in two parts; each part is recessed to receive a screw washer. This enables one to keep the size between the flanges of the box at all times. The flat teeth in the center cutter overlap enough so that there is an adjustment of 3-16 of an inch. The makers of this machine, the Ingersoll Milling Machine Company, Reckford, Ill., offer to mill out I section side-rods in their shops any time to convince railroad master mechanics that they can do this class of work quicker and cheaper than it can possibly be done on a planer. They make a machine similar to the one shown 36 inches wide to mill 8 feet long, which is especially fitted for this class of work.



INGERSOLL 22 X 22 X 60-INCH MILLING MACHINE.



INGERSOLL CUTTER.

---

Lots of engineers getting Jerome metallic packing for the first time are worried to tell how they would clamp the valve-stem in case it became necessary to disconnect one side. There are also a lot of men running it to-day that don't know that there are provisions for holding the stem on all the latest packings. On top of the valve-stem packing will be noticed a small bolt-head with a washer under it. this is a set-screw. In case you have to disconnect a side, take out this bolt and remove the washer, then you will find that the bolt will reach the stem and clamp it just where you want it.

## Brass Thrust Blocks in Eccentric Straps.

Of course, anybody that knows anything about eccentrics at all knows that the straps wear oblong—they do most of their work in the front and rear.

To provide for this wear, Mr. Leeds, of the L. & N., uses a brass inset in the strap, as shown in our engraving.

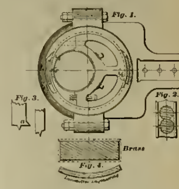
In a private letter (Mr. Leeds is modest about printer's ink) the designer of this strap says:

"This drawing shows our original method of placing these insets, in which we used to counterbore two places and then chip out between the two. In doing this we used to counterbore with the ordinary square ended lip drill and then recess or dovetail with the drill, as per attached sketch. Of course the first drill would leave a little point; taking advantage of this point, we made a flat drill with a round point which would enter the point made by the square tit, and this would crowd the lip *A* out sideways and recess under, making the counterbore dovetailed. Within the last year or two we have been putting these insets in in the form shown at *B*, casting the recesses into the strap. In fact, we cast almost all our straps now to the form, leaving but very little to cut out, an improvement on the original plan of casting them straight across and working out all this metal with a tool.

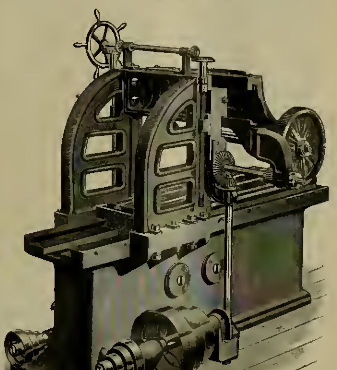
"In the old style we used to have to rough-bore our eccentrics within about 1-16 inch of the finish and then counterbore them, whilst now we put the brass in as the strip comes from the foundry, rough.

"Our practice in filling these cavities has always been to place a piece over the cavity inside the strap, which would form the brass to the circle of the strap but leave it about 1-16 inch higher than the cast iron, and heating the strap by laying it on top of the brass furnace to such an extent as we considered it could be done without putting any strain on the iron, we then poured the brass inset through holes in the cap before mentioned. This leaves the brass somewhat higher than the iron around it, we generally peaned it out until it filled the opening rigidly, and then bored the entire strap together.

"Be careful to warn anyone who is trying this experiment against putting round insets or buttons in without cutting the two holes into one, as should they turn around they of course would wedge between the strap and eccentric, whilst the two being cut into one it is practically impossible for them to turn, as even should they break between the two holes it would



scarcely be in such form as to allow of their revolving. I have used these insets for about eleven years now, and not only have I obtained the best of results from them, but every master mechanic on the road has indorsed them as being an excellent thing. I will say, however, that we use an extremely hard metal in both eccentrics and straps, our eccentrics being made of old wheels, pure and simple, which makes them about as hard as they can be turned. In fact, we had to round all the edges of our pattern to obviate the chilling of the square corners as they were originally made. Our straps are made of old wheels with 25 per cent. of No. 1 charcoal iron. With this material and the generous proportions given our eccentrics, viz., a 4-inch face for everything over an 18-inch cylinder and a 3½-inch face on everything 18 inches and under, we have had excellent results, our straps running for years before they take the tool marks out of the eccentric."



REAR VIEW, SHOWING ADJUSTMENT OF CROSS SLIDE.

## Dear Cheapness.

During the discussion on steel for fire-boxes, which proved such an important part of the proceedings of the last Master Mechanics' Convention, several of the speakers asserted that the price of steel was of secondary consideration compared with the importance of getting material suitable for the severe service that fire-boxes are subject to. The speakers who took this ground were doubtless sincere in their expressed views, and they advocated a line of policy that would be very economical for railroads to follow, but it is sad to relate that they represented a hopelessly small minority. We cannot recall any line in which engineering material is used, where the best is so emphatically within the requirements as in the parts that constitute locomotives and cars; yet there is no line where one per cent. difference in price so frequently leads to the bad being preferred to the good. There are numerous exceptions to this rule, but, unfortunately, the practice of selecting inferior articles on the ground of cheapness is so common that it is the rule among railroad companies.

The matter of steel for boilers is a good illustration of the craze toward cheapness. When steel was first introduced certain companies engaged in making that material devoted all the resources of science, skill and experience, to producing an article which would meet the conflicting requirements. To do this they had to exercise extraordinary care in supervising every process the material went through, from the ore to the finished plate. High-class iron had to be used and the highest priced labor in the market had to be employed. But by meeting the necessary outlay a grade of steel was produced which demonstrated that steel was superior to all other materials for boilers and fire boxes. This steel was necessarily expensive, but railroad companies found it cheaper than copper or the class of iron that would stand the service and they paid the price willingly. The rarity of failure in service made the steel cheap when a high price was asked. This lasted for a few years till the railroad officers began to forget the troubles they had experienced from the use of unsuitable material, and then the cry arose that steel-making companies were paying dividends and that they must therefore of necessity be imposing upon their customers, the artless, helpless railroad companies. As the methods of manufacture were developed the makers of first-class steel found themselves able to reduce the price and fair reductions were made.

The success of any industry is certain to bring the tenth-class species of rivals, and this happened in the steel-plate business. About the time that the reliable steel-makers were beginning to give railroad companies the benefit of lower prices, parties who had engaged in the manufacture of cheap imitations of good steel began offering their miserable stuff to railroad companies at a still lower price than that asked by reputable makers. A great many railroad companies began buying the cheapest steel, and the men responsible for this short-sighted policy closed their eyes and ears to every consideration except the one question, "How much per pound do you ask for your steel?" They know nothing and care less about the comparative value of the steel offered for sale. Railroad officers howl against the public tendency to look closely into profits made in transporting passengers and freights, but many railroad officers are overwhelmed with hate, envy and indignation when they hear that a company manufacturing goods for railroad companies is making a living profit. We sincerely believe that there are railroad officers who will prefer to purchase an inferior article from a struggling company rather than a first-class article at the same price from a company that is prosperous.

With the demand for cheap steel and the tendency to purchase from the lowest bidder, inferior grades were furnished to suit the market. First-class manufacturers reduced prices as far as they could and probably lowered the quality of the article supplied. When the inferior steel got time to prove its quality, complaints began to be heard of the failure of firebox steel. Men seldom discriminate finely between what should be good and what ought logically to be bad, and those who have persisted in making a decent grade of steel have to share the odium of failure due to the inferior grades that are becoming the most common article.

By the purchase of inferior steel a railroad company secures a few dollars in first cost and loses thousands of dollars by waste of fuel due to leakage, by loss of the service of engines and by premature renewals.

In making a journey on a passenger train some time ago, we met with a long detention and learned that the engine of the passenger train had to go up the line and bring in the train of a freight engine that was disabled. The same day we stopped off to visit the shops of the road, and learned that the engine which caused the delay had burst a flue which put out the fire. They were having no end of trouble with flues. The officer controlling the purchases for the company was suffering from a fit of economy and was buying the cheapest flues in the market.

In looking around the same shop we stopped at a wheel lathe which was idle and was examining with some curiosity the light cut begun on a wheel which was in the lathe. Presently the lathesman came up with a newly ground tool and we inquired why he was taking such a light cut. "The tool will not stand even a light cut," he answered. "The worst steel I ever saw used," he added. Here was a first-class tool run at one-third its capacity because some one was saving a few cents a pound on tool steel. All the tools in the shop were more or less affected from the same cause, and it is safe to say that the man responsible for the purchase of inferior tool steel was paralyzing the shop of one-third its capacity.

In no department of railroad mechanism has the craze for cheapness been so expensive or so disastrous as in the purchase of cheap wheels and axles. For a long time there has been a conflict going on between wheel makers and railroad companies. Cast-iron wheels can be made that are reliable for ordinary service, but select iron must be employed in their manufacture and most of the men engaged in this business are anxious to supply wheels of good quality. But many railroad companies appear to think that cast-iron wheels should be got for the price of pig-iron and the maker that comes nearest to the pig-iron figure gets the business. The cost of wrecks and of human lives due to the use of inferior wheels receives no consideration. There has been more inhumanity practiced in the purchase of cheap wheels than in any department of industry we are acquainted with.

Scarcely less creditable than the practice of using the very cheapest cast-iron wheels that can be bought, is that of many roads in regard to axles. An inferior wheel, or an axle that would run without accident at low train speeds, is a constant element of danger at the high speeds now so common on most railroads. Increased precautions ought to be exerted to make every member of the running gear of cars thoroughly reliable, but safety is kept away in the background when first cost is considered. The prevailing policy seems to be, get good wheels and axles if you can, but buy the cheapest. If a railroad company cannot afford to buy selected scrap-iron or good steel axles, they ought to be forced out of business. Muck-bar iron is not equal to modern requirements, and the Bessemer steel axles that are becoming so common are a menace to the life of every man who has to ride on a freight train.

We have known of lots of Bessemer steel axles that broke like pipe-stems when subjected to the ordinary drop test, being rejected by a road that followed a rigid system of inspection. The same axles were quietly taken back and sold to roads that are strong in faith and take material supplies without bothering about tests. First-class iron axles and axles made of toughened steel can be bought for one-half cent a pound more than that paid for the poorest kind of Bessemer steel, yet there is scarcely any market for the reliable material, as the inferior kind is considered the more desirable because it is cheap. This is a matter which deserves the very strongest kind of publicity. The practice of putting into train service wheels and axles admittedly unreliable is a crime, and the parties responsible for the outrage ought to be treated as criminals when their recklessness leads to disaster.

## An Economical Substitute for Waste.

On a great many European roads no waste is used to keep locomotives or other machinery clean, but a cloth, woven loosely of waste material is employed, and this is cleaned by special apparatus several times before it is used up. There is a saving not only of the wiping material but of the oil.

The best example of this practice that the writer saw was at the Gateshead shops of the Northeastern Railway, just across the Tyne from Newcastle.

The wiping cloths are about eighteen inches square, woven very loosely, even coarser than gunny sacks. They are white, like new waste. These are used on engines and in shops where waste is used here, but there is no loss from small pieces catching here and there as waste does, and they are handier to carry, many of the men keep a clean one thrown around their necks, to be handy. I saw firemen on the road carrying them that way.

Soiled "wipes" from engine cleaning are used by the wipers until thoroughly saturated with oil, and are then deposited in iron boxes about the shops and roundhouses.

From these places they are gathered on an iron barrow and wheeled to the wash-house, which is quite a plant of itself.

Here the cloths are, thrown into a tank containing hot water and some loosening chemicals, probably potash. This tank is heated by steam pipes that serve to keep up a high temperature and a great deal of the grease is left here.

From the tank the wiping cloths go into centrifugal wringers such as are used in this country in steam laundries, they are called "washers" there, however, these machines, as most of our readers know, consist of a vertical shaft set in proper bearings and properly belted for high speed. On top of the shaft there is a globe shaped vessel with its sides perforated and an open top. Around this perforated dish there is another of sheet metal that catches the liquid thrown from the inner vessel and conducts it where wanted.

These machines run at a high rate of speed and the cloths are thrown in so as to make a ring several inches deep all around the outside of the revolving globe.

A hot-water pipe is led over each washer, and enough is introduced to make a current through the cloths, carrying grease and dirt with it. The water is allowed to run as long as it comes from the machine discolored.

When taken out of these machines the cloths are only damp; you can't twist a drop of moisture out of them. They are then hung over wooden poles set close together in an iron-ended frame running on a track, this frame is about 1 foot wide and 8 feet long by 4 feet high. It is then rolled into a brick oven or dry room.

There are a large number of these frames running into the dry kiln from either side the kiln is heated by steam pipes and is ventilated by a stack, each rack end forms a door as it slides up to its place in the kiln. The cloths are completely dried here and then packed up and returned to the shops for further use; they are sweet and clean, but they are no longer perfectly white—virginity once sullied can not be entirely purified.

From the dirty water tanks the oil is separated from the water by some simple processes, requiring little apparatus, goes through some steam-refining arrangement and finally runs off into vats.

This oil is of a rich yellow color, like butter, and is about as thick as will run through an open trough; it's pretty thick for oil and pretty thin for grease. It is odorless and clean, and is used for oiling cars.

By this arrangement several losses in using waste are avoided; each piece does eight to twelve times as much work as the same weight of waste, and besides, a large percentage of good engine oil (they use sperm there) is saved for use on the rolling stock.

When the cloths are worn out entirely, they are just as good to build fires with as is our waste with all its original strength, but greasy.

We do not know how much of the light mineral oils used in our country could be saved by such a process, but believe it would pay any company to use the cloths even if the oil was wasted.

We were told at Gateshead that the saving of oil or the saving of waste would either of them alone insure the use of the process. It's worth trying.

## Attacks on the Rules of Interchange of Cars.

A club of railroad superintendents held a meeting at Buffalo last month. The principal subject of discussion was "accelerating the movement of freight cars." A disposition was manifested to tear up the Master Car Builders' rules of interchange of cars and in fact to abolish every rule which directly or indirectly interferes with the free and untrammeled movement of cars.

The superintendents who attended that meeting doubtless were full of good intentions but they are the quality of good intentions that hell is said to be paved with. Good intentions that aim to destroy any system of government be it the government of people or of car movement without providing a superior substitute is merely a step towards chaos. The rules of interchange of cars formulated by the Master Car Builders' Association are the most perfect regulations that practical men impressed with the necessity for moving cars from one company to another expeditiously could devise. There are certain railroad men who have no patience whatever with any restraint that will delay a car for a single hour. Every delay is regarded as unnecessary detention. They cannot understand that there are necessary short delays which provide against prolonged detention. Thorough inspection and the effecting of the minor repairs found necessary will frequently enable a car to finish its journey safely. The neglect of that work will often result in a break down with tedious delay, or even to the wrecking of a train with great damage to property and perhaps loss of life.

The master car builders' rules of interchange of cars are framed to serve two essential principles. First, they provide for the movement of cars without accident, and second, they devise the means of holding the railroad companies that cause the damage to cars responsible for the expense of putting such cars in good order. The men who are striving to abolish or ignore the master car builders' rules are trying to substitute hap-hazard confusion for a salutory system. There are men still in railroad service old enough to remember a time when cars moving from one road to another were not subject to any rules. Such men are very pronounced in their opinions against the confusion that existed then. The rules of interchange were forced into existence by grim necessity and it is better to go very slow in a movement to have them abolished or rendered inoperative.

## Business of the Elevated Roads of New York for Six Months.

It may not be a well known fact, but fact it is, nevertheless, that the Manhattan "L" road carries more passengers than any other road in the world.

The following figures of the business done in the six months ending June 30th, are very interesting

Number of train miles made in six months, 4,288,548 02.

Number of passengers carried in six months, 105,753,101.

Number of engines in service in six months:

Daily average attached to trains, 199.

Daily average in relay, 35.

Daily average baggage trains, 1.

Daily average ash trains, 2.

In service in six months, 43,134

There were made 514,926 trips in six months.

Number of engine miles made in six months, 4,560,647.08.

Average miles per engine for six months, daily, 105.73.

Average miles for six months, 19,242.86.

Number of cars in service, weight and capacity.

Daily average in train service, 935.

In service in six months, 170,170.

Car trips in six months, 2,356,226.

Weight, 30,000 pounds.

Seating 48 persons and carrying on an average 75.

Receipts for passengers carried in six months, $5,287,655.05

Cost of coal per mile and amount used:

Cost per engine mile, .09.75 cents.

Pounds per mile run, 52.16.*

Total consumption in six months, 106,198

[*It must here be observed that this figure is found by dividing the total pounds of coal used by the train miles which is very unfair, as the immense number of hours that engines lay in waiting with fires up consumes a great deal of coal. The actual amount of coal consumed by engines pulling trains has been found to be 41 5 per train mile It will also be seen that 272,099.06 miles were made by engines not pulling trains, for which no allowance was made.]

Number of trains daily

Trains and crews in actual passenger service, 199.

Trains and crews in actual baggage service, 1.

Trains and crews in actual ash service, 2.

Trips or trains, daily, in passenger service, 2,792.

Cost of operating per train, per train mile, 64 cents.

Average speed on road, 15 miles per hour.

Average time of stops, 15 seconds.

In six months engines consumed 237,883,520 pounds of coal. The true measure of engine performance is to ascertain the amount of work performed. Now the road carried 105,753,101 passengers, and it is therefore seen that it required a consumption of 2.2 pounds of coal per passenger.

---

The American system of laying men off is used in Great Britian only for grave offenses, and then with nothing of the severity practiced in the States. The usual plan on English roads is to fine men for minor offenses. There is usually a bulletin printed for each month and put up so that all can see the crimes and punishment thereof. We noticed one at Crewe where men were fined 2*s.* (50 cents) for being absent without leave; this is increased for second and third offenses. Firemen and engineers 2*s.* for neglecting fire, and 10*s.* ($2.50) for running by signals and station platforms. This is an offense always punished, even though the man is trying to stop and runs by; this cast-iron rule makes men more cautious in approaching stopping points. There were several suspensions for from two to ten days, fourteen being the longest ever imposed, if it's worse than that it's dismissal Discharge after long service is a misfortune there more than with us, as there are on most roads different benefits and on some a pension after long service, hospital fees and insurance, all of which is lost with the position, although the man may have been paying into them for a quarter of a century.

---

Around the city of Berlin there is a circular elevated railroad. The elevation is graded except on streets, where handsome bridges are placed. The stations are very large and nice and the rolling stock fair Its engines are tank machines of about 70,000 pounds weight. In riding around, our German interpreter was wondering how on earth the New York Elevated road could load and unload its passengers with end doors only, so we kept time on them. There were forty-six compartments in the train we rode in and certainly room enough to get on and off, and there was no crowd, probably 100 changes at a station. The average stop—we timed twelve—was fifty-four seconds, and two were over a minute. Last year we counted the time lost in stops on the New York Elevated, Third Avenue line, and the average was only seven seconds, and the longest in thirty stops was for twenty-eight seconds, the average for all the lines is fifteen seconds

---

The London & North-Western road have a rule that prohibits the employment of a man who has passed his fortieth birthday. If all roads did this and still persisted in the practice of discharging men "for discipline" it would put into the hands of a few men the power to take away from many a good mechanic and engineer the opportunity to use his experience and skill, and, leaving the gross injustice of the thing aside, the average man is at his very best at 40 years of age; he is skilled, experienced and steady This same road have another inhuman rule and this is the discharge of a man who has been on the sick list for six months. Many a poor devil suffering from a long run of fever, a broken limb or something of that character, has had a notice served on him in the hospital or the workhouse that his name has been stricken from the roll. Refined cruelty, that.

Many of the French locomotives are covered from end to end with sheet brass, stack, dome, boiler and all. As a rule these are not cleaned, and look like a fire engine that has been at a three-days' fire The "spectacle plate" is even smaller than that on the English locomotive, and, on the Northern Railway, many of the throttle levers come down from the dome *ahead* of this plate and the engineer has to reach ahead of what cab he has to use it. Almost all of them have the eccentrics on the main pin and the link motion outside; their looks were fairly well described by a Yankee boy who said, "they looked to him like an American locomotive that had turned over about three times and sorter turned herself outside in."

---

Go where you will in the old country and the fact will be strongly impressed upon you that it is an old man's country In every place of responsibility you will find an old man—mighty few are there pulling passenger trains who are not yet gray headed, and foremen of engine sheds and master mechanics are, almost without exception, men who have seen their fiftieth birthday. I talked with men who had been running extras for more than ten years—hadn't got old enough for a regular run Firemen are in luck to get to running after ten or twelve years of firing—many of ours are kicking at three.

---

In Germany they heat their passenger cars with steam, and, in each compartment, is located a little lever that can be placed in any of three positions—warm, medium or cold. There is also a handle that when moved will apply the air-brake, the Carpenter now being used. The movement of this lever breaks a small string with a lead seal upon it, so that it can be told in what compartment the brake was meddled with. It is a fine of 40 marks ($10) for needlessly applying it.

---

The erroneous impression prevails in America that the English "bull-head" rail is alike, top and bottom, and that when one side is worn the rail is turned This was so of the first of this class of rail, but the practice was long since abandoned Speaking of the old practice of turning rails, a locomotive superintendent said it had caused more loose teeth than all other disturbances combined, including earthquake.

---

Steel or other metals ties are used to a considerable extent on some of the English roads, and, while they may be safer than wood, they certainly produce more noise, it being easy to tell when you pass from one to the other.

## NEW BOOKS.

MAXIMS AND INSTRUCTIONS FOR THE BOILER ROOM, 330 pages, 6 x 9 inches. By N. Hawkins. Price $2 50. Theo. Andel & Co., 91 Liberty street. New York, publishers.

This is quite a large book, containing a great deal of information about boilers and their care. There appears to be very little original work in the volume, but the editor has gathered his facts and figures from every available source. That the average boiler-room attendant, engineer or fireman would be better off with this work, for reference, goes without saying, and a study of it will do all of them good. There is very little in it about firing locomotive boilers, but for those in the stationary service it will be a valuable aid.

---

A table book for civil and mechanical engineers has been compiled for Van Nostrand's Science Series, by Geo. W. Plympton. The tables are remarkably exhaustive and will be a great convenience to engineers, for tables relating to all sorts of subjects are here collected in one handy book. It costs 50 cents.

## PERSONAL.

Mr E. Greenwood, of West Farmington, Me, has been appointed master mechanic of the Sandy River Railroad, with headquarters at Phillips, Me.

Mr. John Medway, who has been master mechanic of the Fitchburg Railroad at Mechanicsville, N Y., for a long time, has been promoted to the position of superintendent of motive power of the same road in place of Mr. O. Stewart, resigned.

Mr. Edward Dauson, late roundhouse foreman for the Chicago & Northwestern Railroad Company at Council Bluffs, Iowa, was appointed assistant master mechanic of the Freemont, Elkhorn & Missouri Valley, appointment to take effect September 1st.

---

Mr L S. Randolph, for some years engineer of tests of the Baltimore & Ohio Railroad, has been appointed electrical engineer of the Baltimore Electric Refining Company. Mr Randolph was previously on the Cumberland & Pennsylvania Railroad at Mt. Savage, Md., and has a very high standing for ability as a mechanical engineer.

Mr Sam W. Simonds has been appointed engine despatcher of the Fitchburg Railroad with headquarters at Boston Mr. Simonds has been employed on the B. & M. Railroad for the past sixteen years as fireman, engineman and assistant engine despatcher, in each of which positions he has shown himself capable, intelligent and trustworthy. His many friends will wish him continued success in the larger field now opening for him.

---

Angus Sinclair and wife started for California on the 16th of last month for a little recreation, but Angus has a Kodak and a note book, and if he comes home without something interesting for the readers of his paper it will be the first time. The junior philosopher is in charge just now, but has agreed to keep over all articles on, and models of, automatic link and pin couplers and other "revolutionizing" inventions until the return of the executioner.

---

Mr. T A Fraser, superintendent of the Wells French Car Works, has been away on a European trip with President Meysenburg The trip was understood to be undertaken for business and pleasure, the business part being the looking up of machinery and methods that might be employed to advantage in the car works. Mr. Fraser would have continued for a long time a railroad master mechanic before he would have been invited to take a European trip at the expense of his employers.

Mr. Albert Griggs, for a number of years superintendent of motive power on the Providence & Worcester Railroad and more recently occupying same position on the New York & New England Railroad, has entered the employ of Page, Newell & Co., Boston, Mass, and will care for the interests of the "Brunswick" wheels. Albert Griggs was raised in the motive-power department of New England railroads, his father having been one of the first general master mechanics in America and the inventor of the brick arch.

---

In the resignation of Mr. O. Stewart from the position of superintendent of motive power of the Fitchburg Railroad, another veteran master mechanic steps out of railroad life. Mr. Stewart, who is treasurer of the Railway Master Mechanics' Association, has been a leading figure in that organization for years and has a host of warm friends who will regret to hear that he is leaving their ranks It is understood that Mr Stewart has managed his private affairs so judiciously that he is quite independent of railroad business.

## Work of a Railroad Poet.

The writer recently stood in a little museum in the base of Robert Burns monument at Edinburgh, and read a letter written by the poet, a few days before his death, begging a friend for the loan of ten pounds. Since his death thousands of dollars have been expended in almost every city of the Christian world in monuments to his memory, and his publishers have made a fortune at every edition of his work. This seems to be the fate of poets generally. Our old friend, Cy Warman, once an engineer on the Rio Grande Road, has written enough good poetry to establish his reputation as a writer of verse, and, when he is dead, will be counted a poet worth reading. He does not go deeply into Greek mythology for comparisons and examples, but—let him explain in the first verse of "I Would Know My Native Land."

"There are those who praise the poet who can soar in starry spheres,
And can mold his mystic phrases from the wrecks of other years;
I would have my inspiration fresh from Nature's open hand;
I would sing a simple sonnet that a child can understand."

Cy Warman's Memorial Day poem, "Our Heroes," should endear him to every railroad man; the first verse reads:

"Now that we've scattered the flowers of May
Over the graves of the blue and the gray—
Over the graves where the women weep,
Over the mounds where the heroes sleep—
Now let us turn to the graves of those
Who have lived and died in their overclothes."

Warman has just issued a little volume entitled "Mountain Melodies," full of little gems that glow with the sunset, sparkle like the mountain dew and murmur like the snow-fed streams—Nature's poetry. Another volume of the same size is in press, called "Rhymes of the Rail." No one will be disappointed in sending fifty cents apiece for them to the author, Denver, Colorado.

Cy's preface to "Mountain Melodies" is typical of the man: "The author offers no apology to the public for the publication of these rhymes. They were inspired largely by Nature and Nature's God. If you have a kick coming, kick higher."

---

George Richardson, the inventor of the "pop" safety-valve and the balanced slide-valve, died at his home in Bridgeport, Conn., on September 1st, at the age of sixty-four years. Mr. Richardson was an engineer on the old Troy & Boston road, now a part of the Fitchburg, when he experimented with the pop-valve, and finally perfected and patented it in 1866. George Richardson was a good mechanic, an original investigator and one of the best-hearted and noblest friends a man could have.

---

The Fall's Hollow Staybolt Company claim that the tensile strength, elongation and elastic limit of their hollow staybolt is much greater than a solid bolt of the same diameter. Half a dozen other makers claim the same thing; why not have a public test by disinterested parties.

---

The Chicago & Western Indiana Belt Railroad have placed order with the Cook Works for five six-wheel engines.

---

Mr. W. T. Hamer has been appointed road foreman of engines of the Atlanta and Brunswick divisions of the East Tennessee, Virginia & Georgia Railway. His duties are to instruct engineers and firemen regarding the proper working and firing of their engines, with a view to obtaining the best and most economical results. To see that engines are properly equipped with tools, signals, etc., and that they are kept in perfect order. To correct any irregularities or errors in connection with the working of the engines that may come to his notice. To consult with the master mechanic or roundhouse foreman regarding the condition and requirements of engines. To report to the division superintendents violations of rules or neglect of duty, and as to qualifications of engineers and firemen, and matters of like character. To report to the superintendent of motive power upon mechanical matters, and to conform to such instructions as may from time to time be received from him.

---

The Brotherhood of Locomotive Firemen held their Biennial Convention at Cincinnati on September 12th; this would have been their nineteenth annual convention under the ordinary yearly convention scheme. The report of Grand Secretary and Treasurer Debs shows that the order is in a promising condition. The total membership is 25,967, a gain of 7,310 in two years. Two thousand four hundred and one men have been expelled in that time, and 3,218 have withdrawn. Mr. Debs took his office in 1880, with the order bankrupt; he received from his predecessor in office $143.15; in the twelve years of his stewardship he has received $3,214,607.55, and paid out the same, less $51,583.64 turned over to his successor. The order has a protective fund of $64,901.55 for use in an emergency; this fund the grand secretary recommends be returned to the lodges contributing it, as he says, "Money cannot win strikes."

---

In a letter received from Mr. H. J. Small, superintendent of motive power, Southern Pacific Railway, we learn particulars of the long service performed by S. C. Clark, one of the locomotive engineers in the service of the company. He commenced to run in 1868 and since that time has made 1,000,051 miles. During that period he has drawn $28,800 for his services. He has had two accidents during his term of service; first about nine years ago, when he had a collision with another train, damaging the pilots of both engines, and two years ago when he ran off a switch, for which he was not responsible. He is now fifty-seven years of age and well and hearty, and expects to make a great many more miles and does not look forward to going out of service for at least ten years.

---

Mr. Clement E. Stretton, the eminent English railroad authority, gives the following incident as the origin of the steam-whistle: "One of the first events in the history of the "Samson," built by Stephenson in 1833, was that it ran into a horse and cart crossing the line at the "Stag and Castle" Inn, Thornton, the cart being loaded with butter and eggs for the Leicester market. The engine-driver had but the usual "horn," and could not attract attention. Mr. Bagster, the manager, suggested the use of a steam-trumpet or whistle; and by Mr. George Stephenson's instructions such an appliance was at once constructed by a local musical instrument maker, and it worked satisfactorily."

---

Walking along the streets of Manchester, England, one day this summer, the junior philosopher of the L. E. espied in the window of a tool store across the street, this large sign: "The best thread gauge in the world." The junior philosopher went right over to view the wonder. Under the sign hung "the best thread gauge," it was made by L. B. Starrett, Athol, Mass. Some of the original and handy kinks for mechanics manufactured by Mr. Starrett had prominent places among the fine English, French and German tools displayed in the window. The dealer informed us that while some of the other makes were, perhaps, finer in finish or heavier, the Yankee tools were the "cutest," most ingenious and original.

---

Among the many friendly notices which we have lately received from the railroad officers regarding LOCOMOTIVE ENGINEERING, we are glad to notice some kind words from Mr. A. M. Smith, assistant-superintendent of the Duluth & Iron Range Railroad, who writes: "While I am not in the motive power department, your paper has been very interesting and I hope instructive also, to me, particularly the air-brake department, as we have air-brakes on all of our cars. I do not know that I could suggest any improvements, further than that you continue in your present course; it is certainly onward and upward."

---

The Pield Feed-Water Purifier Company within the last month has equipped the new plants of the Armour Packing Company and the National Linseed Oil Company, at Kansas City, also the new Electric Light & Power Company plant, at Rockford, Ill., and added to its list of railroads the Chicago & Alton. The Wisconsin Central, since the beginning of the year, have equipped twelve locomotives, which fact substantiates its value by continued use. It is also making several equipments on marine boilers and which, from the success of two large steamers already equipped within the past few months, bid fair to be of great value to this class of large boilers.

---

We understand that Westinghouse, Church, Kerr & Co., have secured exclusive control of the sale of the Hodges & Havenstrite system of refrigeration and ice-making. Refrigerating and ice-making has become such an important business of late that Westinghouse, Church, Kerr & Co. have been negotiating for some time to enter the business. They already have a large number of orders, particularly in the direction of manufactured artificial ice, and they are pushing the work vigorously as they are liable to do with anything which they control.

---

To be in touch with these progressive times, one ought to have an opportunity to see the wonderful advancements made in wood-working machinery, and the Egan Company, of Cincinnati, Ohio, U. S. A., are in a position to present it. This concern has just issued a handsome catalogue of nearly 300 pages, which displays the largest line of the very latest and most improved mechanism for the saving of time and labor and can be had now by duly accredited shop foremen and master car builders, on application. The Egan people are building a special line of tools adapted for car building and car repair work.

---

In May last Charles H. Strain, an engineer on the Pittsburgh, McKeesport & Youghiogheny Railroad, forgot his running orders and had a collision with another train, resulting in a bad wreck and the killing of a fireman. Strain was prosecuted for manslaughter and was convicted of misdemeanor. The judge, in passing sentence, said that it was the first offence of the kind in his district, and he would inflict light punishment as a warning. He sentenced Strain to pay a fine of $100 and go to jail for forty-eight hours.

---

The Servis tie plate is deservedly gaining in favor daily. This little device has virtually widened the rail base, prevented side slipping of rails and prevented the cutting of ties by abrasion of the rail, an important item, as the separation of the fibers of the wood under the rail admitted of loose spikes. With plates all the movement is between the plate and the rail. The idea that they would cause a shearing strain on the spike has been proven without foundation.

---

B. M. Jones & Co., of Boston, have done a wise thing in placing on the market annealed blanks, suitable for milling cutters, taps and dies, rose bits, countersink and twist drills, etc. The price of this annealed brand is 75 cents per pound, but this cuts no figure at all when the *comparative* cost of making and using common steel tools is considered. Those who now consider "Mushet" as indispensable for lathe and planer tools will appreciate the new move.

---

A correspondent writes us that Jared Turrell, a veteran engineer on the New York Central road, has retired from the footboard at the age of 82 years. Of late years he has been running in one of the company's yards. The day he retired he had been running an engine on the New York Central 40 years. Superintendent Burrows would not accept his resignation, but gave him a vacation during life on half pay, which Mr. Turrell accepted.

---

The first order of fifteen 19 x 26-inch cylinder mogul engines, for the Duluth, Messaba & Northern road, has been given to the Pittsburgh Locomotive Works.

---

The twenty-first meeting of the American Society of Superintendents will be at the Hotel Brunswick, New York, on October 10th, at 10:30 A. M.

## A Defense of Crucible Steel for Boiler Purposes.

*Editors:*

In LOCOMOTIVE ENGINEERING for September appeared, under the heading "Crucible Steel for Boiler Plates," an article which, in its tone and statements, argued in favor of open-hearth steel instead of crucible for use in locomotive boilers and fireboxes. As intimated in the circular recently sent out by Mr. James W. Brown, chairman of Howe, Brown & Co., Limited, this firm has facilities for the manufacture of open-hearth plate steel as well as crucible. Their testimony on this subject, therefore, deserves to be considered on a higher plane than as a mere bid for a revival of the use of crucible steel. I lean, in this discussion, on Mr. Brown's practical experience of over thirty years, believing that his acquaintance with the manufacture and use of all grades of open-hearth and crucible steel places his views beyond successful contradiction by any man in the business, most certainly by any maker whose range of vision is limited to the open-hearth process only.

The report of the committee submitted at the Master Mechanics' Convention in 1888 is so far at variance with the present feeling in railroad circles, and with ideas held by some of the most conservative master mechanics, that it can hardly be claimed to represent the sentiment of 1892; and we believe that the longer the railroads postpone their return to crucible steel, the stronger will be their final opinion that this report of 1888 was decidedly unfair to the crucible process. To have this again brought forward in your columns will not change the views of any who can recall the time when crucible firebox steel was so successfully used, but it may carry impressions to others, not familiar with this subject, which would have a tendency to prolong the use of material demonstrated by past experience as unsatisfactory for fireboxes.

Howe, Brown & Co., Limited, in their position, will, of course, meet with the opposition of all open-hearth mills having no crucible furnaces, and they will probably be at the temporary disadvantage of asking for a higher first-cost for their crucible product, but the growing demand for steel that will stand the contraction and expansion of firebox use and give long service will eventually, they believe, put crucible steel again into general use.

The assertion in the report referred to, that crucible steel "is a failure when large masses of homogeneous character are required" can be answered by a denial as positive and emphatic as the charge set forth. The crucible process will produce not only a purer and stronger steel, but also a more uniform and homogeneous body, and the size of the ingot or plate is only controlled by the size of the steam hammer and other machinery necessary for turning it out. Any of your readers who may have attended the Exposition at Philadelphia in 1876, will no doubt remember the large ingot, broken in two, which was there on exhibition by the Krupp Steel Works. This ingot, if I am not mistaken, weighed in the neighborhood of 60 tons, and was perfect and sound in every respect. It is not too much to expect that this same concern will have at the World's Fair in Chicago, another specimen of crucible steel larger than the one sent to Philadelphia, and in keeping with the advancement and improvements in handling crucible steel since that time. Locomotive tires, some weighing from 2,000 lbs. to 3,000 lbs., and Krupp guns of many tons weight, are made of crucible steel. It is true that at the present time, Howe, Brown & Co., Limited, cannot make crucible plates as large as open hearth plates, but this is through no fault of the crucible process. They can with ease make plates large enough for locomotive fireboxes, and if their friends will not ask for boiler sheets weighing more than 1,200 lbs. or 1,300 lbs., they can equip a locomotive complete with crucible steel. There are still mechanical men who question the wisdom of using extremely large plates for boilers, therefore there seems to be no reason why sheets as heavy as 1,200 lbs. should not be large enough for locomotive boiler use. This question, however, does not concern the material for the boiler as much as it does the firebox, where the severe usage has proved to be more than open hearth and basic steels can stand. Crucible firebox steel was used at least 15 years before open hearth steel was introduced and no complaint was made of its failing to answer the purpose. It has been in use nearly thirty years without anybody being able to say that it was not entirely satisfactory, whereas open hearth steel has only been in use about 14 years, and, if we understand the matter correctly, is now condemned by some of the best judges on the largest roads, some of them going so far as to talk of returning to copper and imported iron, the use of which crucible steel superseded, and to which no one thought of returning while crucible plate was used. The facts, therefore, seem clearly to justify the claim that crucible steel successfully displaced what was previously used, while open hearth and basic steels have not successfully displaced the crucible. The only known points in favor of open-hearth firebox and boiler steel are the ease with which it may be worked and the lower price at which it is sold.

The word "homogeneous," as regards steel, has been used very largely in connection with soft boiler-plate, but in reality all steel must be homogeneous in the ingot to be of any account. Crucible steel, as before remarked, is made in very large sheets, and for purposes necessitating a much finer steel of more homogeneous character than is required for a boiler sheet. The crucible process is in every sense a refining process for all metals, and has been so for many hundred years

Your article says further, "it seems certain that the tendency to break down prices has brought into the market steel of inferior quality." That is true. Anything easy to make is fought for by many mills, and the number is rapidly increasing. The great aim has been to produce large plates, soft steel and low prices, and from reports of new mills soon to be erected in this line, it may be expected that this competition and the accompanying results will not be lessened. On the other hand, crucible steel has not deteriorated in quality by reason of excessive and reckless competition, and owing to the great care required in its manufacture and the comparatively small output for firebox purposes, the temptations for investment will not draw men into a specialty of this kind unless they are masters of the crucible process in all its details.

EDWIN S. JACKMAN.

## Some Facts About "Improved" Valve-Gear.

*Editors:*

There is an editorial in the *Railroad Gazette* of September 9th, on "Improvements in Compound Locomotive Valve-Gears," which appears to the writer misleading, to say the least; it is one of the many cases where the circulation of *mis*-information appears to predominate, as its whole tenor is to prove that where saving is conceded in a compound locomotive, it is either the boiler or valve-gear that has been improved which produces it.

I shall not discuss the matter of saving effected by larger boilers at present. But will try to look into the saving by "improving valve-gear."

The *Railroad Gazette's* great effort appears to be to show how much the "Old Stephenson link" motion has been improved with the introduction of the compound locomotive; we will not follow the many figures given in the *Gazette* about lead, lap, etc., of old engines, but I just want to mention something about the Rhode Island Locomotive Works engine, with the "improved valve-gear" mentioned in the *Gazette*. It was on engine No. 40, built for the New York, Providence & Boston Railroad, and was designed to run 62½ miles with eight cars in 62½ minutes. This engine had 7-inch travel of valve, with long lap and large ports, steam ports 2 inches wide and the same length as diameter of cylinder. It was months before this engine could be made to do its work properly after going into service, and after many changes were made on it and to no satisfactory purpose. The valve-seats were finally planed off and false ones put on with smaller ports, and the travel of valve was reduced and the engine then did its work and has been doing it ever since. So much for the improved valve-gear on that engine.

Now, a word about the Reading "fliers," with the 7-inch travel, that run the Royal Blue Line on the Bound Brook road, which astonished the public until the *great secret* leaked out about cutting ¼-inch clearance out of valve (this great secret has been practiced for more than thirty years on many roads.) There is an engine now running on this same Royal Blue Line making the *best record* of any engine on the road, and it has run from Wayne Junction to Jersey City, 85 miles, in 81 minutes, which has not been equaled by any of the celebrated "fliers." This engine, No. 615, Lehigh Valley Railroad, has no "improved valve-gear," but is equipped with just the *old-fashioned Stephenson link*, with 4½-inch travel of valve, ⅞-inch lap outside, with $\frac{1}{64}$ inside. The offset of link-saddle is no secret on this engine, for it has none—it is in center of link-block. No. 615 has 2 inches less diameter of cylinder than the Reading "fliers" and is doing the same work Will the *Railroad Gazette* show where the "improvement" comes in on this link?

How about the long travel and large ports on the compounds that make the saving? The *Gazette* has no more to prove in this than in the long travel theory.

The Webb compound on the Pennsylvania Railroad, New York division, is doing more work with less fuel than any other compound locomotive in America of same weight, and it has only 3½ inches travel of valve with ports only 10 inches long and steam-pipes of much less size than any single expansion engine on the road.

Should any question the above statement they will find no trouble to have them verified by visiting the places where these engines are in service.

If the railroad papers would publish *facts* in place of so much *theory* it would prevent so many from treading the same path that has been worn out by others without making any improvement. It is a well known fact that it is impossible to make an improvement without a change—but it is also well known that many, many changes are made which are not improvements.

COMPOUND.

*Providence, R. I.*

P. S. I will say that the valve-gear of the No. 615 is exactly the same as has been in use for nearly forty years and originated by the *best* locomotive builder the world has ever seen—Wm. Mason.

---

## Double Plate Steel Wheels.

*Editors:*

There appears in the September issue an article, with an illustration, in reference to the manufacture of cast-steel car wheels. Certain statements therein are, to say the least, misleading, and as I do not think it is your purpose to misrepresent matters, I will state certain facts bearing upon the subject in question.

First, as to the claim that "all the patterns had been single plate" in design. The truth of the mattter is that not one single-plate wheel was made, for railroad service, prior to the present management taking charge. With the exception of a few spoke wheels and a special double plate design, all were of the double plate design commonly used by all chilled-wheel makers.

Certain parties attempted to make cast-steel wheels in Boston, as far back as 1887. Such as were put in service broke—not a mere check, but a bad break. They had expended much time and money in these efforts. In 1889, I took charge of the works, being the same as mentioned in your paper. In about two months time I commenced making wheels by methods which I originated, and for which several patents were granted me in 1890 The *first eight castings* made were shipped at once, and put in service within a few weeks, in the year 1889. The same eight castings, constituting a set of wheels, have been in service up to the present time without having been turned off, and the mileage made is very high.

Early in 1890, I designed and made wheels in which the front and back plates extended from the hub to the rim. The wheel illustrated in the article referred to is of precisely the same form, except as to the curve or depression in the front plate. I made the front plate straight, or in the form of a disk, for good reasons.

Upward of 300 of these wheels were cast and most of them put in service before I gave up the work, after carrying it on for two and a half years. You need not go far from your office to find some of these wheels which were in service nearly two years before the present management of the works commenced.

---

## Taking Care of Driver-Brakes.

*Editors.*

There seems to be little said in the columns of our railroad papers concerning the driver-brake. Possibly this is because it is only within a few years that the railroads have come to realize the importance of that part of the brake equipment. A few years ago there were very few engines that boasted the luxury (?) of a driver-brake. Now, however, an engine without one is an exception, at least on all first-class roads. The writer's experience has been that *most* of these brakes are not by any means what they should be, and a little agitation of the subject may be productive of beneficial results. To begin with, many of the arrangements are incorrect as to the leverage, proportion, and location of parts. This is the result of a number of causes. On some roads the design was made by a man who did

not understand the business. On others one design was applied without material modification to a number of different styles of engines, no allowance being made for variations in weight or slight differences in distance between centers.

The toggle-cam is not only a very powerful lever, but it is very sensitive to slight changes in position or curve, a small fraction of an inch one way or another sometimes varying the braking power by several thousand pounds. It is quite an elaborate operation to lay one out properly, and no one should attempt it unless thoroughly familiar with all the best practice in that line of work.

In some cases the design is not followed closely enough in setting up the work, a little carelessness in one or two dimensions throwing the whole out some distance, or the cam faces are not finished to template and many of the castings are out of line. Sometimes the threaded hole is not bored in perfect line. All such things as these preclude the possibility of securing accurate results, and hence the necessity of most careful work in all respects.

In many cases the cylinders and levers are all right, but a mistake is made in arranging the air supply, it being either too great, or, as is most frequently the case, too small. Connection is made from the tender brake triple-valve and thus the pressure in the auxiliary reservoir under the tender is allowed to reduce to too low a point, because it has to supply three cylinders. With this arrangement a very slight leakage in any of the connections around the cylinders will render the brake practically valueless. A separate reservoir and triple valve should in all cases be provided exclusively for the driver-brake, and the capacity of the reservoir should be sufficiently great to allow 70 lbs. to equalize on a full application, with an average travel of piston, at about 50 lbs. or a trifle over.

No other part of the air-brake system is so liable to become inoperative from leakage as the driver-brake. The reasons for this are numerous. The jar of the engine loosening the joints in the pipe, especially where a sufficient number of clamps have not been provided to hold it rightly in position. The amount of piping between the triple and the cylinder being much greater than on cars, and having more bends and turns, makes more joints to work loose and consequently greater liability to leakage. Then the location of the cylinder in close proximity to the firebox dries out the packing leather, causing leakage past the piston-head; this difficulty being especially troublesome where the wrong kind of oil, or an insufficient quantity is used. Leaks around a driver-brake generally receive less prompt attention than in other places, because of the difficulty of locating them or getting at the point when located.

To locate a leak around a driver-brake, the best way to begin is by making it into a straight air brake, which can be done by turning the triple valve handle either straight up or straight down, and if on account of some obstruction it is impossible to do either, then it must be done by removing the handle and with a wrench turning the plug so as to let the air directly from the train-pipe into the cylinder, the direction of the ports through the valve or plug being shown by the usual grooves cut on the end of the plug.

In the meantime the handle of the engineer's valve must be left in the release position so as to allow the main drum pressure to have free access to the train-pipe. It is almost worse than a waste of time to try to find a leak around a driver-brake by an ordinary or automatic application of the brakes, as the pressure even when fully equalized is not over 50 lbs., and if the leak is of any size all the pressure in the pipes and cylinder will escape before the trouble has been found.

Many and frequent are the complaints about the driver-brake, and all because the right method is not pursued in remedying the difficulty.

*First*, locate the seat of the trouble and cause of the disease, and *then* administer the proper remedy. This is a universal rule.

When the brake does not hold properly, many men take a wrench and proceed to tighten all the pipe-joints indiscriminately, when the only cause of difficulty may be dry packing-leather in the cylinder. There would be just about as much reason in the action of a doctor who, not knowing what ailed his patient, gave him half a dozen opposite remedies in succession, in the hope that some one might reach the seat of the disorder.

So far mention has only been made of brakes which did not hold well. Cases are also sometimes encountered in which the brake holds too well. The premonitory symptom of this is a very disagreeable grinding of the engine-brake just before the train comes to a stop. This trouble is almost invariably caused by too great a piston travel, allowing the cam levers to come too close to a horizontal position, thus greatly increasing the power of the toggle.

Setting the shoes closer to the wheels is of course the proper remedy, and one which seldom or never fails to accomplish the desired result.

PAUL SYNNESTVEDT.

*Chicago, Ill.*

## Laying Out Back Cylinder Head.

*Editors:*

I have just read Mr. Hitchcock's ideas in regard to laying out a back cylinder head of a locomotive. I do not wish to criticise Mr. Hitchcock's writings, but wish to offer an improvement. In the first place, we are given to understand the head of the engine is in a roundhouse 200 or more miles from a shop. He then says you are to get a piece of wrapping paper, black lead the end of the cylinder and get the helper to hold the paper while you are getting the impression. Then cut out the paper, lay on the head and mark holes, taking care to have the risers in head correspond with port-hole in cylinder. You then drill holes for bolting on.

Now, some roundhouses have no means of drilling, except by hand. Perhaps he did not make allowance for that. After drilling you grind head to cylinder, then bolt on temporarily and proceed to lay out holes for guide blocks, by leveling engine, using long straight-edge across frames, and then setting level and small straight-edge to long one, striking a line across head according to his instructions, laying holes out for blocks so bottom of block will be 1/16 higher than bottom of crosshead. Now this is not right, as the crosshead might have thin gibs on bottom, or the block might be planed off some time in the past and be out of center. Then, according to his instruction, the holes in head would be too high or low, as the case might be. Then when new gibs or blocks are put in and on it will be discovered that the holes are not in the right position. After block-holes are laid out the head is again taken off and taken somewhere to be drilled, brought back and again put on. He does not give an idea of how to get the thickness of head, as this is very important. And in regard to the paper template or pattern, I do not like that, for I do not think that is a mechanical way of getting at it. Another thing, that far from home, what if a person could not get any wrapping paper, what then would he do? I will endeavor to show how all could be done at the shop before sending head to roundhouse, if thickness was sent, and that can be easily done by measuring from end of guide in position to joint of cylinder head on cylinder, and also sending which side of engine head is intended for.

The C. R. I. & P. R. R. placed order this month, with the Brooks Works for three six-wheel switchers.

## Draining Train Line in Yard Tests.

*Editors:*

I notice that for some time there has been a great deal of discussion as to the practicability of draining the train line in making yard tests. As I have had some experience in that line, and find that it cannot be practiced without a loss of time and a great deal of annoyance, I will try and tell why I think this rule should not become general, especially in freight service.

I would like to say right here, that on this road (A. T. & S. F.) there is a loss of time in testing the air, occasioned by the engineer not starting his pump until ready to attach to train. In charging a train of twenty-five to thirty-five quick-action brakes under such circumstances, and then to deliberately waste all the air in the train line, is certainly a waste of time, because there will not be pressure enough in the main reservoir sufficient to release all the brakes, thereby causing a vast amount of annoyance to the inspector and a great deal of unnecessary work for the pump. I don't think that the order "to drain the train line" could be followed with any degree of satisfaction; for this reason, viz.: The brass check-valve (Plate D 31, No. 15) in the lower case of the new quick-action valve is seated on an iron seat, which is constantly exposed to moisture and in consequence becomes so corroded that the check-valve will not seat, though the valve may have been in service but a short time.

Now if the train-line be drained the air pressure from the train-line (that has been assisting the emergency spring to hold the emergency valve up to its seat) will pass through the defective check-valve seat and pass out with the train-line pressure. By this action of the brake the auxiliary reservoir pressure that has passed to the brake-cylinder and on top of the emergency valve, will overcome the resistance of the emergency valve spring, and pushing the emergency valve from its seat, will allow the brake cylinder pressure to pass down on top of check-valve, thence through the defective seat and follow the train-line pressure to the atmosphere. In other words, it will allow the brakes to speedily leak off. I venture to say that, if 25 to 35 quick-action brakes be taken from actual service and be tested by draining the train-line, that fully 25 per cent. will have leaked entirely off before the inspector had gone the length of the train.

I would like to hear from others on this question, as it is advocated by a number of the best-posted air-brake inspectors in this part of the country.

*Fort Madison, Ia.*

## Lubricator Difficulties.

*Editors:*

I will endeavor to answer the lubricator puzzle that you were kind enough to publish in your March issue of '92.

I have seen but one attempt to answer it as yet. Mr. C. B Conger asked if the condenser-pipe was full length.

The lubricator was in good working order with the exception of a deficient gasket at bottom of sight feed-glass.

Mr. Conger says that when the condenser-pipe breaks off, that the oil will go into the condensing chamber and from there through steam-pipe into boiler, but I think Mr. Conger is mistaken. If he will tell how oil can go against the steam pressure of the boiler, which is greater than that of the cylinders, then I will say that he is right. Mr. Conger answered the puzzle when he said keep a good gasket in bottom of sight-feed glass. The oil in my lubricator went from the oil tank through the cavity around feed-valve and up outside of glass and under glass and up through glass into tallow pipe.

By taking feed-valve out and putting in a small gasket at bottom of glass it stopped the flow of oil around glass and lubricator went to work all right.

In July number there is a lubricator experience from New South Wales. I will try to answer it. When Mr. Hays drained the lubricator the condenser valve was not shut off tight, or there was a leak in valve, and the water went out of the condenser, leaving a vacuum in condenser globe, and a small amount of oil went into the globe. When he attempted to start his lubricator there was no water in condenser and lubricator would not work; but as soon as the globe was condensed full of water his lubricator went to work all right.

## The Wheel that Slid Flat.

*Editors:*

Referring to Mr. Stewart's letter in September LOCOMOTIVE ENGINEERING in which he gives a novel and original solution to this phenomenon, I should like to say that after examining several styles of car and tank trucks and their brake rigging, I fail to see the combination of circumstances that would permit the wheel to climb the brake-shoe. Look at it as I will, his philosophy bears a close resemblance to lifting one's self by the appendages of footwear.

Suppose one hanger is shorter or longer, won't the brake-beam and shoe go up or down with it?

Would not the observation of such phenomenon give rise to the question of safety of running trucks, the wheels of which disregarded the action of gravitation when the brake was applied?

There are many other questions that naturally suggest themselves, none of which could be answered in a satisfactory manner without a sketch, showing the truck and whatsoever else is necessary for a thorough understanding of the question. If the Editors will permit I will respectfully ask Mr. Stewart to contribute such sketch. It would also be well to state the position he was in when he saw the wheel come up. I say this, thinking, if on his engine, that possibly he was deceived by seeing the *truck frame go down* instead of the wheel *coming up*.

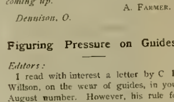
*Dennison, O.*

## Figuring Pressure on Guides.

*Editors:*

I read with interest a letter by C. F. Willson, on the wear of guides, in your August number. However, his rule for finding the pressure on the guide is not correct. An easy and correct way for him to do so would be thus:

On the center line of engine lay off $A\ B$ to scale equal to the pressure on the piston. Draw $B\ C$ at right angles to it



and draw $A\ C$ parallel to the main rod. $B\ C$, to the same scale as $A\ B$, will then represent the pressure on the guide.

This is not necessarily intended for publication, but is directed to you because I have not Mr. Willson's address, and, as he seems to take an interest in the matter, I think it is worth while to set him right.

GEORGE F. D. TRASK.

*Philadelphia, Pa.*

## Relating to Brakes.

*Editors:*

The brake failing to apply on forward section of parted train is explained thus: when the train parted the hose at rear end of box car doubled back, under pressure, and the hose-coupler caught behind hand-brake staff, the hose elbowing and flattening at so sharp an angle as to prevent the

escape of air. The bell-cord caught under the running board of the car roof and was held tight, breaking to the rear of it.

BRAKE LEVERAGE AND CHANGE OF FULCRUM.

It is a pleasure to attempt answering C. B. Conger's questions, as they are always original, but I think he practically answered one of his questions in the August number before he asked it. Regarding Union Line brake-gear, the bracket-pin is a fulcrum to second brake-lever when hand-brake is slack and the braking power is supposed to be distributed equally to each truck, but as Mr. Conger says, the bracket-pin fulcrums the lever at a point between the connection to hand-brake and the source of power; therefore in applying hand-brake and drawing brake-lever away from bracket-pin, a new fulcrum is formed at hand-brake connection, which, being at the extreme end of lever, and further from the source of power, greater leverage is obtained and the brake at that end of the car gets a greater leverage and greater power than the brake at the other end.

But, there will be another result Setting the hand-brake on car roof takes up the entire slack of brake-gear, giving a minimum piston travel and consequently maximum piston pressure, which increases the braking power of every shoe on the car.

LEAKAGE GROOVES.

Brake-cylinders on a vehicle whose train-pipe is always in direct connection with the source of air supply do not need leakage grooves because the pump is continually generating power necessary to hold the triples in release position, and while in that position any leakage of air to the brake-cylinder will pass away through the regular exhaust ports and triples cannot fall while train-line pressure is maintained. In case it becomes necessary to stop the pump, the release cocks on engine and tender auxiliaries may be opened and there will be no pressure to leak to brake-cylinders.

Neither do tender brake-cylinders require leakage grooves, but as they are the standard 8-inch car brake-cylinders they have the groove for the sake of uniformity.

STOPPAGE OF PUMP GOVERNOR.

Before taking up Mr Relyea's latest air-brake puzzle, one might desire that he should complete his explanation of the difficulty he mentions in the July number, by stating exactly the defects of that pump governor. His answer is indefinite enough to create doubt as to the safety of using the Westinghouse pump governor

EDUCATIONAL AIM OF THESE LETTERS

It is so easy to get up an air-brake puzzle, and the field so unlimited, that one might be tempted to work on the credulity of ambitious correspondents, but it should be remembered that LOCOMOTIVE ENGINEERING is read by a great many experts who are inclined to be critical, and as the paper is intended to have an educational effect, one should be accurate in explaining as well as propounding problems.

*Terre Haute, Ind.* WILL W WOOD

## Brakes Applying in Release.

*Editors:*

In reply to Paul Synnestvedt's question in the July number, regarding brakes applying when brake-valve was placed in release position, my idea is the air pump had stopped and there was a leak in main drum or connections, which caused a reduction of air-pressure in drum less than that of train-pipe; a slight leak in train-pipe caused brakes to creep on. When handle of brake-valve was pushed back to release position air flowed back into main drum, causing additional reduction in train-pipe, causing brakes to go on harder. The engineer finding pump had stopped started it, and after he had accumulated enough air in main drum to overcome reduction of main-pipe brakes released.

*Huntington, Ind.* FRED. S. COLNON.

*Editors:*

Would say of those brakes setting in full release, that air pump had stopped, train line pressure had gradually leaked away and brakes crept on quietly. Main reservoir pressure had also leaked away to keep up the drag on train line, till A. R. pressure had almost equalized with the latter. When handle was thrown to release position a greater volume of air striking the bottom of brake-valve piston, raised it from seat, setting brakes harder. The air also acting on pump governor started pump and released brakes.

## Wants Some Break-down Pointers.

*Editors:*

I should like to ask three questions in LOCOMOTIVE ENGINEERING to get the replies of its experienced readers on each. Different men have different ways and I hope you will give all a chance to answer.

1st. I am seeking information and will ask you how I would fix engine if I was on fast stock train and broke right go-a-head eccentric strap, how could I get to end of division with full train that engine could not handle on one side?

2d. If back tire on 6-wheel connected engine broke off and middle wheels had no flanges, how would I block engine so as to get in and back up and go-a-head safely?

3d. Suppose engineer started out and for some cause took down right main rod, threw liners, brasses, straps, all on ground so could not tell anything about where they belonged; master mechanic sent me up to put engine together. Where would I place engine and how could I put up rod and have it right.? K. T.

*Dennison, Tex.*

## Automatic Block Signal Advantages.

*Editors:*

Noticing in the August and September numbers of your valuable journal, editorial notes on the adverse criticisms which have been made upon block signal systems by reason of the failure of one system, (namely, at the Harrisburg accident), I am led to inquire whether you consider it necessary that block systems should depend at all upon human agency for their operation. In the case in point it appears that the accident was occasioned by the failure of the operator in the tower to show the danger signal. There are block signal systems, as for instance, the Union Switch and Signal Co.'s system and the Hall system, in which human agency is not employed, directly, at least, and in which, when a block is occupied, and in case of neglect to attend to the apparatus, or in case of accident to it, the "danger" signal is automatically shown. At all other times "safety" or "caution" signals are shown by electro-magnetic services Are not such systems preferable to those in which human agency is directly employed? Enginemen on the Jersey Central road, on which, as you are aware, one of the automatic systems referred to is employed, tell me they have in it the utmost confidence.

*New York* WM. MAYER, JR

[If we understand the case rightly, the trouble at Harrisburg was because of the want of a check from one tower to another; in other words, the signals were not interlocking, and it was therefore possible to give a wrong signal. Any system that prevents such blunders is an improvement.]

## Wages--The Equalizing Piece-Work System.

*Editors:*

There seems to be a great deal of injustice and inconsistency connected with the much agitated wage question. Let us confine ourselves to machine shops. A large employer may have what he pleases to call a standard or limit to wages paid. Railroad companies have the same system; 25 cents an hour may be called the standard or limit. Men come and represent themselves to be machinists; they are employed and paid 25 cents an hour; they can do a fair job on lathe or planer, but can do nothing at the vise, or they can do an ordinary job at the vise (if you give them time enough) and do nothing on a machine. Yet these men are pitted against the man who can do a first-class job on lathe, planer or vise, yet he is brought down to the same level with the botch, on the wage question, and ability goes for nothing. This condition of things is not right, and is a gross injustice to the first-class man in all branches of mechanics. It costs no more to pay Smith 30 cents an hour and Jones 20 cents than it does to pay each 25 cents; while the abilities of Smith make him worth $1 per day more than Jones, they each get $2.50 because that is the standard. Here is Smith at work in a job shop; a man comes in and complains that his engine will not run the saw, and is using too much fuel for the work done, who is sent out, Smith or Jones? Smith of course, his employers want to build up a reputation, and what does he find? Perhaps the valve or packing is blowing so bad that steam is on both sides of the piston at the same time. Or again, the new valve the shop across the street put in has too much inside lap and the engine is choking herself He applies the proper remedies and the engine makes things whirl. Result the Enterprise Machine Company gets lots of praise and Smith gets 25 cents an hour, the same pay Jones gets, who don't know a valve when he sees it. If any intricate job comes in, in the line of steam-pump, steam-gauge, or injectors, Smith gets the work because he is the only man in the shop who can take anything that comes along, but do his employers appreciate his abilities enough to pay him $3 per day?

These are not fancy sketches but facts coming under the writer's observation and in places where the general foreman and his bosses were stuck on the jobs. Jones belongs to a class of men who are looking for a job, but not for work; or a place to put in the time and draw the pay It is not an uncommon thing for machinist runners while working in the shop to get engineers' shop pay, which is less than regular machinists' pay; this man may be doing first-class work in the shop, yet because he is an engineer he must be paid engineers' shop pay only. The writer has had some bitter experience in that line, and the practice is wrong in every detail.

Note the practice in some railroad shops. The company are always kicking about reducing the operating expenses, and take these things as an excuse to keep down wages. Now, why not look into these things and see where there is money expended that had better go into wages.

An engine comes into the back shop for general repairs; one of the Jones crowd will get a copper injector-pipe and piece of emery-cloth and use up ten hours doing two hours' work; another fellow gets the steam-pipes on the floor and takes a lease on them grinding in the ball joints Two or three men will take the boiler-head attachments and monkey two or three days on them; another of the crowd will get the throttle and grind the life out of it, and if it never leaked before it will now. Yet these louts will get the same pay that the men do who line up guides and shoes and wedges, simply because they are hired as machinists. Why not have one good man at $3 per day, and let two of the Jones gang go.

Main and side rods come in covered with filth and rust; they are polished up in first-class style; the engine goes out on a freight run or in the yard, and the finished surface never sees daylight again. What good does it do? Why not paint them and put some of the emery-paper money into wages.

Now comes the labor agitator and says this extra finish makes work for more men. This same agitator, when he sees a man running two machines and is making money by so doing, says you are keeping another man out of a job. We feel like saying about this *other man* what a certain railroad magnate once said about the public. Some of the leading railroads are adopting the piece-work system in repair work, which is a move in the right direction, as it very soon draws the line of ability between Smith and Jones, and will do what trades unions fail to do, it will give the expert workman a chance to earn wages he is entitled to and put Jones on half pay. A WORKER.

*Baltimore, Md.*

## Relyea's Whistle-Signal Puzzle.

*Editors.*

Mr. Relyea's September nut can be cracked this way The main-reservoir pressure wasted away through a leak in the rubber diaphragm of reducing-valve, but the area of leakage was no greater than the feed space around the stem of whistle-valve, and the air leaking away gradually from both sides of the whistle-valve diaphragm, the valve remained closed and the whistle could not blow

When the hostler put the engine in the roundhouse, he made the stop by throwing the brake full on and exhausted all of the air from the train-pipe, and instead of releasing the brake he only pushed the handle back to lap and left it so. The brake-valve being on lap, all ports are blanked, and with a nicely-seated rotary-valve and tight connections, the small valve-reservoir will retain its air and register a high train-line pressure by the black pointer of the gauge when, perhaps, there is not an ounce of air in the train-pipe

When Brer Relyea made his appearance, the train-pipe was empty, although the black hand stood at 50 pounds. The red hand showed but 10 pounds in main reservoir, and when the pressure is so low there is direct communication between signal line and main reservoir through the reducing-valve. He pushed the brake-valve handle to the full release position and the reduction of main-reservoir pressure in filling the brake-pipe reduced signal line pressure and caused the whistle to blow, and it continued whistling intermittently until the auxiliary reservoirs were charged and pressures equalized, which, in this case, was hastened by starting the air-pump. WILL W. WOOD.

*Terre Haute, Ind.*

*Editors:*

In answer to the air-brake puzzle in August number by W F. Relyea, would say, that as pump had seen enough service to be reported as worn out, that gum had accumulated in countersink of bottom head into which the nut and bottom end of air piston-rod play, which would prevent the piston from pulling trip-rod down far enough to perform its work, and thus supply steam to send the piston up.

BRANDON LEONARD.

*Editors.*

In answer to Mr W. F. Relyea's air-pump puzzle would say, that the boss on lower side of steam cylinder-head was jammed against collar on upper main steam-valve cylinder so that when main steam-valve came to pull upper stroke it became wedged owing to the bush being squeezed out of shape This would prevent pump working and I presume this is what the hammer and chisel was used on.

*Winnipeg, Man.* W. S

## An Old Thing Made New.

*Editors:*

"Connelly's Axle Lubricator" in the September number of the LOCOMOTIVE ENGINEERING, is an old device.

Early in the 50's, Ned Andrews, a foreman in the Philadelphia & Reading Railroad shops at Palo Alto, under J E. Wootten, got up the same device, and it was put in use on a passenger engine running on the Tuscarora branch and gave no extraordinary results.

Andrews had a tin tube fitted with a valve in the one end that opened when forced against the bottom of the hole in axle and allowed the oil to escape. Otherwise it was the same as Connelly's.

# A PLAIN STATEMENT OF FACT.

THE Compound Engine, when non-condensing, so far from possessing an economy superior to the simple engine, has been decisively proven, "much to the disgust of the stockholder," to show normal economy only at or about its rated power, and to fall off in economy faster than a simple engine as the load falls off; moreover, very much faster under the extreme light loads that are common at times in many industries. This point is at last reluctantly admitted by the more candid builders of such engines, most of whom now advise against compounding for variable loads. The reason is in their inability to divide the load and range of temperature proportionately and automatically between the cylinders at all points of cut-off. Hence, the low-pressure cylinder expands its steam below atmosphere under a moderately early cut-off, thus converting itself into an Air Pump, and becoming a load upon the high-pressure cylinder instead of a co-laborer with it. This point was distinctly foreseen by the designers of the Westinghouse Compound Engine, and an entirely new principle was worked out, making expansion below atmosphere impossible under any load, however light. For the first time in the history of Steam Engineering, either Simple or Compound, is built an engine which maintains essentially uniform economy, irrespective of load, and hence for the first time the Compound Non-condensing Engine has been made practicable. The results, demonstrated by test, show that where an ordinary Compound will range from 25 lbs. to 70 lbs. water per H. P. per hour from full to quarter load, the Westinghouse Compound, between the same limits, will range from 23 lbs. to 29 lbs. We have not deceived ourselves in this matter, and propose that the facts shall be understood. To those interested in the nicer points involved we will be pleased to send a reprint of the Paper read by Mr. F. M. Rites on this subject at the late meeting of the American Society of Mechanical Engineers at San Francisco.

## Emergency and Service Application of Brakes.

By George Holmes.

Since your July issue I have found one of the old-style hose couplings with the valve still in it. These were in use before the stop-cocks were put in train-pipes, and if there was such a thing in that coupling on rear of first section of the train that broke in two, as described on page 241, it would have been surprising if it had acted otherwise.

While I can understand how a pump-governor could shut off till a brake leaked on, I fail to see how a train could be handled at all when the governor was in such condition that air would leak through it fast enough to set brakes, and should think there would be so much variation in pressure that it would be noticed and repaired before the engine was sent out.

I am very much pleased with Brother Synnestvedt for his protesting against placing restrictions on engineers, or in giving them a set of rules that would tend to make them automatons in their duties, but I foresee a long discussion on the handling of brake-valves and the action of air-brakes, and hope that all who are posted in any way on these matters will assist in their ventilation, and in order to make good my July statement will describe the situation here.

The road is composed of track under perhaps a greater variety of conditions than are usually met with. There are whole divisions almost level and very straight, and others that are nothing but mountains. Some of the trains are main-line trains, and are handled by many different men; others run on not more than one or two divisions. These engineers know every car, and all are handled very nicely, although the men on this road never had a printed set of rules, neither have instruction-books been issued to them, and the road foremen do not try to chain them down on these matters. It is understood here that a man who is intelligent enough to handle an engine will not injure it willfully, and that such a man, if he knows what he is handling when he has hold of a brake-valve, will be of far more benefit than one who is merely an effect with no cause whatever. We, therefore, instruct engineers as follows, knowing that he has some experience in using power. We tell him about what power is conveyed to the wheels to brake with, and what will slide or lock them. He is then given to understand that the triple valve is the most important factor, and that it is a mediator between the auxiliary reservoir and the brake cylinder, by this showing how the air is passed through the valve and having him time the reservoir while recharging, and watch a gauge on the brake cylinder until he is satisfied he knows the approximate effect of every application. He is also given to understand that the brake-valve, although separated from the triple valve, is nothing but a highly-adjusted throttle and reverse bar, which, kept in order and handled properly, will give him control of the machine or valve that manipulates his reserved volume of air in auxiliary reservoirs. Another arrangement is made with him to the effect that if he finds he has been misinformed or misinstructed, and cannot use air as advised when it is in good order, he is to let me know, and if I cannot make the matter agree with what I told him he is to call me down. I am also to see that his air is kept in as good order as it is when he is instructed.

We have also one way of keeping up brakes on mountain service where but one or two men handle the same train and another on main line where all have it. On main line the piston travel is about 7 inches and many coaches have six-wheel trucks with brakes on four wheels or only 60 per cent. breaking power, and the cars are generally loaded so that figured at 90 per cent. light weight they would stop as quick or quicker in emergency stop than in service stop, although one of our main line runners will stop any passenger train with ordinary air in as short a distance with service stop as emergency, and he will not use it at all unless his service stop fails to act.

Now on the Clinch Valley Division the service is very severe on brakes. It is a mountain road full of curves and nearly new, with all that that implies. Three good men handle the passenger trains there and their travel is set just to clear the leakage grooves, as so much air as is used on long piston-travel cannot be spared. The trains are light and the traffic does not add much to the weight, so they probably have over 100 per cent. braking power. The men do not use much over 12 lbs. of air to make their stops with and the speed is fast for such a road. In the early spring one of the engineers hit a cab and according to instructions usually given in such cases, used the emergency stop to make sure, while he knew he could stop short of the cab on service stop. This brought up a new question, as all these men relied on my instructions, and to test them they in turn stopped at this switch, both on service and emergency stops, and proved to their satisfaction that they could stop shorter by the use of service stop than by emergency. Of course when I came around they were ready for me and we had a love-feast, but by repeating instructions and making clear the action of the brakes I showed that this action was natural and in perfect accord with the best practice.

Now, while these engineers have such brakes and make such stops, it is because they know they have more power than the cars are figured for, and they use it accordingly. Now, the question, is have they a right to use the emergency stop when they know they could stop short of danger with the other? And here I believe should be made a plea for an automatic slack adjuster that will keep all brakes equal, as in this lies often the cause of unsteady trains. If triple-valves would graduate as they were designed this should bring us much nearer that haven so much dreamed of by air men.

Another statement that puzzles me is that after an emergency application the leaking of the triple-valves can be prevented by putting the brake-valve handle on lap. In order to get these valves to leak the train-pipe pressure must be reduced below that in the brake cylinder, and in order to stop the leaks the pressure must rise above it again. As putting the brake-valve handle on lap would not add to the train-pipe pressure, I think they would still leak, and where trains follow each other closely it would not be so easy to start with air exhausted from train-pipe, and in such cases getting away is almost as important as stopping, while, if a quick-action application were made instead of an emergency, there would be some forty or more pounds of air left in the train-pipe, which would be of great benefit, and have a pound or so higher pressure. There may perhaps be a claim made that emergency and quick-action stops are the same; but for my part I think there is a wide difference, and would like to hear what others know of it. And now as I believe this discussion is fairly started, and that I have been heard rather more of late than necessary, I will stand aside for a while and give others a chance, that the ones who have been through the mill may add their experience and assist to clear away the difficulties which unexplained have lent a shadow of mystery to the working of air-brakes, and while it lasts will continue to be a useless source of expense and danger.

*Roanoke, Va.*

---

The Order of Railway Trainmen and the Order of Railway Conductors made a joint request last month on the management of the Chicago, Burlington & Quincy for an adjustment of wages. An amicable agreement was come to between the men and the company.

## Grand Trunk Locomotives.

Of late years the tendency of railroad mechanical officers has been to work down their locomotives to standards, making as many parts as possible interchangeable and making the fewest possible number of engines meet all the requirements of train service. We do not think that any large railroad on this continent has succeeded so well in this line of improvement as the Grand Trunk Railway of Canada. This company have got down their locomotives to fine standards. The leading characteristics of the five styles of engines are

First, a tank double-ended switcher, with cylinders 17 x 22 inches, two pairs of coupled driving wheels 62 inches in diameter, a four-wheel truck in front and a pony truck behind carrying a coal-box that has a capacity of 3½ tons of coal. The total weight of this engine in working order is 126,000 pounds.

Second, an eight-wheel passenger engine with the same cylinder and wheel dimensions as the last and many of the parts of the same size The leading difference is that this engine has a tender and no trailing pony truck The tender has a capacity of 2,500 imperial gallons and 20,000 pounds of coal. The total weight of the engine in working order is 86,300 pounds.

The third class is a six-wheel switcher with cylinders 18 x 22 inches. There is a saddle tank which carries 1,860 imperial gallons of water, and a back tender carried on the main frame which has room for two tons of coal. There is no separate tender. The weight of this engine in working order is 114,632 pounds. All the weight is necessarily carried on the driving wheels, for there are no others.

Class four is an eight-wheel engine suitable for heavy passenger or fast freight service. The cylinders are 18 x 24 inches and the driving wheels 68 inches in diameter. The total weight of the engine in working order is 98,084 pounds, 58,016 pounds resting on the driving wheels. The tender carries 2,500 imperial gallons of water and ten tons of coal.

Class five is the latest designed, and is a mogul engine adapted for either passenger or freight service. The cylinders are 18 x 26 inches and the driving wheels 62 inches in diameter. This engine may be said to embrace all the latest improvements in locomotive design. The weight on the driving wheels is 28,448, 27,216 and 24,752 pounds, respectively. The total weight of the engine is 96,376 pounds. The traction force at the rail per square inch of piston is 135.87 pounds. The grate area is 17.66 square feet, and the total heating surface is 1,231.5 square feet.

All the engines have straight boilers with a big dome in the middle, and the firebox is bound to the shell by radial stays. As compared with the best American practice all these Grand Trunk locomotives are deficient in heating surface, but the engines are said to work very satisfactorily. As the tendency toward greater heating surface has become very pronounced of late, it may be that the mechanical department recognize the shortcomings of their designs, but prefer maintaining uniformity in preference to improving the proportions to meet modern requirements.

## A Genuine All-Round Workman.

The Canadian Eastern Railway is a road 126 miles long, of standard gauge, has 8 locomotives, 8 passenger cars, 4 snow plows and 94 miscellaneous cars. It has a president and general manager, a superintendent and general freight agent, an auditor and car accountant, a treasurer, mechanical superintendent and trackmaster. In short, a full force of executive and operative officers. This is nothing unusual and would not entitle the company to special notice. But after the officials named, there comes a man whose name does not appear in the published list of the company's men of honor, nevertheless he makes the road worthy of notice This individual is rated as a carpenter, but there is no other such carpenter on this continent.

On getting to the shops in the morning, this carpenter starts work by wheeling into the blacksmith shop a supply of coal to last the day. Then he goes out to the yard and inspects all the cars and makes whatever repairs are necessary Then he returns to the shop and repairs the desks, locks and furniture belonging to the offices and stations. This being finished he paints and varnishes any of the rolling stock or furniture requiring any attentions in that line. His next duty is putting glass into headlights, cabs or passenger cars that may have been broken. By this time the electric bath is ready and he proceeds to electro-plate headlight reflectors, lamps or any other things that need that operation. This work accomplished, he turns to his tin shop department and solders up any cans, lamps, pails, ventilators or anything else in this line that calls for attention. He puts in an hour here, occasionally making new oil cans, lamp fountains, etc. When there is nothing else waiting to be done, this carpenter enjoys a turn at his own trade making cabs, tool boxes and hand cars. When a locomotive needs lagging he puts it on and does any repairs needed to the jacket.

A department of the road where he is the sole foreman and workman is the care of buildings and bridges. If a station house wants to be repaired or a new freight shed built, the carpenter is called upon to do the work, and he responds promptly. If a bridge begins to get shaky and needs new timbers or a general overhauling, the carpenter goes out and performs the work. The management appreciates the value of this man of many duties to the extent of paying him $50 a month.

## Hand Brakes on Engines.

It would make an American fireman's heart ache to see how faithfully all hands stick to the hand brakes on engine and tender in Europe. The runner rarely "plugs" his engine around the yard—even the switchers wait for the fireman, the screw brake and the wooden block to do the stopping.

The brake staff is generally incased in a 4 or 5 inch tube and the handle is not unlike a street-car brake except that it is straight. It is generally polished all over and carefully scoured daily, and oiled to prevent rust when the engine is left in the shed or yard

Beside this, the device is almost universally placed in the way, taking up much valuable room.

In some classes of engines there is a screw brake on both sides of the engine, there being no beams across from one to the other, in this case it is not uncommon to see both enginemen screwing away at them. On some of the older tenders there are also two.

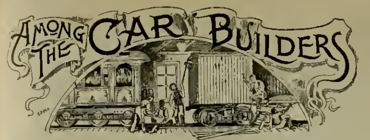
Power brakes on train and engine do not seem to diminish the prestige of the hand "squinch" in Europe as it has in Yankeedom.

## Same as the Footpad.

"The first lesson in the art of money-getting," says Andrew Carnegie, "is the knowledge that it isn't the man who does the work who makes the money, but the man who gets the other men to do it."—*English Magazine*

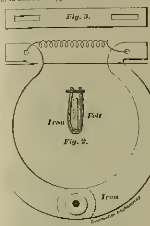
---

Mr. George Vernon, the oldest locomotive engineer on the Pennsylvania Railroad, died at Bordentown, N. J., last month.



## A German Dust Guard.

On the government railroads of Germany they use what seems to be a very sensible and efficient dust guard on their coaches. This is made of ⅛-inch iron cut out of the



flat in pieces like half of Fig. 1; two of these are riveted together, forming a hinge, they are covered with thick soft felt sewed so that the two edges come on the inside. See Fig. 2. This is opened and clasped around the axle, and a yoke piece of flat iron, like Fig. 3, hooked over the top ends This is also covered in the center with felt.

Into the holes in the horns a light coil spring is hooked that tends to keep the felt always pressed against the axle.

These guards run on an average 72,000 miles, and then only need recovering with felt to make them as good as new.

## Tough Cast-Iron Wheels.

The Mt. Vernon Car Manufacturing Company, of Mt. Vernon, Ill., have succeeded in selecting a mixture of iron that makes car wheels of extraordinary toughness. This company has been building cars for the Louisville & Nashville Railroad, and the inspector of the latter company subjected fifty wheels to the Master Car Builders' standard drop test of 140 pounds weight, falling 12 feet. By this test a wheel is required to stand five blows before a piece breaks out. The Mt. Vernon wheels went far above the requirements. It took an average of 37.18 blows to break the wheels, and five of the fifty tested did not break under the ordinary drop, although as many as ninety-five blows were given. This is the best record we have heard of cast-iron wheels making under the drop of 140 pounds falling 12 feet.

## James T. Leighton.

For years one of the most popular men attending the Master Car Builders' conventions has been Mr. James T. Leighton, who had been a member of the association for twenty years. When he joined he was a member of the New Haven Car Works. His numerous friends will learn with sorrow that Mr. Leighton died suddenly at Portland, Me., during the last of August. For some time he has been connected with the Consolidated Car-Heating Co. At a meeting of this company the following resolutions were adopted.

The officers and employés of the Consolidated Car-Heating Co. learn with sorrow of the death of their associate, Mr. James T. Leighton, of New Haven, and at this their first meeting since that sad event desire to put upon record an expression of appreciation of the admirable qualities which endeared Mr. Leighton to so large a circle of friends. Though in the last few years failing health made him able to take up only part of that full measure of service which formerly brought him in active contact with railroad men throughout the country, yet whatever work fell to him was always done cheerfully, and wherever he went he was always accorded a generous welcome.

His life was that of a Christian gentleman, continually thoughtful for others. His loss will truly be felt in many places outside his own family. We deeply sympathize with those of his own household, and trust that these few words may in slight degree convey to them the affectionate regard in which James T. Leighton was held by those who knew him best in business life during the few years just past.

## New Horizontal Tenoning Machine for Car Builders.

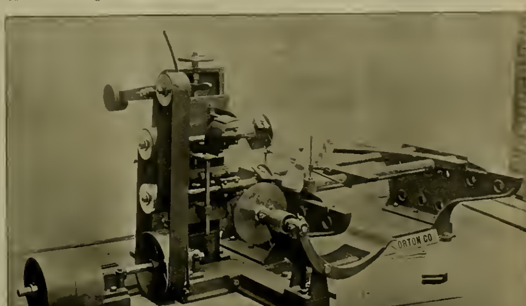
The handsome engraving on this page is itself a good description of a new tenoning machine recently designed by the Berry & Orton Co., of Philadelphia.

It is a horizontal tenoning machine that cuts both sides of the stick down at once, and has a saw that is thrown back, cutting off the "heel" in brace tenons, all at one operation.

The mode of driving the two cutter beads is plainly shown, together with the mode of adjustment for size of tenon.

The table, with its provision for holding work at any desired angle to the cutters, is also plainly shown. With such a tool it is possible to duplicate any piece used in a car frame, and insure uniformity and interchangeability.

One of these tools can be seen in operation in the works of the Haskell & Baker Car Co., at Michigan City, Ind.



New Horizontal Tenoning Machine.

## Master Car Builders' Committees of Investigation for Next Year.

Secretary John W. Cloud reports that the following committees have been appointed to investigate the subjects stated and report at the next meeting of the convention.

*1. Drawbars and Brake-Beams*—To consider the suggestions of the Committee on Standards, as to standard height of drawbars, and as to standard form of brake-beam, and report with recommendations and drawings in detail.—E. D. Nelson, John Bean, J. R. Rankin, C. A. Schroyer.

*2. Axles, Journal Boxes, Lids and Wedges*—To consider the suggestions of the Committee on Standards, and to recommend in detail, with drawings, how these standards should be modified and published.—R. H. Soule, W. H. Day, W. H. Lewis.

*3. Truck Pedestals and Safety Chains*—To consider the suggestions of the Committee on Standards, and to recommend in detail, with drawings, how these standards should be modified and published.—T. A. Bissell, Wm. McWood, A. E. Mitchell.

*4. Protection to Trainmen and Lettering Fast Freight Line Cars*—To consider the suggestions of the Committee on Standards, and to recommend in detail, with drawings, how these standards should be modified and published.—E. P. Lord, Robert Walker, Thomas Sutherland.

*5. Tests of M. C. B. Couplers*—To arrange for and conduct the tests, as proposed by the Committee of 1892 and approved by the Convention, and to consider and report upon all other questions connected with M. C. B. coupler which they might consider advisable, with the exception of the attachment at the rear end of the coupler and the form of the coupler at that point. To confer with the Committee on Attachment of M.C.B. Couplers to Cars.—J. M. Wallis, J. S. Lentz, R. D. Wade, J. H. McConnell, E. Chamberlain, T. G. Duncan.

*6. Attachment of M. C. B Couplers to Cars*—To recommend a form, in detail, of M.C.B. coupler at rear, and so as to take yoke, tail bolt and continuous drawbar attachments; also, to consider and report upon the best form of draft attachment to cars. To confer with Committee on Tests of M. C. B. Couplers.—E. D. Bronner, W. H. Harrison, A. M. Waitt, Wm. Garstang, A. Dolbeer, Jno. H. Davis.

*7. Metal for Brake-Shoes*—To investigate the relative friction and wear of different metals and different shoes in general use on chilled treads and on steel tires.—Wm. Forsyth, Benjamin Welsh, F. D. Adams.

*8. Cast-Iron Wheels*—To investigate and report whether there is any substantial difference in wheels made by different methods, such as by solid chills or contracting chills, or by any other difference in process of manufacture.—G. W. West, W. H. Thomas, Jno. Player.

*9. Steel-Tired Wheels*—To investigate further and report with all data available as to relative values in service.—R. E. Marshall, J. O. Pattee, C. H. Cory.

*10. Air-Brake Tests*—To further investigate and report in detail what tests are desirable to insure best available service.—G. W. Rhodes, E. B. Wall, Geo Gibbs, A. S. Vogt, E. A. Williams.

*11. Freight Car Truck Frames*—To include in its report the relative advantages of fixed bolsters and swing bolsters.—J. C. Barber, W. S. Morris, S. A. Crone.

*12. Steel Center Sills*—To consider and report whether the use of steel for center sills in freight cars would be desirable.—D. L. Barnes, J. N. Barr, J. D. McIlwain.

*13. Steam Heating and Ventilation of Passenger Cars*—To review the report of last year's committee on this subject, which was acted on provisionally, and to recommend any changes that may be deemed proper; also, to further pursue the subject of steam heating in general, informing the association as to what improvement, if any, is being made over the methods now in use.—L. B. Paxson, J. J Hennessy, Jos. Townsend, John Hodge, David White.

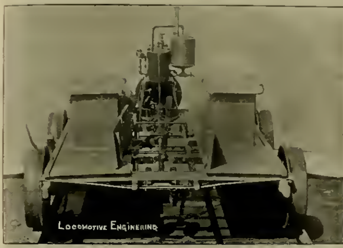
At the Allison Car Works, [illegible]phia, they have introduced th[illegible] tricity for transferring material a[illegible] yard. They have an overhead trolley system and a motor car that traverses [illegible] principal tracks. The system is found [illegible] be much superior to switching en[illegible] is likely to be extended to [illegible] the yard work.

A company known as the Whirlpool Water Purifier Company has been incorporated under the laws of Missouri to purchase the patents and put upon the market the water-purifying apparatus designed and used by Mr. Arthur Pennell, of Kansas City, Mo. Mr. Pennell has several purifying plants at work along the U. P. road where the water is simply awful. The capital stock of the company is only $50,000—a modest sum.

## Locomotive Hand Car.

The annexed engraving illustrates a very neat application of power to hand-cars. One of these cars has been built for the use of a railroad manager, and others have been ordered, so that gas-driven hand-cars may be soon seen on every railroad trying to keep up with the times.

The power used to propel this locomotive is simply made by pumping a very small quantity of gasoline into the cylinder each second stroke of the piston. It is ignited by a small spark from an electric-battery after vaporizing in cylinder; it carries 1½ gallons of gasoline, a sufficient amount to run the locomotive 100 miles. Its total weight is but 550 pounds; can readily be taken off the track by one man on a crossing, and two men can handle it in any locality with ease. Its maximum speed is 12 miles per hour; only requires 20 minutes instruction to manipulate to perfection (or can be handled by printed instructions as well).



Locomotive Hand Car.

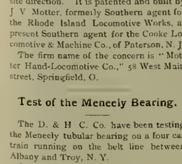
This locomotive is intended for the use of presidents, superintendents, roadmasters, bridge builders, linemen and for all classes of emergencies, by way of inspection. It obviates the necessity of breaking into gangs at work on line for hand-car power; it can be reversed and run in opposite direction. It is patented and built by J. V. Motter, formerly Southern agent for the Rhode Island Locomotive Works, at present Southern agent for the Cooke Locomotive & Machine Co., of Paterson, N. J.

The firm name of the concern is "Motter Hand-Locomotive Co.," 58 West Main street, Springfield, O.

## Test of the Meneely Bearing.

The D. & H. C. Co. have been testing the Meneely tubular bearing on a four car train running on the belt line between Albany and Troy, N. Y.

One train was fitted with ordinary brass



bearings, the other with the tubular, each train weighing 102 tons and both were drawn by the same engine. Eighteen round trips were made with each, a distance of 270 miles.

The coal consumption for this service was 14,800 pounds with the plain bearings and 11,100 with the tubular.

Dynamometer tests showed that a force of 3,276 pounds was required to start the train with plain bearings, while that with the tubular only required a force of 252 pounds.

A gravity test was made by letting the trains run down a slight grade on to a level. The train with plain bearings only rolled 100 feet beyond the incline, while the tubular bearings carried their train 534 feet.

## Cause of Failures in Tempering Steel.

I suppose that all toolsmiths who know anything about steel will agree with you that the lowest heat at which steel will harden is the best, but how is the toolsmith to get this heat? Some smiths have nothing to heat in but a green coal fire; others use coke on the forge; some throw on a little charcoal; others use the hollow fire with coke, and a great many use charcoal in a hollow fire.

In furnaces there is the same diversity; the ordinary green coal or coke furnace, sometimes used with charcoal, the spring furnace used with charcoal, the gas furnace, the lead bath and the piece of gas pipe used either in a furnace or in a green coal or coke fire. The sensible employer supplies his toolsmith with a charcoal furnace which he can regulate to the proper degree for any grade of steel that he may be treating. Where hardening solutions are used that one should be preferred which will harden steel at the lowest heat.

In hardening, the smith must get the same heat each time, a most difficult thing to do where he has nothing better to heat in than the ordinary furnace or forge fire.

Say he gets a tap to harden in the morning before sunrise; he heats it to a very low and even heat; the tap is put to use and gives the best of satisfaction. A month after he gets another made from the same bar, but this time he hardens it later in the day when the sun is shining or, it may be, when a fresh fall of snow is on the ground. He heats to what he believes to be the same heat that he had on the one he hardened before.

The tap is put to use but does not give satisfaction at all, and yet it is the same steel, used by the same man and for the same purpose. Nobody knows what is wrong. The smith goes on and hardens a half dozen more off the same bar, and gets three good taps and three poor ones. The machinist or boilermaker complains and the smith replies that it is in the steel. The taps are laid aside until the steel salesman comes around, when they are examined and in nine cases out of ten nobody has the least idea what is wrong. The steel is blamed and other brands are tried which turn out pretty much the same. Now, the price of one tap would put an end to the whole trouble if used to provide shades for the windows near the forge with which to regulate the light.

If the smith cannot induce his foreman to furnish shades let him get heavy, dark wrapping paper and tack it over the windows, for it is better to nail them up altogether than to let the sun or bright light strike the forge, anvil or water tank. If objection is made to nailing up the windows, let the smith take a piece of old pipe, or an old barrel or keg and hold the cutter or reamer in that before quenching and the benefit to be derived from shades will be fully proved. Shades are also a great help in preventing steel from cracking. I have black shades on my windows which can be raised or lowered to suit the work I am doing, and I use a brine bath of thirty-five to forty degrees temperature and have found both a success. Many steelworkers are afraid to use a solution of this kind for fear of cracking intricate shapes, but if the proper steel has been selected there is no danger. I have softened and hardened some very difficult shapes of milling cutters of Crescent steel thirteen times and there was not a crack of any kind in them. They were used in cutting tool steel and they held as good an edge after the thirteenth time as they did at first. I did not draw the temper a particle. I gave them a low, even heat and dropped them in the solution upon a screen, which was set in the tub at a distance of twenty-four inches from the top and six inches from the bottom where the brine could cool them equally and where they were left until as cold as the bath.

The greatest folly that has ever been practiced among steel workers is to take a cutter out of the water and put it over a keen fire, but I will reserve what I have to say on this subject for another letter.—*W. G. Lottes, Madison, Wis., in "Sparks from the Crescent Anvil."*

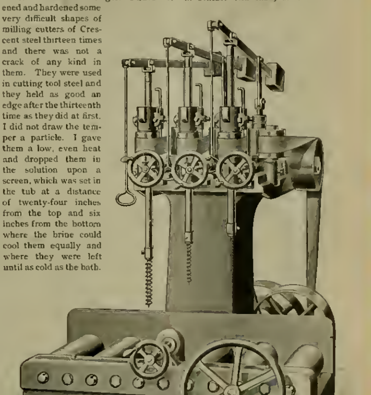
After long tests to prove its efficiency, the Reading road has adopted the Smith Triple Expansion Exhaust Pipe. This pipe does away with the necessity for a draft pipe and allows engines to run with an exhaust nozzle opening nearly equal to the area of the exhaust port.

## Improved Three-Spindle Vertical Timber Borer, With Power Driven Rolls.

The accompanying cut represents the latest improved vertical boring machine for car and bridge work.

The column is cast hollow with ample floor space, and has the roller frame bolted to the front of the same, thereby making a very heavy and reliable machine, capable of standing up to the heaviest work on the largest timbers.

The slides which carry the spindles have a movement of 15 inches, each independent of the other, operated by hand wheel and screw, and working in planed ways with gibs to compensate for wear without changing the tension of the belt. The spindles are made of best cast-steel, and have a vertical movement of 18 inches. Each spindle is driven at a different speed, to suit the auger, and is provided with a stop to gauge the depth of the boring. All spindles pass through a sleeve pulley, consequently do not come in contact with the journal boxes. The



Three-Spindle Vertical Timber Borer.

spindles are also provided with self-oiling boxes at the top. The roller frame is very heavy and of large surface, and is made to carry six large feed rolls, all driven by friction and operated both ways, being controlled by the foot. If it is desired the rolls can be thrown out of gear when the foot is released from the treadle, by means of the large hand wheel. All the movements in this machine are actuated by one single belt. Timbers 15 x 16 can be bored clear through at one operation.

For further information address the builders, the Egan Company, 204–224 West Front Street, Cincinnati, Ohio, U. S. A.

## The Making of a High Grade Wrought-Iron Wheel.

The day when anything but a high-grade wheel can be safely put under passenger stock or used for locomotive trucks ought to be gone We hope it is.

Of the many good wheels on the market the double-plate wheel, long made by Colonel Boies, of Scranton, Pa., has had a reputation worth being proud of; but Mr. Boies determined to simplify it, and made a solid plate wheel, similar in shape to the old one, having corrugations.

Experimenting further, Colonel Boies, at last, settled upon a single-plate wheel to be specially forged, the tire put on so as to compress the wheel and fastened by two retaining rings. All of this he has done and yet has a complete steel-tired wheel having but two pieces

A quarter of a million dollars has been expended in an elaborate plant for the manufacture of this wheel and the company are now ready for business.

Our large engraving shows the immense steam hammer used for welding up and shaping the wheel centers, and the great crane that serves it.

Steam Hammer in Boies' Steel Wheel Works, Scranton, Pa

As can be seen, this crane is a hydraulic affair handled from the platform as shown. On the arm of this crane there is a "crab," a car running on wheels on the crane-arm. Below the frame of this crab there is a long projecting pair of claws that can be opened and closed horizontally. These claws are shown extending well up toward the anvil, they are pivoted on the frame of the crab in front and are opened and closed by a cylinder at the rear,—used just as the hand is with a pair of shears.

A man located on the crab can reach its claws into a furnace, seize upon a piece of metal of the proper weight, that is at a welding heat, withdraw it from the furnace and carry it to the hammer, placing it on the die. Here this immense hammer forces it into the shape shown by the car wheel centers standing against the hammer; all excess metal being forced out of the rim in a thin fin.

From the hammer the wheel blank is turned off on the outside and the tire put on; this is done by shrinking it on. The small engraving shows the form of the forged plate and very plainly illustrates the intregal tire lock, the last of Colonel Boies' inventions. There is a ring similar in form to the Mansel left on the inside edge of the wheel center and a proper groove cut for it in the tire; this ring is shown under the flange. The other ring is on the tire and has a lip extending under a recess turned in the edge of the wheel center. When the tire is on, the inside edge of this lip is forced up into this recess by a rolling process, which amounts to "spinning," as it expands the lip and makes it fill the cavity. This makes a fastening that the makers are willing to guarantee will prevent the separation of the tire from the center, even though a piece be broken entirely out. The beauty of the thing is in its simplicity, no bolts or rivets being used.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 1 shows the front of a finished center.

Fig. 2 the back of the same wheel.

Fig 3 shows the complete wheel, tire and all.

These wheel centers can be re-tired at any railroad shop, it only being necessary to cut off the retaining ring on the tire and then take the tire off.

As there is no wear on these centers there seems to be no reason why an investment in them would not be as permanent as in real estate Certainly, if they are not broken they can be re-tired repeatedly, until the oldest hand has forgotten when they were bought.

These wheels are much lighter than cast wheels and possess several times the strength.

---

The Chicago & Alton recently put in service six ten-wheel engines from the Schenectady Works They have cylinders 19x24 inches, 70-inch driving wheels, carry 170 pounds of steam and weigh 160,000 pounds These are the first ten-wheelers the Alton have used and the heaviest engines they have. Before they were received some little apprehension was felt lest they should give trouble through journals heating in passenger service. On the contrary, however, the engines are running smoothly and no trouble is being experienced whatever. The journal bearings of these engines are fitted with Ajax metal.

## Train Running for the Confederacy.

By Carter S. Anderson

GOOSE-NECK COUPLINGS FOR WAR HISTORY COACHES.

Closing my last letter, we were rolling along that dark and rainy night about Frederickshall, with our ten trains of about twenty cars each, all loaded inside and outside with Jackson's soldiers going—none of us knew where—except that our orders were to go to Beaver Dam, which is forty miles from Richmond, and about twenty-five miles from where it might have been supposed some of General McClellan's men would be scouting. We got orders, just as soon as we pulled up to Beaver Dam, to unload and pull down east a mile or so, to allow the eight rear trains to come up to the station. This threw us down in the woods a mile and a half.

Just as soon as our next neighbor—the following train—came up to us, Engineer Whalley got his engine cooled and came on back to our caboose—a wet and muddy freight car. We were down side by side on the floor, and fast asleep sooner than I can write it down. Mortal was never happier than I was on being relieved of such responsibility. The sun was climbing up out of the tree-tops when we awoke. Being chilled from getting wet and the night air, we crawled up on top of the cars to dry and get warm, wondering what would be our next move. Whalley, my engineer, had no coat along, having thrown his in the firebox at Gordonville to get his engine hot. He had drank right freely of new brandy the past day and being thoroughly drenched with the rain he got chilled so that he trembled awfully. He said he believed he would go up to the station and try to get a dram from some of the officers, and hear what news he could. In half an hour or so he came on back. I took him to be a Confederate officer, but soon discovered that Whalley had on a Confederate brigadier's coat. "Promoted!" he bawled out as he pulled up. He had gotten a good big drink, and the officer happening to remember the circumstance of his being without a coat kindly gave him a really good Confederate officer's gray dress coat. He had it buttoned closely around his other wet and greasy clothes which made him a ridiculous sight.

"What news, John?"

"Plenty of it," he replied. "The men have orders to cook three days' rations, and prepare to march."

"Did you learn anything as to the direction they are going?"

"Not positively," he answered; "but I begin to think that they are going to get into this scrimmage about Richmond, because, when the officer gave me the coat, he remarked that where he was going it would be plenty hot without a coat."

Whalley had scarcely finished telling us this when we heard and soon saw the army moving along the County road, right along side the railroad, where the trains were standing. Conjectures fled, and the solution of the question as to where Jackson was going was solved. He was certainly on the Richmond road. The cavalry in front, artillery next, then the infantry, and some cavalry in the rear. Quietly, that is, no music, no shooting nor boisterous commands, but gleefully and cheerfully marched forward the whole of Jackson's command. Our soldiers loved to go and fight. It was camp that sickened and killed our boys. They longed to fight it out, and go home. They cursed each delay, and worshiped a dashing, daring leader. On, on they passed,

Some to Fame;
Many wounded on the field to lie.
A few to *Shame*,
But most and best of them to *Die!*

The goodbyes given them as they passed along, were mostly said forever.

In a few hours there remained not a sign of any army about Beaver Dam General Jackson left a respectful request for us not to sound the whistles until we got as far as Louisa Court House on our return. Being thus set free from military rule, we held a council and decided upon getting back to our superintendent at Charlottesville. We had not been to bed nor eaten a regular, decent meal for nearly a fortnight. At that time, here in Virginia, a soldier was everything, and a man who was not in the army stood a poor show indeed, so long as there were any soldiers to be attended to. We were near the point of starvation. The engineers decided to examine their engines before starting on the return trip, as the engines would all have to go to Gordonsville before they could be turned around. Tink, tink, tink, under or somewhere on every engine, could be heard the hammers and chisels. The engines had not been near a shop for a month or more, and it is a mystery now how those engineers did the work required to be done, and managed to keep their engines together.

It was arranged that returning the order of trains should be, "The last shall be first, and the first shall be last." This placed in front Conductor D. Pat Woodward and Engineer Westley Huntley, who ran the mountain climber, "C. R. Mason," a Roger engine, built to take four passenger coaches down and up a grade 360 feet to the mile, and was used between Millboro tunnel and Mason's tunnel, where the Lick Run fill now is. Her tender was on top of her, or rather on each side and on top. She had no truck, but was built on four small drivers, and when working waddled about and switched herself from side to side We had her at that time in service on the main line, as engines were so scarce. The tender on top was not sufficient to hold water enough to go from tank to tank, and Master Mechanic C. E. Wildman had attached to her a captured B. & O. tender. She was the laughing stock of the party. It was discovered by Engineer Huntley that the "Mason's" drivers were loose—a serious matter. Huntley hunted up Conductor Lex. Netherland, who usually carried along in his caboose from four to six tons of scrap, which he would pick up and say, "It will come in." Mr. Netherland had a barrel of charcoal and an old 20-gallon iron pot which was in those days used to hang on the rack and boil clothes in. He would build a coal fire in the pot, jab a piece of iron into it, and using a track rail for his anvil, would do a pretty good blacksmith job. Conductor Netherland soon had his shop in full blast for tightening the drivers on the "Mason" With the assistance of some of the older engineers, Huntley soon got her on her feet again and took the lead.

We found an office open at Frederickshall and reported to Col. H. D Whitcomb, at Charlottesville, who ordered us to come to Gordonsville and report. We had nothing to meet and no cause to hurry, so we jogged along, occasionally seeing the rear of the preceding train Passed Louisa, Trevilian, and struck out for Gordonsville. Our train had reached Forest Hill church, about one and a half miles from Melton, when we were flagged down.

"What's the matter ahead?"

Nobody could tell from the fact that everybody except the fireman on each train had gone ahead to find out just what caused the halt. Walking on ahead, we found the colored brakeman on the front train, which was standing with the engine at the tank at Melton, a water station four miles east of Gordonsville.

"What's the matter Tillman? Those drivers loose again?"

Tillman answered

"No, sir. Mars Pat and Mr. Huntley up dar at Harkless' shanty getting something to eat. Mr. Huntley done swore dat de "Mason' shall stand dar till the owls bull dar ness in her biler fore he'll tech her till he get something to eat."

We joined in "Amen!" Harkless was one of two men who pumped water at Melton, and Melton being a place out of the way, no army had ever camped there, and we very often stopped there and got Harkless to cook us something to eat. Harkless, who was a slave, had thereby accumulated a pretty good supply of ham, eggs, coffee, etc, and was patronized that day to his full capacity. Harkless had not sufficient table service to accommodate more than a crew or two at once, and the boys would eat and fall back. Never was royal banquet enjoyed as was that strong, hot coffee, ham and eggs, and hot ash-cakes, which Harkless baked on the large slate rocks of which the hearth was constructed.

We were about through eating, and getting ready oiling up, etc, to go ahead, when an old citizen came walking along down the track from Gordonsville, and as he came up to us, asked some of the men if they had heard the news.

"What news?"

"Why, the Yankees are expected in Gordonsville before night. They say they are now at Orange Court House, on their way to Gordonsville."

What on earth to do we did not know Engineer Ragland said he did not believe it, and would run his engine up there, or at any rate in sight, and see, but it was thought best not to run any engine nearer for fear they would find out about so many trains being there. Well, Ragland said that he would walk up there and see, and off he went, assuring us that he would be back soon if he did not get shot.

We waited and watched, until finding that the day was nearly gone, we walked on up to meet Ragland or somebody else. We found him about a mile from Melton, sitting on the end of a tie, as tight as a tick. We approached him, and earnestly begged him to tell us all about how it was at Gordonsville, but he imagined that he had told us, and would only reply that

"If you all know so much more than I do, it is no use for me to tell you. You can go up to Gordonsville and see for yourself, if you don't believe what I say"

We gave him up, and were about arranging to send another squad this time to find out the state of affairs at Gordonsville, when we saw some one coming rapidly walking down the track from toward Gordonsville, and soon recognized Mr. C. E Wildman, master mechanic

"What on earth is the matter with you all, boys? Col. Whitcomb is on his head, afraid you are all captured or wrecked. Where are your trains?"

We informed him, and also of the rumors we had heard. He told us that there was a rumor that Gen. Pope had crossed the Potomac and was operating toward the direction of Gordonsville, but there was no immediate danger, and that we should go on at once to Gordonsville and get orders to go right on to Charlottesville, which we did, and reached that place some time in the night.

Next morning we all went in a body and reported to our superintendent, Col. Whitcomb, who thanked and congratulated us, remarking, "that it was remarkable that not the slightest accident had occurred nor injury to any soldier, and that we could all rest that day, and that next morning he wanted the engineers to take their engines to Shadwell, where Mr. Wildman had erected a temporary shop, and give them an overhauling, to be in readiness for the next campaign." So we decided to order breakfast at the Exchange Hotel for the whole party, about thirty men. Conductors Finks and Nat Shepherd were appointed a committee to go up and arrange with the proprietor for a big breakfast, or whatever you might call it—it was early in the forenoon. By the time they got breakfast ready the most of the boys had drank their neighbor's health pretty freely, and a merry crowd it was, as we gathered around the perfectly white and clean table with the hot smoking scratchbacks, coffee and steak.

War is very demoralizing, and it did seem to me that the men forgot everything else on earth but just making the most of that jolly hour. One grind on the steak was enough to satisfy the most carniverous that she was tough Then began comparisons; anecdotes the most amusing and ridiculous, not to say any more. Captain D. Pat Woodward always was very touchy about any remark being made which would cast any reflection on what he was eating. He was out of the ring pretty soon and others followed. Finally, Conductor Nat Shepherd, who stammered miserably, raised the question "What sort of meat is this, boys?" Answers came quickly from all around the table Bull beef, calf, dog, mule, goat, wild boar. Nobody had any idea it was mutton. Shepherd bet it was mutton.

"Done," said Whalley, "here's ten dollars it is not."

Proof was called for by all. Shepherd held up a good chunk of the old ram on his fork, and, exhibiting to us a good bunch of wool, pulled in the money, remarking that he never saw that kind of hair grow on a calf.

Breakfast being over and paid for, we pulled for the rooms—the box cars.

"Let's go a-fishing,' met with no favorable response. I determined to go, and buying a small quantity of tackle, was soon on the banks of the muddy River Anna along where she seeks the shadows of Monticello to get herself in good shape before making her terminal flow into the James River.

I had scarcely a nibble; I studied the art of fishing, tried all sorts of bait, disliking so to go back empty-handed. I had gotten down opposite Jefferson's old Shadwell mills, hoping to find a hole where the fish would bite. I saw just ahead of me, under a bending willow, two little negro boys. As I came up to and made friends with them, I saw they were fishing, and they soon showed me how to do it Snatching out a good-sized "cat," the larger of the boys pulled out of the bushes to hang this one on a bunch of fish which weighed at least ten pounds. The idea struck me at once to buy them out They were soon made happy as to the trade, and giving them my hook and line, I struck out for Charlottesville "big as life."

I exposed my luck to the best of my ability, being determined that every railroad man should know of my success, even to our unsuspecting superintendent The fish were served for supper and my point was gained All hands were bent on going early and spending the next day on the River Anna Great preparations were made bread, frying-pans, a two-gallon jug of brandy, and abundant tackle

"Are you not going?" I was asked the next morning

"No," I replied, "yesterday was fishing enough to satisfy me for the season, go on, boys, and success attend your efforts."

They had planned a great fish-fry at old Shadwell Mills

I cannot describe the scene which appeared as those boys came along through the switches of Charlottesville yard, late in the afternoon, returning from their grand fishing excursion. Colonel Whitcomb had been let into the secret, and was so diverted from his usual dignity that the boys suspected me, and finally found it out. No power on earth could have kept us from laughing, but curses fell thicker and faster on me than ever before or after They threatened me all sorts of punishment.

Whilst we were thus trifling precious time away, great military movements were being brought into action around Richmond. Next day, through all Piedmont district—in fact, taking Richmond as the center, for about one hundred miles around—could be heard the thunder, low muttering, and now and then great blasts of artillery, under the command of Generals McClellan, Lee and Jackson.

The historian has the floor as to that Seven-Days' Fight, and I must continue my railroad narrative.

Flying rumors from Richmond were all

favorable to our side, and Colonel Whitcomb energetically set to work organizing a large carpenter force to rebuild the burnt bridges between Richmond, Fredericksburg and Potomac Junction and Richmond, resuming passenger service to Richmond, via the Richmond, Fredericksburg & Potomac from Junction, and transferring passengers and baggage over South Anna bridge to the trains which came up to the burned bridge from Richmond.

The travel increased daily on our road. That from the Southern roads to Richmond became enormous. The reports going out (exaggerated, of course) as to General McClellan's defeat, brought crowds to the city—refugees returning, parents to attend their wounded sons, and many sad ones seeking among the slain to recognize a lost brother or son—many times digging up from a two-foot grave their bodies to be carried home, to City Cemetery, or decently buried on the battle-field.

Being then baggage-master, my trip brought me to Richmond the night of the battle of Malvern Hill. After supper I strolled out into Capitol Square. It had been reported all the afternoon that General McClellan had been surrounded, and his whole army prisoners, but the way those war dogs barked on Malvern Hill convinced us all that it was not true.

Capitol Square was literally packed. I remember there were a large number of beautiful and nicely dressed ladies, many of them strangers in the city, and for three or four hours, it seems to me now, we remained there listening to the thundering, bursting and terrific cannonading on Malvern Hill that hot, clear and starry night. Next morning it was known that General McClellan had gotten under cover of his gunboats and was comparatively safe.

There was now no doubt as to General Pope moving in the direction of Gordonsville, and just as soon as General Lee could spare him he arranged to let General Jackson go to Gordonsville to meet General Pope, and President Edmond Fontaine and Superintendent Whitcomb were urged by the government to hurry the bridge so that the army could go directly back to Gordonsville in time to save, if possible, that very important military station. Then commenced a *hustle* indeed on the part of our railroad officers to connect the two ends of our road, get our machinery together, our engines to the shops, and to satisfy the great military pressure bearing on us for immediate transportation for Jackson's army to meet General Pope, who was pressing toward Gordonsville.

George F. Thomasson, the veteran bridge builder of Virginia and West Virginia, was at that time our master road carpenter and had full charge of rebuilding the bridges and trestling which General McClellan had destroyed between R., F. & P. Junction and Richmond. Acting under Superintendent Whitcomb's orders, he had organized a strong force of carpenters with work train, Conductor Horace Gooch, and a big force of laborers, a good engine and twenty flats to haul the timber, which was being prepared by a part of the carpenter force, whilst Mr. Thomasson and his best men were at the burned bridges removing the debris and preparing to rebuild. After the seven-days' fight a great pressure was brought to bear on Thomasson. Colonel Fontaine, who was as much concerned about the immediate transportation of troops as he was about his road, he being a strong Confederate, took matters into his own hands. He instructed Mr Thomasson to cut timber wherever he found it most convenient and suitable, that the patriotism of the people would allow this on account of the urgent necessities of the government for transportation.

George immediately threw a good force into the beautiful pine timber, about two miles east of South Anna, belonging to Mr William F. Wickham. Returning to the bridge he met Mr. Wickham walking down the track towards Hanover Court House, probably to get the news.

After speaking to Mr. Thomasson in his usual very polite manner, he halted to pass a few words in conversation with regard to the situation of things military and resuming business on the road. His quick ear soon caught the sound of the axes as whack, whack, whack, they very well imitated cavalry pistols.

"Gracious God! Mr. Thomasson, what do I hear," he remarked, as he straightened himself up, placing his hands on his sides, as he always did under excitement. "Is it not cavalry firing?"

"No, sir," answered Mr. Thomasson; "it is my men cutting pine piles to trestle South Anna bridge."

"In the name of God, Mr. Thomasson, by whose authority did you dare enter my premises?"

Mr. Thomasson told Mr Wickham that Col. Fontaine ordered him to do it, repeating to Mr. Wickham what Col. Fontaine had said about the patriotism of the people, etc.

Mr. Wickham snatched the word patriotism out of Mr. Thomasson's mouth with "Patriotism, hell!" and Mr. Thomasson says he never heard cursing put into such grammatical sentences nor such beautiful words as Mr. Wickham laid on him. Mr. Wickham used as fine English as any gentleman in Virginia at that time, and under strong provocation could cuss. Extremes politically met in Mr. W. F. Wickham, who was every inch an Old-Line Whig, and Col. Edmond Fontaine, who was a Democrat, a "red hot rebel."

How these two gentlemen made it with regard to the timber cutting I don't know, but Thomasson got the trees and built the bridges. Col. Fontaine went to another extreme in his eagerness to get his road open. He ordered Road Master William Richardson to bring at once every section-hand east of Gordonsville and let the foremen walk and watch their track.

Negroes soon got so thick around South Anna bridge that Mr. Thomasson ordered Reuben Woolfolk, a great negro preacher, to take them all, except such reliable men as he had selected from among the crowd, and go down on North Anna River banks, all in sight, and preach to them. Or they could fish, as they preferred. Mr. Richardson himself coming down next morning with another great crowd of them, Thomasson ran up some distance to meet him, and pointing over toward the crowd under the trees by the North Anna, he told Mr Richardson to hurry back to the Junction and send these men back; that those over there had made insurrection and were on their way to the Yankees.

No sooner said than done. The next morning Mr. Richardson came down and concluded that he believed it all happened for the best. The raw section-hands knew nothing about bridge building, and the carpenters were afraid to allow them on the bridge to any extent. Mr. Thomasson had the bridges and trestling all up, and Mr. Richardson had the track replaced where it was torn up in a remarkably short time, considering the extent of damage. The track in some places was actually turned over.

Just think of it. Those Northern soldiers would go on a moderate embankment, generally on a curve, and *raise up* the track until it would turn over completely, bottom-side up, and some parts of it setting up like a fence. They knew we were scarce of rails, and would pile up cross-ties, then lay the rails across the pile, set fire to it, and when the rails got red hot, seize them at both ends, with rail tongs, and twist them around the trees, leaving them looking like great snakes.

When the order came to haul Jackson's army to Gordonsville to meet General Pope about August 1, 1862, our road was open and we did not let anybody walk back, but gave them all a ride, and having gotten our rolling stock together, once more we had the pleasure of giving our soldiers rather better accommodations than we could when we brought them down.

## They Say They Will—Will They?

The daily papers of the 14th of September contained the following telegraphic dispatch "The wind blew a hurricane on the Penobscot Mountain last night. A heavy Jersey Central Railroad freight train was coming down the mountain. The violence of the wind drove the train ahead. The engineer could not control it. He whistled down brakes, but the brakemen thought the train was running away, and jumped from their posts. The engineer followed suit. The fireman, John Connors, climbed over the tender, and, mounting the box cars, put on the brakes. He brought the train to a stand-still after running six miles. The railroad company will reward Connors."

---

Secretary Cloud of the Master Car Builders' Association has sent out a circular announcing the results of letter ballot. At the last meeting of the Master Car Builders' Association the proposal was made to change the wheel guarantee, making it a little more favorable to wheel makers. This proposal has been rejected. It was also proposed to adopt the form of coupler gauges recommended by the executive committee of the association. This recommendation has been adopted.

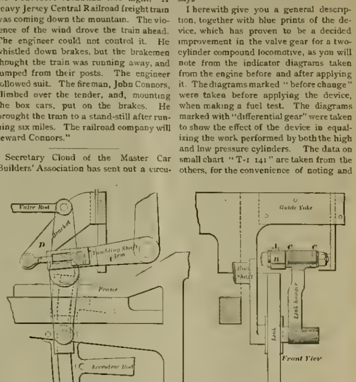
---

J. G. Butterfield having tendered his resignation as master machinist of the Sioux City, Iowa, shops of the C., M. & St. Paul, taking effect September 1st, Thomas Roope has been appointed to fill the vacancy. Mr. Roope has been an engineer on the Pacific Shore line for some years.

## Equalizer for Compound Cylinders.

The device shown in the annexed engraving was invented by Mr. T. W. Heintzelman, master mechanic of the Southern Pacific, at Sacramento. Mr. Heintzelman, writing about the invention, says:

I herewith give you a general description, together with blue prints of the device, which has proven to be a decided improvement in the valve gear for a two-cylinder compound locomotive, as you will note from the indicator diagrams taken from the engine before and after applying it. The diagrams marked "before change" were taken before applying the device, when making a fuel test. The diagrams marked with "differential gear" were taken to show the effect of the device in equalizing the work performed by both the high and low pressure cylinders. The data on small chart "T-1 141" are taken from the others, for the convenience of noting and comparing the difference in the figures between the two above-mentioned charts.



Elevation

Locomotive Engineering

You will note the device consists of an attachment to the ordinary link-valve gear and is so arranged to give a differential cut-off in the cylinders, thereby producing equal work for both sides of the two-cylinder compound at all points of cut-off, as we all have noted that with the ordinary link-valve gear, with both sides of the engine having equal cut-off in a two-cylinder compound, the work performed is very unequal at any point of cut-off after leaving full stroke, and the shorter the cut-off the more unequal the work, the effect of which is very detrimental to the efficient working of the engine and also using steam very uneconomically. Description of device as shown in engraving: The reverse shaft-arm *A*, is provided with slot of required length, into this slot the sliding block *B* is fitted, to this block is attached the top end of link hanger, also one end of radial-arm *C*, the other end of radial-arm *C* being attached to pin or bolt securely held to bracket *D*, which is bolted to guide yoke or any other convenient place.

Referring to the movement of radial-arm *C*, when the valve-gear is at full stroke either in forward or backing motion, the pin connection at top of link hanger is in same relative position that it

COMPARISON OF INDICATOR DIAGRAMS TAKEN WITH ORIGINAL VALVE GEAR, AND DIAGRAMS TAKEN AFTER ENGINE WAS EQUIPPED WITH DIFFERENTIAL VALVE GEAR.

Two Central car repairers, named John Klein and O. Dege, were instantly killed while at work in the "Cripple Yards" at East Buffalo, on September 21. They were under a car when a switch engine ran into it, and the two men were crushed. Three others escaped with slight injuries.

Watson & Stillman have found it necessary to run their hydraulic machinery works at 204-210 East Forty-third street, this city, both night and day to keep pace with their orders. The prospect for future business is very promising.

would be with a fixed link hanger pin in end of reverse shaft-arm, thus making the point of cut-off equal at full stroke for the forward and back motions, and as the link is lifted toward its center to produce a shorter cut-off, the sliding block *B* is moved to the radial arm *C*, inward toward the center of reverse shaft, the effect of which is to lift the link on the high-pressure side in advance of the link on the low-pressure side, increasing the ratio of difference in cut-off as the link approaches its center, the ratio of difference in the cut-off can be increased or decreased as is found necessary, by changing angle of reverse arm or the length of the radial arm *C*.

The expense of applying the device is very nominal as compared with the results obtained.

The device is fully covered by Letters Patent No. 471,253, and the writer will be pleased to give further particulars to any one interested in the invention.

The diagrams shown were taken from No. 367, a consolidation compound engine built at Schenectady for the Southern Pacific Company. The leading dimensions of the engine are

Diameter of high-pressure cylinder, 20 inches.

Diameter of low-pressure cylinder, 29 inches.

Stroke of piston, 26 inches.

Diameter of drivers, 51 inches.

Number of drivers, 8.

Weight on drivers, 109,750 pounds.

Weight of engine, loaded, 139,000 pounds.

Weight of tender, loaded, 71,800 pounds.

Heating surface, 1,884 square feet.

Grate surface, 30.80 square feet.

Outside lap of valve, high-pressure, ⅞ of an inch.

Outside lap of valve, low-pressure, ⅞ of an inches.

Inside lap of valve, high-pressure, ⅜ negative.

Inside lap of valve, low-pressure, ⅜ negative.

Lead of valves at full stroke, $\frac{1}{16}$ of an inch.

Size of steam ports, high-pressure cylinder, 1½×18 inches.

Size of steam ports, low-pressure cylinder, 1½×20 inches.

Size of exhaust ports, high-pressure cylinder, 3½×18 inches.

Size of exhaust ports, low-pressure cylinder, 3½×20 inches.

Area of exhaust nozzle (4⅝-inch), 19.6 square inches.

Table A gives particulars of the diagrams taken before the differential gear was applied.

During the round trip from Sacramento to Truckee, 239 miles, 5.9 pounds of water was evaporated to the pound of coal.

Table B gives particulars of the diagrams taken after the differential gear was applied.

One of the most crooked railways in the world is a little narrow-gauge running to Caracas, the capital of Venezuela. The distance in a direct line between the terminals is only 6 miles; but it takes 23 miles of track to get there.

---

It's the new hand on the wheel lathe that turns up the rear pair of tires first and discovers, when he gets to the main pair, that they are worn more, and he hasn't taken off enough of the other pair, and must give them another cut. The old hand turns the main pair first. He never finds another pair of wheels on the same engine that are worn more.

The railway officers of India have devoted great attention to investigating the best material for axles. They have tried all kinds of steel and the best brands of iron. In a report recently made public the management of the Great Northern of India express the belief that steel axles for locomotives give better results than those made from the best Yorkshire iron.

---

On September 5th a locomotive on the West Shore road went into the Hudson River, killing the engineer and fireman. It is said the accident was caused by the slipping of a truck wheel upon the axle.

Now is the season of hustling for the car heater men. There is enough to do to keep them all busy if only they were put at it by the roads.

## Building Railroads Without Capital.

We have had information repeatedly of railroads being built with remarkably little capital; but some personal reminiscence of Uriah Lott, recently published in the *Railway Review*, gets a little ahead of anything we had previously heard in this line. Our contemporary says

"He started out from Corpus Christi with $5 borrowed money and moved to San Antonio on a two-wheeled Mexican cart. He had been down on the Mexican National, driving a team, and finally he got a sub-contract while that road was building. After he got to San Antonio he set to work to get up a charter for the Aransas Pass Road, the project of which he conceived. He succeeded in getting interested with him the number and means necessary to procure a charter from the State, and without money they went to work and half-way graded about a mile of the road.

"Then Mr. Lott went to Palestine and he secured from Col. Eddy, receiver of the International & Great Northern Railway, enough scrap-iron to lay a mile of the track. After this was done he went back and bought with notes an old engine which I ran on the Texas & Pacific fifteen years ago and which had been laid up for scrap-iron six years before Mr. Lott bought it. He steamed into San Antonio with that old engine and two old cars, which he placed on his mile of track. The cars were painted with lamp black 'S. A. & A. P.' He managed to get some second-hand stuff which a street car company had bought from a narrow gauge road and with that he got down three more miles of track. He then made a trip to Pittsburgh and there he managed to make a trade with a steel mill for enough stuff to lay ten miles of track. When it was shipped into San Antonio he didn't have the money to pay the freight on it, but he got it out and placed it and then he bonded that section of the road for enough to carry it on forty miles, and that section was bonded, and so on until he had completed 600 or 700 miles of the road. He labored under difficulties which, in the hands of other men with less nerve, would have crushed the life out of the enterprise many times.

"I heard him say once that he undertook to ride from Chicago to San Antonio, without anything to eat. He was 'flat broke,' as railroad men say. He has got more grit than any man I ever knew and he did something that no other man has ever attempted—built 600 miles of railroad with hardly a dollar to begin with."

## Standard Sizes of Taps.

Mr. James Meehan, superintendent of motive power, C., N. O. & T. P. Railway (Queen & Crescent), has an admirable system of classifying standard taps and reamers for the purpose of uniformity and insuring to a certainty that all taps and reamers purchased from time to time shall be absolutely to standard. A blue print giving all the standards is lodged with the department originating a requisition and all along the line to the purchasing agent, and also with the manufacturer. It is obvious that all taps will be standard when all are ordered by this standard drawing. The drawing is headed:

Standard sizes of Hand and Machine Taps. *This sheet to be used in ordering Taps.*

Then follows drawings and specifications of dimensions as per sketch, which is taken at random from the nine drawings grouped on the sheet. At the end attention is called to the following directions:

Suggestions in ordering taps. Please state the following essential points:

The exact diameter—Threads per inch.

The shape of thread—If regular hand or machine taps are not wanted, give length over all and length of thread.

*For what they are intended:*

Hand Taps—Taper—plug or bottoming, new or old style.

Machine Nut Taps—Long or short thread.

Boiler Taps—Straight or taper.

Hob Taps—For solid or open dies, Sellers' or short shank.

Pipe Taps—Taper and straight, for hand or machine use.

Machine Screw Taps.

Taper Taps.

Pulley Taps—Give length over all.

Staybolt Taps—Give length over all of reamer and of thread.

Bit Brace Taps.

---

We have received from the Star Brass Manufacturing Company, Boston, a new illustrated catalogue of the goods they make, which embrace pressure and vacuum gauges, safety-valves and all sorts of attachments for steam boilers.

## Making Pipe Fittings.

The advantages gained by sub-division of labor and manufacturing by specially developed methods and appliances have given American workshops the power of producing finished articles better and cheaper than anything found elsewhere. We have never seen a better illustration of this tendency than what we found during a recent visit to the Stanley Flagg Co.'s works in Philadelphia. This firm started out on the manufacture of pipe fittings, such as unions, couplings and elbows, and they have built up a great industry in this contracted line. Railroad men are interested in the work done in this establishment principally from the fact that all the joints and elbows used in air-brake apparatus are made here. The air-brake fittings are made of steel and are so well made that the air-brake companies could not afford to make their own pipe fittings.

What strikes a visitor most forcibly in going through these shops is the quantity of special tools employed. The aim appears to be to have tools that will automatically perform all the operations to be done on the fittings. They have tools that face, bore and tap work, by successive automatic movements. One of the most ingenious tools I have ever seen has lately been introduced. It faces a joint and trues up the back of the flange at the same time. Extraordinary care is taken to make the fittings exactly alike so that interchangeability is absolute. The threads are all run over twice and then tried on a test gauge. To prevent the gauges from departing from the correct size, they are all tested once a week, and the least perceptible wear leads to their being changed. When joints are put up they are all carefully tested under pressure of air. No coupling or joint goes out of the works without going through this ordeal.

There is a soft-lined union made here that ought to be better known to railroad men than it is. A bushing of babbitt metal is squeezed into the mouth of the union and trued up to make a fitting joint with a similar bush on the other part of the union. The joint needs no grinding, and those who have used it say that it is always tight.

## Performance of the Old Colony Compound.

The compound locomotive built by the Old Colony Railroad, which was illustrated in our July issue, is running regularly on the Fall River express trains, pulling from nine to twelve passenger cars. We are informed by Mr. Lauder, superintendent of motive power, that, up to a certain speed, the compound handles the trains rather better than the simple engines of similar capacity, but that she is not so efficient when the piston speed exceeds 1,000 feet per minute. The engine is doing so well, however, that her performance has decided the company to build another compound locomotive, with a view of thoroughly testing this type of engine. The new compound will be of the 8-wheel type, the same as the engine now in service, but the driving-wheels will be larger.

The engine is run against remarkably good simple engines, which makes the performance all the more creditable. Our readers will be interested in studying the comparative performance of the simple and compound engines shown in the above table.

### STATEMENT OF RESULT

*Of Tests of Simple Locomotives Nos. 148 and 229, and Compound Locomotive No. 232, on Fall River Line Steamboat Train between Boston and Fall River, on round trips (100 miles). Coal quantities include coal used for banking fire in Fall River over night.*

* Two special test trips, twelve cars each day, between Boston and Providence.

NOTE. Minimum steam pressure readings were taken when approaching terminal stations and were intentionally low.

---

At 12.26, on the morning of September 20, a car load of powder in transit over the New York & New England road exploded while the train was in motion, between New Hartford and Winston, Connecticut. Two brakemen were severely injured and twelve cars were wrecked.

## A Lesson in Physics.

Talking of liars who invent their tales or what they suppose to be truth, reminds me of an old plug-puller on our road," said General Foreman McDuff, of the C. B. & N., as he changed his seat to get away from the dazzle of Jim Brady's scarf-pin and the smell of Charley Barnard's cigarette.

'Puffy' and the stove committee were deep in an argument about the weight of a new engine that had just come off the scales.

"'I'm a tellin' ye,' says he, 'I'm a tellin' ye that the 'hole thing depends on what the engineer is a doin' when the engine is weighed. Why, here is that old nineteen, don't claim to weigh more'en seventeen ton, and didn't she break down the big bridge over the Cedar? Well, I should say so!'

"'Now, boys, I don't know much, and believe nothin' I hear told, but when I *see a thing with my two eyes*, why, then I know it. Now, one time when I was on the St. Paul, me and the master mechanic got into a jawin' match about the weight on the front trucks of my engine—the hubs was forever gettin' hot. I contendin' that she got hot when the engine was workin' hard and cooled off when running down hill, and the master mechanic sayin' it was 'cause she was too heavy on her truck.

"'Well, the long and the short of it was he said we'd weigh her, and I said he couldn't tell nothin' by that, but he kinder sneered at me.

"'I run her out onto the scales, and she weighed 96,000 to a T. Now,' says he, 'jest back her drivers off and I'll weigh her trucks.

"'I backed her off, put the brake on the tank, stood the reverse lever in the center and pulled her wide open. Jest *slammed the hull boiler pressure right onto ther valves*, and say!—they cudden't find weights enough around them scales to weigh her!'"

Here the president of the club rose gravely, cleared his throat, and said "I trust our visitor will be the bearer of a letter to this gifted young amateur—the secretary will please inclose a free, full membership. We recognize an artist when we see or hear of one, and I trust a little cultivation of this now uncouth engineer, will develop him into a liar worthy to be at the head of this association—who'se got a match?"

## A Plugged Up Vacuum.

"Talk about havin' a 'pull' in politics," said the Old Timer, "a politics pull aint nothin' to a pull with the chief engineer on a road just bein' built.

"Out at the F—— Oh! you needn't yell *chestnuts*. Out at the—er—well, when we was a buildin' into Salt Lake, we had an old plug-puller as had a pull with the chief engineer—they both took the same brand of gin-fiz.

"Well, old Uncle Dan he had his say when new engineers come over to the end—they was under the chief engineer—and it so happened that he got most of 'em their jobs, and a dandy lot of galoots they was, too.

"Uncle Dan recommended a Dutchman once that use to fire for him before the flood; he'd been running an old pelter up around some Pennsylvania coal mine for ten years or better.

"Dutchy Fritz was a good feller enough, but he wan't just up to modern improvements and he'd never seen an injector in his life.

"He went over the unaccepted tail of the line with Uncle Dan to learn the road and then was given a 'hog' to double head to the front with a train of steel.

"It was cold weather, and as the engines stood out, the hostlers had the heaters on and Fritz couldn't get his Monitor to sling a drop of juice—the overflow-valve was screwed down.

"Hank Johns—biggest devil that ever lived for the fun of the thing—go without his dinner to get a sell on you—was behind Fritz and got onto his trouble at sight.

"When the water was flutterin' around the middle spicket, Fritz, he put on the wind-jam, stopped, and come back.

"'Mister Shons, you know off dose inchectors already?' he asked.

"'Oh, sorter so-so. I kin make 'em go, ginnerally,' says Hank, gettin' down and going over ahead.

"He got up in the cab and Fritz followed close to see how he operated. Hank looked wise at the squirt, put his ear down to it and said

"'Get me a cupple of broom straws, stranger.' Fritz stepped back into the gangway to make a raise of the straws and Hank lifted the overflow-valve slyly. He gravely measured the straws on his finger, broke 'em off and slipping them up the overflow wiggled 'em back and forward a few times and then primed and started the injector.

"'How you do dot, Mister Shons?' asked Fritz.

"'Didn't nobody put you onto this bad water?'

"'Yes, 'Tan dold me to look oud if he tond foam.'

"'Yes, but it stops up the vacuum, just like nicotine does a pipe stem. You take a broom straw just the right length and clean out that vacuum before you try to start that squirt and you won't have no trouble, but if I was you I'd go to Alick when you get back to the Junction and kick for a new vacuum, it's a shame to send out an old worn-out vacuum like that.'

"Fritz used the straws regular the whole trip and when he got to the base of supplies demanded a new *waccum*.

"Hank Johns got the hiccoughs from laffin' and liked to choked hisself to death."

## A Dangerous Man.

Once upon a time, away out in the wild and woolly West, there was a town where the colored folks did congregate and have dances and camp-meetings and Sunday-school picnics.

The management of the smoked Sunday-school decided to hold the annual picnic at the Grand Cañon of the Arkansas one year, and to that end chartered a train to be pulled by a dare-devil plug-puller by the name of Walker—John Walker—and he isn't dead yet, either.

The road from this town to the wonderful cañon was, at that time, as crooked as the little stream it followed and about as rough as a corduroy road. The track was narrow gauge—and the train no wider.

While the dusky crowd were packing themselves into the coaches on the fateful picnic day, and balancing the precious baskets of cold hen and watermelon pie out of harm's way, an old, gray-headed sage known as "Uncle" went up to take a look at the neat little engine trimmed up in red, white and blue, with an evergreen shield over her boiler front with the symbols "A. M. E. C. S." thereon, and John Walker, long, lanky, Tar Heel, dropping a little "fluid slipricator," as he called it, on the working parts.

"Dat's de finest little ingin I eber see in my bo'n days, sho' as you lib," mused Uncle to himself.

"Hello, Pharaoh!" said Walker, good-naturedly, "what the devil does these letters mean here?"

Uncle took a look at the shield, put on his specs, and said "I don't 'zactly read dat kind ob writin', but I done 'spec, sir, dat mean Affrickin Meffodis 'Piskopal Cheerch, Souf.'"

"South, hey; south of what?"

"Souf? Sho' I don't know, sir, lessen it's souf ob de Lo'd. I reckon we get used to sayin' souf endurin' de slabe days an' done forget to cut it orf."

"Did you ever see the inside of one of these things, Uncle?" asked the spider, smiling as he wiped off his can.

"Bress you, sir, I neber done hab de chance."

"Well, just get up and take a look."

Old Uncle got up. Walker told him kindly what all the parts were for.

"Dat 'er a wonderfullest ting yet, Mistah, Mistah——"

"Walker."

"Wakker, Mistah Wakker, yessir. What de good Lo'd gwine to do nex' done mak' men crazzy—I tink mebby dey hab wings, leastwise de white men hab wings, den dey gib de steam kayrs to de niggah Den I be de ingineer, Mistah Wakker, you, you flyin' round like er big red-hedded woodpecker, yah, yah!"

"Jest set up on that seat and take a ride with me, Uncle I've taken a likin' to you, nobody but the Ginneral Superintendent ever gets to ride on this engine, but you just git up there and you'll have the best ride of the party."

Old Uncle got upon the fireman's seat, not, however, without some misgivings and many anxious looks at the many cocks and valves so close to him. At last orders came, the bell rang, the dapper new conductor shouted "All aboard," and they were off.

There was a mischievous smile on Walker's face as he read the order and handed it to the fireman.

"Run to Cañon City as fast as consistent with safety, regardless of all trains."

That's what the smoke-shoveler read with a leer, for he knew that such an order meant to Walker to run as fast as the gallant little scrap could turn a wheel.

Old Uncle was chilly as the steam hissed from the cylinder cocks as they got under way and narrowly watched Walker as he handled the levers and hooked her up as she gained speed. Walker got his head outside the window, where he could see the old man through the glass, and let her out.

As the fireman let up for a minute, old Uncle put his hands up to his mouth and yelled

"Tell Mistah Wakker I done wanter go inter de kayrs."

"I dassent," said the tormentor, "you know he's kinder crazy when he hears the steam a sizzin'. You mussent speak to him till he stops."

After the next fire old Uncle asked

"Kin I git off at de first stoppin' place?"

"Oh, yes, 'course!"

"Whar am dat?"

"Cañon City."

"For de Lo'd—we nebber git dar alibe. Mistah Wakker! Mistah Wakker!"

Don't," urged the fireman, as Walker tugged at the lever, blew the whistle and yelled at the fireman, "don't, it makes him worse."

After this Uncle held on to the cab brace and only groaned when the little engine rolled from side to side and bounded over the rails.

But all things come to an end sometime, and while "Mistah Wakker" and his fireman were having the most fun, they had to stop at Cañon, forty miles away. The minute the engine was stopped old Uncle hit the grit, and without as much as "thank you" made for the "kayrs."

The next year the "A. M. E. C. S." had another excursion. The cars were ready, the crowd happy and the engine decorated as usual, when an observer might have seen old Uncle slowly wending his way up the station platform leading a little boy by the hand and "toting" a basket of lunch.

"No, honey, I aint bot' de teckets yit, an' I aint got on de kayrs. I done gotter see who dat on de steam kayr, lessen it's one man, den we go all honkey, bress yo' little hea't, lessen it's dat crazzy loontic, Mistah John Wakker, den——"

Uncle was walking back, the boy crying pitifully.

"Den didn't I tole you, chile, dat if de crazzy man done 'lowed to run dat ingin we des go down an' fish kats in de ribber? Yo' ole uncle kno' all about dat man. Didn't yo' see his eye, honey? He wild crazzy when he heer de steem, like fire in de powder ho'n. Didn't yo' ole uncle done ride wid him last yeah? Didn't he go like de berry ole debbel atter him wid er club? Didn't we dodge all 'round de telegraff poles and outten in among dem little kottenwoods? Wozzent he offen de trac' 'mos' haff de time? Den when yo' ole uncle done 'spos'ulate wid him didn't he keeper urgin' on de ingin all de fasser? Mebbe nex' yeer, honey, mebbe we go den. For lissen what I'se tellin', dat Mistah John Wakker, de loontic, he gwine to run dat 'ere ingin in de kreek one ob dese days an' den he gwine to kill a whol' passul of peepel. Yo' old uncle aint gwine to be dar if he kno' hisself—an' he reccon he do!"

## Washers Ought to Wash.

A daily paper gravely announces as though it were an important piece of news, that

"A new combination washer and nut lock for railroad use has recently proved itself very useful. The nut can be released or tightened up with the greatest ease, and the washer can be rinsed frequently."

It is, of course, of the utmost importance that the washers used with lock nuts should be arranged so that they can be rinsed frequently. The writer or "condenser" of that item knew, of course, that the duty of a washer was to wash things that needed washing (probably in this case Pullman towels and pillow-cases), and in order to do this work effectually it must, of course, be rinsed out occasionally to remove sediment and keep it in good working condition. Hereafter we hope no inventor of a lock nut and washer will think of trying to impose on the public with a washer which cannot be rinsed as often as necessary.—*American Machinist*

Railroad Jack, the great American canine traveler, famed among railroad express messengers, has just completed a tour of the continent. He visited all the large cities of the West, and as far south as Havana, Cuba. He travels in the express cars under the guidance of the messengers, who are fast friends of his. With him he brought a large crate containing a collection of curiosities gathered on his trip.

The monthly list issued by Spon & Chamberlain just to hand, contains a great many books that are of interest to the railroad and engineering fraternity. Parties interested should send for this catalogue.

(93) A. B. C., Sherbroke, Can., asks Will you tell me why an engine will wear inside of stack more in the back than in the front? *A.*—This occurs only when something directs the blast against the part that is worn the most; a crooked nozzle or misplaced draft-pipe will do it.

(94) N. B. T., Graham, Mo., asks · 1st. How old must a person be to get a position as fireman? *A.*—Depends on rule of road; generally eighteen to twenty-five years. 2d How long will he have to fire before promotion *A.*—Much depends on himself and the rules of the road; from three to six years. 3d. Will he have to brake first? *A.*—No.

(95) E. B. B., Mussel's Canal, Ala., asks

Suppose an axle has wheels on the end 5 feet in diameter, and a wheel 12 inches in diameter is put in the middle of the axle and keyed on. Now, if three rails be employed and the middle rail raised to have the wheel bear on it, will the small wheel have to slide or slip to keep up with the large ones? *A.*—Certainly.

(96) S. D. W., Columbus, Ga., says:

What is the rule for finding required dimensions of a locomotive slide-valve, outside and inside lap and exhaust cavity when travel of valve, openings, etc., are known? Also, why is "saddle-pin" placed out of center on links, and give some rule for same. *A.*—These questions call for more information than we can give in this column. The information can be readily obtained by the study of Auchincloss on valve-gears, or in the chapters relating to valve motion in "Sinclair's Locomotive Engine Running."

(97) J. C. E., Palace, Mo., writes.

1. Is there any single-cylinder reciprocating steam engine in use that does not stop on the dead center? *A.*—Many single-cylinder engines have an arrangement of center balance weights which keep them from stopping on the dead center. 2. Has the Corliss valve gear ever been applied to locomotives with success? If not, why not? *A.*—The Corliss gear has been repeatedly applied to locomotives but without success. The first element of weakness is too many parts. the second, that the closing valve is not positive and is not adapted to the high speed of locomotives.

(98). A. B. M., East Las Vegas, N. M., asks two questions and answers them. He says·

1. Will some of your readers explain defect in valve-gear which causes two long exhausts from one side of locomotive and two short from the other side? He answers One side has more lead than the other, or the links are of different radius. *A.*—To this we would add that the link hanger on one side is probably longer than on the other. 2. What protects the top of flues in an upright boiler? He answers There is no combustion on top of flues, only conducted heat, which does not burn iron or steel. *A.*—We would add that makers of upright boilers take care to see that the flues are long enough to absorb the greater part of the heat from the furnace. If the heat getting to the top was very intense, it would burn the sheets, no matter what way it was conveyed.

(99) Machinist, Frankfort, New York, writes·

Suppose in going over the cut of a locomotive we find a valve on the right side cutting off at one end of the stroke at 5 and at the other end at 6 inches; and the left side at 6 and 7 inches respectively. How shall we proceed to right this wrong, the travel having been found correct at the beginning, or the same on both sides of the engine? *A.*—The usual way to remedy this is to set the valves by the cut-off, making them as square as possible at the point where the engine does the most work. The defect may arise from so many different causes that the correct remedies are various. Worn eccentrics, worn links or blocks, the lifting-shaft out of the proper place, the point of suspension wrong, are all defects that will throw out the cut-off, and each must have its own remedy.

---

Chief Smith of the Department of Transportation has secured the promise of two monster locomotives to adorn the entrance to the Railway World's Fair passenger station, inside Jackson Park The Rogers locomotive works have agreed to furnish one and the Brooks company the other. Each locomotive will weigh 160,000 pounds, and be mounted on a pedestal. They will stand one on each side of the main entrance.

---

## The Cause of Mysterious Fires.

Railroad companies are great sufferers from the burning down of repair shops. To not a few companies a big fire is a blessing in disguise and gives the opportunity of disposing of worn-out tools to the best advantage, but we do not believe that the officers of any railroad that has lost a shop lately failed to do the best they knew how to prevent fires. Much has been written of late years about the causes of fires, but many of the men whose duty it is to make provisions against the accidental starting of fires are extremely slow to learn the sources of danger The natural inference when a mysterious fire happens is that some one has thrown a match upon some inflammable material, and that it has smoldered for a time and then broken out into flame when no one was about to extinguish the incipient fire They issue edicts against smoking and against the use of matches in the shop, but they fail to comprehend that there are other ways of kindling fires besides the using of matches.

There are many substances used about shops that are very ready to take fire of their own accord under favorable conditions. Greasy waste is one of these and its danger is seldom appreciated. Many other substances when exposed to the air in a moist condition generate heat and will reach the igniting point if not checked. Some of the materials used in paint shops are extremely liable to generate heat sufficient to cause spontaneous combustion, and constant care is necessary to restrain this source of danger. If the men in charge would make themselves informed on what combinations are liable to cause spontaneous generation of heat there would be a likelihood of this source of danger being restrained. The diffusion of more knowledge on the subject is badly needed at present.

## Hints and Facts for Enginemen —Some Old Pointers in New Words.

By Clinton B. Conger.

The following ideas are old to many of us. Sometimes an old idea in a new dress will catch a man in a new place, so he will get to thinking over it. Most of us do not think and study enough.

Setting eccentrics on the road will be new work to men who have been brought up on a road where the eccentrics are properly keyed on the axle, so they can not slip around out of place; but there are still a great many engines running with set screws only, or set screws bearing on top of toothed feathers to hold the eccentrics in place. These last ways were good enough in old days when a 16 x 24 was a large engine, 125 pounds a heavy pressure of steam and forty miles an hour a very high rate of speed. It won't do with 18 x 24 cylinders, 60-ton engines, carrying 180 pounds of steam and running 50 or 60 miles an hour as soon after starting as they can attain that speed. There is the same good reason for fastening the eccentric cams on securely that there is for any other part of the engine which has only one correct place to be fixed.

It does no good to have them so they will slip when they get hot, as they only make a few turns before they seize fast on the axle and something has to break. It might as well break the first turn as the last, it will break anyhow if it gets hot enough. Where the eccentrics are fastened by set screws only, the strain of the screws is liable to crack the cam, break the bolts that hold it together if it is put on in halves, or twist it out of true with the axle or strap; so it runs hot and invites the very trouble you wish to avoid. When they are keyed on solid with a key let into the axle they come square, as the strain holds them square.

In the first place, sometimes it is quite a trick to find out that an eccentric has slipped. The sound of the exhaust will change suddenly, and instead of the beats being spaced evenly, thus, 1, 2, 3, 4, they will come 1, 2—3, 4 Of course there are other changes in the engine that will make the exhaust sound as if an eccentric was slipped. Some engines with double nozzles have bushings in them to make the exhaust sharper, if *one* of these bushings blows out, the exhaust from that side will sound much softer than the other and is apt to deceive even an old head. When this happens the engine will pull and run just as free, but does not always steam as good. With one slipped eccentric she will be square working one way; with a bushing out she will sound out of square when running either way. When the bolt holes in eccentric strap where blade is fastened on are all slotted, if the bolts work loose so the blade slips a little each stroke, the exhaust will sound something like a slipped eccentric. Occasionally a tumbling shaft will get sprung and the exhaust will be affected thereby, but the engine will be nearly square, working down in the corner. If the bolts that hold the two parts of the eccentric strap together get loose, or one breaks, it will make the exhaust uneven. There will be more lost motion on that side of the engine than the other, and lost motion takes off just so much of the lead. When an eccentric works back around the axle it takes off the lead on that side, when it works ahead or slips back nearly a full turn around the axle, it increases it.

We will conclude that you have noticed something wrong with the sound of the exhaust and the engine is not able to handle her train properly, that you have stopped at a station *inside the switches* or on a straight piece of track where following trains will have a good chance to see your flagman and get stopped, and that you have got down to find what is wrong. Feel of the eccentrics the first thing, if one of them is hot the trouble is likely there, although I have seen a hot eccentric caused by a valve commencing to cut the seat bad, so she was blowing through under it, making the exhaust uneven. Look over all the bolts and connections from the axle clear to the valve-stem, see if any have worked loose. If she is standing on the center the bolts through the link and eccentric rods on that side should be exactly perpendicular with each other when the lever is in the center. If they are not, look for the trouble on that side. When an engine stands on the exact center she should let steam out of the cylinder cock in the end of the cylinder, where the piston is, whether hooked clear down forward or clear back, if she does not trouble can be easily located.

If the valve yoke is broken the valve will be pushed to the front end of steam chest and cover the forward steam port, sometimes uncovering the exhaust port so steam will blow through the exhaust or out of the back cylinder cock only, no matter to what point you move the lever or in what part of the stroke that side of the engine stands.

If you find out right off an eccentric cam is slipped and which one it is, there are several ways of setting it.

By the marks on cam and axle, when there are any. That does very well if you are sure about the marks, but you can not put any marks on the axle for the cam next the driving box. If you know no other way of setting them right but by marks made when cams are in their proper places, before you go out with an engine place her near the forward center so all the cams will be handy to get at, put the reverse lever in the corner, mark across one of the cross-heads and the guides and across the eccentric cams and the straps where it can be seen easily, say the joints in the straps, and when the engine is placed in the same position the marks on all four eccentrics and straps should come exactly together again, if one set does not, move it around till it does. That is an old woman's way of doing business, however, and you are apt to get left at it, as the eccentrics and motion work will not all wear just alike, or some one may make some more marks for you

By the cylinder cocks. This requires that the engine be placed on the exact center on the disabled side. There are several tests for showing when the engine is on the center, some men can place them on the center by noting the position of the side rod when passing the center and having the center of the rod come just opposite the center of the axle; that is, have the middle or center mark in the axle and the center mark in the crank pin in that wheel the same perpendicular distance from the rail. Hook the reverse lever clear in the corner for the eccentric that is slipped and turn it in such a direction as to make the link nearly plumb, both cams about the same distance from the crank pin, and have a little steam come out of the cylinder cock under the piston, which shows that she is taking steam in the same end of the cylinder the piston is beginning its stroke from, and at the proper point, viz. just at the moment of passing the center

By the valve stem. This requires the engine to be on the exact center, as the position of the valve in relation to the good eccentric is used as a guide to set the slipped one. If the eccentric that is not slipped is not just exactly right this method doubles the error and when you get through she will not be square. Some engines have more lead on the back motion than forward. It is done purposely to give a wider port opening when hooked up close, as with lever in the 6-inch notch the cut off will probably not take place till 10 inches or more, which makes them stronger in 6 inches than if both cams had the same position for equal lead. To set by the valve-stem, after placing the engine on the exact center, if the forward motion eccentric is slipped, put the reverse lever clear in back and make a scratch mark on the valve-stem at the end of gland Then hook her in the forward corner and turn the eccentric till this mark comes to the end of gland again.

(*Continued in next number*)

# FOR YOUR LODGE ROOM!

PRICE REDUCED TO **$60.00**

IMPROVED FOR 1892.

## LOCOMOTIVE VALVE MOTION MODEL!

Patents of J. A. HILL and F. J. MILLER.

All brass and iron but the main frame. All parts on one side—you can see 'em. Cranks on both sides. Audible exhaust. As adjustable as a locomotive.

TRAM FOR VALVE SETTING AND COMPLETE DIRECTIONS GO WITH EACH MACHINE.

**Half size of 17 x 24 Engine.——A Machine, not a Toy.**

ESPECIALLY USEFUL IN M. M.'S OFFICE WHEN EXAMINING FIREMEN FOR PROMOTION.

**PEDRICK & AYER, MAKERS, PHILADELPHIA, PA.**

## The New York Central's Latest Express Locomotive.

The success of the "870" class of American locomotives, having six foot six-inch wheels, on the fastest train in America—the Empire State express—has induced Mr Buchanan to go a little farther, and try and do a little better.

His very latest is the "903," a magnificent eight-wheeler having wheels 7 feet, 3½ inches in diameter.

The "903" is not otherwise unlike the now famous "870" class, having the same sized cylinders, 19 x 24.

She weighs 120,000 pounds, carrying 80,000 of it on her drivers.

She has a 58-inch boiler, wagon top, with a grate 96 x 40⅞ inches and 268 2-inch flues 12 feet long, a grate surface of 27.35 square feet, and heating surface of 1,851.30 square feet. Pressure 180.

The tender carries 3,500 gallons of water and 13,750 pounds of coal, weighing ready for the road 80,000 pounds.

The boiler of the "903" stands very high, a man of ordinary height can stand under it, the center being 8 feet and 11 inches from the rail.

Our engraving shows Mr. William Buchanan himself standing by the rear driver, while the gentleman in front is Arthur G Leonard, assistant to the third vice president, for years Mr. Buchanan's secretary. The "903" is only two inches lower than the tunnels and bridge roofs. She was built by the Schenectady Locomotive Works.

One of the engineers standing in a circle of "the boys" was heard to remark: "She's a daisy if she beats the '870.'" Here he caught his first glimpse of her wheel, "Lord, what a kangaroo!" We are a little afraid if they are not careful the breed will be known as the "Kangaroo class."

CENTRAL-HUDSON'S LATEST ENGINE FOR THE FASTEST TRAIN IN THE WORLD 87½-IN. WHEEL

The Rhode Island Locomotive Works have lately delivered several Johnstone compound locomotives for the Mexican Northern Railway. The Johnstone compound locomotives are making a great reputation on the Mexican Central for saving fuel. As coal costs over $10 a ton in Central Mexico, a small percentage of saving counts large in reduction of operating expenses. The compound engines are used exclusively for mountain service and are pulling hard all the time they are using steam. One of these engines stalled while pulling a train on the Santa Fé up a grade of 186 feet to the mile. After the engine came to a dead stand working compound, steam was applied direct and the engine started easily and went over the mountain with little effort.

On the 12th day of October there were 75,000 foot passengers over the Brooklyn bridge and 225,000 carried on the cable cars.

The Southern California have as bright and intelligent a set of enginemen as we have ever met. There is a practice universal among these men that we never found elsewhere, and one which many engineers would condemn This practice is that the fireman always attends to feeding the boiler with water. All concerned agree that it is the most satisfactory plan. They say that considerable fuel is saved by the fireman attending to the water, for he can regulate fire and water to suit the working of the engine. There are no plugs among these firemen.

The passenger engines on the Mexican Central have a Miller hook at the back end of the tender The usual horn is provided for buffing, but it has an improvement in the shape of a spring buffer on the end, which presses against the central buffer of the car.

## A Four Million Pound Train.

[See Inset.]

The splendid engraving presented with this number of LOCOMOTIVE ENGINEERING, represents a train of unusual proportions, hauled all the way from Chicago to Philadelphia over the Pennsylvania Railroad by one engine, a distance of 824 miles.

This fine train consisted of forty standard freight cars, one caboose and a "Class R" consolidation locomotive.

The cars were the company's standard 60,000 pound capacity box cars, 34 feet in length; each carried 60,000 pounds of grain, the 40 cars weighing 3,824,000 pounds; the cabin car weighed 18,000. The train was 1,402 feet long.

The "203" has 20 x 24-inch cylinders, a 60-inch boiler with a firebox 117 x 42 inches and weighed, tender and all, 188,300. She took hold of this train at Chicago at 10 A. M. April 30th, last, and was not uncoupled from it until she reached Girard Point elevator, Philadelphia, at 4:22 P. M. May 4th, a total of 4 days 6¼ hours. Engine and train complete weighed 4,030,300 pounds.

The "203" was not equal to the job of lifting this load over the Alleghenies alone and had help as follows:

One helper engine, Pittsburgh to Derry, 46 miles; helper from Conemaugh to Gallitzin, 25 miles, and also from Columbia to Fifty-second street, Philadelphia, and from Thirty-sixth street over the arsenal bridge.

We could not find out the amount of coal consumed by this engine west of Pittsburgh, but from Pittsburgh to Philadelphia she consumed 20 tons of soft coal, and her helpers got away with 21 tons; 43 tons used in hauling this monster train over the mountains, a distance of 354 miles.

## Topeka Railroad Machine Shops.

MAKING THE BEST OF IT.

The machine shops of the Atchison, Topeka & Santa Fé, at Topeka, are worthy of particular notice as exemplifying how far personal ability, ingenuity and good management can overcome natural drawbacks. The building used as a machine and erecting shop was originally built for some other purpose, and is badly adapted for the business now carried on within its walls. It is low, badly lighted, and so constructed that tools cannot be conveniently located. It is far too small for the requirements, and the floor has to be covered with tools, making the movement of material difficult and inconvenient, and want of room has compelled those in charge to put the erecting department in two places. With all these drawbacks it is questionable if any railroad shop in the country turns out more work in proportion to the number of men employed.

This is done by close attention to details. The tools are all worked up to their full cutting capacity; many labor-saving devices are employed, numerous special appliances are used for doing work quickly, and the workmen are encouraged to devise improved tools and methods, and they have responded cordially.

The shops are lighted during the daytime with incandescent electric lights, the plant having been made from an equipment that had been used for car lighting and did not prove successful.

COMPRESSED AIR FOR SHOP PURPOSES.

Compressed air is employed for a great variety of purposes to provide power. The supply of pressure is generated by an air pump driven by the shop engine. An air cylinder is set in front of the steam cylinder in tandem fashion, and the engine's piston rod is extended into the air cylinder, working the piston of the latter. The pipes leading the air from the compressor are enveloped in a jacket through which cold water constantly runs, absorbing the heat developed by compressing the air. Pipes lead this compressed air to every shop and to the points in the yards where air is required. Small portable Brotherhood engines are operated by this air and, by means of Stow flexible shafting, bore cylinders, drill and tap stay-bolt and other holes, do all the drilling and tapping about frames and cylinders that cannot conveniently be taken to a floor tool, and provide the power for almost every operation usually done by men pulling on ratchets. The air also supplies power to a stay-bolt cutter and a portable uniting machine.

SPECIAL WORK HOLDERS.

They use a great many chucks or work holders for planers and other tools that greatly increase the output. One chuck holds six tender boxes, and the lid face of all are planed at one sweep. A long bar is bolted lengthwise on the bed of a long planer, and a row of driving boxes is placed at each side of it, the bar forming the guide. The boxes are bolted down and the two rows planed at once with the double heads of the planer. All passenger car brasses are bored out before being lined with soft metal. Nine of the brasses are held in a chuck which secures them in the form of a cylinder, and they are all bored out at once. All driving boxes are bored on an old wheel boring machine, and a great variety of other work usually performed by lathes is done on this tool. The man in charge has rigged up a brake formed by a strap encircling the feed pulley, which he operates with his foot, and can stop the table at any point. He bores out eight large driving boxes, and faces off the babbitt in five hours. All the boxes have babbitt lining for the hub of the wheel.

INCREASING CAPACITY OF HYDROSTATIC PRESS.

I noticed a curious plan adopted here to increase the capacity of the hydrostatic press employed for wheel work. Mr. Gunther, the general foreman, noticed that when working the press on the direct power it would run up to twenty tons, but would go no further without resorting to the small pump. This was too slow to suit his ideas, and he began scheming for the means of making the large pump give greater pressure. As an experiment he put a weight of 150 pounds inside the rim of the pump pulley. It looks like a counter-weight, but of course has the opposite effect and acts as a fly-wheel of increased rotative energy. When the pump was started up with the weighted pulley it was found that the pressure ran up to forty tons, which greatly increased the work that the press would accomplish.

A KINK IN SPEEDING UP TOOLS.

They have been speeding up all the planers on the return motion, and they found that the Sellers planers were made to return so fast that the reversing bar or its connections would break with the shock of stopping. After several experiments to find a remedy, Mr. T. Smith, the foreman of the machine shop, cut the reversing bar and connected it with the belt shifter by a spiral spring. In stopping, the spring yields and brings the table to rest without a jar.

TURNING TUMBLING SHAFTS.

An ingenious plan has been adopted for turning tumbling shafts. It is well known that this is one of the most awkward jobs that goes into a machine shop. If the shaft is swung, its long arms require a lathe of large swing, and the arms prevent the tool-post from getting near the work, so that a long tool has to be used, with which there is always more or less spring. In this shop the tumbling shaft is held stationary in brackets bolted to the lathe-carriage and the turning tool is secured on the face plate. The work is fed to the tool instead of the tool being moved to the work.

Mr. John Player, superintendent of motive power, is fortunate in the officials he has running these shops. Mr. George W. Smith, the master mechanic in charge, devotes infinite energy to the management of the establishment, and he is ably and cordially supported by a staff of first-class foremen.

A. S.

## Mexican Central Matters.

All the passenger locomotives on the Northern end of the Mexican Central R. R. are provided with piping for taking water out of supplementary tanks that are drawn over the dry regions. The engines are all well maintained and compare favorably in appearance with the locomotives run on the best managed lines in the States. Most of the engineers are Americans, but the firemen are Mexicans and are reported to be good men. A few of them have been promoted and the intention is to promote more of them as men are required. They have to pass an examination before being promoted and are required to read orders in Spanish and English. The conductors and train dispatchers are English speaking and orders are generally given in this language, but there are a few operators who know no language but Spanish, and orders are consequently given through them in the language of the country. The greater part of the locomotive engineers are Brotherhood men, but their order is not recognized on the road. Men who apply for employment are asked if they are Brotherhood men and if the answer is in the affirmative they are not hired. The officers say that the men looking for employment nearly always deny belonging to the Brotherhood. The officers of the road profess to have no objection to the Brotherhood of Locomotive Engineers as an organization, but they say that the grievance committees need too many conferences. This complaint is heard on all Southwestern railroads.

---

In the Southern California shops at San Bernardino, they are using for brass making, block tin which is made from the ore in a tin refinery at Riverside, the sweet orange raising center. The tin is of an excellent quality and is reported by the foreman molder to be equal to imported tin. The price paid is $22.50 per 100 pounds, being a little less than the cost of the imported article. The concern at Riverside is reported to be rapidly increasing the output and the prospects are that sufficient tin will soon be smelted here to supply the entire needs of the Pacific Coast.

---

Eccentric keys should be put in solidly and good at first, if never afterward. Some new engines were recently sent West by one of our big works with offset keys clumsily supplemented by strips of iron. Manufacturers should turn out work that is *right*. The roundhouse gang can be depended upon to do all the cobbling necessary.

## The Steepest Railroad in the World—2,534.40 Feet Per Mile—48 Feet in 100, or 48 Per Cent.

Mount Rigi, in the Alps, has long been famous, and thousands of sight-seers have gone to its summit because it is reached by two rack-rail roads, and its summit abounds in hotels.

Mount Pilatus stands near Rigi, but is 1000 feet higher, a sheer, slim, barren peak of limestone, between five and six thousand feet high. It seemed for years too steep for a railroad, and every one despaired of ever seeing one up its barren breast. But the railroad is there.

Our engraving was made direct from a photograph taken this summer and shows one of the two combination cars and engines, on a grade of 48 in 100 feet, or 2,534.40 per mile.

All experiments made with ordinary racks, with teeth on top, proved failures, the pinions would mount the rack. At last a Swiss engineer proposed a double rack with teeth cut on the sides and guide wheels to hold them in mesh, this was a success.

The center rack is cut out of plates of mild steel, and are, with the other rails, bolted down to some 2 feet of solid masonry; every rail must stay "put" and not crawl down hill.

The boiler is placed crosswise of the track so as to maintain the water level without trouble, the engines are highly geared, the crankshaft making 180 turns a minute, but driving the horizontal track pinions 47 turns a minute, through a pair of bevel gears. This advances the car about 39 inches per second—1 meter, or 2.2 miles per hour.

The combination is provided with four separate and independent brakes: 1st, a compressed air-brake; 2d, a friction-brake on crank-shaft; 3d, a friction-brake on the leading pinions, and 4th, an automatic apparatus that applies a band to upper pinions as soon as the speed exceeds 1.3 meters per second.

The carriage part has four compartments, each carrying eight persons. The road starts at Alpnach, Switzerland, at 1,440 feet above the sea, and in a little less than three miles reaches an elevation of 6,790 feet. Not all the line is as steep as that shown, but the average for the whole is 42 in 100, the floor and seats being level at this grade. It takes one hour and thirty minutes to go in either direction.

There are two cars and engines, and they pass each other half way up, but with this system switches are an impossibility. So in lieu of one they have a movable section of track, or rather two movable sections. These are on one structure, not unlike a transfer table. The engine going up runs upon this piece of movable track and is then moved by power to one side. This side movement brings another section of track into the main line over which the down train runs. Then the climber is moved back into communication with the main line and proceeds to crawl toward the eternal snow and the clouds

ON MOUNT PILATUS, SWITZERLAND GRADE, 2,534 40 FEET PER MILE—48 PER CENT.

The principal dimensions of the engine and car are as follows:

Gauge—31½ inches. Cylinders—8.66 x 11.81 inches. Carrying wheels are flangeless—15.75 inches diameter. Drivers at pitch line—16.1 diameter. Wheel base—240 inches Grate area—585 square inches. Total heating surface—226 square feet. Pressure — twelve atmospheres, or 168 pounds per square inch.

The boiler carries 1,069 pounds of water in working order, the tank holding 1,763 pounds of water and 770 pounds of coal.

Weight of car and engine complete, with thirty-five persons, 22,960 pounds.

---

The locomotives employed on several of the divisions of the Santo Fé have a very expeditious means of cleaning their ash-pans. The bad water used makes the blow-off cock an important attachment, and contrary to the practice on most roads this cock is always kept in working order. On the engines referred to a pipe is connected with the blow-off cock and leads into the front of the ash-pan. The end of the pipe is flattened so that when water escapes it forms a flat jet. Every time the blow-off cock is opened this jet cleans the ash-pan of every particle of dirt. It is used on all occasions when the ash-pan needs cleaning and is highly popular with the firemen. Besides offering a convenient means of cleaning the ash-pan, the hot-water jet is a certain remedy for frozen ash-pans.

The Schenectady locomotives, one compound, one simple, in use on the New York division of the Pennsylvania Railroad, are equipped with Leach sanding devices, and are favorites with the men. They say they use less than one-third the amount of sand the other engines do, but it gets to the right spot at the right time, especially on the start.

## Reckless Snow Bucking.

The Atchison, Topeka & Santa Fé have ordered two rotary snow plows, one to be held on the Eastern and one on the Western lines This company is not troubled much with snow, but they want to be ready should a blockade be threatened. Where snow comes seldom to the depth that will obstruct the trains, the men in charge are generally unequal to meeting the emergency when it arises. Santo Fé men tell funny stories about the way snow bucking has been done on the rare occasions when it was necessary There was a blockade on one division a few years ago, and the roadmaster took charge of snow plowing. He put a small push plow in front of a flat car and started out. When they were ready to dive into some deep drifts the engineer protested that the flat car would not stand the shock.

"You attend to your engine," remarked the roadmaster, "and I'll attend to the plow." To show his faith in his own judgment, the roadmaster seated himself on the flat car and signaled the engineer to come on with a rush. He did that, and when the plow struck the snow the flat car doubled up and threw the roadmaster over the plow A broken leg gave him time to reflect on the foolishness of refusing advice.

---

The Norfolk & Southern Railroad Company have received from the Tredegar Company, of Richmond, Va., the first installment of the fifty new box cars ordered some time ago. They have also ordered two Vauclain compounds from the Baldwin Locomotive Works, Philadelphia, Pa, which they expect to have delivered this month The engines are duplicates of the freight engines No. 7 and 8, which have given such good service, and are 100,000 pounds in working order having a 56-inch wheel. One of them, however, is for passenger service, and will on that account have a somewhat larger wheel. Otherwise they will be alike in every respect.

---

The Firemen's Convention, recently held at Cincinnati, voted $2,000 to buy a home for its founder, "Josh Leach," and $500 toward a monument to the memory of D. W. Rohinson, founder and first grand chief of the Engineers' Brotherhood, who sleeps in an unmarked grave near Washington, Ind.

## The Last of the Giants.

Our photo-engraving of the Great Western locomotive "Crimea" shows one of the great eight-foot wheeled monsters that for years have pulled the famous "Flying Dutchman" over the Great Western's seven-foot gauge from London up the west coast of England.

Brunel, the great engineer, was in favor of a broad gauge and stuck to seven feet, refusing to narrow up to four feet eight and a half inches when the other wide roads did.

The absence of all opportunity to exchange traffic without transfer has finally driven this famous road to narrow up to standard gauge.

The last broad gauge train went over the road on the [illegible] of last May, and the road was narrowed up in thirty-one hours. It was considered expensive and slow by the system of laying the wide track, the [illegible] not being used. The rails were laid on longitudinal stringers 6 x 11 inches, and cross sleepers at considerable distance apart were used to hold them up; all of these cross sleepers were tenoned into the longitudinals and part of them had iron tie-rods across to keep the gauge. The rails were flat bottomed and bolted direct to the timbers, the fish-plates being under the rail.

The work involved four principal operations. The removal of ballast, shortening the transverse members and tie-rods, the sidewise displacement of the longitudinals with the rails on them, and the bolting up and rough-ballasting. It is the intention of the company to do away with the longitudinal system, and replace it with the ordinary tie.

Five thousand men worked on the job from Saturday morning until Sunday afternoon; in that time the principal work was done on the 180 miles of seven-foot gauge.

There was a great deal of sentimental gush, and grief, and ink wasted about this destruction of the "pink of perfection," but it was, and is, all useless. It may be too bad that Brunel's gauge was not adopted as the world's standard, but that the one road of the kind using it should have to come down to the standard is best for the road and its patrons.

What magnificent chances the engineers of this road had to build engines of great power and speed, but somehow or other sixty miles an hour was fast, even for the Giants.

For more than three years the Great Western have been building engines and cars that could be narrowed up, so as not to throw away so many.

At the works at Swindon there were laid some miles of sidings, eight we understand, that were filled with the broad gauge stock, useless now—like a ship in the desert—because there is nowhere for it to go, except into the scrap.

The Last of the Giants—Seven-Foot Gauge.

## From Dirt to Cleanliness.

There is a division point on the Santa Fé in Southern Kansas called Purcell that used to be noted for being dirty. Dirty, slovenly ways were so common that want of order or cleanliness did not excite much attention; but this place was so exceptionally conspicuous for its filth that it was the talk and jest of the system. The place had gradually fallen into unsavory ways and the habits of the men harmonized with their surroundings, as they generally do. There were few people to criticise, and want of that salutory influence breeds evil habits. The upper officers were tolerant of the dirt and its accessories because changes were not easily effected and zeal for order or neatness was not a prevailing virtue.

It came to pass that a new regime came into power, and the new rulers loved order and cleanliness. They visited Purcell and were moved to wrath by its condition. A fiat of strong sound went forth calling upon all concerned to change their ways, but no change followed. The habits of years cannot be changed by an edict. The mogul in charge was more steeped in filth than the cohorts he ruled, and they all acted as a unit in their hatred of water in all forms, of soap as an element influencing change, and even cotton waste was regarded with suspicion as an article suggesting superfluous labor.

The men wore their clothes without change until they were worn out, when they were done with any tool or implement they threw in on the floor or prairie; when they took down a broken part they left it as it reached the ground. In the course of years the ground around the terminus formed divers layers of miscellaneous accumulations that would have greatly puzzled future geologists had the strata been permitted to remain.

The chief of the new regime, finding that the mogul of Purcell was more set in his ways than the laws of the Medes and Persians, arose on his ear one hot morning and dropped the mogul's head in the official basket. A new mogul named Klinclaus was appointed with orders to clean things up, even if it should take a leg. The new mogul was a man of infinite energy and he had struck a fruitful field for the cultivation of that species of fruit. He got the whole of the field to himself for a time, but being a persistent innovator his precept and example worked wonders.

After the new mogul had been in the place for two months, the rumor reached his ears that the chiefs of the new regime would, the following week, show the light of their countenance at Purcell. Then Klinclaus called a mass meeting and uttered words entreating the boys to aid and abet him in giving the greatest surprise party to the chiefs which they had met with on the Santa Fé. With one accord the boys agreed to co-operate. Paint brushes, scrubbing brushes, soap, handbarrows, rubber cars and divers other means for annihilating and moving away dirt were called into use, and the place from center to circumference was cleansed as it had never been cleansed before, and the men were arrayed in clean garments and washed faces.

When the new chiefs stepped from the car they looked around bewildered. The place was strange to them. Had they been carried to the wrong station? No, and Klinclaus' smiling visage appeared to identify the place. He had many triumphs to show but his greatest satisfaction was with the condition of the men's sleeping room, which was clean, and had an inscription in bold letters, "Please take off your shoes before going to bed." The instructions are obeyed although there were said to be many kickers against such ultra-refined practices.

The boys call the new mogul "Clean Close," which is near enough his correct name to pass muster in Southern Kansas.

---

The prevailing low price of silver has greatly depressed railroad business in Mexico, and reduction of operating expenses is the order of the day. As usual the mechanical and road departments have to bear the burden of retrenchment. The officers in charge are all complaining of the crippled condition of their departments. The low expenditures allowed for maintenance of track appears curious to men not accustomed to the dry road beds of Southern countries. On a division of the Mexican Central, over 700 miles long, only \$5,000 a month is allowed for all kinds of track maintenance.

## An English Flyer.

The handsome engraving shown herewith gives our American enginemen a good idea of how a fast English express engine looks, well, anyway, how one on the Great Northern looks; all English roads have engines of their own peculiar kind and their own peculiar color.

This engine is painted green, boiler, jacket and all, striped black and white.

This is one of the very few English roads using outside cylinder engines, and these have inside chests and direct motion valve gear

The cylinders are 18 x 28, and the wheel 8 feet.

The boiler is 50 inches in diameter, has 1045 square feet of heating surface and 18.4 square feet of grate, weighing 101,136 pounds.

These engines start trains very well and swing ten carriages at 60 miles per hour ry easy.

Great Northern Railway Flyer. Eight-foot Wheel.

## Elementary Heat Problems.

By Angus Sinclair.

The burning of fuel and the boiling of water into steam are the fundamental processes by which the dormant forces of nature are converted inta the power that performs the heavy labor that carries the burdens of mankind. To keep a fire hot so that it will cause a kettle to boil seems a simple operation, yet every one who has to pay the bills for kitchen fuel knows that to produce the same result some firemen of this most simple kind of furnace burn more fuel than others. When we find the fire grate or stove developed to the furnace of a large boiler or the firebox of a heavy locomotive, the difference of the fuel used by a good and a poor fireman becomes a very serious matter. We know of no line where the power of knowledge is likely to effect so much saving for steam users and of the fuel treasures that have been laid up for the use of man as in the spread of information relating to the laws of combustion.

The burning of fuel being a chemical operation, the subject cannot be properly understood without some insight into the science of chemistry as it relates to combustion. To those whom the word science frightens, it may be well to mention that science is merely accurate knowledge. Those who have no inclination to follow the best way of doing things, generally have contempt for everything of a scientific nature. Knowledge and the sense to apply it make a strong combination and produce the man of ability. Science or knowledge does not, however, always bring wisdom. There is truth in Pope's lines on the Seven Sciences

> Good sense, which only is the gift of Heaven,
> And though no *science*, fairly worth the seven.

It is much better to have an engineer or fireman with good sense and no science, than one with much science and no sense. But the man having both is certain to be of greatest value to an employer and to himself.

In treating of combustion and steam making I will frequently have to refer to the laws of nature. Everything in nature is guided by a mysterious power which controls and regulates its formation, growth or action. For want of a better description this power is called the laws of nature. When a seed is put into the ground it produces a plant after its kind, when steel is poured into a mold the molten metal will cool into a very hard substance, when molten lead is treated in the same way the product will be a soft casting If a piece of wood or coal is raised to a certain high temperature in the presence of air it will burn. If the gases hydrogen and oxygen come together at a high temperature they will join into one gas and become steam. If that gas is reduced below the temperature 212° Fahr. it will become water. If the water in turn is subjected to cold greater than 32° Fahr. it will become ice. All these changes come about in obedience to the laws controlling the different substances. We know nothing of how the laws of nature were established and we are ignorant of how the power is applied that enforces them; but the human mind can conceive of nothing more absolute than their action. From the daily rising of the sun and the regular movements of other heavenly orbs, to the more familiar sight of how a seed produces its own leaf and how the frozen rain-drop forms a crystal of a certain shape, all are illustrations of the exactness of the immutable power that rules the universe.

Everybody is familiar with the sensation of heat, but how the sensation is produced is not popularly understood. A fire burns and it gives forth heat, the sun's rays are warm to the touch, the hand of a vigorous man feels warm, and the turnings that fall from a lathe tool making a deep cut are hot enough to burn the fingers. These are all different manifestations of heat. How are they produced?

The question is as old as scientific speculation. Few subjects have received more attention from philosophers. Up to the beginning of the present century heat was supposed to be a kind of subtle fluid which had no weight and was capable of insinuating itself into the inmost recesses of all visible matter This fluid was supposed to have taken up its favorite residence in all kinds of fuel and was resting in a semi-sleeping condition, awaiting the kindling spark to bring it into intense action.

Experiments were made by Davy, in the last year of last century, which led to a thorough scientific investigation of the subject by the ablest philosophers of modern times. By rubbing together pieces of ice, Davy demonstrated that heat could be produced by friction. Others proved the case even more conclusively. The discoveries subsequently made have led to the establishment of what is known as the dynamic theory of heat. This theory holds that heat is a form of energy, and that it is caused by intensely rapid vibratory motion of the molecules forming the heated substance. According to this theory, heat, light, electricity and chemical action are all merely different manifestations of matter in motion.

Heat is measured by what is called the thermal unit or heat unit. After a long series of experiments conducted with extraordinary care and exactness, Dr. Joule, a famous English physicist, discovered that the amount of heat required to increase the temperature of one pound of water one degree Fahr., represented energy sufficient to lift a weight of 772 pounds one foot. This is known as the heat unit, and is used in reckoning the value of fuel and for many other purposes relating to heat and steam.

The energy of heat is estimated by its power of doing work. In physical science the term work means the overcoming of resistance of any kind. All operations performed by animals or machines requiring the exe tion of power is classed as work Heat may be transformed with work and work changed into heat. The science relating to the conversion of heat into mechanical action is called thermodynamics, and its first law says. "*When heat is transformed into mechanical energy or mechanical energy into heat, the quantity of heat equals the mechanical energy.*" That is a scientific law that every one studying steam engineering ought to commit to memory.

If an iron rod set on an anvil is struck several sharp blows with a hammer it is made hot The mechanical energy represented by the descending hammer is converted into heat. If an ordinary drop-hammer is employed the amount of heat generated is the same quantity that would be required to raise the hammer to the point from which it fell.

Work is measured by foot-pounds, or the amount of labor represented by the raising of one pound one foot high. The work done by machinery and engines is gen erally estimated by the horse power, which is equivalent to the raising of 33,000 pounds one foot in one minute. It does not matter in what direction the power may be applied. It may be 330 pounds raised 100 feet in one minute or the height and distance may vary to any extent so long as the unit is 33,000 of weight by pounds and feet performed in one minute. The weight may be pulled or pushed horizontally, or moved at any angle from the perpendicular and the result will be the same so long as the pull or pressure represents 33,000 pounds with the distance in feet traversed in one minute.

The horse-power unit was established by Watt, who found that the heavy horses pulling drays in London were capable of exerting a steady pull of 150 pounds while traveling at the rate of two and a half miles an hour. This is 33,000 foot-pounds.

It is a common thing to find a locomotive that is capable of exerting a pull of [illegible] pound of the draw-bar when running at a slow rate of speed. An engine keeping up this pull at a speed of ten miles an hour exerts 440 horse power.

In connection with elementary mechanical questions an interesting problem for railroad men to solve is the foot-pounds of energy in a moving train and the heat units represented by the conversion of mechanical energy into heat when the train is suddenly stopped. When the losses from friction and air resistances are eliminated, it takes exactly the same amount of energy to stop the train that it takes to force it into speed. Suppose a train of one engine and seven sleeping cars, the whole weighing 600 tons, is running sixty miles an hour, required the energy of the moving mass and the heat unit represented by its conversion into heat? The problem is stated algebraically, $\frac{w \times v^2}{2g}$, in which $w$ is the weight of the train, multiplied by $v^2$, the square of the velocity, and divided by $2g$, twice 32.16 the velocity, which a falling body acquires at the end of one second. The weight of the train is 120,000 pounds, the speed is 88 feet per second, so we have the problem arithmetically

$$1{,}200{,}000 \times 88 \times 88 \div 64.32 = 144{,}477{,}600 \text{ foot-pounds.}$$

That is the energy in the train regarded as a moving body like a huge shot. But something else has to be considered. Each wheel in the train has revolving momentum in itself similar to the inertia of a revolving fly-wheel, and this source of energy has to be calculated, because it tends to keep the train in motion and is an important portion of the momentum to be overcome in the stopping of a train.

The tread of the wheels has the same velocity as the train. This is called the angular velocity of the wheel. If all the weight of a wheel were at the circumference it would be easy calculating the momentum. But as the weight extends from the center of the axle where movement is imperceptible to the tread, where the velocity is the greatest, the energy of rotation has to be estimated from a point called the center of gyration. To find this point with exactness is a complex problem, but it is near enough for practical purposes to assume that the center of gyration of a car wheel is at a distance of one-fifth of its radius from the circumference. The angular velocity of the wheels of our train is, therefore, four-fifths of the speed of the train.

Our whole train has about the following wheel and axle weights

| | lbs. |
|---|---|
| 7 sleepers, 42 wheels, 21 axles, total weight | 37,800 |
| 12 small wheels of engine, 6 axles, total weight | 19,200 |
| 4 driving wheels of engine, 2 axles, total weight | 6,000 |
| Total | 63,000 |

The velocity of our train was 88 feet per second. We have now ⅘ of 63,000 pounds to be calculated in the same way as the energy of the train was figured out. The problem is $63{,}000 \times \frac{4}{5} \times 88 \times 88 \div 64.32 = 6{,}040{,}000$ foot-pounds. This sum added to the energy of the moving train previously found, makes a grand total of 150,517,600 foot-pounds. This sum divided by 772, the number of foot-pounds in a unit of heat, gives 194,970 heat units, into which the mechanical energy of the train will be converted in stopping.

Devil's Cañon.

## A Mineral of Great Possibilities.

English papers have been publishing accounts of the characteristics of a new mineral compound, called litho-carbon, which will be very useful for many railroad purposes if it is half as good as claimed.

It is claimed that it makes a perfect insulator, that as a paint it will resist heat or gases of any kind; that it is capable of being rolled into a tissue free from odor, and practically indestructible when employed in the production of macintoshes, canvas belting, waterproof tents, etc. It possesses peculiar powers, enabling it to enter and fill the pores of iron and steel, rendering these metals impervious to acids, etc. It is also said to make common leather waterproof, and it can be applied to wood-pulp for the transformation of that material into what looks and acts like ebony or horn. The saturation of a ship's plates with hot litho-carbon frustrates the attack of barnacles, and the plate will neither rust nor foul.

A portion of the smokestack of the steamer *Dean Richmond*, where the heat, through the use of a blower, rises to 800 degrees Fahrenheit, was painted with litho-carbon several months ago, and remains undisturbed and unblistered, while other parts of the vessel have necessarily been painted many times. A piece of sheet-iron covered with litho-carbon japan is said to have been subjected to an actual heat of 415 degrees Fahrenheit, without crack or blister, and remained so tenacious that the iron could be bent at any angle without disturbing the glossy surface. For varnishing railway and private cars, painting iron bridges, roofs, steamships, houses, etc., this material acts as an insulator, and it is reported that it will neither crack nor blister under any known atmospheric temperature. At great heat, litho-carbon will soften, but it will not take fire at any point.

## Mystifiers of Science.

In studying scientific books, especially those written by college professors, we have often been led to believe that the information was purposely wrapped up in a form difficult of comprehension. Many writers seem to think that they would not be considered wise unless they involve their thoughts in language that is beyond the grasp of ordinary men. To writers suffering under this delusion we would mention that the most popular and profound scientific men like Tyndall, Huxley, Stewart and others, write in a style that any person with a common school education can understand.

A writer in the *Popular Science Monthly*, lecturing to the mystifiers of science, appears to hit a common ostentation on the head by saying: "Nobody wants you to bring down to popular comprehension that which cannot possibly be popularly comprehended, but we do want you to have, and show that you have, an interest in the general advancement of knowledge, and that you regard your specialty, whatever it may be, as simply a higher development of forms of knowledge that are within the popular grasp, and as being, if remotely, still vitally, connected with the practical concerns of life.

"If such is not the case, if, on the contrary, you are soaring in a region in which practical views have no place and no possible relevance, then we make bold to say that your so-called science is merely a laborious and pretentious idleness. It is one thing to wander far afield in search of that which may some time or other, if not immediately, prove of value to the human race. It is another and very different one to wander far afield for the acknowledged purpose of getting, not only beyond general comprehension, but beyond the sphere of all possible utility.

"The only condition on which science can claim the reverence of mankind is that it devote itself to human service, and it rests with the serious students of science to make good this claim. In order that the relations between science and the age may be what they ought to be, the world at large must be made to feel that science is, in the fullest sense, a ministry of good to all, not the private possession and luxury of a few; that it is the best expression of human intelligence, and not the abracadabra of a school; that it is a guiding light and not a dazzling fog."

## Baltimore & Ohio the Oldest Railroad.

To Baltimore, says Major J. W. Pangborn, belongs the distinction of having first conceived the railroad as the term is understood to-day, and to this city is due the honor of building the pioneer road of the world.

Major Pangborn has been delving into history for months, and has been looking up on both sides of the Atlantic the facts bearing on the railroad. The result, he says, is a mass of proof showing that not until the meeting at Mr. George Brown's house, in Baltimore, February 12, 1827, had there been a contemplation of a railroad save as a means of increasing the output of mines or quarries by facilitating transportation to water-ways. In other words, all lines up to the organization of the Baltimore & Ohio Company were tramways built by coal or quarry companies. The Stockton & Darlington, the English line that was opened in 1825, was a coal road, whose whole equipment consisted of "waggons" for carrying coal. Other freight was transported, but not by the company. Others ran "waggons" over the road when not interfering with coal traffic.

As late as 1833, says the Major, three years following the opening of the Baltimore & Ohio line, seven contractors had running privileges over the Stockton & Darlington for passenger carriages. It was not a railroad in the real sense, as a public servant, as was the Baltimore & Ohio from its inception, as the public had access only when the company was not discommoded thereby. Later it became a railroad.

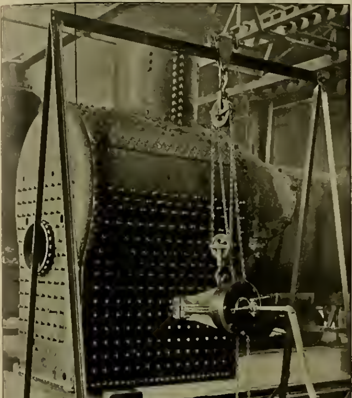
The Liverpool & Manchester was in reality the first European railroad, but it was opened to the public May 22, 1830, six months after the opening of the B. & O. The first shovelful of earth turned to the construction of a railroad in this country was on July 4, 1828, when the corner-stone of the B. & O. was laid. The first tram was the Leiper Road in Pennsylvania, in 1809. It was 180 feet long and was for mining. Later a similar one, a mile long, was constructed in Delaware county, Pennsylvania, to carry stone to Ridway Creek. A three-mile tram, for carrying stone exclusively, was built in Massachusetts in 1827. They have all passed away. The only one of the pioneer roads of the world retaining its original name, and which has ever maintained a regular succession of management, is the B. & O.

Letters, communications and questions sent in without the sender's name are thrown away, don't expect we will answer anything signed by initials only — we won't.

## A Mechanical Boiler Shop.

Any one wishing to see boiler-making, boiler-repairing and the miscellaneous work of boiler-making performed with the highest perfection of science and art should visit the boiler shops of the Santa Fé railroad at Topeka. The foreman in charge, Mr. Archie Baird, is not only one of the best practical boiler-makers of the country, but he is an inventor of high ability, and he has employed his inventive faculties to good purpose in devising appliances for performing boiler-making operations.

An air of neatness, cleanliness and orderly method strikes a visitor at once on entering the shop. These are the outward signs of good management. As we stand watching the business going on we find out that the work is pushed quietly but expeditiously along with power appliances performing the heavy labor generally done by human muscle in boiler shops. The shop is well provided with the ordinary run of boiler-making tools, but in addition to these there are many appliances worked out by the foreman. Compressed air performs a very important part in this shop. It operates the different forms of cranes that do all the handling of boilers and boiler material, it drives Brotherhood engines which do all the drilling, tapping and screwing in of stay-bolts, it operates a machine for cutting off stay-bolts, and it works an apparatus that does riveting at a rate at which riveting was never done before.



AIR-OPERATED STAY-BOLT CUTTER.

BAIRD'S STAY-BOLT CUTTER.

The first of these machines which was illustrated in the June number of LOCOMOTIVE ENGINEERING is shown in the annexed engraving, Fig. 1, as it is handled while doing its work. It is essentially a set of shears worked by air, and it clips off the ends of stay-bolts as neatly as a barber's shears cut off a man's hair. The machine is worked by two men, and working leisurely they can cut 500 stay-bolts an hour. I timed them when they were making an extra effort, and they cut off 24 bolts in one minute. The machine makes a much better job than cutting the stay-bolts by hand, for the operation puts no strain whatever upon the bolt or the thread.

PORTABLE PNEUMATIC RIVETING MACHINE.

The same principle has been employed in the construction of a riveting machine, shown in Fig. 2. The Santa Fé Company has a great many cars with iron trucks, and the riveting is always working loose. The work of repairing these trucks had to be done in the boiler shop, and it became so monopolizing that there was little time left to work on boilers. When cars are scarce the repair work must be done expeditiously, and the men looking for cars generally manage to put the stamp of urgency upon repair operations. Some one in these shops remarked: "The mother of invention is always punching us up." Under the prod of necessity Mr. Baird devised the riveting machine. It does riveting as fast as the rivets can be pushed into the holes, and makes an excellent job, much superior to hand work. The design of the machine is so obvious from the engraving that no description is necessary.

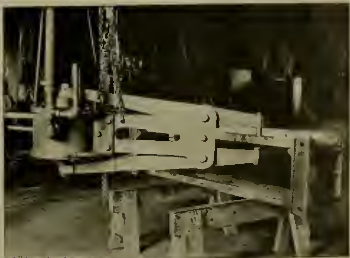
## Property Rights in Patents.

A decision was rendered last month by the United States Court of Appeals in a suit brought by the Edison Electric Light Company against the United States Electric Light Company, that is of interest to many people who are not in any way concerned in proprietary rights in electrical appliances. Edison was the original inventor of the incandescent lamp, where light is produced by the electric current passing through a resisting medium inclosed in a vacuum. Several parties imitated this invention, and have been selling incandescent lights which seemed to avoid the Edison patents. The court has now decided that every known form of incandescent lamp, and every possible form of this lamp, infringes the Edison patents.

This means practically that when an inventor secures a foundation patent for any device, the imitations which obtain the same results by different mechanical arrangements are infringements. The decision is a little more emphatic than several others previously made of the same tenor. The well-known decision on the Richardson safety-valve patents was substantially the same as that now rendered concerning electric lights.

This decision ought to be of direct interest to many railroad companies, for there is no class using mechanical appliances more given to patronizing articles that are notoriously pirated imitations of patents. The great variety of functions demanded of railway machinery presents an unparalleled field for inventive genius, and it is industriously cultivated. But no sooner does an inventor produce an appliance or improvement which promises to be in demand than there is a host of imitators doing their best to produce something which will do the same functions and avoid infringing the original patent. The principal work done by the mechanical engineers employed by some railroad companies is the designing of forms of patented articles which shall perform the functions of the original without incurring the liability to pay royalty. This is a small, mean business, and is nothing more than dishonesty, for it is stealing a man's ideas and dressing them so that their identity may be disguised.

The plain decisions of the courts ought to discourage this sort of industry. The only reason why railroad companies are not paying royalties on numerous patents that they are using illegitimately, is the delay and expense that must be incurred in law suits for infringements of patents. Law's delays are so notoriously tedious in patent suits, that those who have been injured patiently suffer wrong rather than engage in the long and expensive fight.



BAIRD'S AIR RIVETER ON TRUCK WORK.

We have recently heard of a movement among men of means to purchase the originals of patents that have been largely imitated by railroad companies. Should this be done, some of the companies are likely to have to pay damages that will put the money paid to settle the Tanner brake suits far into the shade.

---

The D. & H. C. Co. have recently bought the right to use the Jerome metallic packing on the whole system. They have been using another metallic packing heretofore. The Chicago Elevated has also adopted the Jerome.

---

The La Junta division of the Santa Fé road has some feed water that holds about 100 grains of solid matter to the gallon. It is considered fairly good water that has only half that quantity of impurities. It goes without saying that boiler repairs are heavy. An engine does remarkably well if it runs 30,000 miles without having the flues changed. Some engines do not make 20,000 miles. Means of washing out boilers receive great attention, but no amount of washing will keep the boilers clean. In cleaning out a boiler that had made about 30,000 miles, they removed over 6,000 pounds of solid deposit. They have tried all sorts of purifying devices and chemicals without success. The impurities consist mostly of lime, magnesia and soda in various forms. The only compound they find of any service is crude petroleum. This prevents the scale from adhering tenaciously to the hot surfaces.

---

An observant traveler on the Pacific coast is likely to be struck with the strong personality of the men who have acted as pioneers in the railroads of that region. Among the striking mechanical men to be met in California is William McKenzie, master mechanic and chief engineer of floating equipment of the Southern Pacific, at Oakland, Cal. Mr. McKenzie did his first railroad work on the Chicago, Burlington & Quincy, at Aurora, Ill., and subsequently rose to be foreman of the shops at Peoria. On account of a general cut in wages he left there and went to Australia, where he spent several years in marine work and in setting up mining machinery. Returning to the United States he naturally drifted back into railroad life. He ran an engine on the Central Pacific for some years, and rose by the usual steps to his present position.

---

H. Walter Webb, third vice-president of the New York Central & Hudson River Railroad, has issued an order removing all restrictions to the hauling of cars equipped with the New York air-brake and making no difference between that and the Westinghouse. This order is said to have been decided upon after the result of the recent 50-car train test on the Central, in which no practical difference was found in the action of the two brakes, either in trains of their own or when mixed together. This will probably settle a good many little disputes on this question now occupying attention in different parts of the country.

---

LOCOMOTIVE ENGINEERING appears to have a very popular standing on the Pacific coast. Los Angeles is not a large town, but we found the paper sold at three different news stands. All the principal news stands in San Francisco have it for sale. Besides this, there are clubs at all the principal division points, some of them being very large.

LOCOMOTIVE ENGINEERING.

A Practical Journal of Railway Motive Power and Rolling Stock.

Address all communications and make all orders and checks payable to

LOCOMOTIVE ENGINEERING,

912 TEMPLE COURT, NEW YORK.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } Editors and Props.
JOHN A HILL, }

J W CURRAN, Manager Advertising Department.

Subscription Price.

$2.00, postage paid to any part of the world.
Single Copies 20 cents

Special Notices.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary; always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as Second-class mail matter.

FOR SALE BY NEWSDEALERS EVERYWHERE.

Publishers' Agents

American News Company, New York
International News Co., London, England
W. Williams, 21 Fink's Building, Melbourne, Australia.

The December issue of LOCOMOTIVE ENGINEERING will contain forty-eight pages at least, and the edition will be 30,000 copies. It will go everywhere on earth where there is a railroad, and several places where they are only wishing they had one. Be in it.

## Weak Features of Freight Cars.

The best place to study the strength and the weakness of freight cars is in the repair yards. The most careful figuring in the drawing office and the most rigid attention to details of construction in the building shop will leave points of weakness that are clearly revealed in the repair yard when the car passes through the searching ordeal of heavy trains, rough roadbeds and violent yard service.

The writer has recently enjoyed the privilege of making close inspection of the work going on in a great variety of repair yards extending from New York to San Francisco. Everywhere he found that the same lines of weakness or the same species of defects were keeping car repairers busy. It is a conservative estimate to say that 50 per cent of the breakages that are holding cars in the bad order tracks are due to failure of some part of the draft attachments. Those who ought to be most familiar with the subject say that at least half the defects to cars are caused by handling them in switching yards. There is no class of railroad men so little under control as switchmen, and the destructive tendencies of this class appear to increase faster than the work of improving drawbars and their connections. The officers in charge of switchmen are frequently strangely apathetic in checking the destructive tendencies of their men. Damage to a car falls upon the mechanical department which is presumably to blame for sending out cars that will break. Where division superintendents and yard masters are required to make a correct report of all the cars that have sustained damage in the hands of their men, the destruction to draft appliances has been greatly reduced.

Where an evil exists it is natural to look for a remedy. The failure of the draft-rigging of cars is the source of so much expense to railroad companies that the ablest men in the service ought to be engaged devising means to prevent the breakage. The first line of cure which we would suggest is the means of placing the responsibility for breakage where it belongs. When that is done systematically there will not be so many bad order cars to care for. The next move is strengthening the parts that break in ordinary service. The practice which all railroad companies have followed of attaching the draft timbers below the sills makes this important part weak, since the line of resistance is not continuous. Some railroad companies strengthen their draft timbers by filling up the space between the needle-beams, making the draft timbers practically continuous, while the Chicago, Burlington & Quincy have adopted a radical remedy in cars lately designed and put the drawbar in the line of the sills. Both these methods strengthen the parts of a car most given to failing, and must materially reduce the cost of repairs. The different attachments designed to connect the drawbar substantially with the supporting timbers, such as the Butler drawbar attachment, are of decided value and strengthen a weak point. Cars that have the draft-gear secured to continuous timbers by substantial attachments rarely obstruct the repair tracks. They are coining money for their owners, while those having weaker draft rigging are rousing animosities between departments over the problem of dealing with bad order cars. The moral of this condition of affairs appears to be obvious enough.

Next to the draft attachments, the ends of box cars provide the most business for the bad order tracks. In the course of our inspections we found several cars that were nearly new which had the ends driven out. The shocks that prove fatal to weak drawbar attachments, project the load against the car ends, and they are not made strong enough to resist matter in motion. The measure of strength in the end of a car is two posts about 2 x 4 inches. It takes a very small blow to break them. Several attempts have been made to brace the end of cars but with very little success. The most obvious and common sense way of making this part stronger would be to make the posts the full width of the end sill. When cars reputed to be first-class are so weak in the ends that the sudden application of brakes has resulted in making the load of corn shoot through the end, it is time designers were working out a stronger form.

Middle sills of cars are also much given to breaking in a way which indicates that they are structurally weak. These sills are badly weakened at the transoms and fail accordingly.

Car trucks give much less trouble than they did a few years ago. The numerous wrecks, due to weak trucks, have conveyed a good practical lesson, and the parts have been strengthened to withstand the searching requirements. The hangers of swing beam trucks, or the pins supporting them fail occasionally, but swing motion trucks are becoming a thing of the past under freight cars, although a few roads still cling to them. Failures of arch bars which used to be common are now almost unknown. The only improvement now needed for the diamond truck is making the whole transom and bolster of iron. There are said to be a great many Fox trucks already under freight cars, but we failed to hear of any of them being in need of repairs.

Among the miscellaneous parts of cars that fail in service, the first part that deserves notice is the brake-beam. The plain wooden beam is fast disappearing, but it has too many representatives in use for the severe braking now necessary on heavy trains. Next to the brake-beam comes the hangers and the attachment that holds up the same. Hangers are frequently ridiculously weak and the bracket is nearly always unsuitable for resisting shocks and strains. This part is decidedly in want of attention. Another point of weakness in many cars is the under trussing. The queen posts are so short that the truss rods do little good, and the car sags in the middle every time a heavy load is carried. If all the weak points mentioned were strengthened, the repair tracks would not engage the work of half the men now kept busy there.

## Some Reasons Why English Roads Will Never Adopt the Long American Freight Car.

The average "goods waggon" in Great Britain is a four-wheeled concern weighing nearly as much as its load, and very clumsy looking to an American. Many of our railroad mechanics think the Europeans behind the age because they don't adopt the long American car, weighing less than half its load, capable of holding large freight, reducing the number of cars to look after, report and carry on books, and especially to handle.

If the English had to haul heavy trains long distances there is little doubt but they would have "bogie cars" quick enough—but they do not have such service to perform.

If we had the English freight service to handle we would do so at a loss until we provided rolling stock to meet it. Our long cars of 60,000 pounds capacity would be as useless to us with their conditions as their cars would be to meet our present conditions.

In Great Britain there are very few long hauls. We probably pull as many loaded cars without changing freight 1,000 miles in this country, as they do 100 miles. Their hauls are mostly short ones and they are made in good time. "Waiting to make up a car load" of anything is an absurdity there that would'nt be listened to. If a merchant in Liverpool has a barrel to go to Glasgow he takes it to the freight station and loads it upon an open car. If there is other freight to go, that is put on the same car, but if there is none that barrel goes alone ready for delivery in the morning.

The average freight car load on a big road there only averaged three tons each for a whole year, counting in coal and mineral cars, which are always fully loaded.

All the freight platforms in that country are cut full of stalls with room for one or two cars, and short turn-tables in the regular platform track allows cars to be turned into these stalls. As the platform is just the height of the car floor this facilitates loading and increases the "frontage" of the platform.

Car turn-tables are common, every station and dock having many. The long car would call for throwing away all these tables and doing away with the platform loading stalls, this would make it necessary to extend the station platform. Station platforms there are usually 4 feet high, of solid stone, they will last forever,—and it costs money to change them.

The introduction of the long American car would call for new car scales; thousands of expensive scales would be useless.

"Well," says the Yankee, "in coal and mineral trains, always loaded full, our cars would be best." Well, let us see. The coal of that country is hauled in four-wheeled cars with sides about 3 feet high, a large part of it goes into vessels either as their own fuel or for export. At all coaling cities elaborate and expensive cranes are provided that pick up these cars and literally *pour the coal out of them* into the ship, and set them back on the track, and that quickly. All this efficient plant would be useless with our 34-foot cars, and the coal would have to be handled twice or more before it reached the ship's bunkers. Then, again, all coal cars need weighing and they are fixed to weigh the little cars and not the big ones.

If all coal and mineral were hauled for their own use or to drop into yards, our system could be used with profit, but not under the present conditions.

Both countries have conditions of traffic that require a different service to handle it, and it seems to the writer that the railroad mechanics of each country have provided the equipment best fitted to take care of the work. Certainly, the English freight service would never get any where with our grain and cattle trade, neither would ours do for their—well, you might call it "retail" freight business.

There is no good reason why the abominable compartment system of passenger "carriages" should exist over there, and the American "coach" will surely take its place, but there are good reasons why their freight cars are the best for their work.

## How Good Bad Things Can Be If All Alike.

A well-known railroad man said, in the discussion of the car-coupler question at a recent convention, "If we only had adopted the *worst* one and stuck to it, we would have had a safer coupler as far as killing and maiming men is concerned."

This remark was brought to the mind of the writer this summer while in Europe, there they have a uniform style of coupler, and a very primitive one—the hook and chain.

This clumsy device, small and weak, gives very little trouble and men are very rarely injured in handling them.

On passenger cars there are usually two links drawn together by a bolt swiveled to one and threaded into a nut fast in the other; after hanging the links over the hooks the slack is taken up with the screw. Buffers placed at the corners of the cars receive the compression strains, the link and chain simply stand the pulling.

On freight trains there is slack enough left to put the links over the hooks, there is no provision for taking up slack.

Yet men couple and uncouple these cars during switching operations with considerable speed, and with safety.

They are not hurt because they know just what kind of a coupler and buffer they are going to find on every car that they get hold of—they are never ambushed and surprised.

Very few breakages occur and, reading of the grief and expense we have in America, lots of the best men there are surprised that we don't adopt the hook and chain. Their advantage comes, not from their superior coupler, but from its universal use.

When the American railroads are equipped with a uniform coupler—no matter what one or what kind—the record of coupler accidents will fade away like mist.

## We Have Met the Enemy—And We Are Theirs.

Experience is a good teacher—we know something now.

It pays to get taken in once or twice in a while—we've been "took."

After all our talking and warning of our neighbors to beware of the Brotherhood-souvenir fiend, he came along with his scheme while the junior philosopher (who has done most of the kicking) was away and faked the senior philosopher into giving an advertising contract, "just to help the boys."

"The boys" didn't get any great help, not even a copy of the noted "souvenir" for the grand officers—just enough of the promised 11,000 having been printed to go around to all the advertisers, perhaps 200.

This souvenir racket is a plain unvarnished swindle, handled in the name and allowed to exist to the disgrace of the Brotherhoods.

The orders get a mere trifle for letting some slick advertising schemers get up a book in their name, and hold up the manufacturers of the country. Isn't it obtaining money under false pretense.

Grand Secretary Debs, of the Firemen, roasted this swindle in his last report to the grand lodge in September. Mr. Arthur, of the B. L. E., has denounced it, and yet local lodges are allowed to farm out the privilege of robbing people in the name of the order.

No sensible business man expects that the "ad." buried in this book is going to do him any good. He does it to "help the boys." If he won't do this, he is blackmailed by an implied threat that "the boys" will make his goods a failure when placed in their hands. This is blackmail of the manufacturer and a libel on the men.

The firemen's souvenir of the last convention is before us, it contains 206 pages, half rot about the City of Cincinnati and the order, and the rest ads. from good houses. At a low estimate, $10,000 was collected for this thing; did the Brotherhood get a quarter of it?

The S. P. is posted now, and we won't do so any more, and we hope that every manufacturer will require a letter from the grand lodge of any order requesting his contribution—for such it is—to their entertainment committee, before they allow themselves to be bilked in broad daylight. The Brotherhoods ought to expel members who trade on their reputation. The gift fiend is only a dude compared to the souvenir robber.]

Brotherhood engineers and firemen get good wages, and are not beggars asking manufacturers of goods used by railroads to put up fifty or a hundred dollars every year or two to entertain their delegates. They would scorn to do this, yet they will allow, for a few hundred dollars, a swindle of this kind in the name of their order. It's about time some action was taken against this fraud, it is hurting the reputation of the Brotherhoods.

## How Palace Stock Cars Are Used.

The most arrant humbug in railroading to be seen on Western lines is the fancy line stock car. It is fitted up with numerous luxuries for the comfort and accommodation of stock that greatly increase the expense and weight of the car. The representatives of the owners interview stock-raisers and expatiate upon the advantages of using palace stock cars, and secure the bulk of the business. When the stock is shipped the water-troughs are kept upside down and the hay-racks are left empty, but the owners of the stock imagine that the animals are at liberty to eat and drink when they so desire. The owners of the cars get their mileage rates from the railroad companies, and the railroad men swear about the humbugs practiced to defraud their employers of legitimate revenue.

In the course of a Western journey of five thousand miles the writer watched the stock cars on numerous trains and did not find a single case where the water troughs and hay-racks were used. The train men questioned invariably said that they never watered the troughs.

---

One of the principal reasons why there are fewer "busy seasons" on European railroads than on those in this country and the traffic more uniform there, is doubtless the condition of the common roads. The writer took particular notice, during this summer spent across the water, of the excellent condition of all the country roads that feed the railroad lines. In France, where the roads are exceptionally good, farmers can be seen every day drawing immense loads of produce along the country roads, perhaps in a heavy rain, with one horse. Two-horse teams are the exception, and I honestly believe that the average load is heavier than those hauled over the average American road with a span. The longer it rains there the better the road, the loose dirt and dust being washed away. In our country a heavy rain prevents the hauling of produce to market, and dry roads overcrowd the elevators, warehouses and railroads. Railroad officers do not pay enough attention to the condition of public highways; they are as directly feeders of their lines as is a mining or logging railroad. Would not the employment of the convicts of each State upon the public roads be a good thing for the commonwealth and better for the convict? This would do away with the curse of contract jobs, abuse of leased prisoners, the interfering with trades, and prevent the rising of working men against the introduction of convict labor into their special calling by contractors, an abuse they are justified in resisting. If the convict owes the State his labor for a time, let him pay it to the people to its full value in a lasting improvement of the public highways instead of giving the State forty cents per day through a contractor paying him twice that amount for doing the financiering. Our country needs good public roads more than any other public improvement.

---

During the Columbian celebration in this city, October 10th, 11th and 12th, every mode of transit was crowded to its utmost and the elevated system carried the largest number of passengers ever moved by a railroad in a day. The record for three days (of 24 hours) was as follows:

| Date. | Passengers. |
|---|---|
| Monday, Oct. 10 | 945,002 |
| Tuesday, Oct. 11 | 901,325 |
| Wednesday, Oct. 12 | 1,075,537 |
| Total for three days | 2,921,864 |

Think of handling 1,075,537 people on thirty-two miles of road in twenty-four hours. Perhaps two-thirds of this number were handled on the lower half of the system and inside of eighteen hours out of the twenty-four. Because there was fearful overcrowding most of the papers in this city have attacked the road and its management for inefficiency. Every wheel was turning that could turn, and every effort made to move the trains quickly, but as there is no center track and all trains must stop at all stations, delays were caused by people trying to get on and off. However far the "L" comes from filling the ideal of the rapid transit crank, there is no other system at present in use that could have handled so many people. There was a slight rear collision caused by an engineer's neglect, in which some people were injured; otherwise, there were moved over the streets of New York almost three million people in three days with safety.

---

There is war on hand between the metallic packing companies. Some time ago the first twenty engines that went to the Chicago elevated road gave trouble on account of the metallic packing leaking, it was of the U. S. make. More trouble was caused in this way than any other and Mr. Vauclain, inventor of the engines, put on five sets of Jerome packing as a trial, and, we understand, all the engines were finally equipped with it. Shortly after the change it was reported that an attempt had been made to bribe certain parties to destroy this packing by the use of emery or otherwise, and a row was raised. Since then Mr. C. C. Jerome has entered suit for $100,000 damages against the U. S. Metallic Packing Co. and Mr. E. D. Hurley, their representative. The suit promises to be interesting. We do not presume to know anything of the merits or demerits of this particular case, but the method of introducing goods by secretly destroying those of a competitor is far from a business or an honorable transaction, and we sincerely hope that when discovered it will be discouraged by punishment that will be remembered.

---

In German shops and factories you will see all wheel pits in the floors and all belts running through floors or walls surrounded by an iron fence painted a bright red. All gears around the heads of lathes and drills, and the shifters on planers, are cased in tin painted as red as red can be. All exposed shafting, pulleys, etc., are protected in the same way. When a workman is crippled in a machine there the owner is obliged to foot his medical bills, and, if totally disabled, pay him a pension for life and his family one in case of death. Hence all this care. A foreman of a government railroad shop told the writer that since the rigid enforcement of this law accidents have decreased 45 per cent. Every exposed possible mangler was at once covered and a careless workman is discharged. Good thing, is it not?

---

Men who ride bicycles soon learn to appreciate how great a figure wind resistance is to moving bodies. The least little breeze affects the rider, and professionals soon learned how to present less surface to the wind by stooping over. Enginemen know how wind affects the movement of trains, but don't recognize the amount of work the engine does to overcome it. Train dispatchers and superintendents who order trains lightened on a windy night, to let them make time, are few and far between. To a large majority of the latter class of gentlemen an engine is an engine—anything with a whistle and a number ought to pull a train, and weather that don't blow down the telegraph lines ought not to affect the running time of trains.

## NEW BOOKS.

SIMPLE LESSONS IN DRAWING for the Shops. By Orville H. Reynolds, Chief Draughtsman of the Northern Pacific Railroad. Eugene V. Debs Pub. Co., Terre Haute, Ind. Price, $1.

This little work will hardly need an introduction to readers of this paper as the chapters originally appeared in our columns. The design of the author was to teach shop apprentices and others how to make good working drawings with a set of instruments costing not more than ten dollars. He tells first how to select the tools and what to get, then how to take care of them. Simple lessons are given and a pattern set (there is a plate with each lesson), so that the green boy can follow a right line and the instructions teach the language of drawings. If a man studied this little book without ever trying to draw, it would teach him to "read drawings," a very important thing to a shop man in this day and age. We advise every machinist, apprentice, and all others interested in learning drawing, to send a dollar for this little book; it may lay the foundation to lift you above the ordinary level. It can do you some good if you let it, it can't possibly do you any harm.

POOR'S DIRECTORY OF RAILWAY OFFICIALS and Manual of Street Railways for 1892. H. V. & W. H. Poor New York.

This work contains a very complete list of railroad officials in the United States, a directory of the street railroads, and a list of roads that are projected or under construction. This feature might be made of considerable use by contractors and manufacturers of railway supplies. The book is an improvement over last year.

THE ENGINEERS' EPITOME. By N. J. Smith. Published by the Mason Regulator Co., of Boston, Mass. Price 50 cents.

This little work is composed principally of rules and tables for the use of engineers. The work is good and well worth twice its cost, but it abounds in algebraic examples and terms—something that should be avoided in cheap books intended for the masses of engineers. This is the third work of a series that the Mason Regulator people have issued and are making popular.

---

The Union Tank Line Co. are putting the Smillie coupler on their new cars. This coupler seems to be gaining favor steadily. The Tank Line own upward of 7,000 cars and if applied to all, eventually, will make a nice little job of itself.

## PERSONAL.

W. S. Hughes, of Hopewell Junction, N. Y., has been appointed master mechanic of the Central division of the New York & New England in place of Charles W. Gates, resigned.

Morris E. Ward, for a long time with the Allen Paper Car Wheel Co., and latterly with the Wicks Refrigerator Car Co., has associated himself with a car roofing concern at Chicago.

---

Mr. W. H. Johnson has been appointed general foreman of the Southern California shops at San Bernardino, Cal. Mr. Johnson is a New England man and before going to the Pacific coast worked on the Boston & Albany and on the Old Colony Railroads.

---

Frank Arnold, past grand master of the order of Locomotive Firemen, was elected at Cincinnati to fill the office of secretary and treasurer, made vacant by the resignation of Eugene V. Debs. Arnold was for six years a faithful officer of the grand lodge, and will be found as good again.

---

J. S. Chambers, formerly general foreman, has been promoted to the position of master mechanic of the St. Joseph Terminal R. R. Co. This road is composed of the city end of the A., T. & S. F. and the St. J. & G. I., and the work is done for the motive power and rolling stock for both lines under Mr. Chambers.

---

Mr. W. J. Robertson, for many years in charge of the motive power of the Central Vermont, gives up the general supervision and will devote all his energies to the maintainance of the cars. No officer of a New England road has been more faithful to the interests in his hands, or has gotten along with less facilities and material to keep up his work

---

Secretary John W. Cloud, of the Master Car Builders' Association, has issued the twenty-sixth annual report of the association and it is saying nothing against the other reports to aver that this is the most interesting one ever issued. There are 315 pages of matter besides a large number of folders containing drawings of the Association's standards.

---

John Kirby, ex-president of the Master Car Builders' Association, and for the past 40 years at the head of the car department of the Lake Shore road, has retired from that position and taken an easier job in supervising the construction of new cars built by contract work It was in John Kirby's little office at Adrian, Mich., that the Master Car Builders' Association was born in 1866. He is succeeded as general M. C. B. of the Lake Shore by his assistant, Mr. A. M. Waitt.

---

This summer, Henry Getner, chief draughtsman for Pedrick & Ayer, of Philadelphia, visited Europe, to renew old acquaintance, see what they had over there in the way of machine tools, and tell them what we had. Whatever else he saw or did we do not know, but that he convinced some of them that we had good tools here is shown by the fact that Fried. Krupp, of Essen, the great gun maker, has ordered two of P. & A.'s largest and best milling machines.

---

Master Mechanic Charles W. Gates, of the New York & New England, at Plainfield, Conn., resigned on October 2d to go into business for himself. Mr. Gates commenced on the road as a fireman twenty-nine years ago, and went through the mill, engineer, roundhouse foreman and master mechanic. When leaving he was enticed into the roundhouse and given a complete surprise in the shape of a crowd of officials and men from all parts of the road, who gave him three cheers and a gold watch and chain.

Continuing testimony against the safety of using swing-beam trucks under tenders is given by Mr G. W. Prescott, master mechanic of the Southern California. This is a road with a great many sharp curves, and, therefore, a good test track for rolling stock All the tenders had swing-beam trucks and they were constantly getting off the track and the wear of wheel flanges was very great The swing beams have all been blocked and it entirely remedies the trouble A similar experience was encountered on the Sante Fé

Mr Alexander Campbell, general foreman of the Southern Pacific shops at Los Angeles, was run over by a locomotive two years ago and badly mutilated. He lay a long time in the hospital between life and death, but finally conquered and has lately got back to duty He needs a pair of crutches to help him around. The boys say that though his movements are more tardy than they were before the accident, his perception is in no way impaired, and that those who try to do any skulking find that crutches make rapid enough motion to overtake them

J. I. Davis, master mechanic of the Boston & Maine shops at Boston, Mass., has accepted the position of superintendent of the new Boies Wheel Works at Scranton, Pa Mr Davis is one of the best shop managers in New England, and we venture the prediction that the B. & M. will have a hard time to get so good a man in his place while Colonel Boies is to be congratulated upon his selection Brother Davis will feel lonesome for a while, not being called out to wrecks and having no chance to be called up in the night by an emergency, but he will get used to it

Mr James Collinson, master mechanic of the Santa Fé at Fort Madison, Ia., has some eight-wheel engines pulling passenger trains that he is prepared to back against anything in the country for efficiency. One of these engines has been pulling trains of from eight to thirteen cars daily for about a year and has made 100,000 miles without missing a single trip. Mr. Collinson thinks that this is a trifle ahead of anything else in the country, and is inclined to put up a hat on his engine beating anything else on wheels when the test is doing the work regularly with the least expense for repairs and fuel.

A. M. Waitt, who succeeded, on October 1st, to the position of M. C. B. of the Lake Shore, has for some years been assistant to Mr. Kirby and in actual charge of the work. Mr. Waitt, unlike most men in charge of the still independent car departments, came up through the locomotive department. He was formerly chief draughtsman on the Eastern Railway of Massachusetts, now part of the B. & M., under John Thompson, and made the drawings for the first extension front; this was some fifteen years ago. Mr. Waitt is one of the brightest men in his line of business, and there is no doubt of his success.

Mr. George Gregg, master mechanic of the Southern Pacific, at Los Angeles, Cal., is a graduate of Altoona, Pa., having been in the shops there when several men who are now prominent in the railroad world were apprentices. He worked in the shops along with Frank Thomson, who is now Vice-President of the Pennsylvania, and Mr. Thomson fired for Mr Gregg for a short time but retired from the scoop because it was too hard work Another of Mr. Gregg's shop associates was Enoch Lewis, now general purchasing agent of the Pennsylvania. He says that nearly all the young fellows who were his associates in the shops forty years ago attained prominent positions

Mr. J. Conroe, who attained much celebrity as chairman of the Brotherhood of Locomotive Engineers of the Santa Fé system, is now master mechanic at La Junta. The vim and energy which commended Mr Conroe for the position of leader among the engineers are now successfully employed in managing the hardest division on the Santa Fé system. With shop accommodation far behind the requirements of the rapidly increasing business, Mr Conroe contrives to keep the rolling stock in excellent order, and performs his duties in a way that is pleasant to the men and profitable to his employers. He was one of the best engineers on the road, and he is now making a record that entitles him to the reputation of being one of the best master mechanics in the West.

General Master Car Builder George Grambling, of the South Carolina road, died at Charleston on the 8th of October. Mr. Grambling has been a master car builder for many years. His father was master car builder for one of the Southern roads before the war. Mr. Grambling suffered from a severe wound received in the Confederate army, but was an uncomplaining sufferer. When Lee surrendered Mr. Grambling offered his services to the United States Government as a mechanic, and went to work for Uncle Sam in his old grey uniform. He was soon in charge of the cars on a division of the R. & D., and in 1880 went to the South Carolina. He was a member of a number of orders, some five or six turning out to escort his remains to the train. He was buried at his old home in Atlanta.

Charles E. Fuller, Jr., for the past two and a half years master mechanic of the Eastern division of the Erie, has accepted the position of superintendent of motive power of the Central Vermont. Mr. Fuller is a young man and has been quietly making a record for himself in his position at Jersey City. A banquet was given Mr Fuller by the men under him, and he was invited to a surprise party. The engineers and firemen did the principal talking, the burden of which was that Mr. Fuller had been just to them and fair to all; the division superintendent, train master, traveling engineer, and other master mechanics also spoke, and then Mr. Fuller was presented with a testimonial signed by 1400 men who had been serving under him. Mr. Fuller was unable to speak in reply, but the boys knew what was in his heart.

## Traveling Engineers—Notice.

Several prominent road foremen of engines met recently, and all agreed that it would be a grand good thing to have an association for mutual benefit and the exchange of ideas and information. Traveling engineers are not now eligible to membership in the Master Mechanics' Association, yet are welcome there; an association of their own would be of much benefit to them, as all the subjects discussed would refer directly to their work. As the master mechanic's assistant, the traveling engineer is generally intrusted with the duty of examining fireman for promotion, and a more uniform and better plan can be made and maintained where it is the rule rather than the exception. No doubt the roads will be glad to furnish transportation facilities to those men to meet once a year, and it will be beneficial if a man only sees what is done elsewhere, if nothing else. The expense of membership can be kept at nothing, for some time, at least. All traveling engineers or road foremen of engines are requested to correspond with John A. Hill, 912 Temple Court, New York, who will act as secretary until such time as a meeting can be fixed upon. If enough are found who are interested, a regular call will be issued next month.

## Notice to Correspondents.

Hereafter we must ask all our friends who contribute puzzles to these columns to send the answers with them; this will insure an answer without too long a wait, and give the "thinkers" time enough to solve the problems given, too. Don't forget this, you air-brake doctors.

## Boiler Turning Device.

*Editors:*

I have been requested to sketch the device used in these shops (C., R. I. & P.) for turning boilers, and do so herewith.

A similar plan, used by John Mitchell, foreman boiler-maker of the D. & R. G., at Denver, was shown in the LOCOMOTIVE ENGINEER for March, 1890, but his has no support for the fire-box end of the boiler, all right with a straight boiler, but not reliable and steady with a wagon-top, especially a long one. The horn bolted on back-head of boiler in our rig supports the fire-box end firmly and is not at all in the way. This plan has been in use here for some years.

## Tool Steel, Smiths and Users.

*Editors:*

The tool-smith doubtless lives by making and dressing tools, and it is equally true that he has a reputation at stake as well as a living. But there is a second element which must be considered—the user of tools. It is for the user that this article is written. Now, the relation of the tool-smith and the user of tools should be one of co-operation. Yet most of the risks are taken by the tool-smith. It is the rule of the trade.

Two machinists bring one chisel each, and the tool-smith dresses and tempers them carefully, but he makes a distinction in the temper. "He forecasts the user." One chisel is tempered to a purple or a dark straw, the other is left a low blue; both men work on the same class of work, metal being alike as to hardness. In about fifteen minutes in comes the blue looking friend complaining that his chisel is too hard; he has ground it a half dozen times and it still keeps breaking. Well, tool-smith explains that he cannot, under "the conditions" do any better, and his low-tempered and blue friend feels that there is a fault with the tool-smith, or condemns the steel.

Five hours later tool-smith chances to see his purple-colored friend. "Well, Joe, how does your chisel stand?" "Oh, I am through with the job; chisel is all right." In order to receive good results from steel made into tools there must, or should be, some way to equalize conditions. As it is, in numerous instances, both tool-smith and steel depend upon circumstances of which there is only a partial record.

So we might enumerate through the whole category of cutting tools. Some men can accomplish results beyond all expectations, whereas others are devoid of ability of how to use same tools, and fail. It is obvious that there is a demand for better application in the use of tools, and, if the steel is all that is claimed for it, there is in it a vast amount of unused power.

Men that make a study of heating apparatuses tell us that about 90 per cent. of the fuel we burn goes up the chimney. So it is with steel. Hence, it is evident that the proper handling of cutting tools, after they have left the tool-smith, will have its influence for good, bad or indifferent, and thereby increase or diminish the actual value of that most useful article, steel. There are many things that are difficult to overcome and they must be given some place in reckoning all the chances that tool steel is subject to. We read a great deal about heating, annealing and tempering steel, and strive to obtain all that is known.

Let me cite a very important instance. We have been using Mushet steel for turning hard steel tires and we have encountered more or less trouble on account of some very hard metal, and we came to the erroneous conclusion that if Mushet could not get there, nothing else could. But we learned different, we met with a hard tire, used Mushet, got good results, but we wanted to do better, so we made a pair of tools "right and left hand" out of 2 x 1-inch Crescent special, exercised the utmost care in heating and hardening, the result was that the Crescent tools gave better satisfaction than the Mushet. Now this is an instance where there must be some relation between the steel, the tool-smith and the man that used the tool.

## That Lamp Problem.

*Editors:*

In your answer to query No. 92, of P. R. L., given in September number, would not lamp *C* be *nine* times the value of lamp *A*?

The law of photometry is that of the inverse squares, and not that of a simple proportion. See Part IV, "Deschanel's Philosophy," paragraph on Photometry.

*Jersey City, N. J.* S. I. T.

[Our correspondent is correct.]

## Bad Roundhouse Work.

*Editors:*

In this day of steel crossheads, steel crank-pins, steel connecting-rod straps, etc., one would naturally suppose that the builders of locomotives had got beyond the possibility of breaking any of the parts used in locomotive construction, yet any day an observer passing through almost any roundhouse will have cause to believe that the parts of locomotives are not strong enough to withstand the outrages perpetrated on them by some of the careless workmen.

I have seen the main crank-pin bent, the front main rod strap broken, the front and back cylinder-heads and casings broken, the flange of cylinder broken off, and the piston broken, all on account of a little carelessness on the part of the roundhouse machinist.

The piston had but small clearance in the cylinder, the main rod had been taken down, and the front and back brasses had been filed, and the rod and brass put back in place, without any attention being given to the position of piston in the cylinder. The result was that the piston hammered the inside of the back cylinder-head, which could be plainly seen by the marks on inside of back head; this broke the strap across key-way in front of main rod, the result was as described. All of this could have been avoided by taking the extreme travel of crosshead, or striking points, as commonly called, marking points on guides, and adjusting main rods accordingly, this is no uncommon occurrence.

Another bad practice I have observed by some workmen claiming to be A 1 machinists, when taking down connection rods to file brasses they will sometimes find the straps sprung together at open end of strap, which makes the brasses hard to drive out, instead of using the proper remedy, opening the strap a little, they will file off body of brasses until they slip through tight part of strap, the result is that when the brasses are put back in their position in strap, and keyed up easily in their place, that they are loose in the strap. When the engine is at work out on the road, the engineer finds that the rod pounds; he drives down the keys a little the first chance he has, but still it pounds, he drives down the keys a little more, the next time he stops, then the brass runs hot. It was not the brasses that were pounding the pin, *but the strap that was pounding the brass*. The machinist tells the engineer if he had left the keys in his rods alone, and would in future let *well enough alone*, he would not be troubled with hot brasses.

Another bad feature I observe is in filing brasses open; sometimes they are filed open on purpose, sometimes they are filed open through carelessness. Connection rod brasses should not be filed so as to be open at joints (excepting front end main rod brasses), but should be keyed brass to brass. I have seen a good many brasses filed open, but have the first time to see one that needed filing again, until there were liners sweat or pinned on face of brass, and keyed brass to brass, once filed open, they always file themselves thereafter. A good practice, when connection rod brasses are made new, is to bore them out $\frac{1}{16}$ in larger than crank-pin journal. In nearly every case, when rod brasses are new, they will heat up less or more on the start, when hot, the brass will expand more than the strap, compress the brass in the strap, then, when the brass cools, if bored out to fit crank pin, it will pinch the pin and cause it to keep heating for a time. But if bored out $\frac{1}{16}$ in. larger than journal, after the engine has made a trip or two, and the brasses of connection rods have worn down to their natural bearings, file a little off the face of the brass and you will then have your rod brass in good shape.

OBSERVER.

## Where the Blow Was.

*Editors:*

We recently had a curious experience with a brand new Schenectady locomotive on the C. & E. T. Ry. that fooled all of us.

From the start she had a bad blow and no one could find it, sometimes she would run a full trip without blowing at all, then again she blowed badly.

Her valves and packing were examined early and her steam pipes ground in later, when it was found that when blowing

had she forced fire out of the door, in one instance burning the overalls off a fireman.

The master mechanic rode on her and the engineer from the works did the same, but neither of them discovered anything new.

Her flues were examined, as it seemed like a bursted flue, but they were sound. Finally the engineer and fireman were changed.

After a long time it was accidentally discovered. It was an arch pipe in the fire-box, used for supporting the brick arch. These arch pipes were put into the boiler sheets with a tapered copper ferrule, and when the engine was worked very hard the tube moved enough in the flue sheet to withdraw its taper ferrule and blow badly, and would take up as quick as it commenced.

The pipes were taken out and the blowing stopped altogether, grinding in steam and exhaust pipes, setting out Dunbar packing, and facing valves did no good.

*Chicago, Ill.* ARCHPIPE.

## Too Much Reduction for Service Stops.

*Editors:*

Brother George Holmes should inform the engineers on the Clinch Valley Division, that a 12-pound reduction with a 4-inch piston travel is not good braking, as your article would have us infer. In this part of the country, all good air-brake enginemen know that with standard equipment and maximum pressure the auxiliary and brake-cylinder will equalize under the above conditions. And if more than a 12-pound reduction is made, they are doing just what it appears to us that you are guarding against so strenuously—i. e., getting train-pipe pressure lower than that of brake-cylinder. We should have been delighted to have been present at the "love-feast," but sincerely hope you will enlighten us more fully as to what transpired on the occasion.

WISCONSIN.

*Kaukauna, Wis.*

## Answer to Relyea's Puzzle.

*Editors:*

In answer to my last puzzle will say that there was a small hole in diaphragm No. 7, of the pressure-reducing valve and dirt under valve No. 5, which allowed the air in drum to leak past valve 5, through diaphragm 7, and out of vent-hole in cap 3, thus reducing pressure in drum below that of train while handle was on lap. Throwing handle in release allowed train pressure to return to drum, which caused brakes to set, and now comes the "sticker." I am unable to explain why the whistle should blow under the above conditions and not blow while pressure was leaking off of drum from 50 pounds to 10 pounds.

*Syracuse, N. Y.* W. F. RELYEA.

## Those Breakdown Puzzles of K. T.

*Editors:*

I would like to answer the questions asked by K. T. in the October number.

First. I would take down the back-up eccentric strap and put it on in place of the go-ahead strap that was broken, leaving one of the bolt holes in back end of go-ahead blade vacant, then take a long bolt and put it through this hole and through one of the holes in back end of back-up blade, thus bolting the back ends of both blades together and go ahead.

Hooking the lever up will not have any effect on the valve travel on the right side, and you cannot back up, but you can take a full train in and run as fast as you wish.

Second. I would take down both back side rods, block engine so as to take as much weight as possible off of back drivers. If it was right back driver, would chain right side of back end of engine across to left side of front end of tank, keep front end of tank loaded heavy as possible and go ahead, running carefully, especially around curves.

Third. Place the engine on center, forward or back, it does not matter which, and put up your rod and look out for your striking points, and she will run all right.

*Wells, Nev.* M. B. B.

[The third question is not answered. K. T. wants to know *how*.]

*Editors:*

Please insert the following in answer to K. T. break-down questions.

First. Place reverse in full gear, take out broken parts. Now rob back-up eccentric on same side, and put in place of broken one. Now place a block of wood in link under link block, so it cannot move up or down, securing it there. Then you may proceed in this way; engine cannot be reversed, and will work steam full stroke.

Second. In my estimation you will be totally disabled.

Third. Place engine at ¼-stroke on disconnected side. Now measure from one axle-center to the other; the pin centers must measure the same; in case they don't they must be moved till they do, by means of bars and jacks. Having pin and axle centers to correspond, straps, brasses, rods, etc., will be marked where they belong; in case they are not, a walk to opposite side will aid you to find where they belong. Having found out proceed to box side rods by placing as many liners at one end of rod as the others. Having finished side rods, place engine you are working at on dead center. Push piston in till it strikes front head, and make a mark on guide-bars flush with crosshead; now pull out piston till it strikes back head; make a mark on guide-bars flush with crosshead. Now measure from mark on front of guides to crosshead. Suppose it measured 22¼ inches, now measure from pin center to axle center. Suppose it measures 11 inches, twice this = 22 inches, the stroke of the engine. The remaining ¼-inch equally divided for clearance on each end will be ⅛-inch; now connect rod to crosshead, equally divide the liners. Now push piston in ⅛-inch from mark on guides; lift the rod up and place in the brass; the space between the brass and rod must be filled with liners. Now place the other brass in strap and push it on, the distance it goes past the bolt holes is the amount of liners it requires. Having bolts and keys in, engine is finished.

R. BACHMAN.

*Beaver Meadow, Penn.*

*Editors:*

In answering K. T.'s third question on main-rod brasses, will say that engine brasses have oil holes drilled on top, and one is cut to allow clearance for set-screw for key. That will tell how brasses go to put engine on center, put up front brass, force crosshead back, and by looking at striking points on guides will tell how many lines to put in to allow clearance. Then put up back brass, key it up, turn engine on the opposite center, and see if clearance is equal. If not, change liners to make both clearances equal, and I think it will be all right.

EDWARD GIBSON.

*Wilmington, Del.*

*Editors:*

In reply to K. T. in your last issue, I will give him my own experience with a break similar to the one in question. The only possible way by which you could pull the entire train would be by moving the back-up eccentric in a go-ahead position. Take broken part of strap off of blade, bolt both blades securely together with a bolt taken from broken strap, which will be the required length, and to avoid link-pins chafing put a block about 1½ inches thick between butt ends of blades. By this method you can pull as many cars as before breaking.

Second. The only practical way that suggests itself to my mind would be to take out cellar, and block securely between axle and pedestal brace. Proceed carefully, but do not attempt to back up unless on straight track.

Third. Put engine on dead center, allowing about one quarter of an inch for clearance. It will be impossible to get the rod up wrong if the holes in strap match those in rod. If rod is too long put liner in back, if too short put liner in front. If you do not feel sure that your work is correct, pinch engine to front and back centers and notice whether you have the proper amount of clearance.

## Results for Air-Brake Instruction Car.

*Editors:*

The New York Central air-brake instruction car has been here a week in charge of Mr. Shanon, who is so well known all over the country as an air-brake expert. The men are loud in their praise of Mr. Shanon for the able manner in which he has instructed them. This car is fitted up with a rack inside, on which is placed air-brake equipment equal to twenty cars. There is also an engineer's brake-valve with duplex gauge attached to show drum and train pressure, while other gauges show pressure on car cylinders and auxiliary reservoirs. There is also the standard and quick-action triple-valves and brake-valve with sections cut out to show how they work and where they are liable to give out. This car proves conclusively many points that have been the cause of much discussion and have been thought impossible by men who thought they knew something about air-brakes. Among the many things that this car proves to or convinces the unbeliever of are the following. First—If you have made a light application and placed the handle of brake-valve on lap, then throw it around to emergency notch, you don't get the benefit of the emergency brake, or in other words the emergency-valve don't open because there is not enough pressure left in train-pipe to open it. Second—With a very bad leak in train-pipe, brakes can be kept off and you can leave the handle in running notch all the while. Third—If when you slow down going into a station you think you are going to stop too soon, you can release the brakes and catch them again and not run by the place you want to stop at. Fourth—It shows that a reduction of twenty pounds on train line sets the brake in full, and a further reduction is a waste of air. These are but a very few of the many valuable points which Mr Shanon can prove to your entire satisfaction. Mr. Shanon has with him an assistant in the person of Mr. Burgess, of Buffalo, a very genial gentleman and thoroughly posted, who will have charge of the air-brake equipment on this road.

*Syracuse, N. Y.*

## The Equalizing Discharge Valve.

*Editors:*

In reading the various articles written in the LOCOMOTIVE ENGINEERING about the equalizing discharge valve, one who is ignorant of the philosophy of this valve would say without hesitation this valve must certainly be something very fine, as every writer speaks so highly of it, but I, as a fireman, say darn the valve—no, not exactly the valve, but those who look after its welfare. I am a close observer of all things connected with air-brakes, and in consequence am inclined to be a critic when any of its parts are allowed to get out of order and go for weeks and months without being fixed. On a road in Southern California we have quite a number of engines equipped with the equalizing discharge valve, and the way the majority of these valves work is simply horrible. I am firing an engine equipped with the old engineer's valve, and the engineer can make a stop any place with from 5 to 8 pounds of air, but occasionally our engine goes up for a few light repairs and to be washed out, and invariably we get an engine with the equalizing valve on. Well, the first thing to be done is to start the pump, then wait and see what the results are. The first stroke the pump makes is one with the hammer; the next is a groan that would chill the hydrogen in an ice plant, then she slips an eccentric, and away she goes on one leg, one valve open, the other one shut, and the one that is shut is always the lower one. Why is it that the lower valve (when I say the lower valve I mean the receiving valve on the lower end of air-cylinder) always sticks? Some of the engineers use a compound for lubricating the air-cylinder made of the following elements. Water, engine oil, valve oil and signal oil, equal parts, mixed in the cover of the tallow-pot, and about one-half a teacupful is fed to the air cylinder through the lower valve once or twice a day. Still she howls for more, and the lower valve is stuck about one-third of the time. Does she need more oil?

When we get enough air to couple on the train, which consists of two coaches, we do so, but right here our grief begins, the pump has to run so fast to keep 70 or 80 pounds of air, that it would make a person sea-sick to hear it.

This is the way we stop in regular service, all the air is exhausted from the air gauge, and likeways, I suppose, from the train pipe, as both are connected, and when the pointer on gauge shows 0, the train pipe should be empty, but it is not, nine times out of ten there has not been enough air exhausted from train pipe to set the brakes, and why? The emergency port is opened wide every time, and as far as making a stop by exhausting air from small reservoir connected to top of rotary valve, you might as well spit on the rail, the one would have as much effect as the other. When the equalizing discharge valve is kept in good working order, it is, in my estimation, the only valve at the present time that is what may be called perfect, but when they are allowed to get out of order, and remain so, they become an all-around nuisance.

A FIREMAN.

*Los Angeles, Cal.*

[Our correspondent must not blame the equalizing discharge valve for the ignorance and abuse of those in whose care it is unfortunate enough to fall. The way your pump is oiled is enough to paralyze it—a spoonful of thin mineral oil once a week is enough in the air cylinder, and it should *never* be put in through the air suction. That the pump valves stick, it heats and pounds, is no wonder; clean out the valves and the air passages from them to the cylinder and you will have less trouble. A man used to the old valve, or a three-way cock, can do nice work with a two-car train, but the new valve will do as well, if clean and given a show. Probably that oil cocktail that the pump has been taking has got the engineer's valve so stuck up that there is no chance for it to work. Clean house and read up on handling that valve.]

## In Virginia.

*Editors:*

In the writer's estimation, one of the best railroad shops to visit and see new kinks and wrinkles being constantly worked out, is that of the Richmond & Danville system at Richmond, Va., under the direction and management of Mr. T. W. Gentry, master mechanic.

It would take more pages than you could spare in your monthly reports of the doings of our many hundreds of machine shops to give in detail all the new things that are valuable which Mr Gentry and his efficient lieutenant and general foreman, Mr. J. J. Bayley, have devised to cheapen the cost of repairs since my last visit.

One of the first things that strikes a visitor through the foundry is the cleanli-

...ness to be found in every corner and the fine quality of their castings. I saw heavy cylinder castings direct from the sand that were smoother and freer from blemishes than some stove-plate work I have seen, and I found on examination that they were just as hard as it was possible for them to be and have Mushet's tools cut under the scale and hold their edge. A rotary screen rigged up inexpensively on wooden uprights and used for mixing sand and facings serves its purpose well in reducing the pay-roll, and is one of the small items of practical economy in their foundry department. Every casting made is by piece-work, and the cost is quickly estimated and kept at a minimum.

Several heavy engines are being overhauled for freight service, and I was surprised at the small force employed in the machine shop in comparison with the amount of work being turned out. A device I saw here impressed me very favorably with Mr. Bayley's quick adaptation of ideas foreign to the shop to accomplish his ends. Needles for rod-cups are very essential, also very much in demand as they are constantly getting lost. To point a needle in an engine lathe in the ordinary way is a tedious job requiring some care, so he had a "pencil sharpener" made on an enlarged scale. It is caught in the lathe chuck, the ends of the needles forced into it, and say, they sharpen wire-rods just as nice as new lead pencils.

In the tool room, which, by the way, is too small, they have a system of "size cards" whereby the boys in charge of tools can tell just what sized drill to give a workman when he asks for a "tap or reamer and drill to suit." All the apprentices in the shops have to serve a certain portion of their time in the tool room, learning the uses of and becoming familiar with the various mechanical appliances used in shop practice. Regarding apprentices, I discovered that the sons of employés of the company are always given preference over other applicants, and that all "cubs" at work were the sons of employés.

Air has become quite a factor of importance around many shops, but I have never seen it so thoroughly utilized as it is here. All through the car-repair yards "air hydrants" are to be found for testing air-brakes. It is used in the roundhouse for testing engine-brakes and pumps; it is also used as a blower whereby a cold engine can be got out on the table hot within twenty-five minutes from the time the air nozzle is coupled to her blower pipe. In the oil house it is again to be found in use emptying oil from barrels into the various tanks, and they are just completing a set of rolls for rolling the leaves of driver springs the top roll of which is raised and lowered by an air cylinder. This machine is going to be a "money saver" for them, and looks very neat, while its cost is but a trifle, as the majority of its parts were resurrected from the scrap-pile.

In the machine shop they have discovered that the turret lathe is the most important tool in the place when rapid lathe work is required and that it is not good only as a screw machine.

The pattern shop is a picture of neatness. While in this department I had an opportunity to see the result of too much labor and too little brains in the drawing room. A blue print of a cab bracket had come from the draughtsman, who had made a front and two end views of it marked right and left, dotted lines ran everywhere and the pattern makers lost considerable valuable time studying out the puzzle before beginning to work on it, and probably after they were putting it together their doubts on the matter caused them to go slow. Remember this drawing was correct, what I am condemning is that there was too much of it. If there had been simply a front view and a view of it in section, the idea wanted would have loomed up before that pattern maker as plain as the Capitol at Washington, and it would have been so much easier for the draughtsman, not mentioning the time saved both in the drawing room and pattern shop.

I called on Master Mechanic O'Brien, of the Atlantic Coast Line, whose shops, just at the end of the long bridge across the river, are so antiquated that it keeps my friend John busy thinking all the time how to make both ends meet. There are several young men I am acquainted with in the North who are sitting in comfortably furnished offices and who are being continually flattered on account of their success as superintendents of motive power, who would prove total failures if they were suddenly transposed from the aid of their helpers in subordinate positions and placed in John O'Brien's office on the Petersburg Road.

Two compounds from the Baldwin Works have just arrived on this division of the Coast Line for trial in comparison with simple engines. As Mr. O'Brien is just as conservative on the compound question as Mr. Lauder, of the Old Colony, or Mr. Dolbeer, of the Buffalo, Rochester & Pittsburgh, results on his road will be devoid of all sentiment and without favor.

*Richmond, Va.* AN OLD MAN.

## Troubled With Too Good Memory.

*Editors*:

I see in the *Sun* an account of Jackson Richards' 100-miles-an-hour (?) engine. Can't you get a cut and description of it for your readers? It is disagreeable to be an "old cuss" with a retentive memory.

Some time about 1850, the P., W. & B. R. R. Co. built a three-cylinder engine, two out and one inside, connected and set at thirds. Inside was equal to the two outside, and there was the blunder, as you will see. She was to do wonders! Did you ever hear of her? Only *one* was built.

Shortly after a Baltimore firm—Smith & Perkins, I think—built or designed to build a "binary" engine to compete with and excell Ross Winans' eight-wheel connected. The "binary" had, or was to have, four cylinders, two out and two inside, the inside connected to a crank-axle, and the two pairs of drivers were coupled with side or parallel rods. Outside cylinders were coupled same as any other four-wheeled connected engine. The benefits supposed to be derived from this arrangement were perfect counter-balance and freer curving, as only two pairs of wheels were coupled. It was to knock the "camel-back" higher than Gilderoy's kite. (By the way, who in thunder *was* Gilderoy, and what kind of a *kite* did he have?) The camel-back *stayed*, the "binary" did not *materialize* to any extent. I do not know that any were built, although pamphlets were sent all over the country, one of which I had.

You see, from foregoing that the *Shaw* 4-cylinder-double-back-action-perfect-counter-balance idea was not original, and I think Richards' 100-mile-an-hour engine embodies most of the essentials of the two engines I have quoted, and will fall in line with them and the *Fontaine*—on the scrap pile!

Newspaper accounts of railroad inventions are, as a rule, interesting reading matter, but not always instructive. When "Norris Sons" first put on the "V" hooks, dispensing with "starting bars," they had an engine on exhibition (jacked up) at the Franklin Institute Exhibition in Philadelphia. The engineer would reverse her under steam. Of course the wheels would change motion instantly. Newspapers said, No more railroad collisions! Engineers could now stop a train *instantly* and go back Lately I saw a statement of a brake that would stop a train at fifty miles per hour instantly. I have known of cases where the head end of a train stopped *almost* instantly, but the rear kept right on and made it bad for passengers or freight.

E. J. RAUCH.

## Hints and Facts for Enginemen—Some Old Pointers in New Words.

BY CLINTON B. CONGER.

[*Continued from Page 379, October number.*]

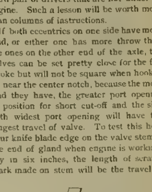
When the mark on the valve stem comes to the right place again it shows that the valve is opening for the forward motion just where it did for the back motion. If the crank-pin is a little below the forward center, the back motion will have the valve *almost* ready to open; of course if the go-ahead is set to the same place it will be "blind," as they say. From this you can understand how important that the engine is on the exact center, *not pretty near*.

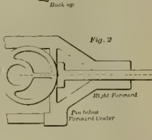
Some men uncouple the eccentric rod of the slipped eccentric from the link after hooking her down in the corner in gear with the good one, then put the lever in the other corner, taking good care that the rocker arm does not get moved; then move the slipped eccentric till the eccentric-rod can be coupled on the link again. The principle involved in this method is the same as using the valve-stem, but it is more trouble and less exact.

Four out of five engineers set their slipped eccentrics by the spoke of the wheel, by which they mean, set one eccentric about the same distance or same number of spokes of the wheel from the crank-pin as the other. When the crank-pin is on the forward center the forward motion eccentric should be nearly over the axle, less than a quarter of a turn behind the crank-pin, the back motion one will be below and in front of the axle, or ahead of the pin. Once fix these positions in your mind and the reasons for it, and you will not need any instructions about eccentrics. Neither will it be necessary to pinch the engine on the exact center to set them, as you can set the cams at any place in the revolution she may stop. It is a little handier to have her near the forward center, as in that case both cams will come on front side of axle away from the firebox, where you can get at them handy. If there was no lead or lap on the valves, the cams would come on the opposite side of the axle just a quarter of a turn from the pin; they have to be moved toward the pin enough to move the valve the amount of the lap, say ⅞-inch, which on a 6-inch axle for 5-inch throw will be about an inch at the surface of the axle; then enough more to give the lead in full gear, say $\frac{1}{16}$-inch, and you will find the spoke or brace in the middle of the cam is quite a distance around toward the pin. If the good eccentric has its spokes or brace opposite the fourth spoke of the wheel from the pin, set the slipped one the same distance from the pin on the other side of it, set up your set-screws tight and pull out—she will go all right. If it is less than four spokes from the crank-pin, set at the same distance. Remember it is not *always* four spokes from the pin, some engines are three and a half spokes away, but it is the same distance from crank-pin to each eccentric. See Fig. 1.

There is another way of setting the eccentrics, in which we use the position of the cam for the same motion on the other side of the engine for a guide. For instance, the forward motion eccentric on left side is out of the proper place. Turn it around till it is just exactly at right angles, or a quarter of a turn behind the right side one, for same motion. The crank-pins for same axle are exactly a quarter of a turn from each other and the cams should be also. If you can pinch the engine, get her a little below the forward center on right side so the forward motion cam on that side will point straight ahead, parallel with the frame and the forward motion on left side should be above the axle, parallel with the shoe or at right angles with the frame. The illustrations will make it plainer. Fig. 2 shows right side in proper position, move your left forward motion eccentric to position in Fig. 3 and she will be O. K. Remember these eccentrics are on opposite ends of the axle. Fig. 1 shows the position of eccentrics on same end of axle back up next the box. When you get the hang of setting them this way you will be able to locate them in their proper positions without pinching or otherwise moving the engine, as you can judge by your eye when they are a quarter of a turn apart. Get in the back shop with some one who knows how, and practice on a forward pair of drivers that are not under an engine. Such a lesson will be worth more than columns of instructions.

If both eccentrics on one side have more lead, or either one has more throw than the ones on the other end of the axle, the valves can be set pretty close for the full stroke but will not be square when hooked up near the center notch, because the more lead they have, the greater port opening in position for short cut-off and the side with widest port opening will have the longest travel of valve. To test this hold your knife blade edge on the valve stem at the end of gland when engine is working say in six inches, the length of scratch mark made on stem will be the travel at





that point, then compare it with mark made on the other stem in same manner, working in same notch. Try it also in full stroke and sometimes the results will give you pointers. If one valve-stem has more travel than the other it is fair to suppose its valve has more travel.

When the link on one side hangs lower than the other, the lowest one gives longer travel when working ahead and shorter when working in back gear, because the link block-pin is a different distance from the end of link and moves further each stroke. If the link hangers are same length and pins in connections not worn, raise one end of tumbling shaft a little to correct this error, but it is impossible to make an engine exactly square if the motion work is not the same on both sides of the engine. When the valve-rod has a turn-buckle or stretcher on it with a right and left hand thread, and they are put up the wrong length, after disconnecting out on the road, it is hard to fix on the exact length again. This mistake can be avoided if you will make a mark on the valve-stem and one on the valve-rod on opposite sides

of the stretcher some exact distance apart, say twelve inches, when you put it up again it can be set to these marks. I speak of these other derangements of the valve motion because the eccentrics may be just right and still the engine will not beat square. If she is not square at all points have her run over while under steam, so connections will all be warm, by the machinist-valve setter and made square where you work her most; the 10-inch notch is a good place.

When your engine is pulling *very* slow, walk along beside the guides, at the instant she makes an exhaust make a mark just behind the crosshead across the edge of the guide. Do this for all four points of the exhaust and you will have four marks showing how far from clearance points the piston has moved when exhaust takes place; these marks should be nearly the same distances from the striking points at ends of guides, but they won't be, and no one can make them exactly the same. But if there is a great difference, say two or three inches, it should be remedied, and you can soon see which exhaust is too quick and which too slow. Where the difference is slight it is caused by the "angularity of the main rod." The eccentrics are set in a certain relation to the crank-pin; when the pin is on the dead center, the piston and crosshead is at the extreme travel on that end, but when the crank-pin is half-way between the dead points, on the quarter, the piston is not half-way between the dead points, it is nearer the wheel than half-way, so exhaust will be some later from front end of cylinder. Moving the pin in the link-saddle or frog corrects part of this error. Of course this pin cannot be changed out on the road unless the frog is put on wrong. The pin should be nearer the back half of link than the center line. When a young runner begins to monkey with the valve motion, unless it gets out of square on the road, the wrath of the round-house machinists settles on him because they are sure he don't know anything about it. Learn how to go about it right and get it done right and they will be ready to help and take your say so on what is the matter.

---

## Locomotive Running Among the Bushwhackers.

By Old Soldier.

*(Continued.)*

I should have mentioned that, previous to putting on this hospital train, we hauled the wounded and sick in box cars. I mention this so that you can see the necessity of this kind of a train. If I should explain the suffering of human beings in those box and stock cars it would make your hearts ache. The coaches we had were not sufficient, but they relieved a great deal of suffering. I have heard many of our wounded soldiers say that our coaches were palaces alongside of the hospital tents, but my readers must not think they were any comparison to the trains that roads are running at the present time.

As I stated in my other article, we were soon to be out of Nashville. We only stopped there long enough to unload the wounded, then we proceeded South with empty train, excepting nurses and crews. The nurses cleaned out the cars under way.

About this time engineers and firemen came to Nashville very thick. Among the good runners that came and staid were Billy Smith, Dave Gardiner (we called him Sugar Foot), Bill Lenning, George Preston, Tom Doyle and Mike Hughes.

Mike was an old fireman on the Chattanooga road, and was set up there. I remember one poor fellow by the name of Jack Bryan. I think he came from the Pittsburgh & Fort Wayne Railroad. I remember of his telling me he had been foreman of a roundhouse. He had a watch presented to him when he left that road. I think he only made one short trip on the Nashville & Chattanooga road when he was captured by the Johnnies. they did not hurt him, but only took his watch and jewelry and all his money and exchanged clothes, as he was better dressed than any of the Johnnies.

Poor Jack was a hard looking citizen when he got back to Nashville. The next morning after he got back, he came down to the M. M.'s office, and was telling us all about it, and planning how he would get revenge out of the Johnnies. I could not help but laugh at him. While he was talking to us he kept feeling his left breast. I made the remark to him that we must all expect to be robbed or killed running on such roads. I just stepped into the office and said something to the clerk, when the news spread that Bryan was dead—he keeled over and never spoke afterward. It was caused by heart disease and the excitement of the time. I think his yarn made some of the new men hunt their way back North. I never learned whether his watch was recovered or not.

I will mention a little more in regard to the hospital train. The fare at the table could not be beaten anywhere, nor could the train be surpassed in war times for safety. Now I imagine you young runners will say that this train was the kind to stick to in war times; well, a few trips satisfied me and I gave it up and have wished a thousand times I had never seen it. The horrors of that train will never be erased from my memory. My partner, old Charley Butterworth, and myself gave it up, and Tom Doyle and George Preston took our places. Old Charley Butterworth, I think, gave up running altogether. I took my old run on passenger train back again.

I see Mr. Anderson writing up the Johnnies' side in the last issue. The Johnnies' orders must have been very severe on tail-end collisions—about the same as they are at present in Mexico. We did not have any such orders as those, but I would have hated to have been the one that run into the hind end and killed or hurt a Yank.

I tell you a soldier at this time was worth more money than a negro in slave times. I can say one thing for our train crews, engineers, firemen, conductors and brakemen—you never met any of them drunk on duty, and the old boys, if they chose to tell it, would say that there was more whiskey carried over that road than was ever carried over any other road of its length, and the boys all know what I mean by this. This whiskey fell into the hands of sutlers. Do you remember, boys, the cotton cards, which were $1.50 in Nashville? Now, you old sly coons, you all know the price along the road. Messrs. Editors, we were not running there for glory or $145 a month, but we could not afford to let Uncle Sam into the secret because he might blow on us. If I had formed an idea then of writing this up I would have kept a diary.

I would state here that whenever we wanted to push forward the Johnnies had to move. We could raise three men to their one. You know some say we overpowered them, while some say we whipped them. I leave this matter to history, for you to judge, but it mattered not how far we pushed them ahead, bushwhackers were left in the rear and their sole aim was to capture and rob trains. At one time we were compelled to carry five or six rebel prisoners and barricade our engine with them. We would do it in this way. Say we carried five prisoners, we would put two on each side of the tank and make one sit out on the front end of the engine. We would have the shackles on them, and the train-guard to watch them. I tell you my heart ached many a time for them, but you know war is war, and what brutes we all got to be on both sides! One cannot believe it unless he was there to see it for himself. It becomes disgusting for a man to sit down for one moment and think of civil war carried on for the benefit of politicians that would faint at the smell of powder. Well, boys, it is exciting and gives you lots to think about if you go through safely.

I am well acquainted with an engineer running a passenger train out of Houston, west, to San Antonio. He has passed through twenty-six hard-fought battles with only one or two slight wounds, but he has wrecked his constitution and he does not draw a pension, but he should draw one.

How much would any of you good runners or machinists take to go out with a gun and stand up in a three-days' fight, like the battle of Stone River, where 25,000 or 30,000 men were killed on both sides and as many more wounded? I guess the most of you would rather serve on the Grievance Committee. When we ran from Nashville to Chattanooga we hardly ever made a trip without being fired into. I was coming down Cumberland Mountain one night, about half a mile from the corner. I reached forward to open the pet-cock, and just as I started to straighten up a bullet came through the side window and close enough up to raise a blue blister on my back. I thought I was cut in two. The fireman thought the bullet passed through me. He was back in the well of the tank. I dropped on the deck; several shots were fired on us and struck the cab and jacket. I was suffering intense pain, but had to stand it until I reached Nashville, as I had no one to relieve me. When I reached Nashville I was laid up for a couple of weeks. After I got well I took my old engine and run again.

The army pushed on to Big Shanty and Atlanta, Georgia. I do not remember who was in the lead with the supply train, but I had orders to proceed with the passenger train to Big Shanty and from there to Atlanta.

Now, boys, just imagine what a looking country this was after two large armies passed through it. I always thought that the Rebs in evacuating their own country devastated it more than we did. They thought they would not leave anything for us to forage on, but that did not bother us, as we always had plenty. In saying us, I mean the whole Yankee army.

Sometimes a supply train would get belated and the boys in front would get a little hungry, but train crews did not suffer, nor the guards at bridges and stations. I think about the hardest time our army had for grub was at Chattanooga. They got there several weeks ahead of the rebuilding of the road. They were put on half rations for some time, and before wagon trains or the railroad could be gotten there they were down to one hard cracker a day, but this did not last long, as old Uncle Sam pushed up his grub trains as fast as he could and soon gave the boys a good feast.

I will say here, to you readers who do not know what a government ration is, that no hearty man can possibly eat one soldier's ration a day. I tell you this so you may know that our army was well supplied with plenty to eat, while the poor Johnnies were always short, and some of them looked very gaunt when captured, and after they were taken I never saw one that did not enjoy a square meal at Uncle Sam's traveling boarding-houses. How their old lantern-jaws would palpitate at sight of a good big cup of coffee!

Now, boys, if we had gone hungry as long as they did we would have been lantern-jawed too. I do not think history could record any great army in the world that was as well fixed and clothed as the Federal army was. I think all good soldiers will bear me out in this statement, but the poor Confederates suffered for clothing and went hungry, but fought like devils, and I defy anyone to gainsay this. I have seen more suffering among Confederate families while passing along the road than I could possibly describe to you. I always carried my coffee mill, coffee and coffee-pot and made coffee whenever I wanted it. I had a good drip-pot and could always get hot water from my gauge cocks by removing the dripper. Of course I always had a part of mine and my fireman's rations in the boxes, so, you see, I fared better on military roads than I did on civil roads. I do not know how many of the boys did this, but I advised all who talked to me to do the same.

Well, as I said, we proceeded on our journey to Atlanta, and when we arrived there what a sight it was. All of you that know Atlanta to-day could not think it possible that it was the same place it was the day we arrived there. It was desolate and in ruins and all its people—women and children—left by the Confederates to take care of themselves until their husbands and fathers returned, which many of them never did. But in as far as my memory serves me, none of them appealed in vain to our commanding generals for food. It is hard when you hear little children and women crying for bread, but may all of you who read this remember, that should you ever be called to go to war, this fate may meet your loved ones as it did the poor Southerners who once lived on the best that the land of the United States afforded, surrounded with their black slaves to attend to their every wish. So remember, hot-headed young politicians, how you move, or this may be your fate.

Tell your readers to have a little patience with me for getting off of my subject. In my next I will give them a little account of General Grant's trips on the military roads, as I was the man that pulled him around on his special trips, and I am in a position to deny the story of some of those trips that he is said to have taken through the enemy's country on horseback.

Please say to your readers that my time at present is not my own, as I am in the employ of a railroad and have a great many duties to attend to besides writing up. Writing is not my forte. Setting valves and setting up wedges and driving-rod keys suits me better, but in my next I will tell you all about how I took General Grant over the mountains, and how we parted.

---

Numerous improvements have been effected lately in the works of the Egan Company, Cincinnati, Ohio. They have built a large addition to the works, and it is in running order and equipped with the best machinery to be found for finishing machine work accurately and expeditiously. A new Brown engine has been provided for driving the machinery, and the whole place is well lighted by electricity. Every machine in the shop is provided with a portable incandescent light protected by a wire cage. A superintendent of motive power noted for shop ability in walking around these shops lately remarked that the tools had the leading attributes necessary to success. They are evidently made of good material, have stiff, strong frames, ample bearings, heavy gearing accurately made and a good margin of belt power.

---

The mechanical department of the Chicago & Alton are preparing drawings for a class of heavy engine adapted for the hard work to be done on the steep grades of the Western divisions. The engines will be ten-wheelers, suitable for freight or passenger service. The cylinders will be 19 x 26 inches, and the boiler will be made large enough to supply steam freely under the most severe conditions of service. About ten of the engines will be contracted for as soon as the drawings are ready.

---

The Barney & Smith Manufacturing Company was reorganized some time ago, and formed with a joint stock company. Stock in the new company has been offered to many railroad officers with a view of interesting that class of men in the prosperity of the car-building company.

---

**WANTED!** Ever since April has come the demand for January and February copies—we've been out since then. Now, here is the last and only chance to get them. We have 100 copies, 50 of these will be bound up with the year's issue in time for Christmas. Price of volume, $3.00. The other 50 will be sold with the full year's numbers only—no single numbers of either month can be had. Price of year, 12 numbers, $2.00. Single copies of any month, except January and February, 20 cents each. We will receive orders now for these papers—first come, first served. This was our reserve for binding. There will be no others printed.

DO YOU WANT TO MAKE YOUR FILE COMPLETE?

## New Side-Dumping Coal Car.

Engravings will be found on this page showing the arrangement of a new 50,000-pound capacity side-dumping coal car, recently put in service on the Lake Shore road. Mr. A. M. Waitt, general master car builder, describes the car in the following letter:

"The car is intended especially for carrying coal to be unloaded on our standard coal chutes. The cars run up on the trestle, and, by means which I will describe below, the coal, without shoveling, runs by gravity into the compartments in the coal chute, all ready to be dumped into the tender of the locomotive. These cars can also be used for ore, although the incline in the floors of the cars is not sufficient for ore to unload itself without the aid of shoveling.

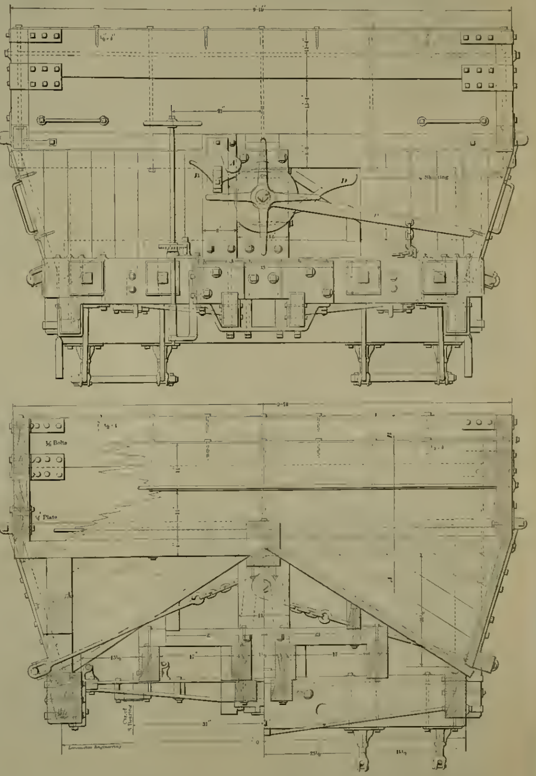
"The car is divided into five compartments, each of which has a door on each side. The bottom of the car slopes at an angle of about 30 degrees from the horizontal from the center of the car toward the sides. The sides of the car, the bottom part of which is composed of doors, slope inward, so that when the doors are released from the closed position they naturally swing open from their own weight, allowing the contents of the car to slide out.

"Through the center of the car, the entire length, runs a 1¾-inch square winding shaft. Located on this shaft, opposite the space between the doors, are cast-iron worms, having connected with them short chains and tie-rods, which extend on each side to the side of the car, and connecting with a strap extending across the space between each of the doors, the strap being securely bolted to each door.

"When the doors are closed and the car is loaded and it is desired to dump the load, the dog, *A*, is turned around until it rests upon the projecting arm of the ratchet pawl, *T*. The lever, *C*, connected with the unwinding shaft, is forced down far enough to allow the ratchet pawl, *T*, to disengage itself from the ratchet wheel. The lever, *C*, is allowed to travel as high as the short chain attached to the end of it will allow. Then the lever pawl, *D*, is released from the ratchet wheel. If the weight of the coal is not sufficient to start them open when thus released, the arm wheel, *E*, at the end of the winding-shaft is used to unwind the chain, which being done, the doors, from the force of gravity, will assume a vertical position.

"To close the doors the lever ratchet pawl and dog for ratchet pawl are placed in position, as shown on drawing, and the chain wound up on the winding-shaft by means of the lever alone.

"The trucks which we use under these cars are our regular standard truck for 60,000-pound capacity cars, trucks having the standard M. C. B. 4¼ x 8 axle."



## Where Brake-Shoes are Made.

Passengers passing over the Chicago & Erie Railroad have for years been familiar with the sight of a modest foundry about four miles from Chicago, marked Congdon Brake-Shoe Co. Within the last few months this foundry has developed into iron and steel works, with several large buildings for the accommodation of a plant which is devoted to producing various kinds of metal used on railroad rolling stock.

The company now call themselves iron and steel founders. The cast-iron work that built up the place is not neglected, and an excellent foundry, provided with the best facilities for doing work, is in active operation. Brake-shoes are the principal product of this department, but the company undertake to make any kind of castings for railroads, and they do a good general business in this line. They employ molding machines to good advantage in doing work that calls for many products of one pattern, and they are preparing to further develop this line of business.

The radical additions to the plant have been facilities for making steel. They have put in a fine open-hearth Siemens-Martin furnace, with a capacity of twelve tons per heat, and by running continuously they can get three heats per day. This furnace was designed and built by Mr. J. Herrick, the well-known metallurgical engineer. An eloquent testimony in favor of the ability displayed in building the plant, is the fact that good serviceable steel was produced at the first heat.

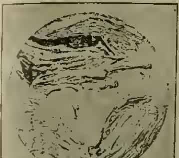
This open-hearth plant is devoted to the making of steel castings. Besides their steel shoes, the company are making a steel coupler and all sorts of coupler knuckles. They are also making steel gears, rocker-arms, crossheads and any parts that railroad companies prefer to have formed of steel. A place where thoroughly reliable steel castings were made has been badly wanted in the neighborhood of Chicago, and this place appears to fill the want.

As crucible steel must be employed for the eroding pieces of the consolidation brake-shoe, this company concluded that they had better provide themselves with a cast-steel plant, and they have done so. They have a 24-pot Siemens crucible furnace, and are making all the cast-steel they need.

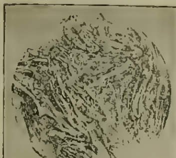
The whole of the plant is put up with a view to combine convenience in operating with the production of first-class material. They make their own gas for the furnaces, use oil under their boilers, and have good electric means of transmitting power. The works are traversed in every direction by the C. W. Hunt system of tramways, and cars and material are handled with the least possible expense and delay. The works are run under the immediate charge of Mr. Will Sargent, son of Mr. George W. Sargent, president of the company.

## Dangerous Axles.

The etchings shown in the annexed engraving were taken from a car axle that broke and caused a wreck which cost the Santa Fé Company $8,000. The axle was under a lot of refrigerator line cars built by the Michigan Car Company, and is a good illustration of the ultimate result of the race for cheapness which we have commented on at different times. The axles under several of these cars broke, causing much destruction of property, and the railroad company has decided not to permit any more of the cars to be run until the axles are replaced with others that will be safe. An inspection of the etching will show that the metal is inferior. Inspection and tests of the iron itself seem to indicate that it is a mass of cold short pieces of iron very badly stuck together with cinder. When subjected to



¾-inch Plate cut off end of axle near where it broke
Print taken from face nearest breaking point



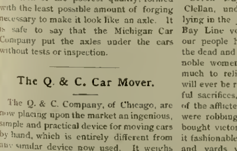
¾-inch Plate cut off end of axle near where it broke
Print taken from face farthest from breaking point

physical tests, one specimen from this axle broke under a tensile strain of less than 28,000 pounds. The axle when broken showed a crystalline mass of globules as large as the crystals of sulphate of iron. The axles are stamped M F & I. Co. They were supposed to be made of scrap iron, but it must have been iron of the poorest quality, formed with the least possible amount of forging necessary to make it look like an axle. It is safe to say that the Michigan Car Company put the axles under the cars without tests or inspection.

## The Q. & C. Car Mover.

The Q. & C. Company, of Chicago, are now placing upon the market an ingenious, simple and practical device for moving cars by hand, which is entirely different from any similar device now used. It weighs only about thirty pounds.

The working grip of the mover on the axle of the car is obtained by a sharp pull on the handle, so that, with a little prac-



tice, the operator is enabled to take advantage of the momentum gained and thereby keep the car moving. It is possible for one man to move a loaded car quite readily and with comparatively little effort.

In Fig. *A* the "mover" is shown on axle in position to push the car from the operator, while Fig. *B* shows it in position to move the car toward the operator. This latter is a feature not possessed by other movers.

## Effects of a Washout.

The disastrous wreck illustrated in the annexed engraving happened on a Western railroad to a heavily-loaded passenger train, and resulted in the death of seven persons. It was during the time of a severe sudden flood, which sent a large volume of water through the trestle. The engineer pulling the train stopped before passing over the trestle, and thinking from an examination that the structure was sound, attempted to proceed. The engine went over all right, although the piling under the sills was washed out. The cars were not so fortunate. Under their weight the structure collapsed, and several cars were crowded into the deep gully, trestle timbers and fractured cars making a scene of devastation and ruin. The first sleeper rested as shown and the others remained upon the track.

## Train Running for the Confederacy.

By Carter S. Anderson.

As I stated in closing my last letter, the stormy and terrific battle of Malvern Hill, which was fought at night, closed the "Seven Days Fight." General McClellan, under cover of his gun-boats, lying in the James River, arranged for a Bay Line voyage to Washington, while our people had their hands full burying the dead and caring for the wounded. The noble women of Richmond helped very much to relieve the suffering, and they will ever be remembered for their beautiful sacrifices, which they made in behalf of the afflicted whom pain and suffering were robbing of the joys of their blood-bought victory. Richmond society made it fashionable to deck the parlors, porches and yards with the cots, pallets and benches of the crippled boys, carrying and sending delicacies to the hospitals for the more seriously wounded, who could not be allowed outside. "*Belle Monde*" tied on Bridget's apron and gracefully performed her duties, making the boys feel at home. At that time Richmond had lost nothing by the war (by the way, the war made Richmond), and so was well prepared to entertain the visitors whom the fortunes of war had suddenly cast upon her Virginia women, while they do not meddle with business or politics, do not ask any advice or take any suggestions as to how they must manage the disbursement department of the family.

We felt now that the Confederacy was a government *de facto*, and that the offensive must be taken at once. Many of our officers obtained a twenty-four or forty-eight hour furlough, in order to run home and let their people know that they had escaped the fire of battle, and in many cases to receive the last fond kiss before going back to Northern Virginia to meet the enemy, for our boys were always saying "We can whip the Yankees, but they won't stay whipped—like Banquo's ghost, they will not down." But I beg pardon for this digression, and will now confine myself to my railroad narrative and try to stay on the track.

We will now go back a few days before the "Seven Days' Fight." General McClellan, you remember, had destroyed all the bridges on the Virginia Central between Richmond, Fredricksburg and Potomac Junction and Richmond, which would throw all of our machinery and rolling stock into General McClellan's hands, should he defeat Lee. Like all other fights, of course nobody knew what the result would be. I know our railroad president, Fontaine, and Superintendent Whitcomb felt very much anxiety as to how it would end. The government was equally as much concerned in this matter of transportation, as the railroad men had already laid a track in Eighth street, from the old R. F. & P. depot, (corner Eighth and Broad) to the Petersburg depot, corner Eighth and Canal streets. The track was just laid down right on top of the street ballast and set up high and dry. This was the first southern connection ever made through Richmond, and it of course gave an outlet for all R. F. & P. rolling stock, but it did not furnish any relief to us down in "Butcher Flat" (Seventeenth and Broad streets). We were in a hole, for a fact. Fortunately for all concerned, Superintendent Whitcomb was an experienced engineer. He had taken a very active part in building the temporary track over Blue Ridge Mountain while Blue Ridge tunnel was under construction, and in many other equally as heavy but not so long grades on the western part of our new Chesapeake & Ohio Railroad where it intersected the North and the Allegheny mountains.

One Sunday afternoon, while we boys were all gathered in the corner room of the large brick building, corner of Broad and Seventeenth streets, Superintendent Whitcomb came in looking serious. We knew something was the matter. Walking up to the front window, which looked out upon Broad street and through which we had for an hour or more watched the pretty girls going to and from church, he said: "Boys, we must get our engines and cars up *that hill* or we will run the risk of going into the army, for if General McClellan gains the victory, he will clean us up of railroads." We soon found he was in dead earnest, and early next morning, having gotten permission from the authorities to lay a track from our Seventeenth street track to the R. F. & P. depot, corner Eighth and Broad, we soon had Broad street full of cross-ties, rails, etc., and a very large force of laborers.

He had Mr. Stephen Hunter and all the depot force, the Seventeenth street shop-carpenters and of course all the trackmen working at it. He was much laughed at, (the idea of running an engine up *that* hill!) and was of course much abused for obstructing the street. Mr. Whitcomb, however, very soon had the track laid, connecting it with the Eighth street track corner Eighth and Broad. The grade will average 350 feet to the mile and in one place (at intersection of Jail alley) it must be 375 feet or over to the mile. To make sure of this grade I have had the city engineer give me the figures from his office. At Broad street and Eleventh the street level is 160.50 feet above tide; the distance from Seventeenth to Eleventh is 1,950 feet, the engines had to raise 131.31 feet in this distance. At the intersection of Seventeenth and Broad the street level is but 28.99 feet above tide. The up-hill Broad street track intersected our Seventeenth street track with a Y running out east on Broad street so that the engines backing down from the roundhouse into the Y would switch front into the Broad street track. The engines were brought down for trial. Then excitement ran high. All of the city, government officers and all, came out to witness the experiment.

The old "Millboro" was to make the first trial. Engineer Fendal Ragland was then not the nervous old man he now is. He soon had the "Millboro" headed into Broad street, and an odd sight she looked to all. Mr. Whitcomb showed anxiety. He had Yard Master Dandridge Lowry and a force with "chocks" to place behind the wheels to prevent the engines running back, down the hill, should they fail to go up. Mr. Lowry told Ragland to go ahead. The old ten-wheeler took out up the hill at a pretty good rate until she struck the highest part of the hill at Jail alley, then she commenced slipping her drivers. The fire flew. We placed the "chocks" and held her fast, but never an inch would she budge further up. "Just as I said," could be heard all around. Ragland kept cool, he told Mr. Lowry to remove the "chocks" back and let him try her a short distance lower down. Same result. By this though, Ragland found that he could let her back and told them to take the "chocks" up and let him go back, which he did, and backing as far back into the east end of the Y as he could, he sent for Mr. Whitcomb, who came to him at once looking mortified and disappointed. Ragland told Mr. Whitcomb that he must either run her up the Seventeenth street track to pump her up or *run* her up the hill. Mr. Whitcomb replied: "Why, Ragland, you have just tried and failed, so you had better let some of the other men try her or try their own engines, but if 'Millboro' won't go up, none of them will."

This nettled Ragland, and he said firmly and determinedly: "Mr. Whitcomb, if you will throw them 'chocks' away and let me have my own way, I will be at Powhatan

Hotel (the top of the hill) in ten minutes from the time I pull my engine open." Mr. Whitcomb granted him his request, cautioning him, "By all means don't burn her, but put out the fire just as soon as you get up the hill." The men heard what passed and stood aside to see her launch. Ragland gave her a good oiling, he crept all down under her and examined her machinery quickly. Crawling out, and wiping his hands with the waste, he patted the "Millboro" and said

"Well, old girl, you and I will be in h—— or at the Powhatan Hotel in ten minutes!" He slipped up and pulling her wide open, she bounced up and jumped on the unsurfaced track, and by the time she got to that tight place in the grade, she had gotten such a swing that the old

Broad street, or about on the R., F. & P., or Petersburg side. Remember this was all prior to the battles, and now that the fortunes of war had left us in possession again of our road, we headed at once all of our rolling stock back down the hill. In getting the cars back, some cars got loose near the R., F. & P. depot and took the half-mile flight down to Seventeenth street. They came like lightning, hitting broadside against a car which happened at this moment to be standing in the street, lifting it entirely off the wheels and throwing it around into the vacant lot south of Broad street.

Yardmaster Lowry could say some funny things. Walking up to the box as it lay on its side, end toward the track, and seeing that it was not much broken,

consummation in cr^d succession of curves shops. The lake in ^as in a rich coffee-pro- the pond seen behind t^e transportation of almost entirely filled up, and of fre' are building a fine new roundhouse in the front and a car shop behind. Both shops are substantial brick buildings, the roundhouse being one of the best buildings for that purpose we have ever seen. It is eighty feet between walls, and is built on stone arches that sustain the brick walls.

## Strength of I-Section Rods.

One of our leading railroads has a number of locomotives with channel side rods of the section in Fig. *A* of the annexed engravings. The rods began to break and the mechanical department proceeded to

## Notes from Brazil.

BY LEWIS GLEASON.

GENTLEMEN: As it is many days since I have had the pleasure of receiving a copy of LOCOMOTIVE ENGINEERING, I regret to say that there must be a hitch somewhere in the post-office business between the States and this country. I received two copies O. K. April and May, since then I mourn its absence. I presume the post-office is conducted in this country in keeping with all other institutions, a kind of "go-as-you-please" manner, so to speak.

The especial duties for which I was sent out here are now about completed. I erected two engines at this place, one of which has been in service during the past three months and is doing good work and giving excellent satisfaction, the other has been ready for service for some time, but the track-laying is not far enough extended to require two engines; however, I have made a trial trip with her and everything worked to perfection. The home road of these engines is about eighty miles from this place, we run them under steam to destination. So far as the trip through the country is concerned, it is pleasant, but the accommodations in the hotel line are far from sumptuous, however, I am treated very kindly, and on the whole I have not much to complain of.

The average Brazilian railroad is run on a system rather peculiar to us people. As I am not acquainted much, only on one road, the Leopoldina, I will speak more particularly of that system. The Leopoldina, with its main line from Nitheroy to Campos, and several branch lines, furnishes the State of Rio de Janeiro with very fair facilities. Nitheroy is situated on Rio Bay, and to get there from Rio you have to take a not very commodious nor over clean ferry boat. After a ride of forty-five minutes you are landed on the railroad pier.

B., C. R. & N. SHOPS, CEDAR RAPIDS, IOWA.

clumsy thing shot up to the top of the sharp grade.

The track being laid on top of the street ballast, as the old engine rose, she looked to us, down in the bottom at the Seventeenth street depot, as if she had concluded to wing Ragland in a heavenly flight instead of that down grade he threatened her with before starting. The shouting crowd having followed up the hill, we soon saw the old Millboro standing in front of the Powhatan Hotel, with a crowd of curious spectators standing around her. The hotel proprietor, Scammell, told Ragland that as soon as he could leave his engine to come down into the bar, as one of the servants had *found* a bottle of old rye in the *lumber-room* and he wanted Ragland to help him to hide it.

At that time the government had a strict prohibition law in Richmond. It was the only time in my life of fifty-five years that I ever loved and drank whiskey, but to get it and drink it on the sly was so funny and the whiskey was good. But to explain about "finding a bottle"—the barkeeper had a dark room in the basement of the old Powhatan. He had a couple of bricks loose in the partition wall between his room and the "old lumber-room," through which aperture he would pass the bottle to the middle man, who would give out that he had found "a bottle of rye in the old lumber-room." The bottle was taken care of and the finder rewarded, and the "Dark Horse" too.

The next engine which came up was the "Whitcomb," J. W. McClandish, engineer, and soon all were up. It only needed what our present energetic M. M., T. G. Lloyd, tells his engineers when they complain of their engines not pulling a certain number of cars on certain grades "Give her the swing before you strike the tight place."

Soon all of our engines and cars that were on our Richmond end were up on

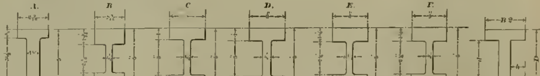
he remarked, as he turned and looked at the mess of wheels, etc., in the middle of the street "Old lady, it's well you did get out of the way."

Mr. Nathan Wildman soon had the Seventeenth street shop on double duty day and night getting ready the machinery and coaches to carry the army to North Virginia. The government was pressing our officers for unbroken transportation—Richmond to Gordonsville—which brings us back to where we left Thomasson building the bridges.

The road was soon *in statu quo* to Staunton, Va., and how we got the first train of Gray Jackets to Gordonsville to actually see from the depot the Blues com-

ascertain the cause. Calculations indicated that the rod was a bad form which did not yield strength in proportion to the weight of material employed. The same weight of material was put in another form, *B*, and tests proved that the rod was greatly strengthened. A still stronger form was obtained with less material in the form shown in Fig. *C*. In the sections shown in Figs. *D*, *E* and *F*, a little more material was put in with a very decided increase of strength. This is an excellent illustration of how material may be distributed to obtain the greatest strength. It was not desirable to make the rods any heavier, as all the counterbalancing would have required re-adjusting, but the required results were

The train on which I rode was composed of six cars, such as they were, two of these were transferred to a branch line about twenty miles out from our starting point; four went through to Macahe. They consisted of two first-class cars of American manufacture, one English carriage (about the size of a Saratoga trunk) for second-class passengers and a box-car for baggage, all drawn by a very fine looking eight-wheel engine of Baldwin build. A passenger is not allowed any free baggage, only what he can crowd into the car—all that goes in the baggage wagon must be paid for, and I know from experience they are not very moderate in their charges. Power brakes are not used on this road, only on the engines. They are equipped with Eames' vacuum brake. Each station on the line is furnished with a bell, from



ing down those little mountains—and many silly and ridiculous occurrences such as only we can produce, I will have to tell you later, if it will interest your readers.

## Cedar Rapids Shops.

The engraving on this page gives what is almost a bird's-eye view of the machine shops of the Burlington, Cedar Rapids & Northern Railway at Cedar Rapids, Ia., for the photograph which is reproduced in the engraving was taken from the top of a high smokestack on a hill overlooking the place. It is a very striking scene, the grounds where the shops are located being almost surrounded by the Cedar River.

Great improvements are in course of

obtained with the old weight of rod. The following table givas particulars obtained by the tests:

| | A | B | C |
|---|---|---|---|
| Breaking weight in pounds | 13,104 | 11,816 | 11,806 |
| Section area in square inches | 7.78 | 7.78 | 7.5 |
| Weight of rod in pounds... | 222 | 222 | 214 |
| | **D** | **E** | **F** |
| Breaking weight in pounds | 15,120 | 15,825 | 10,063 |
| Section area in square inches | 7.84 | 8.13 | 8.47 |
| Weight of rod in pounds | 225 | 232 | 240 |

The tests were made by Robert W. Hunt & Co.'s Bureau of Inspection, Pittsburgh. The tests were done under the formula illustrated in Fig. *B* 2. Ends supported; weight in center. $K$ = 68 cwt. $L$ length between supports.

Formula—$4 K L$, $B D^2 - 2 b d^2$ = breaking weight in cwts.

which a cord is in communication with the agent's office. When the agent thinks that all the passengers are received and discharged, and the time being up, he rings the bell, the conductor blows his whistle, the engineer gives one short blast of the engine whistle and starts the train.

As the train leaves it is heralded at the next station by the agent ringing his bell. The system of ticket collecting is the same as on our American roads. On arrival of train at Macahe, a station about 110 miles from Rio, all passengers for Campos and intermediate stations must change cars, as the road changes gauge here, from Nitheroy to Macahe the gauge is one meter ten centimeters, from Macahe to Campos the gauge is one meter. Just

think of a road in the States with a main line of 175 miles having two different gauges, and the difference only four inches. On the Brazilian Central, the chief road of the country, a similar state of affairs exists between Rio and San Paulo, only the difference is much more, the gauge out of Rio is five feet and three inches, into San Paulo it is only three feet and three inches—shriveled up on the way, as it were.

The equipment on this road is principally American, with a few freaks in the shape more or less of locomotive engines built in England, and the boss freak of all is a German built engine; it is fearfully and wonderfully made.

The working force, such as train and engine crews, shop hands, etc., are all native, but I cannot say that they are "to the manner born" in their different vocations. Somehow or other they do not appear to be intended for the business; however, they get along, and furthermore if you ask any information from a conductor or brakeman on a passenger train, provided you can speak Portuguese, you will be politely replied to, and the information sought will be given if they can possibly do so, in that respect they are far ahead of our average American train crews.

I cannot find out from any official the number of miles operated or the number of engines in service. They have no shop of any importance, a small repair shop at the end of each division answers their purpose, except Imbetiha and Porto Novo. At these shops they employ, I am informed, from 150 to 200 men, and do general repairs for the system.

It was always my idea that the "walking delegate" was an institution not to be found outside of our own beloved country, in this surmise I am vastly mistaken, for his Brazilian brother can give him points in how to get rid of an obnoxious official and as to the formalities of inaugurating a strike, as the following facts will vouch for.

The *chefe de locomotion*, or, in plain English, the superintendent of motive power, of the "Leopoldina" happens to be, so it is said, a very unpopular person amongst the working classes. In the first place he is not a mechanic, nor has he had any experience in railroad business in any manner until his appointment to his present position, which was secured by influence with the director. What few good mechanics that were in the service of the company, as master mechanics in the various branches, left the service on his appointment, consequently their places have been filled by people just as incompetent as their chief. To one of these appointees the workmen having taken a decided antipathy, he has been driven away from every shop he has been sent to; on his appointment to any particular shop he would be greeted by flaming notices reading "Death to ——," with the customary illustrations in the shape of skull and crossbones. I do not write his name simply because it is about a yard long, consequently I have not the time to put it all down. His last appointment was to the shop of Porto Novo, one of the principal shops, he was accompanied by a guard of forty-five soldiers; but, notwithstanding the guard of brave Brazilian soldiers, the shopmen proved the more valiant of the two, and to the martial music of a tin-can band, official and soldiers made a very masterly retreat, after a sincere promise on the official's part that he would leave the field of mechanics to those whose qualifications entitled them to occupy it. So you see, the Brazilian is not that submissive creature that our people may describe him. I cannot vouch for the above from personal knowledge, but my informant is a man whose reputation for veracity cannot be doubted.

In closing, I might add that, on Brazilian passenger trains, they have no baggage masters on the train, the baggage is put off and taken on at each station by a man kept there for that purpose. The news butcher is an unknown quantity. The mail agent has no nice room partitioned off for his especial use, with hooks, bags, pigeon holes, etc., he takes his seat in the passenger coach, and has his mail matter tied up in bundles for each station. That it is a crude and slovenly way of doing business is apparent from the fact that, in the country towns, if you receive one letter out of six addressed to you, you might consider yourself fortunate. As very few, if any, trains are run by night, they have no tail lights, nor markers by day. When trainmen have to work at night, they use a lamp about ten inches square and equal height; it has a light of glass on each side, and the illumination is furnished by a fat-looking tallow dip.

That very useful and generally very busy person on home roads, the train dispatcher, is an unknown person here. An official styled the *chefe de traffica* has charge of all trains, but on this particular road of which I write the trains are few and generally run on time card. When a special is sent over the road, all stations are notified, and somehow or other they manage to get through.

At this point I had to cease writing on account of being informed that the "Santa Maria Magdalena" engine was ordered to her home road. I have just returned after four days' absence in that weird and mountainous country. We started out with a train of two box cars and one passenger coach. "The Director" and a few of his friends were on board. On the engine was a *machinista and fogista* (engineer and fireman) and your correspondent. Our journey lay over the roads of two different companies, and we got there in good shape, the engine working to perfection. We made the journey without a brakeman, pilot or conductor, without any orders, only permission to use the tracks. Twenty-five miles of this journey was made up the mountain. A grade of 4 per cent. the entire distance, the little "Brooks" got down to business like an old timer, it did me good to hear her bark as she swept around the curves, her gauge showing the maximum pressure the entire distance. Considering the poor fuel and indifferent firing, she proved herself, in steaming qualities as in all other respects, A No. 1. At our journey's end we were greeted with fireworks and music. The musical part of the programme consisted of an accordeon, operated on by aged gentleman of color. The "Doctor," whose name the engine bears, set up a bottle of champagne in honor of the event, and everything went "as merry as a marriage bell." I am glad to say that the two first engines built for this country by the Brooks Locomotive Works are a grand success. I have watched over these engines from the time of their arrival until I turned them over to the owners with much solicitude. I was bound to make their maiden effort a grand success. I am proud to say that there are no two better engines in this or any other country for their size and weight. I am sorry they are placed on a road where they are virtually buried from the sight of people whom it would be desirable to reach. The road is amongst the mountains, and, I might say, the clouds, and such a road! It's a succession of curves and heavy grades; it is in a rich coffee-producing district and the transportation of that berry will be its only source of freight.

I return to Rio de Janeiro to-morrow. While I have had a very pleasant time at this place, on account of sea bathing and heathfulness, yet I was cut off from the business world. The only information I could glean was from the daily paper we got from Rio.

When I get to know more of the country I will get up an article for the paper. This is not written for publication, but if there is anything in it you can work into an item, very good; do so.

I hope that the post-office people will be good enough to let me have a copy of the paper in the near future, as I miss its well-stored pages very much.

*Rio de Janeiro.*

## Solid Rod Cups.

Many roads are now making rod cups solid on the rods, forged on, and the advantages of such a plan are self evident.

Figure 1 shows a cup forged on a strap and machined up as thin and light as a brass cup. Figure 2 is the same cup forged on a solid-ended rod with a plug in it to prevent rod bush from turning. These cups were made by the Schenectady Locomotive Works and are in use on the Pennsylvania compound of their make.

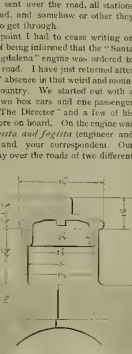


*Fig 1.*

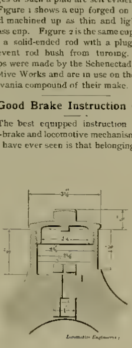

*Fig. 2.*

## Good Brake Instruction Car.

The best equipped instruction car for air-brake and locomotive mechanism which we have ever seen is that belonging to the Burlington, Cedar Rapids & Northern, at Cedar Rapids, Iowa. We have seen cars of the kind that were of a much more costly character, and we have seen others more elaborately fitted, but for the practical work of instructing trainmen and for making the mechanism intelligible to the learner we have seen nothing equal to the equipment and arrangement of this car.

A long way car with monitor roof was used to hold the equipment. Brake cylinders, reservoirs and piping for thirty cars are used. The bulky parts are arranged compactly along the middle of the car and the piping is secured in the least possible space around the clear story. The air-pump, triple-valve and engineer's valve of the Westinghouse brake are shown in sections, the parts moving along with like parts of the valves in operation. They have also the principal parts of the New York air-brake, and of the Boyden brake. Besides these they have lubricators, injectors, Leach sanding apparatus, a valve-motion model and other mechanism that trainmen ought to understand the construction and working of.

The car is in charge of Mr. John H. Burns, the traveling engineer, who used it as an office and is ever ready to give instruction to those seeking information. Mr. Burns is one of the best posted men in the country on air-brake and train mechanism, and he has in an eminent degree the faculty of making what he knows intelligible to others. The car is set beside the roundhouse and has connection with the steam pipes, so that the air-pumps can be started at any time. All trainmen belonging to the road, conductors and brakemen as well as engineers and firemen, are required to show themselves proficient in the knowledge of brakes. Firemen and brakemen have to pass an examination before they are promoted, and in this car they explain what they know about brakes. If anything happens to conductors or engineers of the older school to indicate that they are not properly posted about brakes, they are sent here to receive instruction from Mr Burns. The training given to the men by the aid of this car has greatly reduced the delays due to trouble with brakes.

## Successful Electric Car Lighting.

The Atchison, Topeka & Santa Fé have one train of four cars which is lighted by the Silvey system of electricity. This is a storage system and appears to be specially designed to stand the jarring incident to train service. The train has been running constantly since February last, and has not cost a cent for repairs of the electrical apparatus. Two batteries, each containing six cells, are placed in each car, a reservoir for the batteries being provided beneath the floor of the car. The two batteries weigh about 1,000 pounds.

The plates, forming most of the storage batteries tried for car lighting, have been placed on edge and the jarring shook them apart, so that failure soon ensued. In the Silvey system the plates lie flat and appear to be unaffected by the vibration they are subjected to.

Each car has ten incandescent lamps, eight inside and one over each platform. They give an excellent light, and the train is very popular with the patrons of the road on the Topeka & St. Joseph division, where the train is run. The guarantee of the inventor of this light is, that the lamps in the car will burn the same length of time that the batteries were subjected to the process of charging. In practice, the railroad people find that when the batteries have been charged for ten hours the lamps will burn seventeen or eighteen hours. The cost of the light is about three cents per hour for each lamp. This includes fuel, attendance and rent for the engine and dynamo.

Trainmen on the Northern portion of the Santa Fé system remark about a peculiarity of the natives of different States. If an accident, wreck or other casualty occurs to a train which causes delay in Missouri, there is soon a crowd of the natives round, and they lounge about the place till everything is cleaned up. If the same kind of an accident happens in Iowa, Illinois or Kansas, there is seldom a native to be seen about. The bump of curiosity appears to be abnormally developed in Missouri.

The Pullman Palace Car Co. held its annual meeting in Chicago on October 13, and the financial statement of the year showed a total revenue of $10,002,356. Of this $5,061,081 was from the earning of cars, and the remainder was from patents, manufacturing, etc. The disbursement was $6,751,967. The total assets are $53,345,050, and the total liabilities $31,361,370. The company owns or controls 2,239 cars, and 415 sleeping, dining and parlor cars are under construction to meet the demands of the World's Fair. During the last year 5,279,020 passengers were carried and the number of miles run was 191,255,656. The company employs 12,809 persons and paid out in wages last year, $6,619,156.

The method of using the piston of an air-brake cylinder as a ram for forcing the fittings into air-brake hose, which is to be seen in use in a variety of railroad shops, was invented and patented by Mr Ludlow, master car builder of the Southern Pacific shops at Oakland, Cal., and by Mr Angwin, one of his workmen. The patentees are after the royalty from roads that are using the invention.

## Pittsburgh Compound Locomotive.

We present herewith photo engraving of the compound locomotive recently turned out by the Pittsburgh Locomotive Works and now running on the Vandalia road.

This engine has the Colvin plan of reducing and intercepting-valve (illustrated in our issue of January last). The runner can work the engine as a "simple" just as long as he wants to, both cylinders having an exhaust to the atmosphere, and the reducing-valve automatically admitting enough steam to the large cylinder to do the same amount of work as that done in the high-pressure cylinder.

When starting, or on a grade, the engineer can have a plain engine as long as he wants to, and throws in his compound gear whenever he wants to.

Pittsburgh Compound Locomotive

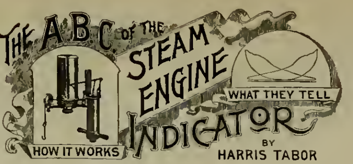
The general dimensions of the engine are as follows

Type, 10-wheel freight, gauge, 4 feet 8½ inches; cylinders, 19 inches and 29 inches by 26 inches; driving-wheel base, 11 feet; total wheel base, 21 feet 8 inches; driving wheels, 56 inches diameter, total weight, 120,000 pounds, weight on drivers, 95,000 pounds.

The engine has not been put down to any fancy test, but the engineers and firemen say she is very economical of fuel and will run over a whole division without having to have her fire cleaned.

There are some remarkably fine indicator cards from this engine illustrated in Mr. Tabor's article in this paper.

---



An article over the signature of "Compound," condemning generally large steam ports and long travel valve, appeared in your October issue, which contains considerable food for thought. A single instance of reducing steam ports and valve-travel does not prove that the general tendency to make ports larger and valve travel longer is wrong or that the locomotive valve gear of forty years ago was right. There are many conditions to be considered in putting this question on its merits. In each case cited by "Compound" there may have been conditions unfavorable to free admission. Wire-drawing of steam is not due to small ports and reduced valve travel solely. The friction offered to the steam by the walls of the ports is small when compared to a long steam-pipe of insufficient size The throttle may also wire-draw. In the case of the Rhode Island locomotive, if the throttle and pipe were insufficient to deliver all the steam the ports would pass, a reduction of ports and valve travel would be followed by good results. The same reasoning would apply to the Lehigh "flyer."

Before passing final judgment on isolated cases like these it would be interesting to know what would be the effect of larger steam-pipe, and possibly more ample throttle area. If the larger pipe would increase the coal efficiency in the case of the Rhode Island, it would prove that the steam-pipe had been too small for the port openings, and account for the better results when the ports were reduced On the other hand if no gain appeared from an enlarged pipe, and the engine were driven under the best conditions, the case would prove too much expansion for the best economy It is right here that "Compound's" statement becomes interesting. Where is the economical limit of expansion in one cylinder which is exposed to generally low temperature, as in the case of the average locomotive If the running conditions were all fair in the case cited by your correspondent it would seem that the limit had been exceeded and less expansion was demanded. The reduction of port area did lessen expansion by wire-drawing.

Admitting the loss, with the larger ports, came from condensation, there would be a gain, aside from reduced expansion, which would follow reduced steam ports Wire-drawing tends to dry the steam and reduce initial condensation In this case, the reduced ports made the gain, and it is probable that we must look to less waste by condensation as the cause, and that the reduced condensation came from less expansion and dryer steam as a result of wire-drawing.

Assuming that the limit to economical expansion is so soon reached as your correspondent's statement would indicate, it is only a stronger argument in favor of compounding and expanding through two or more cylinders This also brings up the question of the correct ratio between the sizes of the cylinders in a compound locomotive. If, with forty years' experience in building American locomotives, our best designers have been moving like

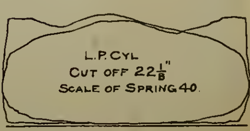
LIFT OF THROTTLE VALVE 1".



---

We have been interested in the examination of baggage by Custom House officers in many places and in a variety of countries, but the deliberate, thorough and imposing way the work is performed on the border of Mexico is far beyond any previous experience. All the baggage is taken into a shed, trunks, valises, handbags and every other kind of personal impedimenta. This shed is full of fierce-looking officials, armed with clubs and blood-thirsty revolvers stuck conspicuously in their belts. One legal bandit opens the article and dives down to its foundation, turning the contents upside down. Then another associate gives it an overhauling while two men with guns guard his flank and keep a suspicious eye on the owner of the baggage. We did not see anybody shot, and concluded that the lack of bloodshed arose from no contraband goods being discovered.

the crab, backward,—and have over-reached in expanding steam too many times, who is wise enough to determine the number of expansions that may be profitably used in the compound? The fact that some builders make the low pressure cylinder twice the size of high pressure, and others make the difference three times, proves nothing. The engineer who has charge of the compound with the greater ratio will soon discover if he is expanding his steam too much, and will correct the evil with his link, even though he may have to wire-draw at the throttle. If the man with the smaller ratio of two to one discovers that his fireman has an easier time when he is expanding freely in each cylinder, he will keep his link well hooked up and will run with full throttle. It is possible that about the same expansion will be used in these engines with widely different ratios.

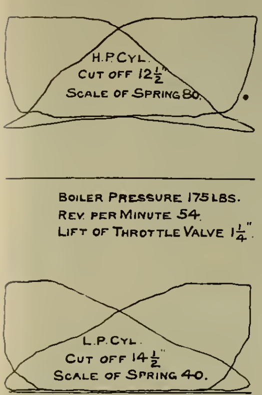
Time only can determine the best practice. It is fortunate that so many ratios between high and low pressure cylinders are in use, for from this large range the best proportions may be selected.

The following diagrams were taken from a compound locomotive recently built by the Pittsburgh Locomotive Works, of Pittsburgh. In some ways it differs from the standard type put out by other makers. It is of the two-cylinder type, as the cards would indicate. It has no automatic intercepting-valve. In its stead a reducing-valve, and admission-valve to low-pressure cylinder, operated by hand, are used. Each cylinder has an independent exhaust to the atmosphere, under control of the engineer, so that the engine may be used simple for any length of time The reducing-valve checks the danger of getting too high pressure in the low-pressure cylinder.

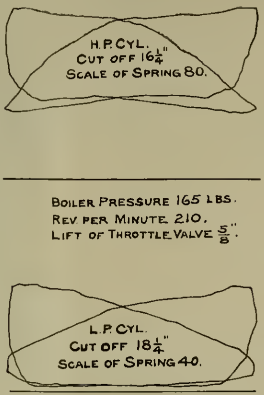
Diagrams No. 1 were taken when working, with the high-pressure cylinder exhausting through its own pipe to the air. These cards show no expansion except a trifle in the low-pressure cylinder, which is due to wire-drawing. As the engine is intended to work in this condition only at starting and during a hard pull, economy may be ignored.

No. 2 were taken when running compound with a late cut-off in both cylinders. These may also be considered heavy work cards, and do not represent average running condition. No. 2 are interesting from the fact that they indicate clearly a feature which belongs to the two-cylinder type of compound with a small receiver, which is shown in the undulating steam lines on low-pressure card. If we follow the relative movements of the pistons, in connection with the cards, we shall discover the cause of these irregular lines.

No. 3.



No. 4.



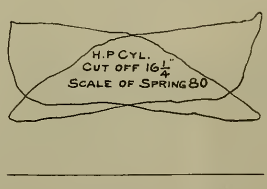
When the high-pressure piston is at the commencement of its stroke it has exhausted into the receiver or steam-pipe to the low-pressure cylinder, and is moving from its slowest to its highest velocity, the low-pressure piston is at mid-stroke and is moving from its highest to its slowest velocity; the increasing motion of the high-pressure piston and the reducing motion of the low-pressure piston change the ratio of size between the cylinders and cause the fall in the steam line on low-pressure card near the beginning of the stroke, and the rise at mid-stroke. Just before the low-pressure piston reaches mid-stroke the exhaust from the high-pressure cylinder takes place and adds to the pressure in low-pressure cylinder at this point. When the cranks are at an angle of ninety degrees there are points in the stroke of both cylinders where they are too large and too small. It is only when the motions of the two pistons are coincident that an exact ratio may be had throughout the whole stroke. This can be obtained only by placing the cranks at an angle of 180 degrees, which is not practical in the two-cylinder compound. A large receiver, such as is used in stationary practice, would reduce these irregularities. But the introduction of a large storage reservoir would be substituting, in this case, a greater for a lesser evil. The effect of this varying ratio is not felt when the engine is running under average conditions, as the cards Nos. 3, 4 and 5 show. These are all the vainest designer might hope for.

No. 3 were taken when the position of the link allowed liberal expansion in both cylinders. They are excellent cards and are creditable to the designer. Such cards, showing as they do more than five expansions, would show remarkable duty in a stationary engine, where the cylinders may be protected from cold It is a question, however, whether they would show as high duty on the road as the two following sets with less expansion.

Nos 4 and 5 were taken with the link in the same position. Any difference that may appear in the lines is due to the increased speed when No. 5 was taken. The back pressure is very low reaching only eight pounds with a piston speed of 1,373 feet. The entire steam distribution is excellent. The horse powers developed when these cards (No. 5) were taken was 1,466, of which the low-pressure cylinder furnished 57 per cent.

If the man who did the counting is correct, this is a remarkable performance.

No. 5.

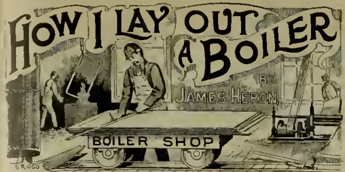


## Inconvenient and Uncomfortable Locomotives.

The designers of locomotives intended for service on railroads that have numerous curves, ought to take into consideration the importance and necessity of the engineer seeing ahead when the engine is rounding a curve. We have enjoyed the best of opportunities for observing the limited outlook from the cabs of a great many locomotives employed on very crooked roads, where cuttings are numerous, and the impression received is that the practice is becoming general of making a solid line of obstructions from the cab to the smoke-stack The cabs are now so placed that an engineer cannot step to the left hand side to see that all is clear when he is rounding a curve; the duties of the fireman are too arduous to give him any time for keeping a systematic lookout on curves, and so the practice is for the engine to rush along blindly, depending on the good fortune of finding a clear track. We have heard of more than one instance where tail-end collisions have happened that could be directly traced to the engineer not being able to see ahead in rounding a curve. There is a growing sentiment among railroad commissioners to require a third man to be carried on locomotives where the fireman is so located that he cannot keep a lookout ahead When juries begin to find out that accidents are happening through the engineer being unable to see the reach of the track visible on curves, they will stimulate public sentiment to demand the presence of more eyes on the monster locomotives that are becoming the rule as train haulers. The proper way to stave off this source of expense is the devoting attention to opening the view for the engineer across the boiler This can be helped materially by a little attention to the locating of dome and sandbox.

Another thing that demands attention is the location and width of cab. Many cabs are made as if they were intended for lilliputians, a man of moderate size having to squeeze himself to get in position to reach the working levers. This may be quite comfortable as viewed from the drawing office, and it entails no great hardship upon the man who goes in inspecting the arrangement when the engine is cold in the builder's shop. On the road it is a different matter. With hot weather and the intimate proximity to a hot boiler, the man in the cab is parboiled during a great part of the time he is at work Is it surprising that the man who is subjected to this ordeal, day after day, gets convinced that engineers are a poorly paid class considering the discomforts they have to endure? A very little forethought and no extra expense would make the cab comfortable. Apart from humanitarian considerations we believe that it would pay railroad companies to effect a reform in the locomotive cabs

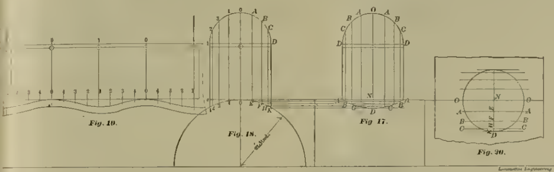
The P. R. R. are figuring on 1,500 new freight cars.



## Laying Out Dome Sheets.

Figs. 17 and 18 show front and side views of dome on boiler. To lay out a dome sheet it is not necessary to lay down Fig. 17, but when you want aperture, or dome hole, very accurate, then you must use that figure. Strike radius of segment of a circle, the size called for on drawing, draw center line $OD$. Height of dome is of no importance. I have put it full size to make it more plain. Strike radius or semi-circle on top. The dome of boiler we are laying out is 30 inches inside diameter. Thickness of material, ¼-inch, so as to have our lines an equal distance apart on semi-circle on top of dome, Fig. 18. And on flat plate, or Fig. 19, we must strike our radius 15¼ inches or 30½ inches diameter of dome. Divide semicircle into any number of parts, the more parts or spaces the more accurate will be your line of curvature. But four spaces, as on sketch, will answer all practical purposes, as at 1, 2, 3, 4, 0. Strike perpendicular as from 1 to 1, 2 to 2, etc., intersecting radius of boiler. Strike line on top of boiler parallel with center of boiler. The distance from where your perpendicular lines cut parallel line to radius of boiler, is the space to be added at corresponding numbers on flat plate. Now we roll up a plate to form a dome, with all edges square with each other, and put it on top at points marked 1 on Fig. 19; repeat with all the numbers measuring from parallel line down to radius of boiler on the lines as numbered, and from parallel line down at flat plate at corresponding numbers; this will give you your line of curvature. Now you must allow for flange and laps all around your sheet and the plate is complete.

Fig. 20 shows method of finding shape of aperture, or dome hole, in plate when flat, you will note that hole is not round when plate is flat, but will be when rolled. *K H F E O* are the same distance apart as corresponding letters at Fig. 18. Square sheet at center of boiler, plumb the sides. Then you would find you were short of stock as from 1 to *s*. Now, suppose we set divider that distance and scratch a line on dome, by letting dividers follow a radius of boiler, we would have to cut dome away at 0, the distance from 1 to *s*, to make sheet fit boiler. Fig. 19 shows plate when flat, laid out to form dome sheet. Inside diameter 30 inches, plate ¼-inch or 30½, 30.50 x 31416 = 95.95, or 96 inches nearly. Divide this into four equal parts, as at 1, 0, 1, 0, 1. Sub-divide these quarters into four parts or spaces, as at 1, 2, 3, 4, 0 Now, by setting your dividers at 1 *s*, Fig. 18, and marking the distance there on all where you are to locate dome Set divider from *N* to *D*, Fig. 20, mark distance from *N* to *N*, Fig. 20; do the same from *N* to *A*, on line marked *AA*. Do the same on lines *BB*, *CC*, *D*; this will form your aperture. I will give a simpler method later.

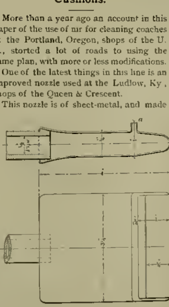


## Air-Nozzle for Cleaning Plush Cushions.

More than a year ago an account in this paper of the use of air for cleaning coaches at the Portland, Oregon, shops of the U. P., started a lot of roads to using the same plan, with more or less modifications.

One of the latest things in this line is an improved nozzle used at the Ludlow, Ky., shops of the Queen & Crescent.

This nozzle is of sheet-metal, and made

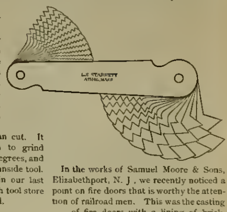


as shown in accompanying cut, the outlet is a long slot, located on the *side* of the nozzle and in front of a heel or raised bead. The orifice is closed at the ends by a rib. Now, when this nozzle is used the opening is down and the heel, marked *A*, is pressed down on the plush it opens up the pile (if that is the right word) and the air has a chance to get clear down to the scalp—so to speak.

These sides and heel prevent the dust from being blown backward or sideways, and a current carries it ahead, away from the operator and the work, and can be made to throw the dust out of a window or into some place where it can be got rid of.

This little device will do much more effective work that a plain nozzle, because it gets its jet of air to the right place and takes the dirt out and removes it Try one of them, and you will waste no more energy pounding cushions with tennis racquets.

## A New Screw Pitch Gauge.



The accompanying engraving shows the plan of a screw pitch gauge having more and coarser pitches than usually found in such devices. This tool is the handiest made, as the gauges will go inside of a nut as well as on a bolt; it has the following pitches 4, 4½, 5, 5½, 6, 7, 8, 9, 10 11, 11½, 12, 13, 14, 15, 16, 18, 20, 22, 24, 26, 27, 28, 30. The teeth are sharp and clean cut. It is a reliable gauge by which to grind and test a threading tool at 60 degrees, and is especially convenient for an inside tool.

This is the tool mentioned in our last paper as exhibited in an English tool store window as the best in the world.

There was a considerable assemblage of prominent railroad men at the office of the Railroad Commissioners of the State of New York, at Albany, on Monday last, October 17th. This meeting was for the purpose of making application for an extension of time in which to apply automatic freight car-couplers to cars running within the State of New York. The New York State law requires that all cars shall be equipped by November 1, 1892, and it is asked that this time shall be extended for one year, that is until November 1, 1893, on the ground that it would be a physical impossibility for railroads to make the change within the time originally fixed. The meeting adjourned at 1 P. M., and all the gentlemen present were invited to the Fort Orange Club. After lunch the party took a run about Albany on an electric car of the Albany Railway, which has been recently equipped by the Consolidated Company with its electric heater, and during this run a visit was paid to the new offices and large factory of the Consolidated Company just completed. Among the railroad men present were Messrs. Tuttle, vice-president, New York, New Haven & Hartford R. R., MacKenzie of the "Nickel Plate," Boon and Bradley of the West Shore, Lentz of the Lehigh Valley, French of the Chateaugay, Baldwin of the Central Vermont, Hedding of the Lake Champlain & Mariah, Hammond & Blackall of the Delaware & Hudson Canal Co., Hinsdale of the Long Island, Robeson of the Boston & Albany, Armstrong of the Philadelphia & Reading, Locke of the Delaware Lackawanna & Western, Merchant of the Buffalo, Rochester & Pittsburgh, Marden of the Fitchburg, and many others.

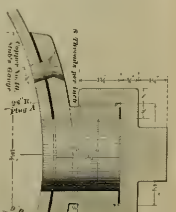
The Santa Fé people have to haul water for use on some of the divisions of the road, and they use for this purpose wooden tanks which are carried on flat cars. The country is so dry where these tanks are used that they are always leaking or falling apart from the shrinkage of the wood. To remedy this the management have called for iron tanks, and the mechanical department are getting up a tank-car that will be adapted for carrying water or oil. There are oil wells on some parts of the system that promise a good supply, and it will be carried to market soon. A novelty in these tanks will be a frost-proof valve.

In the works of Samuel Moore & Sons, Elizabethport, N. J., we recently noticed a point on fire doors that is worthy the attention of railroad men. This was the casting of fire doors with a lining of brick. The bricks are laid in the sand and a frame of cast-iron poured around them, making a light lining that does not burn out readily. With the shallow locomotive fire-boxes now in use, there is much difficulty with the burning out of the fire-door lining To those wrestling with this difficulty we would suggest the fire bricks as a remedy.

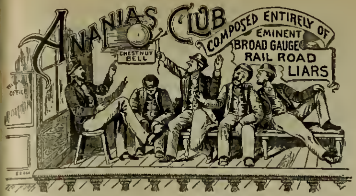
The Shaw four-cylinder locomotive has recently been overhauled at the Baldwin shops and put in condition to run. It was claimed that one fault prevented her from properly showing her speed—a small dry pipe. A new 8-inch pipe has been put in, and it is hoped that this will deliver all the steam that four ten-inch cylinders can use

## Cap Wash-Out Plugs.

The annexed engraving illustrates the form of boiler cleaning and wash-out hole plugs adopted by the Cleveland, Cincinnati, Chicago & St Louis mechanical department as standard. With the ordinary wash-out plug hole where the thread is cut on the sheet, the wash-out rods constantly tear and grind the thread, with the result



that there is a constant round of leaking, tapping out and putting in bigger plugs. This plan of a sleeve on which the thread is cut obviates all the ordinary annoyance This form of wash-out hole cap has been in use on the Pittsburgh & Fort Wayne divisions of the Pennsylvania Railroad for several years and is found to be highly satisfactory.



## No Place to Put It.

"Pete Beckley got one of his eyes put out chippin' a crosshead one day a long while ago," said the Long Island machinist, "and was known far and near as One-Eyed Pete."

"Pete was a good all-'round man, and usually got in considerable overtime, repairing tools, lining up shafting and overhauling the engines.

"One time our old man—an awful dry old customer—struck Pete in the yard; says he:

"'Peter, I reckon you'd better come back to-night and bore them tire; we're behind on 'em; you don't mind a little time-and-a-half, hey, Pete?'

"'Well,' says Pete, 'you know, sir, I worked overtime last night till 1 o'clock.'

"'Oh, well, that's nothin'—when I was your age I didn't mind a——'

"'But I worked night afore that, and I——'

"'Well, well, what if you did, you can——'

"'But say, don't you suppose I want some sleep. Jones worked two nights, but he wouldn't come last night, and ain't I as good a right to as much sleep as him?'

"'No, sir,' said the old man, dry like; 'you ain't; you don't need as much, and you can't git as much. Half as much ort to do ye—*you've only got one eye!*'"

## A Way to Tell.

"I see," said the old timer, wiping his mouth on the back of his hand, "I see a good deal in the papers about the exact right heat to flange boiler steel and forge tool steel, to say nothin' at all about the exact amount o' heat required to heat a train that you can git out o' the front end for nothin,' and the heat saved in compounds and manufactured in receivers.

"Heat is the main thing on a railroad; anyway it's a good thing to know when you've got it jest to a T'yt; and that reminds me o' a receipt o' Cy. Pratt's, an old chum o' mine, for hot crown sheets. Cy. were sent out on the road to haul in an engine as had her rafters cooked, and the stopper and starter, a no-good sorter a drinkin' cuss, says to Cy. says he, 'I'll take my oath on a stack o' Bibles higher 'en this cab that I had three gauges o' lime juice in her. Them 'air radius stays ain't no good. Jest look at that sheet an' see what you think o' it.' Cy. got up and took a look in the fire-box door; the crown-sheet was hanging half way down to the grates, blue and crooked. 'Well,' says the plug, 'what'd you think?' 'I think perhaps you biled it too long,' says Cy., 'for when pertaters crack open like that, they're done.'"

## A Dead Corpse.

"It was on the C., B. & Q.," says the *Express-Gazette*. "The east-bound passenger train, then called the 'Cannon-Ball,' had on board five corpses. It was in hot weather. The baggageman, finding the atmosphere in the car becoming undesirable, moved three of the boxes, containing a corpse each, to the platform of the car, outside, one on top of the other.

"As the train was nearing Ottumwa, the baggageman, upon looking out, was horrified to discover one of the boxes missing. Surmising that one of the boxes had slid off in rounding a curve, owing to the high rate of speed the train had been running, he wired Superintendent Dugan apprising him of the loss. Dugan wired the section foreman at Ottumwa as follows

"'Patrick McGann—Look out for corpse lost off Cannon Ball three miles west of Ottumwa and report condition of same when found.'

"Patrick immediately started out with the section gang and found the box intact. It was seldom that Patrick received orders direct from the superintendent, the roadmaster being his immediate superior. Consequently Patrick concluded the time to win promotion had arrived, and after reading Dugan's order over for the twentieth time, wired his superintendent as follows

"'Mishter Doogun—I hev found the koropse and the koropse was dead.'"

## A Transaction in Watermelons.

There is a curious legal question stirring the people of Topeka. A car load of watermelons was purchased by a citizen of this thirsty town, and while he was unloading them a gentleman of color happened along and asked for a watermelon. The request was denied.

"Say, boss, can I have a melon out o' de nex' kear?" asked the darky.

"Yes," replied the citizen, who was fond of a joke, and knew that the melons in the next car belonged to a rival. "Yes, you may take all you want."

The colored man carried away all the melons he could carry and spread the joyful intelligence among his sisters and his cousins and his aunts, that a car of watermelons was on the side-track free to all. Just as the colored population began to gather round the car the shop whistle blew and word spread among the men going home from work that the melons were there for the taking. In the twinkling of an eye the car was empty, and a string of men were walking home with cooling mouthfuls under their arms.

The owner of the watermelons called for his fruit the next day and found the car empty. The story of how the melons had been distributed became known, and the originator of the joke assumed a grin so broad that it threatened to permanently widen his face. The man who lost his melons called upon the railroad company to reimburse him for the loss and their attorney notified the joker that he would be required to pay for the melons that he had given away. His face at once turned from broad to long, and the citizens feel that the joke is widely distributed. They are still torn with uncertainty as to who will pay the bill. Meanwhile the watermelons have gone where they will do the most good.

The Consolidated Car-Heating Co., of Albany, N. Y., have recently put on the market a special steam-valve for their heater system and a dust guard for the rear hose on train, this guard is fastened to the chain of the hose and serves to hold up the end when not coupled.

## Origin of the Bell Rope.

A correspondent writes us As you have been saying a good word for the old Erie lately I send you particulars of an event which is interesting to every person who has anything to do with railroad trains. The bell rope is fast giving way to the pneumatic signal, but it has played an important part in train control and its origin ought to be matter of proper record.

In the early days of the railroad in this country the locomotive engineer was the master of the train. He ran it according to his judgment, and the conductor had very little voice in the matter. Collecting fare, superintending the loading and unloading of freight, and shouting "All aboard!" were all that the conductor was expected to do.

The Erie Railroad was then the New York and Erie Railroad. One of the pioneer conductors on this line was Captain Ayres. He ran the only train then called for between the two terminal points. It was made up of freight and passenger cars. The idea of the engineer, without any knowledge of what was going on back of the locomotive, having his way as to how the train was to be run did not strike the Captain as being according to the propriety of things. He frequently encountered a fractious passenger who insisted on riding without paying his fare. As there was no way of signaling the engineer, and the passenger could not be thrown from the train while it was in motion, the conductor in such cases had no choice but to let him ride until a regular stop was made.

Captain Ayres finally determined to institute a new system in the running of trains. He procured a stout twine, sufficiently long to reach from the locomotive to the rear car. To the end of this string next the engineer he fastened a stick of wood. He ran this cord back over the cars to the last one. He informed the engineer, who was a German named Abe Hammil, that if he desired to have the train stopped he would pull the string and raise the stick, and he would expect the signal to be obeyed. Hammil looked upon this innovation as a direct blow at his authority, and when the train left Piermont he cut the stick loose. At Turner's he told Captain Ayres that he proposed to run the train himself, without interference from any conductor. The next day the Captain rigged up his string and stick of wood again.

"Abe," said he, "this thing's got to be settled one way or the other to-day. If that stick of wood is not on the end of this cord when we get to Turner's, you've got to lick me or I'll lick you."

The stick was not on the string when the train reached Turner's. The Captain pulled off his coat, and told Hammil to get off his engine. Hammil declined to get off Captain Ayres climbed to the engineer's place, and Hammil started to jump off on the opposite side. The conductor hit him under the ear, and saved him the trouble of jumping. That settled forever the question of authority on railroad trains. Hammil abdicated as autocrat of the pioneer Erie train, and the twine and stick of wood manipulated by the conductor controlled its management. That was the origin of the bell rope. The idea was quickly adopted by the few roads then in operation, and the bell or gong in time took the place of the stick of wood to signal the engineer.

The Illinois Central are reorganizing their service preparatory to the World's Fair business. They have shortened the divisions as formerly operated, the Chicago division ending at Homewood and the Freeport division at South Addison. The line between Chicago and Homewood, including the South Chicago and Blue Island branches, and between St. Charles Air Line Junction and South Addison, including the Addison branch, will form the Chicago Terminal District. John T McBride has been appointed superintendent of the new district.

The Baltimore & Ohio Railway Company will make a historical exhibit at the World's Fair which will be of absorbing interest to all railroad men. Major J. W. Pangborn has charge of its preparation. The Baltimore & Ohio claims to be the oldest railroad in the world, its two or three predecessors having been mere tramways for transporting coal, stone or ore. The actual construction of the road began on July 4, 1828, and its first section was in operation six months before the Liverpool & Manchester road, the first railroad, in the present sense of the word, in Europe. The Baltimore and Ohio claims also to be the only one of the pioneer roads which has retained its original name and has remained under a continuous succession of management.

A long time ago old John Alexander described the short-comings of overclothes and brought attention to the fact that railroad men wore more overclothes than the men in all other trades combined. John kicked about the uncomfortableness of the blasted things—and he told a heap of truth There is a quiet sort of a railroad man, H. S. Peters, an ex-engineer, in Brooklyn, who is making overclothes to wear—the things actually fit and feel good—and all the engineers and firemen (Peters belongs to both Brotherhoods) who read this ought to help a brother out by asking for and insisting on having overalls with the buttons marked "Brotherhood." They are just as cheap as the "Sheeney Shrinkable" brands and far better.

One of the large number of railroad men who have succeeded in business off the road is John J. McGrane, the wholesale jeweler of 48 Maiden Lane, this city. Mr. McGrane put in a long term of years on a locomotive and still retains his membership in the B. of L. E. His place of business is headquarters for all railroad men around New York who want anything in the shape of time-pieces or jewelry. John always keeps the best, tells the truth about them and lives up to his guarantees—hence his business grows. He sells a great many fine watches direct to railroad men all over the country, who dispose of them to their friends direct with a profit to themselves and a saving to the buyer.

The Pond Engineering Co., St. Louis, Mo., have sent out an illustrated circular of a dry-steam separator which they have on the market. The separator consists of an outer cylindrical shell into which the steam enters with the entrained water and leaves through an inner pipe extending from the top down to about one-half the length of the separator, leaving an annular space between the two. The separator is guaranteed to relieve the steam of all entrained water and return this water to the boiler, either direct or by means of a trap, as the location of the separator may determine.

Railroad companies that use retaining valves on the air brakes of their freight cars, find great difficulty in preventing the brass fittings from being stolen As a remedy most of them have adopted the practice of making the fittings of cast-iron. Even this does not entirely prevent thieves from carrying away the parts. In some regions they would carry away the whole car if it was not too heavy.

Stannard & White, of Appleton, Wis., have announced that they will give a year's subscription to LOCOMOTIVE ENGINEERING to every purchaser before January 1st of one of their Brotherhood cab seats. This is the best seat in the world, and any engineman who rides one will have less backache and live longer. A neater Christmas present couldn't be given to an engineer or fireman.

The Ingersoll Milling Machine Co., Rockford, Ill., have just built one of the largest slab milling machines which has ever been turned out. This machine mills at one cut 42 inches wide. Total weight of machine over 11 tons.

(100). L. D., Harlem, N. Y., asks:

What sized grates are used on the N. Y. Elevated locomotives? *A.*—42 x 52 is the largest, we believe.

(100) W. H. T., St. Helen, Mich.

Will you please give me position of locomotive valve with lever in center notch, and why "out of gear." We disagree on that point here and want to settle it. *A.*—The valve is in position to cover both ports, and is called "out of gear" because the engine will not run in either direction with lever in center notch.

(101) H. T. F., Kent, Va., writes: Are not the drivers on the Dickson engine, which is shown in the L. E., on page 381, of the October number, put very far forward? On all the eight-wheel engines that I ever saw, the drivers are located just as they are on the Rogers engine illustrated on same page? *A.*—The engine shown is a good specimen of hard-coal burner as used on some of the lines in Pennsylvania.

(102) H. W. K., Auburn, N. Y., writes: Will you please tell me through your column of "What you want to know" where and how long ago the build of engines, called "Tweed engines," were built? *A.*—Mr. Tweed was for years agent of the Taunton Locomotive Manufacturing Co., and many of the engines turned out during his time were known as "Tweed engines." These works quit building locomotives some three years ago.

(103). R. Cutter, Alton, Ill., asks:

Can you let me know in your paper the proportions of different kinds of metal to make metallic packing for pistons and valve stems? *A.*—The exact proportion of metals varies with different makers. Many use regular babbitt with success. One of the best makers (Jerome) keeps his mixture a secret. The U. S. people use 100 parts of tin, 9 of copper and 6 of antimony. The latter metal is used to harden. Vary it until you get the desired result.

(104). J. T. E., Gottenburg, Neb., asks.

What is the best protection for the valves, cylinders and rods of an engine that lays idle nine months in the year. *A.*—Graphite grease is as good a thing as we know of, especially on the cylinder and valves. It can be introduced with oil and a few turns of the engine made by hand to coat the surfaces. Tallow and white lead are excellent and will stand considerable handling without rubbing off, but you will have to take off the chest cover and cylinder-head to apply it.

(105) A. S. S., Kingston, Jamaca, asks: Is not a two-cylinder compound, high-pressure cylinder 18 inches and low-pressure 26 inches, both 24-inch stroke, 180 pounds pressure, supposed to be more powerful than a simple engine with 18-inch by 24-inch cylinders carrying 170 pounds pressure; engines otherwise alike? *A.*—Hardly. The rule of the Schenectady Works is to make two-cylinder compounds with the high-pressure cylinder 1 inch larger in diameter than a simple engine of similar design and for similar work, the low-pressure cylinder is usually made 2.2 times the area of the high-pressure cylinder. Engines so built have been found to do the same work as simple engines of their class.

(106) Edward Gibson, Wilmington, Del., writes:

Would it be asking too much to get you to explain the answer you gave to the question asked by E. B. B., Mussels Canal, as I don't understand why that small wheel would have to slip or slide to keep up when everything is solid. *A.*—E. B. B. asked if an axle had three wheels on it, one at each end two feet in diameter and one in the center one foot in diameter, these three wheels resting on three rails, the center one raised up to the wheel, if the small wheel would have to slip to keep up with the large ones. The 2-foot wheels would roll about six feet in one revolution, the 1-foot wheel would roll but about three, hence if it kept up it would do more than roll.

(107) M., Frankfort, Ky., writes:

My question and answer (No. 99) was perhaps misunderstood, so I am not quite satisfied. What I wish to know is this: "The travel being found correct and the cut-off *out*, can the cut-off be made correct and still leave the travel as it was before the cut-off was corrected?" In correcting the cut-off wont it change the travel? *A.*—The length of travel is fixed by the throw of eccentrics and length of the rocker-arms, its even movement each side of the center of the seat is adjusted by the length of the eccentric blades. The point of cut-off (and all other functions of the valve) can be hurried or retarded by moving the eccentrics on the axle, as this can not affect the throw of the eccentrics, the length of the arms of the rocker, or the length of the blades, it is plain that the cut-off may be changed without changing the travel.

A patent has been granted to Mr. F. W. Johnstone, superintendent of motive power of the Mexican Central Railroad, for an improvement in brick arches for the fireboxes of locomotives. The improvement consists principally of the supporting of the brick arch by means of a girder attached to the mud ring instead of hanging the arch by the side sheets. As the damage done to side sheets by the expansion and contraction of the bricks is held by some men to be a serious objection to the use of the brick arch, the plan adopted by Mr. Johnstone will overcome the difficulty.

---

The Mt. Vernon Car Manufacturing Company have recently booked orders for 1,000 Hicks' patent stock cars, to be operated on the C., C., C. & St. L., 100 box cars, 150 coke cars and 10 cabooses for the Monterey & Mexican Gulf, 100 box and 100 palace stock cars for the Illinois Central and 200 coal cars for the Evansville & Terre Haute. This plant have six months' work ahead, and have been obliged to refuse orders lately.

---

The Butler Drawbar Attachment Company, of Cleveland, O., have just issued a neat catalogue and price-list. The pamphlet contains drawings of their draft-gear applied to all kinds of drawbars and cars, the drawings being large and clear. The prices of each pattern of stops and springs is also given, the whole being neat and convenient. It should be on the desk of every car-builder and inspector—there's pointers in it.

"Inventive Progress" is the title of a small pamphlet just issued by Wm. A. Rosenbaum, electrical expert and patent attorney, *Times* building, New York. The book contains a great deal of readable information about the patent office, with good pictures of prominent inventors and inventions. If you are interested and say you saw this in LOCOMOTIVE ENGINEERING, Mr. Rosenbaum will send you one of the books. We notice one statement that may interest men with a new car-coupler bug in their ears: "There have been 4,931 patents issued on car-couplers."

---

After we had accompanied Master Mechanic Symons around his clean and orderly shops at Raton, N. M., he remarked "Come into the office and I will show you something you will be interested in." We went and certainly were interested to find an engine board made up after the style of board designed by Mr. J. R. Groves, superintendent of rolling stock of the St. Louis & San Francisco, and illustrated in LOCOMOTIVE ENGINEERING. Mr. Symons is proud of his board and considers it a great convenience.

---

A correspondent of the *English Mechanic* writes that he had the misfortune to break off a tap in a half-inch hole at the end of a shaft. After trying unsuccessfully to soften it by the blowpipe, he bethought himself of trying electricity, and accordingly, by means of an arc-light carbon, brought to bear on the shaft an electric current of 30 or 40 amperes, which raised it to a dull red heat in about three minutes. When cooled the tap was of course easily drilled out.

---

The fashionable thing among railroad men in Southern California is to be owner of an orange grove. Some of the finest groves in the neighborhood of Los Angeles belong to railroad men. One trackman on the Southern California has an orange grove worth $10,000. It originally cost him about $500 of hard scraped earnings. The rise in values has a kind of gambling aspect that is very attractive to men with small sums to invest.

---

After the last meeting of the Southern Railroad Club at Atlanta was over, a few of those who were at the Kimball House had a little joke at the expense of Mr. A. G. Richardson, of the Ewald Iron Co. Shaeffer, the champion billiard player, happened to be in the hotel and they started Mr. Richardson to play with the famous expert, without knowing who was his opponent. The jokers did not get much to laugh over.

---

The N. Y. C. & H. R. Ry. are taking off the buffers, or dead-woods, each side of the drawhead of their freight cars equipped with vertical plane couplers. It is said 15,000 cars are being changed.

---

All over Europe, wherever Pintsch gas is used for car lighting, they employ lead pipe to fill train receivers where we use rubber hose.

## A Grave Condition of Affairs.

There is something curious about the tenacity with which landowners in many parts of the West cling to their possessions in land. This characteristic is developed with remarkable prominence on the Pacific coast, and it causes railroad companies great inconvenience at times. Mr. W. G. Curtis, assistant general manager of the Southern Pacific, tells an amusing story illustrating this peculiarity. A certain man who had obtained extensive possessions in land was, after much persuasion, prevailed upon to part with enough ground to permit a railroad company to pass through his numerous acres. A station was established on his land, and demand for town lots arising, he was induced to sell lots enough for the building up of a small town. Houses were built and the community began to increase. The course of nature also called for the use of a burying-ground. But about the time this necessity arose, the owner of the land was seized with a spasm of pride of possession and he would not grant a foot of ground for a cemetery. The result was that the people had to carry their dead seven miles for burial to the land of a man with less restrictive sympathies, and they are doing that to this day.

The worst of the case was, that the new cemetery was located under a high trestle which the railroad passes over. The company are now anxious to fill up the gap that the trestle spans, but they cannot get the work done because it would obliterate the only burying-ground in the district.

## Whetstones.

The use for which the stone is wanted must always be considered carefully, for then the general character of the stone desired is easily decided, and it only remains to find a suitable stone. A few tests to decide what sort of stone is being offered one by the dealer are often useful. The hardness may be tested by a pocket knife. If the stone is soft, like the water-of-Ayr stone, the knife edge will cut it easily on its flat sides without injury to the knife; stone of medium hardness, like the Hindostan, will cut on the edges with some difficulty; a hard stone, the Ouachita, for example, can be scratched by the knife point; while a very hard stone, like the Arkansas, receives no scratch from the knife point. The fineness of the grit can best be judged by drawing the edge of the finger nail backward over the stone; the sensation produced indicates well the coarseness of the grit, and a little practice with various stones soon gives one expertness in judging their fineness. The finger nail will tell whether the stone is coarse or contains coarse particles by showing scratches; fine gritted stone will make no visible scratches. The sharpness of the grit also will be indicated by the amount of the nail worn away.

A dull tool with a notched edge should no more be placed on a good whetstone than a carpenter's chisel should be used to drill rock; yet such a use of whetstones is a common one. The purpose for which a whetstone is bought should be kept in mind, and it must be remembered that if used for purposes widely different from those for which it is best adapted, the stone will be spoiled for its ordinary work. For this reason it is economy to have stones of different grades wherever tools are in constant use, as in carpenter and machine shops. For reasons already given, it must be expected that a whetstone will lose a little of its abrading quality with use; if it loses much, however, the conclusion may be drawn that it is not being properly used, that proper care is not being taken of it, or that it is a poor stone; only do not be too ready to condemn the stone. Many good stones are condemned and given a bad reputation, when the fault lies either in the original choice of the stone, or in the use made of it, or the care taken of it.—*Ark. Geo. Survey.*

## Brooks Compound Locomotive.

The perspective engraving on this page and the sectional views that follow, illustrate a two-cylinder compound locomotive built by the Brooks Locomotive Works for the Lake Shore & Michigan Southern Railway, and now at work on that road.

The component parts of a compound locomotive that require particular care in designing are those that regulate the admission of steam in starting in such a way that the engine will start as easily as a simple locomotive. It is known to most of our readers that in a compound engine the over to the high-pressure cylinder. In the Brooks compound the appliances for giving the engine sufficient starting power were designed and patented by Mr. John Player, mechanical engineer of the works. The engine is of the receiver type, the steam pipe leading from the high-pressure to the low-pressure cylinder constituting the receiver. High-pressure steam is employed in both cylinders simultaneously, the supply being automatically reduced in pressure and controlled at even pressure, so that the mean effective pressure is equalized on both sides of the engine. Means are taken to prevent the live steam in the low-pressure cylinder, the intercepting-valve at the same time closing. When the exhaust steam from the high-pressure cylinder raises the pressure of the receiver above the pressure of steam in the low-pressure steam-chest, the intercepting-valve is opened and the engine begins working compound.

Referring to the engravings, Fig. 1 shows a transverse sectional view through the cylinders, receiver, steam pipes, combined valve, steam-chest, etc. Fig. 2 is a plan of the cylinders and connections. Fig. 3 is a longitudinal view of smokebox and low-pressure cylinder. Figs. 17, 18 and 19 starting passes through the small pipe *J* to the pressure-regulating *G*, forcing it open, and flowing through the inside of the valve, passes by openings through the intercepting-valve into the receiver. The pressure-regulating valve has a greater area on the low-pressure than on the high-pressure side, which tends to close the valve when a certain pressure is attained in the receiver. This pressure is regulated by the designers. When the exhaust steam escapes from the high-pressure cylinder and reaches a pressure greater than that in the low-pressure side, it forces the intercepting-valve open, and the area of the

BROOKS COMPOUND TEN-WHEELER.

steam is admitted direct from the boiler to the high-pressure cylinder, and after doing its work there is exhausted into the low-pressure cylinder, where it performs more work. As the low-pressure cylinder in ordinary working is dependent upon the exhaust of the high-pressure cylinder for its supply of steam, it is readily seen that in starting from a state of rest there is no steam in the low-pressure cylinder unless it is admitted directly from the boiler. This is usually done. As the steam-chest of the low-pressure cylinder is in open communication with the exhaust passage of the high-pressure cylinder, pressure admitted direct from the boiler to the low-pressure steam-chest will act as a back pressure upon the piston of the high-pressure cylinder unless an intercepting-valve or some equivalent device is employed to prevent the steam from passing low-pressure steam-chest from passing over to act against the high-pressure piston. Provision is also made for automatically shutting off the supply of live steam from the low-pressure steam chest or receiver when the exhaust steam from the high-pressure cylinder reaches the same pressure as the directly admitted steam in the receiver. At the instant the direct steam is shut off both ends of the receiver are opened so that the exhaust steam from the high-pressure cylinder may pass unimpeded to the low-pressure steam-chest.

To perform these functions there is introduced into the receiver-pipe (*D*, Fig. 1) between the high and low-pressure cylinders a combined admission pressure regulating and intercepting valve *G*. On the throttle being opened the combined valve admits steam at reduced pressure to the show views of the intercepting and pressure-regulating valves in different positions. The intercepting-valve is a cylinder closed at one end, the closed end forming a disk which covers when closed the steam pipe opening to the high-pressure cylinder. The inside of the intercepting forms a seat for one end of the admission and regulating-valve.

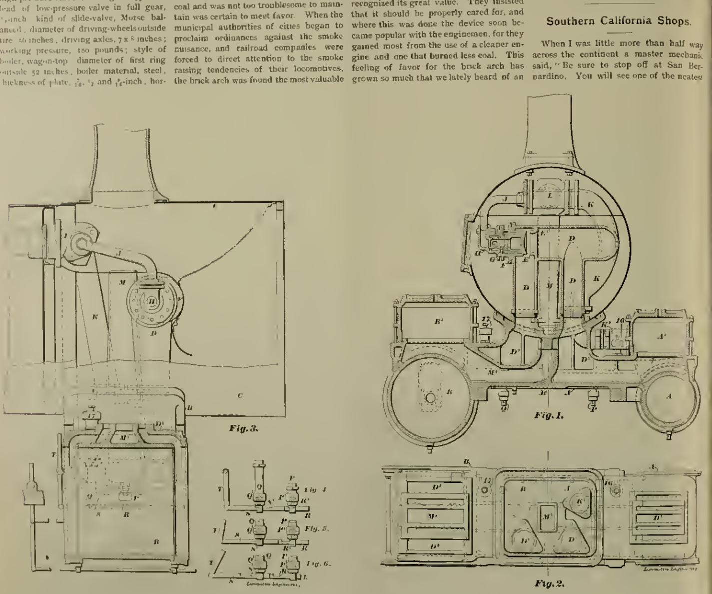
In Fig 17 the combined valve is shown in the position it stands in when the engine is working compound. Fig. 19 shows the position of the valve when steam is shut off, a spring being used in the intercepting-valve to close the latter. The action of the valves can be followed by reference to Figs 1 and 18. When the throttle-valve is opened the steam passes through the pipe *K* in the ordinary way to the high-pressure steam-chest. The steam intended to use the low-pressure cylinder in intercepting-valve disk is so much greater than the area exposed by the starting-valve to the live steam, that the valve is held closed until steam is shut off.

Figs. 4, 5 and 6 show what are called controlling-valves, which are used for admitting a small quantity of steam for moving the engine light. They are operated by a lever in the cab separate from the throttle, and are seen beneath the cylinder saddle in Fig. 1.

The details of the starting appliances appear to be well worked out.

Figs. 7 and 8 show in transverse section and plan an arrangement which may be employed where the intercepting valve is placed in the saddle of the low-pressure cylinder.

The leading particulars of the engine are Weight in working order, 102,000 pounds, weight on drivers, 75,000 pounds, wheel base, 23 feet 3 inches, driving-wheel base, 13 feet 3 inches, cylinders, 17 and 28½ x 24 inches, steam ports of high-pressure cylinders, 16 x 1⅝ inches, exhaust ports of high-pressure cylinders, 16 x 3 inches, maximum travel of valve, high-pressure cylinders, 5¼ inches, maximum travel of valve, low-pressure cylinders, 7 inches; inside lap of valve, high-pressure cylinders, ¾-inch, inside lap of valve, low-pressare cylinders, ⅞-inch, inside clearance of high-pressure valve, $\frac{3}{16}$-inch, inside clearance of low-pressure valve, ¼-inch, lead of high-pressure valve in full gear, $\frac{1}{16}$-inch; lead of low-pressure valve in full gear, ⅛-inch kind of slide-valve, Morse balanced, diameter of driving-wheels outside tire 56 inches, driving axles, 7 x 8 inches; working pressure, 180 pounds; style of boiler, wagon-top diameter of first ring outside 52 inches, boiler material, steel, thickness of plate, $\frac{7}{16}$, ½ and $\frac{9}{16}$-inch, horizontal seams, quadruple riveted lap joints, circumferential seams, double riveted, size of firebox, 96 x 34 inches; water space, 4 inches front, 3 inches side and back; tubes, diameter, 2 inches, tubes, number, 186, tubes, length over sheet 12 feet; crown supported by crown bars, exhaust nozzle, single, exhaust nozzle, diameter, 4½ inches, smokestack, diameter inside, 13½ inches, feed-water supplied by two No. 8 Monitor injectors, ratio of high to low-pressure cylinders, 1 to 2.81 inches; ratio of high-pressure cylinder to receiver, 1 to 4.05 inches, smallest diameter receiver passage, 7 inches, diameter of intercepting-valve, 7 inches, smallest diameter of reducing-vale, 3 inches, inside diameter of live steam supply pipe to reducing-valve, 2¾ inches.



Details—Brooks Compound.

## Growth Into Favor of the Brick Arch.

No attachment of the American locomotive has risen more rapidly into favor of late years than the brick arch. Yet it is not ten years ago since a committee of the Railway Master Mechanics' Association appointed to investigate the advantage of brick arches presented a report which condemned or underrated the value of this aid to combustion.

Several circumstances have contributed to the popularity of the brick arch and to the deciding of its proper value. When railroad companies began to call for care and economy in fuel consumption a sentiment was cultivated which prepared the way for the general introduction of the brick arch. Anything that would save coal and was not too troublesome to maintain was certain to meet favor. When the municipal authorities of cities began to proclaim ordinances against the smoke nuisance, and railroad companies were forced to direct attention to the smoke raising tendencies of their locomotives, the brick arch was found the most valuable aid in the protection of railroad companies from prosecution. This has quickly led to the brick arch being considered by all well managed railroads an essential part of the locomotive firebox.

The rapid advance of the brick arch into popularity is not stranger than the sentiments which long kept it tabooed as worthless. The opposition offered to this valuable adjunct of combustion was due to the fact that it required some attention, and it was declared a nuisance by people who had no interest in fuel economy and had no patience with anything that they had not always been accustomed to. A brick arch would be applied to one or two fireboxes on a road where none had been used before. Likely enough they were built so that a shovelful of coal could not be thrown into the firebox without striking the arch. It was nobody's business to make the thing a success. The fireman discovered that it interfered with his free and easy fashion of throwing lumps of coal into the firebox and he declared the thing no good. By carelessly throwing a portion of the coal on the top of the arch instead of under it, he choked up part of the flues and the engine did not steam so well as with a plain firebox. When the arch was finally knocked down by being hit in a vital part by a lump of coal, and time lost in getting the fragments removed from the firebox, the master mechanic concluded that the arch was more trouble than it was worth. This was for years the experience of the brick arch on various railroads.

That the arch survived is due to the persistence of a few master mechanics who recognized its great value. They insisted that it should be properly cared for, and where this was done the device soon became popular with the enginemen, for they gained most from the use of a cleaner engine and one that burned less coal. This feeling of favor for the brick arch has grown so much that we lately heard of an engineer who went to the master mechanic and offered to bear the expense of renewing a brick arch since the company did not seem inclined to put a new one in. The cost of a new arch was of small consideration compared with the increase of comfort he found by using it. There are many other novelties that enginemen and others look upon with suspicion that merely need acquaintance to be thoroughly appreciated.

## Fighting by Boycott.

Some time ago the general passenger agents of nearly all railroads formed a compact or conspiracy to boycott the Chicago & Alton. The boycotted road moved along in the even tenor of its way and carried more passengers than it had ever done before. The boycotters became tired of the boycott sooner than the boycotted. When they had properly demonstrated to the world at large what roaring asses they could make of themselves, the general passenger agents decided to raise the boycott. It is hard for some classes to acquire wisdom, for part of the men who favored the Alton with a boycott have now decided to put the same humbug upon the Union Pacific.

That kind of boys' play makes railroad officials appear ridiculous before the reflecting public. The officers of the roads who are taking this boycotting method will yell with protest when striking employés adopt similar fighting tactics. Are the latter not drawing inspirations of this kind of warfare from the railroad companies themselves?

## Southern California Shops.

When I was little more than half way across the continent a master mechanic said, "Be sure to stop off at San Bernardino. You will see one of the neatest shops there is in this country and run as well as anything to be found in the East."

I took this advice, and severed my attention from the novelties of orange groves, peach orchards, luscious vineyards and blooming flowers to search for Mr. G. W. Prescott, the superintendent of motive power. In a country where there is no ice or snow and very little rain, elaborate buildings are not necessary for shops, but those at San Bernardino compare very favorably with buildings to be found East of the Missouri. The shops are small but well arranged for doing the work for about 40 engines, 60 passenger cars and 200 freight cars. Between San Bernardino and Los Angeles the road passes through a series of fruit gardens and villages that supply a large volume of passenger business similar to suburban traffic. On this account the road has a large percentage of passenger cars and engines which make big mileage.

Labor is expensive here and the men in charge of this road have done all in their power to make machines do all the work possible The shops are well provided with tools when compared to other Pacific Coast establishments. The tool room is particularly well equipped and the blacksmith shop would be notable were it in the East for the extent and variety of formers and [illegible]. The shop is also exceptionally well supplied with punches, shears, rolls, bolt-[illegible], steam-hammer and other ma-[illegible] Here there is a novelty in the [illegible] of a flue cutter which has a frame [illegible] from the bolster of an iron truck In the machine shop they make good use

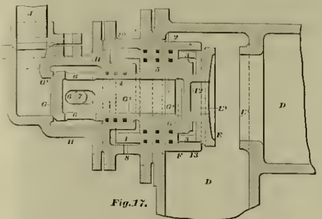


Fig. 17.

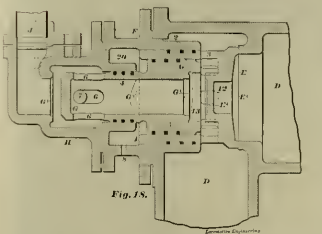

Fig. 18.

Locomotive Engineering

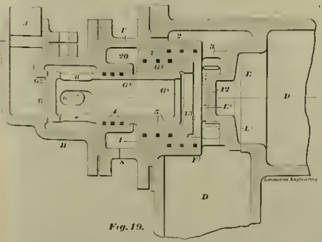

Fig. 19.

Locomotive Engineering

of an air rotary engine which drills, taps, bores cylinders and does a variety of other jobs.

The brass foundry is particularly well run and a small furnace is used for melting brass. A novelty about this furnace is that all the brass scrap from lathes and sweepings of the floor is put into the furnace without having the iron separated. The heats are kept down to the melting temperature of brass and the iron does not melt. When the heat is run off the iron is found in the bottom of the furnace and is dropped out. Mr J B McGill, foreman of the foundry, is an expert in the business

## Sellers Machine Works.

Work is very active in the Wm. Sellers & Co. Works in Philadelphia, but the complaint is heard here as well as in other machine tool works, that railroad companies have ordered very few tools in the last year. The demand for turntables keeps up very well, and the cranes are in demand. The new injector is making satisfactory progress into the favor of railroad companies and is gaining upon the 1876 injector, which has always been very popular. It will be gratifying for those interested in the demand of American articles abroad to learn that the Sellers injector is used largely in France, and that several railway companies in that country have adopted it A commissioner who was in this country lately from Russia examining railway appliances was very much struck with the merits of this injector, and it is likely to be tried on the Russian railroads.

These works have recently completed for the Southwark Foundry & Machine Company a floor boring machine that is operated electrically from a motor placed upon and connected directly with the machine itself. This tool is a special one and is to be used for boring, drilling or milling. It has 7 feet traverse for the vertical lift of head and 30-inch stroke of the spindle. The Ward-Leonard system of electrical transmission is used The direction of motion of all parts can be changed instantly by a reversal of the motor. The Wm. Sellers Company are also building one thirty-ton and one sixty-ton traveling crane for the Carnegie Steel Company, of Pittsburgh, and one fifty-ton crane for the A Garrison Foundry Company, of Pittsburgh The crane that this company is to place in the machinery building of the World's Fair is approaching completion and will be ready for delivery in December.

## An Irish Railway Shop.

The cleanest shops that I visited in all Great Britain were those of the Great Southern & Western of Ireland at Inchacore, in the suburbs of Dublin.

The yards are carefully kept, grass plots abound and not a piece of scrap or material can be found out of its proper place.

The buildings are of stone or brick and very good ones, and the machinery as good as can be found elsewhere

The locomotive superintendent, Mr H. A Ivatt was formerly general foreman of the works and has been in the employ of the road for a good many years

The shops stand on a large plot of ground surrounded by a high stone wall. Inside the inclosure, besides the shops, there are a great many brick cottages which are rented by the company to the employés, these have a sewerage system of their own which is carried to a farm back of the shops, which are cropped to keep the soil in shape.

Like the other Irish roads the gauge is 5 feet 3 inches, yet their locomotives are comparatively small, the largest cylinders being 18 x 24 inches.

A great many suburban engines are used and very neat little engines they are.

They have one compound, 2-cylinder type, a freight engine converted. When I asked how she did the superintendent said he had not run her long enough to tell —only twelve months—said he could tell better after he found out how much extra he would have to put into her repair that would have to be charged to her fuel account. The engineer told me that she could make a round trip on considerably less coal than the other engines.

This road once had a great many kinds of engines but the present locomotive

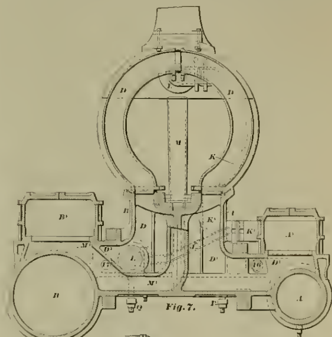

Fig. 7.

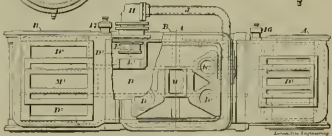

Fig. 8.

Locomotive Engineering

Details—Brooks Compound

superintendent has reduced the classes to three, and rests there.

The engines are fitted up with great care and are very handy for their kind. The vacuum-brake is used and the ejector pipe goes directly through the boiler and empties into an annular opening around the exhaust-nozzle

They use one little trick that seemed to me to be worth imitating. They have a tube made of perforated metal that is just the size of the water hole in the tank and reaching almost to the bottom, this has a flange at the top that prevents it from going entirely down and a pair of handles to lift it out. Coal or other foreign substances are thus kept out of the tank, for no matter if a pail full of coal falls in it makes no difference, anything that will go through the perforation will go through the injectors. This long basket can be lifted out instantly and emptied On suburban engines where coal is piled all over the man-hole as a rule, the device seems particularly useful.

Crown bars are used, and as they never wear out, but are used over and over, that form of boiler is still built

The front ends have a perforated tube the same size as the stack, extending down around the nozzles, the perforations are ⅜ inch or ½ inch by 4 inches long.

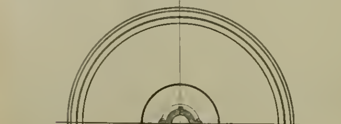
Mr. Ivatt has recently compounded the shop engine

They make their own engines and cars, in fact nearly everything they use, and more progressive ideas prevail than just across the Irish Sea, especially about their cars. Some new coaches just turned out are finished in natural wood and lighted by Pintsch gas. The English idea of beauty seems to be a white painted ceiling with a thin gilt molding. The modern American day coach with its quartered and carved oak finish is as a palace to a hovel when compared with the English carriage. These Irish cars look neat and clean. Their mail cars have an elaborate net for catching mail bags. This has an iron frame and a net of ropes fully four feet wide and twice that long, which folds up beside the car and is operated by a lever on the inside. They also have a cumbersome device for throwing bags off. It is said the bags often break the net, yet our Yankee hook seems to take them in without trouble.

The cars ride better than any compartment cars I rode in, and perhaps this can be accounted for by the system of balancing wheels. Mr. Ivatt does not believe in the knife-edge balance, and uses an ingenious device of his own. This is illustrated by the sketch. A pair of long carriage springs are placed as shown, one end fast to the floor and the other mounted on a guide, or slipper, free to move endwise. At the centers of the springs there are adjustable bronze boxes to take the journal of a pair of wheels. A light split pulley is bolted to the center of the axle, and a small round belt arranged to drive the wheels. When revolved the wheels show at once any unevenness in balance by moving the slippers. This is remedied by screwing weights upon the inside of the wheel-plates until the wheels can be run at the rate of sixty miles per hour without moving the springs. This is done with every pair of wheels, the weights marked in pounds and a record kept. It is claimed that a great saving in wear and tear, heating, etc., has been noticed since this was done, but the great result has been better riding cars.

All wood used for car frames, shops or permanent works is creosoted, a good plant being provided for this work.

Irish railroading is rather deliberate; of course this road runs the Irish mail, hauling the Atlantic mails and passengers from Queenstown to Dublin at a very high rate of speed, but this effort seems to take all the "hustle" of the road. I went down to Cork from Dublin on the engine. The driver was a jolly chap and anxious to know if I knew his two brothers in America, one an engine driver in Canada and one a machinist at Paterson. We ran fast enough between stations, but would loaf from five to ten minutes every time we stopped. There was a third-class carriage next the engine, and at one long stop where the driver took water and told me a five-act story, and the stoker oiled around, I heard an old fellow in the car say: "Tha dhriver has shtopped to bile the wather agin, I wonder phy they don't bile it runnin', like they do in England." J. A. H.



IRISH WHEEL-BALANCING DEVICE.

## Another Outrage.

Railroad companies do not get half the credit they deserve for benevolence. In some parts of the country the greater part of the poor people steal from railroad companies all the coal they use, and the privilege is regarded as almost a right. The Union Pacific Railroad Company put a high fence around one of their principal yards lately, and it nearly caused a riot in the town. People who were in fairly good circumstances complained bitterly about the curtailing of their privileges, and considered it very hard that they could not send their wagon to the coal cars in the yard to be loaded up without charge.

## At the Root of the Evil.

An overworked signalman caused a fatal railroad accident lately by jumping up when half asleep and pulling the wrong lever. The coroner's jury that sat on the accident have returned a verdict which is equivalent to one of manslaughter against the directors of the road. Among the directors are three members of Parliament. It would be a great boon to the managers of certain American railroads if coroners' juries would adopt this practice of going up to the fountain head when accidents occurred that were due to the policy of the company. We would then have more policy in favor of improved safety appliances.

---

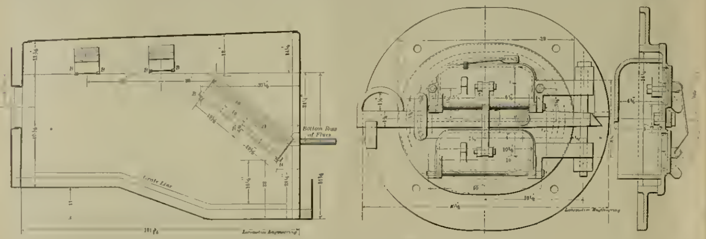
There is considerable friction on some railroads between the transportation and mechanical departments about the car rating of engines. The load and weight of cars is so varied that a number of cars of one kind that will be a light load for an engine will be beyond its capacity with another kind of cars. The only fair way to estimate the capacity of an engine is on a tonnage basis. Even that is not entirely satisfactory, for there is so much underbilling of freight that a ton is much heavier on some roads than on others.

## Illinois Central Fire Door and Brick Arch Arrangement.

Here is a new idea in brick arches now in use on the Illinois Central road. The usual arch and two smaller ones high up in the box and back of the main arch.

The fire-door has a deflector cast on the inside, as shown, and carries two long narrow doors hinged at the bottom and coupled together by a handle; a pull on this opens them both and admits air over the fire; this being deflected down by the shape of the door line, strikes the flames at an angle and rising is thoroughly mixed and ignited before escaping from the box.

The trouble from black smoke in Chicago has led to these devices being introduced, and it is said they prevent in a great measure this nuisance when properly handled.



ILLINOIS CENTRAL FIRE DOOR AND BRICK ARCH.

## Canadian Pacific Water Hose Coupling and Strainer.

The engraving shown herewith will give a very good idea of a new water hose coupling adopted by the C. P. road. As can be seen, the coupling is made something of the form of an air-brake coupling, but held together with a screw-and-lock nut.

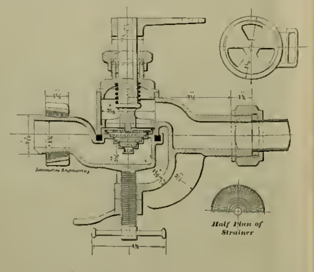
The piece fast on the engine, the right hand one in the cut, carries the valve, a flat one with three openings, as shown in the plan; the handle of this valve extends up into the cab, and is used the same as a lazy cock for pump.

The strainer is a cone-shaped cast-brass piece that merely sets into the tank half of coupling.

The tank, or hose piece of the device is very simple, having a side opening end with a recess for the rubber packing ring.

The lower arm of the main casting carries the screw and jam-nut to hold the device in position.

This coupling can be opened and closed almost instantly without nice adjustment for entering threads, in fact, it can be kicked apart—an advantage in cold climates.



CANADIAN PACIFIC HOSE COUPLING.

## Typical English Freight Engines.

The engraving shown on this page gives a very good idea of the average English freight engine. This machine was the type made by the Midland company until very recently, and the only change now made is to put the frames between the wheels and put the crank pins in the wheels themselves.

Typical English Freight Engine.

This engine has 17 x 24-inch cylinders and 62-inch wheels, with a rigid wheel-base 16 feet 6 inches.

The different locomotive works in the country were building these engines while the writer visited them this summer, an order for 100 having been divided between the principal builders.

The engines have wrought-iron driving-boxes case-hardened; horn blocks each side of them are made of chilled iron, there is no provision for taking up wear, yet they run two years without attention. Every joint in the spring and brake rigging is case-hardened.

All the joints about the cylinder heads, chests, etc., are scraped to a fit, every boiler-cock goes on to a wrought-iron boss riveted to the boiler with a scraped joint, all joints flanged, no screwed-in joints at all.

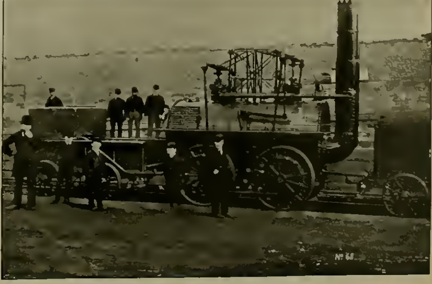
Everything about them is wrought-iron—no castings used worth mentioning. A great deal of the outside pieces are polished, such as the hand-rails, edge of frame and cab, buffers, rods, etc.

The inside cylinder allows the placing of the driving-wheels as shown, and does away with trucks of every kind, as you will see, the spring hangers are fast directly to the frame, no equalizers being employed; this causes them to ride uncomfortably, especially as the crew are obliged to stand up.

In front will be seen the sand-boxes, and between them a trap-door that when raised up exposes the cylinder-heads and chests, there being a lubricator in each cylinder-head.

## In the Oldest Locomotive Works in the World.

The shops of Robert Stephenson & Co., L'td., Newcastle-on-Tyne, England, are the oldest locomotive works in the world. Here George Stephenson constructed his "Billy" in 1825, and later on the "Rocket." One part of the works is the old shop in which this work was done It is a small stone building, in the center of which is a small crane, the jib and arm of wood and geared up with cast gears, just as thousands of its class are made to-day. This crane was made by George Stephenson himself, as was also the stationary engine still driving the tools. This engine is of the old-fashioned beam type. The connecting-rod for crosshead is connected to a walking-beam near its center, one end of which is pivoted to a vertical standard from the frame and the other end carries the connecting rod to the crank The balance wheel is of wood. The plate on the frame reads," Built by Robt. Stephenson & Co., Newcastle, 1823." The only renewal has been a new cylinder For seventy years this old engine has been at work faithfully, but it is now proposed to replace it by a modern high-speeder and let it rest on its past record.



George Stephenson's First-Born.

These shops are far, far behind the age. There are very few new or modern tools to be found in the place and no old ones seem ever to have escaped.

The introduction of cast-steel in Europe has made many special tools for making and finishing wrought-iron wheels obsolete.

The manager of the works, Mr. Crow, is a very ingenious man, and has invented many tools; one, a shaper for cutting out the inside of the wheel rim on a circle is used in many English shops. He also invented a very ingenious drill table, by the use of which it is possible to drill all the holes in a crooked or twisted bar of iron at one setting; this is useful there where so many forged pieces are employed.

Most of the lathes and planers are very old and decrepid. Copper fireboxes are used exclusively, and some special tools are employed to stay the crowns. Crown bars run lengthwise, and, by the way, are now generally made of cast-steel with the thimbles cast on them instead of bolts and nuts; tap-bolts are usually screwed into threads. Great care is taken, however, to make the bolt fit the hole in the sheet. After the box is done and the holes made, a template crown-bar is placed in position and fastened down; this template has long, straight holes in every thimble, this hole is used to guide a reamer, the end of which is plain to go into hole, this reamer cuts out the hole in the sheet on a taper and a cutter faces off the sheet. This insures a tight joint, as all the tap-bolts are taper under the head, and the inside of head is faced true. Copper or brass flues are used, and we noticed one that had a piece broken off the end in expanding was put into a crude old drawing device and drawn out until long enough, this, of course, making it smaller in diameter.

The best tools in the place are the heavy slotters and wheel lathes—the slab-framed engine is made on a slotter, anyway.

They do some metal sawing, mostly thin material. We noticed that these saws were sharpened on an American saw-filer.

One machine planes and bores both cylinders and chests at one setting.

The grinding room is a feature of all English shops, many large grindstones are used to finish bright parts

One thing was noticeable, the elaborate smoke-flue in the erecting shop. Between each track, long pits, there is a smoke tunnel, these being connected to a large stack At intervals along the tunnel there are connections and a pipe running up higher than the stacks of the engines. When they fire up a new engine to test it, they connect an elbow to the stack and draw the products of combustion into the tunnel, this leaves the shop clear for cranes.

They were building ten suburban tank engines during our visit and some small engines for China Work is very dull, not over 20 engines going out in a year, where they used to build 80.

After visiting other modern shops in that country it seems wonderful that this sleepy old place could build a locomotive at all and compete in the open market.

For years the old "Rocket" lay around these shops and was finally given to the South Kensington Museum. On the end of the high level bridge, also built by Stephenson, stands as a monument, Stephenson's "Billy," just like the engine in the picture, this one, "Locomotion," being shown at the Darlington exposition These old engines had extra crank-pin bosses cast in the wheels, so that if a pin was broken off, or had cracked or worn the hole, a new pin could be put in a new hole.

---

The people of Illinois are talking of a fast run made on the Chicago & Alton with an engine and single car containing Vice President-elect Stevenson A run of 131 miles was made in 155 minutes with several stops. It was said that during the trip 15.9 miles was run in twelve minutes. The run was no doubt very fast for Illinois.

---

They were nearly having a strike of car repairers on the Santa Fé at Raton, lately, under rather peculiar circumstances. A man who was working in the car-repair shop was building a house for himself One day it was found that he came to the shops and checked and then sneaked out and went to work on his house. It was also found that he was using some of the company's lumber in building his house. For the double offense he was discharged He belonged to the Brotherhood of Car Repairers, and the local lodge took up the case and demanded the man's reinstatement. The company stood firm, and the local lodge did not venture to call on the organization at large to make an issue on such a case.

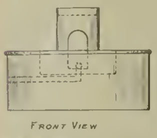
## Railroad Blacksmithing.

By W. G. Lottis

In the last Locomotive Engineering I promised to explain the benefit of the different forge fires as represented.

In the first place a fire as represented in Figs. 1 and 2, effects saving of fuel, the next thing is the rapid and uniform heating, if your work requires it. But for steel and tool-work you generally want a low and uniform heat, and not too rapid.

*Fig. 1*



Front View

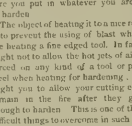
Especially for annealing and hardening you use a fire of this kind after it is coked enough, which will only take one half or three-quarters of an hour, and it gives the best satisfaction of anything I have seen. You have the same heat all around, which is one of the most important things in annealing and hardening steel. If you take and use a keen blast for a few minutes so as to do away with black spots in your fire, and get your coke or charcoal to a nice red heat, then shut off your blast and put in your steel and take a small piece of sheet-iron and set it up against each opening you will find that your steel will heat as quickly as it will in a furnace, and just as uniform if not more so. The center will be as hot as the outside. This is the best way to heat for annealing. I am satisfied, and especially where you have nothing but the forge to do it with. It must be remembered that an uneven heat for annealing has the same effect as it has for tempering, for the higher the heat the greater the expansion, and unequal heat must certainly cause unequal expansion and unequal strain. To convince yourself of this take a circular saw ⅛-inch thick and from 6 to 18 inches in diameter, or any other piece of steel the same size, take and heat it to a perfect uniform heat and put it in dry lime or fine dry charcoal and leave there until cold. When you take it out it is perfectly straight. Then take and heat ¼ of it or ½ to a light-blue heat, then let it cool off slow, and you will find that your piece has warped.

Now, a great many smiths believe that by heating this same piece red-hot and straightening it while it is red-hot, and putting it back in the lime or charcoal and leaving it until it is cold, that the treatment will do away with the unequal strain that was put on by the heating of ¼ or ½ of it, or any uneven heat that may have been put on in the above-stated way. Now this is a mistake. About the only way to do away with this unequal strain is to take the piece after you have warped it, and heat it red-hot, having a perfect uniform and low heat on it, and put it in your lime or charcoal, being careful that your lime or charcoal is perfectly dry, and your piece covered air-tight and left until cold, then taken and filed, planed, turned or ground. If heated right for hardening, it ought to come out straight, at least straight enough, so that it can be trued up by very little grinding, but pains and time must be taken in heating for hardening. Your piece must be heated uniform, it will not do to allow it to heat more rapidly in one place than another. If you do you will cause unequal expansion, which induces unequal strain, and the piece will surely warp in hardening.

There is a large percentage of tools spoiled by allowing them to heat more rapidly in one place than in another, which cannot be prevented in an ordinary open forge fire as represented in Fig. 6, and especially when smiths have not learned enough to build a fire that will give them coke enough in one day to last the next day, and use it in the place of green coal. There is a large percentage of blacksmiths that still burn green coal in the place of coke, especially in agriculture shops. You take a fire, as represented in Fig. 1 and 2, and it can be used for hardening most any kind of a tool, while Fig. 4 is just as good for short taps, milling cutters or any tool that you don't want to be hardened over 8 or 10 inches in length. Fill up with charcoal and let the fire heat to a nice red heat before you put in whatever you are going to harden.

The object of heating it to a nice red heat is to prevent the using of blast while you are heating a fine edged tool. In fact, you ought not to allow the hot jets of air to be forced on any kind of a tool or piece of steel when heating for hardening, neither ought you to allow your cutting edges to remain in the fire after they get hot enough to harden. This is one of the most difficult things to overcome in such articles as large reamers, taps and milling cutters. You take a tap or reamer 2 inches in diameter and if your fire is anyway hot your cutting parts will be red hot when the body is still at black heat, which certainly causes uneven expansion, and has a tendency to shorten your tap, because by heating your cutting parts to red-heat and leaving your body at a black-heat, you expand your cutting parts again as much as your body, but the body being by far the strongest, won't allow the cutting parts to expand more than it does itself, and the result is that your cutting parts must upset when they get any hotter than the body. Now, the question may be asked, will the cutting parts carry the body with them if laid down and let cool slowly? The answer would be no, if the tap is 2 inches in diameter. But if you take a tap 1 inch in diameter and which has been properly annealed before it went to the machine shop, it will generally get shorter by heating in the above stated way and letting it cool slowly because your cutting parts contain about as much material as your body. If, however, you take either one of these pieces and heat them as already explained, having your cutting parts a red heat and your body a black, and quench them instantly after you get them to a refining heat in a solution that will cool quickly enough to refine, you will find that it will shorten nearly as much again as it would by having a perfect uniform heat on it. At least that has been my experience, and that is one of the objections to the lead-bath for hardening, especially such as long stay-bolt taps, for your lead will heat your outside so quick that your center has no chance to get hot unless you soak your tap until the heat runs through, and if you do that you are going to spoil your tap. It will be an open and porous grain.

*Fig. 2.*



Side View.

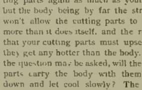


*Fig. 6.*

In order to refine your steel you must quench it as soon as you get it to the lowest heat it will refine at, and especially when you heat it in hot lead. I don't know of any place you can spoil steel quicker than you can in hot lead, for you have got to judge your heat from the looks of your lead pot on the outside which requires considerable practice and good judgment, especially when you have three or four different grades or makes of steel.

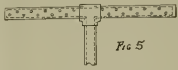

*Fig 5*

One of the necessaries in hardening taps in the above-stated way is seven or eight hours' sleep, and cold water is a very suitable drink the night before.

Another one of the benefits of a fire as represented in Fig. 1 and 2, is the preventing of getting fire blind, because the smith is not looking direct into the bright blazing fire all the time neither has he got the heat in his face and eyes.

Now I know that a great many toolsmiths won't place any confidence in this argument, neither will they believe that the fire has any such effect on their eyes as would cause them to over-heat a piece of steel.

If any smith wants to convince himself of this, let him take a welding heat on a piece of iron, or look into a white-hot fire for a few minutes, and then take a piece of high carbon steel, or an old tap or reamer, and try to get a low uniform heat on it. Take the lowest heat you think your steel will harden at and don't satisfy yourself the first time but try it five or six times and by breaking off your five or six hardened pieces you will find that you won't have three alike in grain.

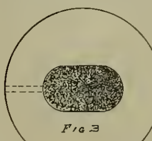

*Fig 3*

Top View.

It is deceiving enough to cause you to quench your steel at such different heats that it can be seen in the grain of your steel. It certainly ought not to puzzle you when you get three good taps and three poor ones that are made of the same bar of steel. If followed up, you will find that it happens quite often, especially in a railroad shop, where every man carries his own tools to the toolsmith and you have five or six men standing around you, all in a hurry for their tools, the tool-room man with a tap, the latheman with a lathe tool, the planer man with a planer tool, the floorman with a chipping chisel or scraper, the boiler-maker with a calking tool or a cape chisel, the carpenter with a plane knife and the roundhouse man with a ratchet drill, not saying anything about the section foreman and car repairers. Now, all of these tools are different in shape and have got to be forged and hardened differently, and the toolsmith is expected to do a good job on all of them. Perhaps he has got two or three of them in an open fire at a time, trying to get them out of his way as quickly as he can. Perhaps he is not thinking or not knowing the result that will come from soaking his tools in an open fire, as represented in Fig. 6, the cold air striking it on one side and the hot jets of air from the other side, and as a rule the cutting edges are down buried with green coal or coke where the smith cannot see it. The result is, the cutting edges are generally overheated, where if you had a fire as represented in Fig. 4 you could plainly see your cutting edges and would not overheat them once where you would five times in an open fire, as represented in Fig. 6.

## American Cars in England.

In a recent railroad collision in England a Pullman car withstood the shock which crushed the carriages ahead of it, and thus saved the rear of the train.

An Englishman writes to the London *Times* to say that similar results have been observed wherever fore-end collisions have occurred to English trains including one of the new Pullmans. The structure of the American car prevents telescoping, and the strength of its frame, together with its peculiar platform and buffer arrangements, makes crushing very difficult.

This Englishman urges the adoption of the American system of construction even to the vestibule, which he regards as a safety device worth copying, apart from the superior convenience and comfort of the American car.

Some progress in overcoming British prejudice in this matter has been already made. On nearly all the great lines our British cousins now run occasional cars which they call Pullmans, and they show a disposition grumblingly to admire them and grudgingly to enjoy their superior comfort.

These cars are not our Pullmans by any means. They are only about one-half as long as ours and less than two-thirds as wide. They have double seats on one side and single seats on the other, with an extremely narrow aisle between. To the American traveler they seem uncomfortably lacking in room and otherwise a poor imitation.

Unfortunately they are the best that our English friends can have, now or hereafter. Their tunnels and masonry road bridges have been solidly built to accommodate cars of the foreign pattern. They are not wide enough to permit ordinary American cars to pass through them. English roads must continue to run narrow cars, and without additional width they cannot make their cars the comfortable, luxurious affairs that ours are. They may get rid of the compartment system however. They may add many conveniences which they now lack. They may take profitable lessons in the matter of strong building, and above all they may step forward forty years by abandoning the old two-wheeled truck which still prevails everywhere in Europe to the great discomfort of passengers.—*New York World*.

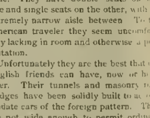

*Fig 4*

Front View

Railroad men may be depended upon to find the most epigrammatic by-name for a railroad. They are calling the Pike's Peak railroad the "Cogwheel Route."

The Rogers Locomotive Works have just finished the building of a two-cylinder compound locomotive.

## A Railroad Man's Paradise.

It was my good fortune to make a very long journey lately, which took me through the grandest and most romantic scenery on this continent. There were so many beautiful places seen, and the attractions and climate were so numerous, that it seems invidious to decide on one region surpassing all others in the charms that please without alloy. We traversed plains and valleys without number that were good to look upon; we passed through defiles where the earth seems to be rent in twain, and mountain, wood and stream combined to form scenes of the wildest grandeur. There were between these extremes many picturesque vales with bluffs and brae sufficient to break the monotony and to lend beauty to retreats that nature had blessed with fertility and bloom. To see all these allurements and to select one scene as attractive beyond others may appear narrow. The restful and subdued grandeur of one cañon enamored me far more than any other scene of the journey.

We had been traveling on the Atchison, Topeka & Santa Fé, through Kansas, Colorado and New Mexico. We had looked upon prairie and plain till we wished that the earth was not quite so flat, we had crossed spurs of the Rocky Mountain range, and while watching the tortuous windings of the train and noting its angle from the perpendicular, were inclined to regret the absence of monotonous levels. But every change had its attractions, every new scene its own beauties. After nightfall our car was detached from the main-line train, and a fiercely puffing little engine dragged us up four or five miles into what seemed to be the heart of the mountains. There was little to be seen but silhouettes of cloud-like mountains and solemn shadows. Then a turn of the track brought us facing the glare of electric lights and the sheen from the numerous windows of a great building.

In the morning we were up with the sun to examine the famous Las Vegas hot springs. These springs have probably been famous ever since human beings with diseases to cure were within reach of the place. This region is the center of what was once a great civilization. The peaceful people whom savage enemies turned into cliff-dwellers no doubt bathed in the waters of these warm springs long before the pioneer robbers from Europe devastated Mexico. It is certain that the savage Indians who roamed here in the period between the two civilizations resorted to the springs to remedy all their ailments.

The hot springs stream up through the limestone rocks all over a small dale at the side of a rapid creek, the water varying in temperature from blood heat to 140 degrees Fahrenheit. The place is in a widened cañon, which in some countries would be called a glen. Bold mountains, whose sides are covered with brush and pine trees, extend upward on each side of the creek, and the folds and furrows which the tumult of their molding and the ravages of storm and flood have put upon these great ridges form scenes that are varied, imposing and interesting.

On a sloping hillside above the springs, in a most commanding position, stands the Montezuma Hotel, the electric-lighted structure which had appeared so conspicuous in the dark cañon. It is an exceedingly handsome building, said to be one of the most comfortable hotels in the country. Our company was shown through the hotel, and it certainly had a most attractive appearance. There were several well-known railroad men staying there for rest and the benefit of the springs, and they all talked enthusiastically about the comfort and health-inspiring features of the place. The hotel is fitted up with all metropolitan luxuries and conveniences. Water as pure as that from the skies is brought from a neighboring mountain, the rooms are warmed by steam, and the house and grounds are lighted by electricity. All that money directed by refined taste can do has been exerted to give artistic finish to nature's striking surroundings.

A novelty in connection with this hotel is the water reservoir, which is a square cistern some 20 feet deep, and 50 feet of a side cut out of the solid limestone rock. This reservoir is on the top of a hill behind the hotel, and is also the source of ice supply. A chute leads from its brink to the ice houses 300 feet below, and the hotel enjoys the use of ice made from perfectly pure water.

The climate is perfect. The average throughout the year is a cool summer temperature. Here the student can rest, with rich inspirations before him for future thought. Here the active man may breathe pure air and bathe in life-giving water, while the energy that will not be stifled may be worked off by rambles over the aspiring mountains. The lover of scenery will find many a memorable view with little exertion, the sportsman may fish or hunt, and the naturalist will find abundant novel fields rich in animal, vegetable and mineral specimens. The invalid finds that the equable climate, the alkaline-saline water and the careful nursing to be health-inspiring, and even the lazy man finds it a good place to rest and escape exertion. The weary editor drinks in the scene—and the water—and exclaims "Wouldn't this be a glorious place to write in, unworried by the man with the new car-coupler and the inventor with the new form of compound engine?" and he hopes some time to come here and work at his book. But we must return to the stern realities of life and only dream of the clear bubbling springs, the rugged cañon, the breezy hillsides glittering in the sunshine, the waving pines, and the creek wimpling over its rocky bed.

A. S.

## In Castle Gate, Utah.

Our engraving, reproduced direct from a photograph, shows a very striking point on the Rio Grande Western, in Price Cañon, the East Portal of Castle Gate.

At every turn of the road—and it's all turns—the tourist sees something grand in nature when he goes over the D. & R. G., on the Rio Grande Western.

The noted scenery of Europe is fine, mostly because of the historic interest and the evidence of man's work for ages there, but for grandeur of natural scenery the Rocky Mountains have more to offer in a single pass than the Alps have in a whole country; the Hudson is finer than the Rhine and the St. Lawrence has more natural beauty per mile than the much advertised and aped-after Dutch stream has from A to Izzard.

In Castle Gate, Utah.

## Railway Notes From Australia.

BY I. VUITAUL.

There is a great deal of discontent among the engine drivers of Victoria, owing to a movement being made to curtail their pay. Some parties, who are evidently looking for an excuse to do the engine drivers injustice, are insisting that the guards have as important duty to perform as the engine drivers, and that the former are paid 40 per cent. less than the latter. That on account of this, pay ought to be equalized, the drivers' reduced and the guards' increased. The highest pay for engine drivers has been the first class, which was 15s. per day. This was made an honorary class, to which six men were admitted yearly on the recommendation of the locomotive superintendent. This has been done away with. At the present time promotion in all classes has been canceled for three years.

As regards the responsibility of the guards, it has been reduced to a minimum through the introduction of the Westinghouse brake, which has done away with the necessity of getting out of the van at night and dropping brakes in the bank. The block system, which has been introduced of late years, has also relieved the guard of the responsibility which he formerly had, so that the guard of the present day has what is commonly called a rosy time of it, especially on night goods trains, which are generally run through.

Having started his train on the journey, the guard coils himself up in his overcoat and sleeps the sleep of one who has done his duty. Should the van begin to rock too much going down a bank for him to rest in comfort, he gets up and screws the brake on to steady the van a bit and returns to his slumbers at once and forgets to release the brake. When the train sticks on the next bank and the driver goes back to see what is the matter, he finds the van brake blocks red hot and the man with the responsibility of the train slumbering peacefully.

I will give you one illustration. About eighteen months ago a train left Melbourne for Woodend with a through load of coal. It is an up-grade all the way. The brake was only partly through the train. When about 22 miles out, the train divided and the van and eight trucks proceeded back to Melbourne. The signalman, seeing the train going back on the wrong road, signaled to the other station, and a following train was shunted just in time to let the runaway pass. At the Melbourne end there is a mile of level road, so by putting gravel along the rails, they succeeded in reducing the speed sufficiently for one of the shunters to get on the van and apply the brake and stop the train. Then they found the guard sleeping soundly and none the worse for his ride.

As to a driver, his responsibility has increased in every way with the improvements introduced, as he has to take responsibilities which were formerly shared by the guard. The rolling stock consists of two classes of old four-wheel or English style of wagon, with the old style of Westinghouse brake, and the new eight-wheeled or American class of wagon, which are fitted with the new quick-action triple-valve. When a driver gets a train of these cars mixed up with a couple of passenger cars at the back, you can imagine the care that must be exercised to handle the brake and keep from knocking the passengers from one car to another.

---

Not a few of our readers would do a wise thing by being guided by the advice of "Geo. L. De Witt," who has his say in another page under the heading, "The Mechanical Department." George does not sign the name he is usually known by, but his advice is nevertheless quite wholesome. He is an old master mechanic himself and knows what he is writing about. There are often good excuses for the heads of railroad shops engaging in the manufacture of tools and the doing of other work besides that of repairs, but the practices are generally followed with the belief that the articles can be made cheaper than they can be bought. This idea is nearly always based on misconceptions. The actual cost has not all been counted. But there is something fascinating about being able to point out tools of home manufacture. The man who is tempted, however, is encouraging his own downfall.

---

The railroad companies using retaining valves on their freight cars are nearly all making the fittings of cast-iron, because when made of brass the parts are stolen by petty thieves. Even the cheap material does not always prevent the thieves from getting in their work. The entire cars would be stolen in some sections if they were not too heavy to carry away.

## Rights and Wrongs in Using the M. C. B. Car Coupler.

Railroad men are a remarkably busy class, and it is not surprising that they sometimes forget things which ought to be remembered. There has lately been a lapse of memory among railroad managers and their advisors which is liable to involve serious consequences. In 1888, when the adopting of a standard type of car-coupler by the Master Car Builders Association was under consideration, it was found that certain contour lines must be established for the vertical-plane form of coupler, and the lines patented by the Janney Car Coupler Company were the lines most to be desired. In negotiations with the Executive Committee of the Master Car Builders' Association, the directors of the Janney Car Coupler Company agreed to waive all claims for patent on contour lines of the coupling used on railroads that belonged to the Master Car Builders' Association. The only conditions imposed were that, before applying to cars couplers with the Janney contour lines, railroad companies should apply to the Janney Car Coupler Company for permission to use the lines. An agreement was made between the Master Car Builders' Association and the Janney Car Coupler Company, and the contour lines of the latter company's coupler were adopted as standard of the Master Car Builders' Association.

That was four years ago, and the different railroad companies have been applying the standard coupler in large numbers. Nearly every maker of this type of coupler—and they are already legion—adopted the standard contour lines and made their couplers to conform to the same—an act highly important if the different makes of couplers are to be shaped so that they will couple together and keep coupled. The Janney Company had agreed to permit any maker of car-couplers to follow their contour lines and to apply them to cars on condition that the railroad company asked for the right of application. After the standard lines were adopted, a few railroad companies which used standard couplers other than the Janney, applied for the legal right to use the contour lines, but cases of this kind were the exception rather than the rule. Many railroad companies adopted the M. C. B. standard coupler and began purchasing them from different makers without remembering to go through the formality of asking for the legal right. There is a certain type of railroad manager, with many representatives, who has got into a painfully embarrassing position in this coupler matter. He is the kind of man who is constantly harassed lest the original patentee of an article should build up a monopoly on the rights to the invention. To guard against this danger to society, the railroad manager is always ready to patronize imitations, and he is inclined to wantonly ignore the presumed rights of the original inventor. These men have carefully avoided using the Janney coupler proper, and few of them have applied for legal permission to use the patented lines. We understand that the officers of the Janney coupler company have been looking over their fences lately and taking notes of the trespassers. It will serve more than one manager justly if his company is compelled to pay royalty on all the standard couplers in use, and there is said to be some prospect of the car-coupler people asserting their rights.

## The Traveling Engineers' Association.

The preliminary meeting, held at the Lake Shore roundhouse in Chicago, Nov. 12th, served to confirm the opinion of the projectors that the traveling engineers or road foremen of engines of this country ought to have an association of their own; and a baker's dozen of good men issued a call that's sure to bring a goodly number of traveling engineers together, and men interested in one line of work cannot meet without exchanging views and "talking shop," and they can't talk shop without gaining information themselves, and information to a good traveling engineer means information to all the men who come under his instruction.

Traveling engineers are usually selected from the best runners; they are officials, and are expected to stand between the officers of the company and the men, and, when the right kind of a man is selected, he improves conditions for both.

He is the man consulted to see if actual every-day practice stands in the way of putting into force some plan that seems to the commercial men of the road to be an improvement. It is to the traveling engineer that the officials of the motive power department trust to report condition of power and recommend changes or repairs. He is expected to know and test the qualifications of firemen before they are promoted, and to go out with every new man to see that he gets over the road without trouble.

The road foreman must be able to instruct those who are deficient in knowledge of how to handle the brakes, etc., and ought to be able to *show* a fireman how to fire just as well as to *tell* him.

Few railroad men realize how important the position is and what possibilities for good or ill lay in it.

It is important that the duties and results aimed at by this class of men be as nearly uniform as possible and that they should get together once a year to exchange ideas and report on methods of reaching desired ends. We believe the higher officers of our American roads will be only too glad to encourage this new association, as its only aim will be "How best to improve the engine service of American railroads."

The constitution and by-laws will be as brief as possible, the meetings will be open, and only such subjects as relate to the aims of the association discussed.

The expense to members will be very small—not above $5 per year, if that—and it is hoped that the ship may sail on her maiden trip with a large volunteer crew on January 9th. If you are a traveling engineer or road foreman, see the "call" elsewhere in this paper—see it, and be "one" of the fathers."

## Articles on Blacksmithing.

We would like to direct the attention of men in charge of railroad shops to the valuable articles on blacksmithing which Mr. W. G. Lottes is contributing to our pages. The literature of the blacksmith's art is exceedingly limited, and good articles by a practical blacksmith who is a master of his business ought to be of great value. There are suggestions in Mr. Lottes' articles which would give valuable information to nearly all blacksmiths and would lead to improved work in this important department. How often do we hear complaints about the finest grades of steel being lacking in uniformity. Milling cutters and other expensive tools frequently break immediately after being put in use, and the cause of the breakage is a mystery. The points given in the articles referred to make it plain how unexpected failures may naturally happen.

It would be for the interest of railroad companies for the officers in charge of shops to see that these articles were brought to the notice of their blacksmiths. Complaints are often made that blacksmiths, as a class, display little interest in the literature of their business. We think this is due to the fact that very few men have written on this business whose views are of a practical and reliable character. The articles presented in LOCOMOTIVE ENGINEERING are both practical and reliable.

## Concerning Track Ties.

In the course of a recent extended journey the writer accompanied railroad officers of different lines on tours of inspection. The condition of bridges and track received searching attention, and there was much talk among the railroad men about how the problem of maintaining track in first-class order could be worked out at the least expense. Keep down the expense is everywhere repeated and emphasized, but keep the structure in first-class order is still more emphatically enjoined. The great difficulty everywhere encountered is that of ties for the rails. Ties seem to be scarce everywhere, and the most desirable quality is hardly to be obtained. The next question is how to make the best of the ties to be had. These are mostly of soft wood which has many faults. As heard from the voice of the railroad officer, the leading faults of soft wood ties are the rail rapidly beds itself into the tie and the spikes do not hold tenaciously enough to make soft wood ties safe on curves.

With all due respect to the men who abuse soft wood ties for the shortcomings of the material, we, as onlookers, would soy that the principal mistake made is in treating a soft tie in the same way that a hard wood tie used to be dealt with, and then complaining because it fails to give satisfaction. The material ought to receive treatment adapted to obtain all the strength possible out of its weakness. No link of the railroad structure has been more barbarously used than the hard wood tie. Under the very worst usage it gave fair results in efficiency and durability, and it is natural that men should be impatient when a weaker material fails to come up smiling out of the same hard ordeal. There is a wonderful absence of elasticity in the method of management pursued by some classes of railroad men. This tie question is a good illustration. Instead of treating soft ties as if they were made of the toughest oak, the men responsible for the roadbed ought to consider what kind of treatment would secure the best service from the ties that are now becoming most common. Were this done there would be a general introduction of plates to prevent the rail imbedding itself into the ties, spikes that have greater holding tenacity than the common destructive article would be generally employed, and some simple plan for re-enforcing the fastenings at curves would be used. If this line of treatment was accorded to the soft tie its life and usefulness would be very much increased. This kind of policy must be adopted some time, and it is better that it should begin at once, for there is no possibility of the tough hard-wood tie ever meeting the supply again.

Some railroad officers think that metallic ties will soon take the place of wood, and that the new material will put an end to all the tribulations connected with rail-fastening. It is likely that this change will come eventually, but it is not now in sight. The experiments with metallic ties have not been satisfactory. They are used to a great extent in India, but the traffic is light and slow, and passengers there have no voice in restraining the use of appliances that cause discomfort. People in America would not stand the noise that this fastening introduces, and there are other shortcomings to the metal tie which will cause our railroad companies to cling to wood as long as the material can be had.

If the use of wooden ties is to be continued, it looks as if railroad companies would find it to their interest to introduce processes for preventing the rapid decay of the timber. The annual demand for ties is now said to be about 80,000,000. Any improvement which would prolong the life of a tie for one year will help to provide against the inevitable day of exhaustion of the forests. The most promising aid in this line is in preservative processes. The Southern Pacific Company have an extensive plant at Oakland, Cal., for the preservation of timber, and the officers of the road speak very highly about the economical results obtained. In Europe, where ties are very expensive, the practice of subjecting them to a preserving process before putting them down is general. There are two leading processes followed for the preservation of timber. One is what is known as creosoting, which consists of replacing the juices of the timber by heavy oil of tar. The other process is called burnettizing, and consists of injecting chloride of zinc into the pores of the wood. Those who have had experience with the different processes say that chloride of sodium or common salt is just as good as chloride of zinc, and that both are worthless where the timber gets soaked with water, for then the preserving ingredient gets washed out. When good creosote is used, a hemlock or pine tie will last as long as oak as far as decay is concerned.

---

The engineers and firemen of the B. C. R. & N., at Cedar Rapids, Iowa, have organized what they call the "Locomotive Educational Association." They have rented rooms and fixed them up in neat shape, put in a valve-motion model and some good books, and are discussing live subjects relating to their work. All this can have but one result—better posted enginemen. We notice in their plan that members are expected to ask questions and make statements; this is hard to do, men, especially engineers, dislike to ask information on subjects that they are supposed to know about. Some experience of the writer in this line developed a better plan; we had a "question box," a cigar box with a slot in the cover; into this any question about locomotives or rolling stock could be placed; no one knew who asked the question; these were taken out at random and the subject talked over. This plan prevents embarrassment and lets the information sift through the service, a benefit to all. We are glad that the master mechanic, general foreman and traveling engineer, all take an active interest.

---

The Southern California Railroad people are changing one of their locomotives to adapt it for the burning of anthracite coal. There are large deposits of this coal on the Santa Fé system, and the intention is to use it on the Pacific slope locomotives.

## Varying Temperature of Passenger Cars.

Winter weather has come upon us rather earlier than usual this year, and with the necessity for heat comes the complaints about the suffering from the varying temperature of cars. A great want in our steam-heated cars is some means of holding the temperature to a range which is some distance away from the freezing and also from the boiling point. Extremes in this thing are much to be avoided, but the average porter and brakeman, to whom the regulation of car temperature is relegated, delights in extremes. There appears to be very loose training among the porters of the Wagner car service in the small details which do so much to influence the comfort of passengers, and attention to the regulation of car temperature seems not yet to be reached. We would respectfully beseech the Wagner Car Company to give this matter their attention before the winter is over. Pullman's people manage to keep their cars endurable, and we cannot understand why the other sleeping-car company cannot do the same thing if they will only try and go about the business in the right way.

While on this subject, we would suggest to division superintendents that they ride in the day cars occasionally and note the manner in which brakemen attend to the regulating of the heat. A thermometer is not a bad thing to use in regulating the temperature of a car. We decidedly prefer it to the sensations of a brakeman, for the latter are not so regular as a discriminating public might be inclined to demand. At one time a brakeman has been out flagging and when called in runs up to the car and reaches it heated and perspiring. The car seems stifling, and he goes through, pulling open the sashes and lets them stay open till a freezing temperature causes complaint. Next time he goes back he gets well chilled and takes his time returning to the train. The cars seem too cool for his frozen limbs, and he closes all the inlets for air and turns the cars into hot ovens. This kind of change may be amusing to some people but it is annoying and distressing to others. If it was the custom to hold conductors responsible for keeping the temperature of the cars fairly equable, and inspection by superintendents or train masters were made occasionally, it would greatly enhance the comfort of the unfortunate beings who have to travel in railroad trains during the winter.

## Vapor Needed in Combustion.

Scientific writers on combustion of fuel have always maintained that any vapor of water present in a fire causes a waste of heat. It is taught that dampness in the fuel or steam admitted to the fire in the process of injecting air all detracts from the heating efficiency of the fuel to the extent of the amount of fuel necessary to raise the water or steam to the temperature of the gases of combustion. In a paper read before the British Association lately, an eminent engineer controverts the old theory, and holds that combustion in a furnace cannot take place properly unless aqueous vapor is present. The experience obtained in laboratories and in blast furnaces with perfectly dry air in the combustion of gas, leads to the belief that the new theory is well founded. The efficiency of the fuel has been increased by admitting steam along with the air.

This thing has been noticed repeatedly in connection with the introduction of the Clark jet for introducing air through the sides of locomotive fireboxes. As the increase of efficiency could not all be due to the increased supply of air, certain patentees of smoke-preventing devices entailing the use of the Clark jet, held that the steam acted as fuel. Science ridiculed the claim, but it looks now as if the claim was partly correct. The act of combustion has always been considered complex, but there appears yet to be mysteries to it which science has not elucidated.

## Pay of Men on Chicago Elevated.

Executive Order No. 1 of the Chicago & South Side (elevated) road defines the hours of duty and rates of pay for all men in the transportation department. We observe that the rate of pay for machinists, blacksmiths, etc., is $3 for ten hours' work. Engineers and firemen work eight hours and fifteen minutes for a day; engineers receive $3.50 per day for the first six months, $3.75 for the second six months, $4 for the second year, $4.25 for the third, and $4.50 thereafter. Firemen get $2.25 for the first six months, $2.50 for the second, and $2.75 thereafter. This is extraordinary good pay and ought to bring to the road an excellent class of men; the work is not hard, there is no danger on the structure except from carelessness, and the hours short and rest regular. The management of this road seem to be inclined to do well by the men; during the recent Columbian celebration in the city there was a rush on the new elevated, but it was carried without mishap, and General Manager Barnard, in writing a letter of thanks and congratulation to the men, added these interesting and important words

"In expressing his warm personal thanks to each officer and employé who, by his energy and devotion contributed to this result, the General Manager has pleasure in announcing that in recognition of their services a day's pay will be added on the October pay-roll to the time of each officer and employé of the operating department."

---

We have repeatedly heard the expression used about railroad officers. "He is a good Methodist, a good Catholic, a good Mason, a good Democrat, etc." We venture to say that when a man lets his religion, his clubs or his politics enter into his business, that he is a very unprofitable railroad man. One in charge of men, who selects for promotion or for special positions men whose religion or politics is the recommendation, is certain to serve his employers badly. The influences of church or party should be kept outside of railroad life.

---

Among the questions that have come in for answers during the last month, there are several that are too puerile to deserve reply. If those who send in questions would try to do a little thinking for themselves they would not send queries that are silly. Some of them would be ashamed to see their names and addresses put to their questions.

## NEW BOOKS.

MODERN LOCOMOTIVE CONSTRUCTION. By J. G. A. Meyer, associate editor of the *American Machinist*, formerly chief draughtsman Grant Locomotive Works. Published by John Wiley & Sons, New York. Price $10.

Probably no mechanical book has ever been so anxiously awaited as this one has, or will be more welcome to the more advanced locomotive men, those in charge of design, repairs etc., as well as many who simply want a ready reference to keep them straight on rules and formulæ needed in their work. Mr. Meyer contributed the first chapters of this work to the columns of his paper, and the subject-matter of the book has become well known. Any student who wants to know the why and wherefore, who wants to know how the size, proportion and strength are figured for every piece in a locomotive, needs this work. It has all the best rules for figuring out valve motion, adhesion or any other point necessary to determine in a locomotive. It gives proportions and strength of every part of the boiler, the values of different materials, and how to figure all the strains a boiler is subject to. There are more than 1,000 illustrations in the book, every detail of a locomotive being shown and proportions given. This is the book needed by all the young men who have written us for something to guide them in building a small locomotive and the many more who write weekly for a book "naming every part of a locomotive and showing a picture of it." The book will become a standard and remain so until the form of the modern locomotive shall have been radically changed.

THE LOCOMOTIVE ENGINE AND ITS DEVELOPMENT. By Clement E. Stretton C. E., author of "Safe Railway Working." Crosby, Lockwood & Son. London. Price 3*s*. 6*d*.

This is an 8vo of 154 pages, on the early history of the locomotive in England. It is profusely illustrated and is very interesting to one who likes to read up on the development of the modern locomotive. The author is one of the best posted men in England and being disinterested his reports on various practices are better than a biased judge; for instance, in his preface we note the following paragraph

> The question of railway speed is one which constantly engages the attention of passengers, and we often *hear* of 90 and 100 miles an hour. During the past twenty-five years the author has ridden upon many engines, and has traveled in in all the fastest trains on all the railways of this country, for the special purpose of ascertaining their rate of speed. Upon a few occasions, and under favorable circumstances, he has recorded the very high rate of speed of 79.9 miles an hour, but he has never been able to time a train or engine at actually 80 miles an hour. As long ago as 1853, 81 miles an hour was run by engines on the Bristol and Exeter Railway, but these have now been changed and their speed reduced. It is not wise to predict what *may* be done in the future but at present 80 miles an hour is the maximum pace.

The author does not seem to think that "facts" as he calls them, have proven that the modern compound locomotive is a better or more economical machine than the simple engines, and says: "Whatever the compounds can do the simples can do, and often with more efficiency." The book is a valuable addition to any engineer's library.

SPON'S ENGINEER'S TABLES. A new edition. By J. T. Hurst. Spon & Chamberlain, New York. Price, 40 cents; in a cloth case, 50 cents.

This little book is 1½ inches wide by 2½ inches long, and contains a great deal of information in small space. It is an English work and many of its teachings would mislead an American who did not know there was a difference between the English and American standards. Their bolt and nut proportions, wire gauges, etc., are entirely different from ours. We notice that under "farm labor," they allow a man eighteen days to dig one acre of stubble land (1 spit, whatever that means to an engineer) and that 2½ days would be the proper time in which to pull one acre of mangel-wurzels. For all this, there are many little things in the book that are nice to know. It is one of those little collections of facts and figures that are very attractive at sight, but that an engineer would seldom consult.

---

It is not wise for train men to be too exacting in holding the company they serve to the last letter of the contract of employment. On a road which we know of the train men have a contract in which the agreement is made that all passenger trains shall have a conductor and two brakemen. On that system there is a branch five miles long which has a passenger train that makes three trips a day. The company's officers thought that one brakeman might perform the duty of riding thirty miles a day on this train, which generally consists of one baggage and one passenger car, but the grievance committee made such a vigorous protest that the two brakemen were left on. The company are now arranging to operate the branch by electric cars. In a case of this kind it is possible for the pay of one man to turn the balance that exists between the expense of operating a railroad by steam or by electricity.

## PERSONALS.

Mr. H. B. Hodges has been appointed engineer of tests of the Baltimore & Ohio, in the place of Mr. Randolph.

The B. & O. have ordered sixty new engines from Baldwin's. They propose to be ready for the Fair business.

Mr. J. H. Sheldon has become agent for the Taylor Iron and Steel Company. His headquarters are in the Central building, New York.

Mr. George N. Terry has been appointed agent for the Safety Car-Heating and Lighting Company, with charge of the office at Chicago.

Mr. John Ortton, for several years superintendent of motive power of the Toledo, St. Louis & Kansas City, has resigned, owing to ill health.

Mr. Henry James has again connected himself with the Parrott Varnish Company, as sales agent. His office is at 29 Broadway, New York.

Mr Peter Clark, for many years assistant mechanical superintendent of the N. & N. W. division of the Grand Trunk, at Toronto, Ont., has retired.

Mr David Mackenzie, for some time purchasing agent of the Central Vermont, has been made superintendent of the New London division of the road.

Mr. T. W. Ranson, master mechanic of the Erie at Hornellsville, has resigned. He has been succeeded by Mr. Isaac Bond, with the title of general foreman.

Mr. E. A. Gilbert has been appointed general foreman of the Harvey Steel Car Works at Chicago. Mr. Gilbert was formerly master car-builder of the Boston & Maine.

Mr J. C. Blackwood, a son of General Foreman Jas. P. Blackwood, of the S. C. road, at Charleston, S. C., has entered the Rogers Locomotive Works to complete his trade.

Mr. W S. Hughes, for many years in the service of the Long Island road, has been appointed general foreman of the New York and New England shops at Providence, R. I.

Mr H. A. Childs, general foreman of the Erie shops at Jersey City, has been appointed acting master mechanic in place of Mr. C. E. Fuller, who has gone to the Central Vermont.

Mr. A. Leofred, mining engineer, Quebec, reports that he is kept as busy as he can be all the year around, making assays or preparing reports on American and Canadian mines.

Mr. George James has been appointed master mechanic of the western divisions of the New York, Chicago & St. Louis, with charge of the road's repair shops at Stoney Island, Chicago.

Mr. W. F. Strong has been appointed general foreman of the car shops of the South Carolina, at Charleston, S. C. The office of master car builder has been abolished, and Mr. E. M. Roberts takes general charge of that department.

Mr. T. B. Hindel, formerly master mechanic, and Mr L. C. Leach, at one time master car builder, of the New York, Chicago & St. Louis, have formed a partnership for engaging in the manufacture of a car-wheel patented by the latter.

Mr. John Hawthorn, master mechanic of the Chicago & Erie at Huntington, Ind. has been very sick and it was feared for a time that he would not recover. We are pleased to learn that he is getting better now and expects to be able to resume work soon.

Mr. W. F. Johnstone, superintendent of motive power of the Mexican Central, was visiting Providence, R. I., lately, looking over the big compound locomotives his road is getting built there. He reports that the compounds in use are doing remarkably good work.

Mr. C. R. Fitch, for some time superintendent of the eastern division of the Erie, has been made general superintendent. He came from the Long Island to the Erie and made a very decided success in the way he performed the difficult duties of the position.

Mr. J. S. Porter has resigned his position as master mechanic of the Cleveland, Cincinnati, Chicago & St. Louis, at Sandusky. Mr. Porter has been long in charge there, and was general master mechanic of the Indianapolis, Bloomington & Western before it was absorbed by the Big Four.

Mr. J. G. Hubbard has been promoted to the position of master mechanic of the New York, Lake Erie & Western at Buffalo, in place of Mr. Geo. B. Ross, resigned. Mr. Hubbard has been foreman of the car repair shops and was formerly master mechanic of the Buffalo Southwestern.

Mr. Robert M. Dixon, mechanical engineer of the New York Car Heating and Lighting Company, has been appointed manager of the Pintsch light department of the same company. His brother, who has been agent for the company at Boston, takes the position of mechanical engineer.

The directors of the Western New York & Pennsylvania have presented a testimonial to Mr. Richard Connolley a passenger conductor. This was done in recognition of his courage, coolness and good judgment in getting his train to a place of safety at the time of the great fire in Oil City.

Mr. C. S. Mellen, who went from the Union Pacific to be general manager of the New York & New England, has become second vice-president of the New York, New Haven & Hartford. It is understood that he will be in immediate charge of the transportation department of the road.

Mr. W. T. Reed, superintendent of motive power of the Chicago, St. Paul & Kansas City road, is said to be a recognized expert on boilers. When any accident happens to a boiler in the neighborhood of St. Paul, Mr. Reed's views on the cause of the accident are said to be considered conclusive. He is often employed by insurance companies to inspect boilers.

Mr. F. R. F. Brown, for several years mechanical superintendent of the Canadian Pacific, has been appointed mechanical superintendent of the Intercolonial Railway in place of Mr. H. A. Whitney, who has been placed upon the retired list. Mr. Brown is a particularly able mechanical engineer and railroad officer. He has been engaged in private enterprises since he left the Canadian Pacific.

Mr. George E. Sampson, road foreman of engines of the Chesapeake & Ohio, having been assigned to other duties, Mr. J. R. Belton has been appointed road foreman of engines, Cincinnati, Lexington and Big Sandy divisions, effective November 1. He will report to and receive his instructions from the superintendents and master mechanics. The jurisdiction of R. W. Harris, road foreman of engines, has been extended over Kanawha district, Huntington division.

Mr. M. M. Reid, for some time general foreman of the New York Southern shops at Berkley, Va., has been appointed master mechanic of the Savannah, Americus & Montgomery, with headquarters at Americus, Ga. Mr. Reid is an energetic and studious mechanic whose upward progress we have been watching with interest. He went from the Baltimore & Ohio to Virginia, and before that worked in New England. If energy and good management can achieve success on the same road, Mr. Reid will give satisfaction.

Mr. T. B. Purves, Jr., has been appointed master mechanic of the Boston & Albany Railroad at East Albany in place of his father, who becomes his son's assistant, reversing the old arrangement. This was a change made with the consent of the father. The young Mr. Purves has been a particularly successful shop manager, which has commended him to the attention of others looking for good men. This has brought him several offers by other roads and by private firms. The Boston & Albany people appreciate his worth, and the superintendent of motive power proposed the new arrangement that would keep Mr. Purves with the company.

Mr. H. A. Gillis, master mechanic of the New York, Lake Erie & Western, has enjoyed a more varied experience than most of our younger mechanical officers. He was educated as a naval engineer and graduated from Annapolis. Finding that the prospects of success in life were far from brilliant in the navy, he retired to private life and went to work as a mechanical engineer. He was with the New York Safety Car Heating and Lighting Company for a long time, and from there he drifted into railroad life. He was general foreman at Meadville for a time, and there earned his promotion to the position of master mechanic.

Mr. Jacob Johann, for several years agent for the New York Safety Heating and Lighting Company, at Chicago, has accepted the position of superintendent of motive power of the Chicago & Alton, in place of Mr. Quackenbush. Mr. Johann is one of the best known of our master mechanics, and was noted as an excellent mechanic and good executive officer. He was long superintendent of motive power of the Wabash. He has been a leading member of the Railway Master Mechanics' Association, and was president one term. He was the prime mover in the action taken by the association to convert the Boston Fund into scientific scholarships.

One of the most impressive men we met with during a long journey was Mr. P. A. Reynolds, an engineer on the Southern California Railway. He is a big man of striking appearance, strong personality, and a natural leader of men. He is chief of the Brotherhood division, and is generally appointed to represent the order at the annual conventions. Mr. Reynolds was originally from the New York, New Haven & Hartford, and is well acquainted with the many engineers who passed from that road into good railroad positions. He drifted out to the Atlantic & Pacific when that road was new and passed through the severe ordeal that all successful men had to endure on that road. Here none but the fittest survived, and the methods of selection were savagely severe—often succeed or die. In some regions the feed-water used was so heavily charged with solids that gauge-cocks could not be kept open an hour, and the smokestacks were habitually used as gauge-cocks. The engineer who could keep the crown-sheet wet under these circumstances had a turn for the business. While on construction Mr. Reynolds was once overtaken in a cañon by a flood and escaped by climbing up the cliffs. The engine was not reached for two months.

Chiropodists and corn-doctors will, with difficulty, choke down a leer of contented glee when they get a glimpse of the Illinois Central's new cars for the World's Fair traffic—for if those seats don't put corns and bunions on other parts of the riders' anatomy than the feet, we miss our guess. These cars are a cross between a country school-house and a palace stock-car, and, while they might do for sheep they are not fit for human beings, and especially to show to the world as the representative American suburban car. These are freight cars with diamond trucks, air-brakes and vertical hook couplers, the bodies are box car, except that there are openings on each side of the car and wooden seats running across on each side of the door-ways—like an open street car—the victims sit facing each other, the same as in the English compartment car. There are curtains in case it rains, and a sort of a muskrat trap in the shape of an iron bar over each runway that are all handled from one end of the car. The spring planks of the trucks are 15 inches wide and provisions made for three elliptic springs side-and-side, the center one has been kindly left out to provide for easier riding until the cars go into the dead-freight business where they belong. The World's Fair has been located on ground that practically gives the I. C. road the bulk of the enormous business of hauling the people back and forth between the Fair and the city, and they can well afford to buy real, made-a-purpose, suburban cars that would at least be comfortable and let foreigners go home with the conviction that, while we do not have as many classes of travel as they do, we at least make a distinction between man and beast. It was just such seats as these, in a Western Sunday school, that made the junior philosopher often wonder if they had the same kind in that eternal-damnation place, and fixed the belief forever in his mind that it would be about as slow and lingering a penance as fire and hot coal tar.

The Thatcher Car & Construction Co. of this city have recently built for exhibition two of their dumping cars and tested them in the presence of a large number of railroad men. They already have a couple of trains in service on the Canadian Pacific. The cars hold ten cubic yards of earth, and are dumped by an air cylinder under the car, the whole train being dumped and replaced in upright position and locked there by the simple movement of a valve on the locomotive. This device was first designed by Thatcher & Gearhart, at Leadville, Col., and was illustrated in the L. E. for December, 1891. The present device, however, is an improvement on that.

## Traveling Engineers' Call.

At a preliminary meeting held at Chicago, Ill., Saturday, November 12th, the following call was decided upon and is hereby issued:

We, the undersigned road foremen of engines, or traveling engineers, deeming that an association of men in our calling would be beneficial in that an exchange of ideas would tend to uniformity in our work, and to widening our information and usefulness, and, if properly conducted, would make the position of traveling engineer recognized as one of great usefulness to railroads and to enginemen. It would prevent friction by promptly rectifying small abuses; prevent waste by conducting a practical education and the encouragement of economical practices.

We ask all traveling engineers and road foremen of engines to meet for the purpose of organizing an association similar to the Master Mechanics' Association; said meeting to be held at 2 P. M. Monday, January 9, 1893, at room 912, No. 5 Beekman street, New York City, office of LOCOMOTIVE ENGINEERING. If this meets with your approval, will you kindly correspond with John A. Hill, at above address, at your earliest convenience, stating if you will be present, or if not, if you will join the association.

C. B. Conger (chairman), C. & W. M.; W. O. Thompson (secretary), L. S. & M. S.; J. S. Boder, L. S. & M. S., W. A. Pitcher, P. & L. E.; T. J. Hennesy, Mich. C., M. Mast, C. & E.; W. T. Simpson, C. & G. T.; A. H. Polhamus, P. R. R.; John King, P. R. R.; A. S. Work, N. Y. C. & St. L.; N. S. Mora, C. & N. W.; W. A. Murdock, C. & N. W., W. A. Anthony, C. & N. W.

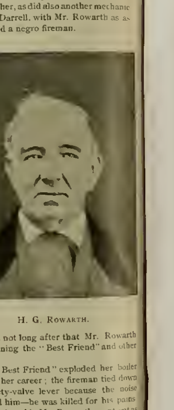
## H. G. Rowarth, Engineer of the First Locomotive Built in America.

The locomotive "Best Friend" was the first one built in the United States for actual work. She was made by E. L. Miller at the West Point Foundry in New York City, and sent to the then biggest road in the country, the South Carolina.

This engine had a vertical boiler at one end and inclined cylinders at the other, the cylinders being over the tank, the whole resting on four coupled wheels.

Mr. Rowarth was born in Charleston, S. C., in 1810, and when twenty years of age was an apprentice in the machine shop of a Mr. Dotterer.

The "Best Friend" came to Charleston in 1830, but there being yellow fever there, Northern mechanics would not go down to set her up. Mr. Dotterer sent machinist Julius Petch to set up the engine, with H. G. Rowarth as helper. When the engine went into service, January 15, 1831, Mr. Petch ran her, as did also another mechanic Nicholas Darrell, with Mr. Rowarth as assistant and a negro fireman.



H. G. ROWARTH.

It was not long after that Mr. Rowarth was running the "Best Friend" and other engines.

The "Best Friend" exploded her boiler early in her career; the fireman tied down her safety-valve lever because the noise annoyed him—he was killed for his pains.

Soon after this Mr. Rowarth went out as engineer of a river steamer and let railroading alone for a few years, but came back to the road in 1838, and was running the engine, "Reading."

He remained in the service as engineer until 1885, nearly fifty years; thirty-one of this was put in on the pusher on Aiken Hill. He is at present living with his son, T. S. Rowarth, at Augusta, Ga.; his health is good but his eyesight and memory are failing.

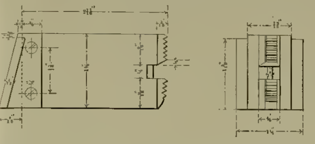
It seems remarkable that the man who ran the very first locomotive built in America should live to see more than fifty thousand locomotives constructed in the land. It shows what hustlers we are in this age, anyway.

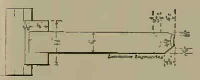
While visiting a Scotch locomotive shop last summer, our conductor said "Come into the erecting shop and I will show you some engines with all your American tricks on them, they are awful trappy." These engines had headlights, bells, extension fronts, cabs and pilots—all extras over the European engine.

Saddle-tank switches are as common in Great Britain as in this country, but in all we saw there the saddle tank extended over the front end, the stack going through it. This plan admits of a shallower tank and a less top-heavy engine.

## Slotted Machine Screw Thread Dies.

The annexed engraving illustrates a form of die used by the Atchison, Topeka & Santa Fé people for their screw thread cutting machines. It is well known that the ordinary form of die used in such machines is greatly given to choking up with the cuttings, and breakage is often caused by this when the work is pushed. In the improved dies shown a slot is made in the middle of the die which lets the cuttings





out. In practice it is found that this can be forced to any extent without fear of breakage. It is a small invention that greatly facilitates the cutting of screw threads, and is well worthy of general application to screw machines.

## Progress of the Vestibule.

The vestibule for passenger cars is becoming one of the recognized features of a first-class train. The indications are that within a very few years all the passenger equipment in the country will have vestibules. The vestibule is a luxurious addition to a train which might have been easily dispensed with had it never been applied. The use of a vestibule appears to make a train harder to pull, and therefore slightly increases the cost of train service. Platform gates might have been put on that would have made the cars as safe for passengers moving from car to car. But the vestibule is much more comfortable, especially in bad weather, and it keeps the cars cleaner than having the doors exposed to the entrance of smoke and cinders. The traveling public having been made familiar with the comforts of the vestibule, there is getting to be a sentiment that a train that does not have vestibules on the cars provides inferior accommodation for first-class passengers. This is creating a demand for vestibules which is urging railroad managers to adopt this improvement where some of them are not ready to incur the great expense involved.

Among the railroad companies that expect soon to apply vestibules to their passenger equipment is the Southern Pacific. This company has about 200 passenger train cars, a large proportion of them being employed on long distance trains. The equipping of all these with vestibules will be a costly operation.

The few vestibuled cars that are in use in Great Britain have been rapidly gaining friends for this style of car among the traveling public, and there is a likelihood that this improvement will exercise great influence in overcoming the prejudice against Yankee innovations, a form of prejudice that has stood in the way of the rapid introduction of open-seated cars to displace compartment cars. In several accidents the vestibuled Pullman cars have exhibited great resisting power to destructive shocks, and John Bull is inclined to take the safe place in traveling. This will, no doubt, accelerate the popularity of the improvement to cars.

There are several vestibuled trains running in Germany, and they are reported to be highly popular. The cars are short and of the four-wheel type which are greatly given to pitching and lurching at high speed. It is found that the vestibules tend to steady the cars, and this, no doubt, continues to make them appreciated.

## Urgent Demand for New Cars.

In spite of the great promise of business that a bountiful harvest in all sections of this continent conveys, the railroad companies held off from placing orders till they were embarrassed for want of cars to carry the freight offered. This is a phrase of railroad management that has grown familiar by repetition. The railroad companies now want cars very badly, and they want immediate delivery. After a few months of semi-stagnation, all car-building establishments are rushed with orders and all are turning out cars as fast as they can be thrown together. This is the time when cars are built which help to keep the car-building business active, and which tends to cripple the finances of the purchasers. It is no use preaching at railroad companies for the sins which have become recognized practices; but the owners of this kind of property follow a very expensive policy in habitually delaying the ordering of rolling stock until they can no longer do business without the forced filling of orders.

## New York Railroad Club Meeting.

The annual meeting of the New York Railroad Club was held in the rooms of the American Society of Mechanical Engineers, New York, on November 17th. President R. C. Blackall was in the chair. A large number of members and visitors were present. Among them were the following railroad men R. C. Blackall, Delaware & Hudson; A. E. Mitchell, H. A. Childs and H. A Gillis, New York, Lake Erie & Western; Wm. Lewis and T. Muir, Delaware, Lackawanna & Western, W. C Ennis, New York, Susquehanna & Western; H. H. Vreeland and Thos. Millen, New York & Northern; Geo. W. West, New York, Ontario & Western; A E. Benson, Ulster & Delaware, E. M Hedley, Brooklyn Elevated; F. Hedley, Kings County Elevated; L. Ames, Beech Creek, S W Huston, Chicago Elevated, —Mendenhall, Pennsylvania; R B. Reading, Manhattan Elevated; C Mayeau, New York, New Haven & Hartford.

The first business was the election of officers, with the following choice President, R C. Blackall; first vice-president, Geo. W West, second vice-president, A E. Mitchell, third vice-president, W. H Lewis; secretary, John A Hill, treasurer, C. A. Smith; executive committee, Thos Millen, W. C. Ennis, H. H Vreeland, W. W Snow, W. G. Wattson; finance committee, Thos. Prosser, E H. Andress, F. M. Patrick.

A paper on "Location of Tools in Railroad Shops" was read by Mr. W S. Rogers. The paper will be found on another page of this issue.

The question of satisfactory car lubrication does not yet appear to be settled to the satisfaction of people who travel on some of our railroads. It is a very bad advertisement for a railroad company to have a train stop for twenty minutes at a station while all the trainmen are exerting themselves to cool a hot box, and all the passengers are out looking on and sneering at the company. On some roads you never hear of a hot box on a passenger train, while others are constantly meeting with delays from this cause. On the train, we were riding on lately, stopping for the second time to cool off a hot box, we jumped down and watched things. The waste in the box had dropped away below the journal. Common kind of cotton waste was used. Woolen waste would have prevented the delays.

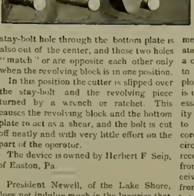
The far Western roads are not taking very readily to the standard Master Car Builders' car-coupler. They say that the vertical hooks make too rigid a connection for passing around the sharp curves, and that it is frequently necessary to put links between the hook couplers. Those who are opposed to this form of coupler think that this objection will ultimately result in the abandoning of the present standard. At the same time we noticed that the long passenger cars on the Denver & Rio Grande, and other excessively crooked roads, went around the worst of the curves without the Miller hooks causing any disturbance.

## A Simple Stay-Bolt Cutter.

The illustration on this page shows the construction of a stay-bolt cutter, the invention of Ellwood Hay, a machinist in the L. V shops at South Easton, Pa.

As will be seen, the body of the cutter has a projection on one side that prevents it from turning by bracing against another bolt, the length of stay left outside the sheet is determined by the thickness of the back plate, which is part of the shear, this plate is removable. The revolving block is prevented from coming out of the body by the top plate, the outer end terminates in a hexagonal head.

Through this revolving piece is drilled a hole large enough to slip over the stay-bolt, this hole being out of the center The



stay-bolt hole through the bottom plate is also out of the center, and these two holes "match" or are opposite each other only when the revolving block is in one position.

In this position the cutter is slipped over the stay-bolt and the revolving piece turned by a wrench or ratchet. This causes the revolving block and the bottom plate to act as a shear, and the bolt is cut off neatly and with very little effort on the part of the operator.

The device is owned by Herbert F Seip, of Easton, Pa.

President Newell, of the Lake Shore, does not indulge much in the luxuries that might be called for by his position, but he is getting a private car built in the Wagner car shops that will hold its own among the finest private cars on wheels. It is finished in mahogany and contains elaborate hand-carving. The fittings and furniture are in the latest style of car furnishings Particular attention has been bestowed upon the framing, which at the ends is a combination of wood and iron that gives an extremely strong structure.

## An English Way of Running Trains on a Single Track. Webb & Thompson Electric Staff System.

This consists of a magazine formed of a cast-iron pillar, 3 feet 6 inches in height, having a slot, *A*, about 1¾ inches wide down the center of the pillar, and capable of holding eighteen staffs. Where it is necessary to have a larger number of staffs, a pillar is used having a double slot capable of holding twice the number of staffs. On the top of the column is fixed what is termed the head of the pillar, which contains the whole of the mechanical and electrical parts of the instrument. On the face of this there are two indicating disks, *B* and *C*, and underneath the right-hand indicating disk, *C*, is fixed a tapper key, *F*. In the center of the face there is an ordinary galvanometer, or current indicator needle, *D*. *E* is the continuation of the slot through which the staffs must be withdrawn or deposited. An ordinary single-stroke bell is fixed between the cabins of a section.

In the interior of each magazine are the electrical and mechanical parts, which are as follows

Turning on a center pin are five metal disks secured together. Each disk has four notches at equal distances apart cut out of its periphery, of such a width as to admit the shank of a staff, and when a staff is being withdrawn from the magazine it carries the whole set of disks round with it as it follows the curved portion of the slot until it reaches the enlargement, through which it is withdrawn. At this moment the disks will have made exactly one-quarter of a revolution, and another set of notches will be exactly over the slot in the column. In replacing the staff the disks will be rotated in the opposite direction.

To lock the disks in position three of them are provided with pawls which fit into the notches, but each staff is fitted with lifting pieces which disengage these pawls, and allow the disk to move whenever a staff is being replaced or withdrawn. So far it will be seen that any number of staffs can be withdrawn one after the other, and the arrangement will now be described by which the magazines are electrically controlled to prevent more than one staff from the two apparatuses being out at a time. One of the disks is locked in position by means of an electric lock, which is conjointly energized by a local current and a current sent from the station to which the staff is to be sent. This lock is an important feature of the apparatus. The bolt being very heavy, a magnet and current of great power would be involved to lift it through the space necessary, and to avoid this the poles of a comparatively small magnet are placed normally in contact with the bolt which forms an armature, and the magnet is lifted mechanically by a tail piece which is actuated by a projection on the staff. Thus a comparatively small current is required to lift the heavy bolt. The magnet employed is interesting As a single wire is used for working the system, it is necessary that magnetism of a certain polarity should be induced in the cores, and to do this a magnet was adopted, the cores of which form a closed magnetic circuit energized by four coils, two coils receiving a current of a fixed polarity from a local battery and two coils receiving the current alternating in polarity from the line wire, the poles being placed between the two sets of coils. The magnetic circuit being closed, no magnetism is induced at the poles by a local current alone, or by the line current alone, or by both if in opposition, but a powerful magnetic attraction is induced if both currents are in unison.

On the right side of the drumhead are placed five electric switches. Two are automatically worked by the turning of the disks, and alternately change the polarity and direction of the current in the line wire, and three are worked by the right-hand dial and tapper key

Assuming now that a single line railway has four stations, A, B, C, D One apparatus is fixed at A two at B, two at C, and one at D As a rule, each apparatus is provided with ten staffs, but double or treble this number can be provided for. The staffs for the section A B are so constructed that they cannot be used for the section B C, and similarly those for B C [illegible] not be used for C D, thus a staff sent from A cannot be used by B for the apparatus between B C

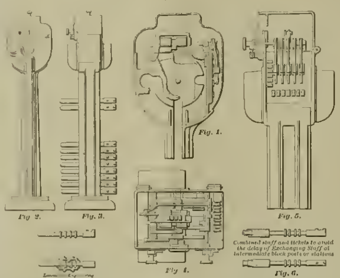
We will now describe the operation of signaling a train from A to B The signalman at A rings to B by depressing the tapper key B acknowledges the signal. A then rings to B the description of the train he is sending in accordance with a prearranged code B acknowledges the [illegible], and A then rings that he wants to [illegible] a staff and at once turns his [illegible] hand dial to "For staff," this operation switching on the current from the local battery to the local coils. On receipt of the last signal B depresses the plunger [illegible] which sends a current through the galvanometer of both apparatuses, the needles of which are deflected to the [illegible] the electric lock of A's apparatus A, seeing his galvanometer needle deflected, lifts a staff from the slot in the column and through the curved slot in the column head, withdrawing the staff at the enlarged portion of the slot

Having withdrawn the staff, A turns [illegible] left-hand indicator, which registers the fact that a train has been despatched from A to B the turning of this indicator [illegible] the line wire circuit, and the galvanometer needle of B's apparatus falls to zero informing him that a staff has been withdrawn and the direction of the train registered

It must now be explained how the withdrawal of a staff makes it impossible for a second staff to be taken from the apparatus at A or B When B sent a current to A each apparatus, so to speak, was in unison, or in other words the current flowed through the line coils of A's electro-magnet in a direction non-opposed to the current in the local coils and a strong magnetism was induced at the poles, and similarly a current sent from A would energize the magnet at B When A withdrew the staff, the disks were turned a quarter of a circle, and the automatic switches reversed, if B now sent a current, which, of course, would be of the same polarity as before, it would be changed in direction through the coils, and would consequently be opposed to the current in the local coils, and if A sent a current to B, it would also be opposed to the current in the local coils of B' apparatus, as the reversal of the automatic switches in A's apparatus not only reversed the direction of the current from B, but changes the polarity of a current sent from A If the staff withdrawn from A's apparatus is replaced, the disks would be turned back and the working restored as before, but if the staff is taken to B, and placed in the apparatus, the disks of B's apparatus would be turned back and the automatic switches reversed, which would have the effect of reversing the polarity of the current sent from B and altering the direction of the current in the line coils sent from A Thus both apparatuses would be again in unison, and a staff could be signaled for and obtained at either end of the section

To work single lines on the time system, or where it is desired to have intermediate block posts which are not staff stations, tickets can be used in connection with the electric staff apparatus on the principle of the old staff and ticket system, but retaining all the advantages of the electric staff system. In this case a ticket-box is secured to the side of the apparatus and a ticket staff provided, which is retained in an independent slot in the column When it is desired to send say three trains from A to B, the signalman at A obtains permission from B in the usual way, and instead of taking an ordinary staff he withdraws the ticket staff He is then able with this staff to unlock the ticket box and withdraw a ticket, the withdrawal of the ticket prevents the ticket staff from being replaced in the column, and thus no other staff can be obtained either at A or B. The first train is then sent away with a ticket, and at a stated interval of time, in case the line is worked on the time system, or when the train has been signaled as having passed the intermediate block post, the second train is dispatched with a second ticket, the third train is then dispatched with the ticket staff. When the two tickets and staff have arrived at Station B, the signalman at B places the tickets in his box, and only when this is done can he place the ticket staff in his instrument and restore the working Complete arrangements are also made in connection with this system for switching out intermediate staff stations, for picking up and depositing the staffs at intermediate posts when the train is running at speed, and for the locking of siding points by means of keys combined with the staffs

*Fig. 2.*



The Crescent Steel Company, 480 Pearl Street, New York, report a growing demand for their steel in railroad shops. The fine crucible steel made by this company is admirably adapted for the construction of tools of all kinds. In railroad shops it is largely used for taps, dies, milling cutters and all kinds of cutting tools.

A large order for hydraulic projectile drawing presses has been awarded to Messrs. Watson & Stillman, of New York, by the United States Projectile Company, of Brooklyn. Orders for hydraulic presses, pumps and accumulators have been so abundant during the past year that it has been found necessary to operate their plant both day and night, notwithstanding increased facilities in the several departments. This firm is getting out a hydraulic weighing machine which will be a highly valuable apparatus for railroad companies. It will weigh cars accurately when they are run over the machine at ordinary freight train speed, an electric register being employed to record the weight. The machine can also be made to weigh different pairs of wheels separately

The Buffalo, Rochester & Pittsburgh have just received from the Brooks Locomotive Works six freight and two passenger engines. The freights are consolidations, weighing about 106,000 pounds, with cylinders $17\frac{1}{2} \times 26$ inches, and carrying 160 pounds of steam on the boilers. They are an improvement in minor details of an engine that has given remarkably good service on the road. The passenger engines have cylinders $18 \times 24$ inches, wheel centers 66 inches. They have the most modern attachments, including Boies steel-tired wheels for tender and truck.

The Swain Lubricator Company, of Chicago, have sent us an illustrated pamphlet showing the "Permanent" metallic rod packing which they are now making. The packing looks to be very simple, and it is said to have shown a record of sixteen months' service in valve-stem glands without indications of wear. Beveled rings of a soft metal are used which obviate the necessity for springs. This packing can be used in an ordinary gland stuffing-box

During one week last month the Baldwin Locomotive Works received orders for 130 engines. There were forty compounds among them. There were thirty-five of the engines for the Brazilian state railways.

## Santa Fe Passenger Locomotive.

The accompanying engraving shows an eight-wheel engine built in the Atchison, Topeka & Santa Fé at Topeka, Kan., which is doing remarkably good work, and is, withal, an excellent specimen of a well-designed locomotive. The engine has

PASSENGER ENGINE BUILT IN TOPEKA SHOPS

cylinders 17 x 24 inches, driving wheels, ...ters, 56 inches, and a boiler 56 inches diameter at the smallest ring. The boiler carries steam of 160 pounds pressure With a train of seven cars this engine makes fifty miles to the ton of coal, and does the work with remarkable ease The working parts are very strong and the bearings large, and the engine promises to be remarkably economical on repairs.

## Fast Express Engine, London, Brighton & South Coast Road.

Of all the English locomotive designers of recent years, perhaps the late Mr. Wm. Stroudey was most original and the quickest to try a new idea

As long ago as 1882 he decided to make something new to handle the heavy express trains between London Bridge and Brighton, a distance of 50½ miles. This line is crooked for an English road, and has several stiff grades.

The express trains often contained twenty-five carriages—very heavy trains—and the public demanded a schedule of one hour.

The big engine, with 7-foot "single," shown on page 439, could not perform this work every day with certainty, and Mr. Stroudley built the first of his coupled engines, like the "Jonas Levy," and named it "Gladstone."

By using inside cylinders he was enabled to place his driving-wheels in front, and the small trailing-wheel admitted of a fire-box as big as he wanted,—an important feature.

These engines have cylinders 18¼ x 26 inches, have 6-foot 6-inch drivers, 1,485 square feet of heating surface, and weigh, ready for the road, 85,000 pounds.

This road uses air-brakes, and these engines have an ingenious reversing device operated by air

To avoid cutting the leading flanges, a pipe is brought from the exhaust passages to the flange of the wheel, and a small jet of wet and greasy steam is thrown against the flange, this lubricates well and cut flanges are avoided

The engines are painted a light orange and striped with a broad black band, and the bright work is extra-well finished.

They get the big trains over the road on time, making over a mile a minute every day.

A FAST ENGLISH EXPRESS ENGINE.

## High Speed Trains.

At the New England Club meeting last month, Mr C. A. McAlpine, superintendent of the Old Colony Railroad, read a paper, "Higher Speed of Railroad Trains; System and Appliances Necessary to Accomplish It." He discussed the higher grades of train speed that are practicable, which is what the public are ready to pay for. When the public are ready to pay for a three hours' ride between New York and Boston, it is likely to be provided even though the train speed required should be very great. Locomotives might be built to run 80 or 90 miles an hour, but the public are not yet ready to pay for the outlay involved to make that speed safe If trains were called for to be run so that an average speed of 70 or 80 miles was made between terminals, special tracks of a very substantial character would be necessary, provided with perfect means of preventing collisions.

One of the most important things to be considered when we start a train is our ability to stop it. Mr. Westinghouse tells us that with a perfect brake acting upon all the wheels of an express train running at a speed of 90 miles an hour, at the end of ten seconds after the application of the brake the train would still be moving at 60 miles an hour, and would have traveled 1,130 feet, and it would be brought to a stand in about 1,200 feet more, or 2,330 feet in all; while under the best actual conditions now existing, at the end of sixteen seconds the train would be moving at 60 miles an hour and would have traveled about 1,800 feet. With this fact staring us in the face it seems a waste of time to talk of running at such speed on our present tracks and in connection with the ordinary passenger and freight traffic. It is possible to put our present roads in condition to meet the requirements, but there is no reasonable probability that it would result in a sufficiently increased revenue to warrant the outlay.

The difficulty of maintaining an average speed of fifty or sixty miles an hour was discussed. Seventy-miles-an-hour speed is often reached by trains that do not average forty-five miles an hour. This would indicate that by making a more uniform speed a greater average could be obtained without faster running For trains making a running time of fifty or sixty miles an hour, he considered better means of stopping promptly should be provided. He favored having all switches interlocked and a satisfactory system of signals for protecting trains. A source of danger apprehended to fast express trains was the freight trains running on the adjoining track. The breaking down and wrecking of freight trains from the use of defective material or car apparatus was considered a danger to be dealt with.

In counting the cost of high speed it was estimated that the train resistance to a train running sixty miles an hour was twice as much as it was when the train was running half the speed. Every well informed railroad man knows this to be a mistake, but the cost of high speed is no doubt made greater than that of low speed.

---

A notice appeared lately in the press dispatches of a heroic action performed by Engineer James Butler on the Lake Shore & Michigan Southern. On reading this account of how this man readily risked his life to save his train, Mr. Eberhardt, of the firm of Gould & Eberhardt, Newark, N. J., sent us ten dollars as a present to the heroic engineer.

---

We have received from the Congdon Brake Shoe Co., of Chicago, a handsomely prepared catalogue giving particulars of the various forms and qualities of castings made by the company. They comprise all varieties of iron and steel. The high reputation of the makers, which has been growing for years, guarantees a first-class article. The Congdon Works are making first-class steel castings for all kinds of rolling stock and track work. This is a line of industry that has been greatly needed in the West, and railroad men would do well to give the enterprise all the encouragement in their power. The brake shoes made by the company are of national reputation. They make the Ross, Meehan, corundum and steel shoes for locomotives. For cars they make the Ross, Meehan, Congdon and plain cast iron shoes.

## Work at Baldwin's.

Baldwin's people have lately built for the Chicago North Side Railway some motors with air-condensing engines, the condenser being coils of pipe exposed on the roof of the car. The motors are closed in and look like a small street car. Among engines which we noticed in the erecting shop of the Baldwin Works during a recent visit, were two compounds for the Sandusky & Columbus, and eight simple engines for the same road. A number of the compounds for the Chicago South Side Elevated were nearly ready for delivery. There were a variety of engines for different countries in South America, and some curious specimens for working round steel works. The boilers for some of the engines belonging to the large Pennsylvania order were in the boiler shop nearly ready for moving to the erecting shops the World's Fair. There was a warm contest for the seats of these cars. The Hale & Kilburn Co. got the entire order.

The Duluth & Iron Range Railroad has just sent out specifications for a number of ore cars to be built to the recently established ore car standard of the road. The order, when placed, will be for from 450 to 500 cars; these cars will be 22 feet long and 8 feet wide, they will be fitted with the Safford draw-bar, the Butler draw-bar attachment, and the Schoen pressed steel center plate, the National hollow brake beams, Hewitt box lids, Westinghouse automatic quick action brakes. Brakes will be applied to both trucks and will be hung inside.—*Railway Age.*

The following railroad companies are reported to be in the market for cars The Long Island, for passenger cars, Central Railroad of New Jersey, for passenger cars; the Great Northern, for passenger cars, New Jersey & New York, for six passenger cars; the Wilkes-Barre & Hudson River, for general equipment.

The Bridgeport Machine and Tool Company have made additions to their shops lately. There is an extension of the machine shop 96 x 80 feet. There is a Yale & Towne's 10-ton traveling crane in one side of this building and the other side is two story with light tools in the upper floor. The tool room, 20 x 40 feet, has been placed at the end of the new building, which puts it near the middle of the works. These works have lately gone into the manufacture of Fox lathes and are meeting with good demand for this useful tool. Mr. C. L. Libby is superintendent

The Lukens Iron & Steel Company report a steady and satisfactory business. Among recent roads added to the list are the C., M. & St. P., Fitchburg, Grand Rapids & Indiana, Chicago & W. Michigan and Buffalo, Rochester & Pittsburgh railroads.

The Cambria Iron Company report that their business among railroads is rapidly increasing Recently they have received orders from the Beech Creek, the Southern Pacific, Delaware & Hudson, Nickel Plate, and Nashville, Chattanooga & St. Louis. The steel toughened by the Coffin process is becoming popular.

We are very much gratified to learn that the *Railway Age* is about to publish a new edition of their Biographical Directory of railroad men. The last directory was got out in 1887, and it is getting very far behind the age. We have used the book till it is in totters, and every time we open it to search for original information of a personal character, we breathe a long-ing for a new edition. We strongly advise all who are asked to contribute biographical notices to send them in without delay and make the particulars full enough. When we are writing an obituary of a man or a notice of his rise in the world, we like to have reliable information, and on that account we are interested in the new Biographical Directory.

SEVEN-FOOT WHEEL "SINGLE," LONDON, BRIGHTON AND SOUTH COAST. (SEE PAGE 437.)

Two engines were on the floor for Sweden. The railways of that country get locomotives regularly from these shops.

They have lately delivered two compounds to the Chicago & Northwestern, and others for the Missouri, Kansas & Texas. The latter was the second order, the compounds in use working so satisfactorily that others were ordered. They are building one two-cylinder compound for the Chicago South Side Elevated Railroad

Among the orders for cars placed during the last month are: Erie, 1,000 freight cars; Delaware, Lackawanna & Western, 500 freight cars; Baltimore & Ohio, 2,000 box cars and 500 gondolas, Green Bay, Winona & St. Paul, 1,000 box cars; Huntington & Broad Top, 250 coal cars. The The New York Central has let 130 passenger cars in preparation for the business of

The Chicago & Western Indiana have ordered 4 locomotives from Cooke's The Chicago, Rock Island & Pacific have ordered from Baldwin's 6 ten-wheel engines and 6 Forney suburban engines, with three pairs of drivers connected and three pairs of tender wheels. The Baltimore & Ohio have ordered 50 engines from Baldwin's.

The general offices of the Congdon Brake Shoe Co. have been removed from the Monadnock Block, Chicago, to the works at 59 Wallace Street, where all communications should be addressed.

The compound built by the Pittsburgh Locomotive Works, which we illustrated last month, is giving high satisfaction in service. She went to work pulling trains without a single change. The engine has been running on the Pittsburgh & Lake Erie, the Columbus, Hocking Valley & Toledo, and the Cincinnati, Hamilton & Dayton. All the men in connection with these roads admit that the compound has badly beaten the simple engines in fuel economy.

The Pennsylvania Railroad compound, built at Altoona, has been pulling trains for about two months, and has given entire satisfaction in every respect The engine steams so freely and uses so little fuel that the intention is to use oil as fuel, and they are now putting on the necessary apparatus.

A sanding device for railway cars has been patented by W B. Leitch, Allerton. Ia. It is worked in connection with the air-brakes and is intended to prevent the sliding of wheels when the brakes are applied.

At the car shops of the Delaware, Lackawanna & Western, at Dover, N J., a new style of car has been built for the transportation of horses and cattle. Accommodations have been provided for twelve horses, and the car is so constructed that it can be hauled on first-class trains.

## B. & O.'S NEW THROUGH LINE.

### Preparing for the Immense Traffic Incident to the World's Fair.

The management of the Baltimore and Ohio Railroad is preparing for an immense business in 1893 while the World's Fair is open in Chicago. The terminals at Chicago are capable of accommodating a much heavier traffic than is now being done, and important changes are being arranged for the handling of very heavy freight and passenger business to the West from New York, Philadelphia and Baltimore. New equipment for largely increased passenger business and an extensive stock of freight cars have been ordered. The various roads of the system will be improved by straightened lines, reduced grades, extra side-tracks and interlocking switches. The new line between Chicago Junction and Akron has shortened the distance between Chicago and tide water twenty five miles, and between Pittsburgh and Chicago fifty-eight miles.

The distance between Chicago and Pittsburgh and Chicago and Cleveland by the construction of the Akron line and the acquisition of the Pittsburgh and Western line and the Valley Railroad of Ohio, is about the same as via the Lake Shore from Cleveland to Chicago, and by the Pennsylvania from Pittsburgh to Chicago. The alignment is to be changed and grades reduced to a maximum of twenty-six feet. It is expected that within twelve months the old Baltimore and Ohio through line between Chicago and the Atlantic Ocean will have passed away and the new line via Pittsburgh be established, with no greater grades or curvature than on any of the trunk lines.

Work has already begun east of Pittsburgh to meet improvements making west of Pittsburgh. These improvements will consist of additional second and third tracks, a general correction of the alignment and completion of the double track on the Metropolitan branch. It is expected that the new through line will be ready simultaneously with the completion of the Belt line through the city of Baltimore, which is intended to unite the Washington branch with the Philadelphia division and do away with the present line via Locust Point. Forty new and powerful locomotive engines were added to the equipment during the last two months, and others are in process of construction. The permanent improvements now under way and in contemplation involve the expenditure of some five millions of dollars.—*Baltimore American.*

### Dear Cheapness.

*Editors:*

I have read with a great deal of interest your article in the LOCOMOTIVE ENGINEERING, subject, "Dear Cheapness," and I think if ever there was a truthful article presented to the railroad fraternity it was that headed as above.

If such matters were brought to the notice of railway managers oftener, in the fearless manner as quoted in your article, it would, in my opinion, have a tendency in bringing those who consider only the first cost to a sense of duty in regard to safety, and make it much more pleasant for those that are trying to get that which in their judgment is the best material to save life and property.

I am pleased to say for the management of the Chesapeake & Ohio Railroad that their policy has always been, first, to purchase that which will insure them safety to life and rolling stock, the price of same being a secondary consideration, especially so on all material where human life is involved.

W. GARSTANG,
S. M. P., Chesapeake & Ohio Railway.
*Richmond, Va.*

### A Lame Exhaust Puzzle.

*Editors:*

The different puzzles about air pumps, and other mechanical questions presented to the readers of LOCOMOTIVE ENGINEERING appear to excite much attention and set the men a-thinking. So I shall submit notes about a defect which caused me great difficulty:

A locomotive on a passenger train came in and the engineer reported that she had lost an exhaust. I naturally expected that an eccentric or blade had slipped, and examined the engine carefully, but the motion was all right. To make sure, I put the engine on different centers and trammed the valves in full gear, and found them set correctly. Thinking that the trouble must be in the nozzles, I opened the smoke-box and found that they were all right. Then I was puzzled. What do your readers think was wrong?

TRAVELING ENGINEER.
*San Francisco, Cal.*

### Guaranteeing Steel for Fire-boxes.

*Editors:*

It has been suggested for years that fire-box steel be guaranteed to run a certain number of miles, the same as cast car wheels, varnish etc. And there is no good reason why this should not be done. Some steel-makers refuse absolutely to make a guarantee, on the ground that having once delivered the steel their responsibility ends. There is as much ground for this claim as there is for the car-wheel maker to urge a similar one. It is claimed also that the steel-maker cannot guarantee the workmanship or use of the steel by the railroad company, which is quite true, but as in case of failure of a sheet in use it is easy to determine whether the failure was due to the quality of the steel or wrong use by the railroad company, this objection disappears. I am aware that this assertion is disputed, but the writer has made such guarantees to the full satisfaction of the steel manufacturer and the user.

When a manufacturer fears from past experience the good performance of his steel, he does well, probably, to fight making a guarantee; but as it is both rational and right that steel should be guaranteed, it follows that the manufacturers who do first make a guarantee will first take the lead in supplying railroads.

The car-wheel maker is no more apt to suffer from bad use of his wheel than the steel-maker of his firebox steel, and the wheel is just as apt to be injured by the lathe hand fitting the axle as the side sheet by the boiler-maker, or by maltreatment when in service; but as these features leave their tracks, it is not difficult to ascertain *why* a wheel fails, nor is it any more difficult to determine the cause of failure of a side sheet.

*Cincinnati, O.* FRANK CORBETT.

### Defense of Richmond & Danville Drawings.

*Editors:*

I read a piece in your paper this month. It was signed, An Old Man. He said that while in the pattern shop at Manchester, Va., he saw a print of a cab bracket, and that it had dotted lines running everywhere and that it showed more labor than brains.

To show you that the gentleman did not know what he was talking about, I herewith inclose blue print of the bracket, which you will see is a very simple and inexpensive drawing. It would make an awkward section, as you can readily see. I wonder what the gentleman would say if he saw the drawing I made of a 20 x 24-inch cylinder in which I showed six views, as follows: Plan, inverted plan, transverse section, longitudinal section through center of cylinder, section where fastened to frame, and face view at center of bedplate. I think the dotted line in that drawing would rather confuse the old gentleman.

I desire to say here, that by maneuvering I saved two good weeks' work on the elevation of the new 20 x 24-inch ten-wheel passenger engines which the Richmond & Danville Railroad are having built at the Baldwin Locomotive Works. I am the only draughtsman in the superintendent motive power department now, since returning to Washington from Atlanta, Ga., so you can see that I have no time to loaf.

I have to make anything that comes to hand. Besides drawing, I have to get the tracings out of the case for blue printing, and afterward to put them back again. The 20 x 24-inch ten-wheel passenger engine and tender together have about *160* drawings, and are formed into two books 24 x 36 inches. I had been with the Richmond & Danville Railroad three years and seven months, when I took hold of the drawing department. It was in a very poor condition and no system. Now we have system and drawings which we are not ashamed of.

At the age of eighteen I entered the shops of the Baltimore & Ohio Railroad at Mount Clare, Baltimore, Md.; that was January 3, 1873, as an apprentice in the machine shop. Nearly one year after finishing my trade I took up drawing at the Maryland Institute night school, and graduated June 4, 1877, with the highest honor in the mechanical grade. One year later I was transferred to the drawing-room and, after being there over four years, I accepted a position with the Richmond Locomotive Works, and after being there over two years I received a call to the Richmond & Danville Railroad, where I now am. While in Richmond I taught mechanical design at the Virginia Mechanical Institute night school.

H. K. GRIFFITH.
*Richmond, Va.*

[We have examined the drawings of the bracket referred to and see nothing the matter with it.—EDS.]

### Using Emergency After Service Application — Some Exoerience — Some Everyday Trouble to Think About.

*Editors:*

The November number of your paper contains an article by W. F. Relyea, on the New York Central air-brake instruction car. He says, among the many things that this car proves to, or convinces the unbeliever of, are the following. First, "If you have made a light application and placed the handle of brake-valve on lap, then throw it around to the emergency notch, you don't get the benefit of the emergency-brake, or, in other words, the emergency-valve don't open because there is not enough pressure in train-pipe to open it." I beg leave to differ with the gentleman on that point.

I have fitted up an instruction-room in roundhouse, with pump, main reservoir, brake-valve, auxiliary reservoirs, brake-cylinders, signal-whistle, all complete, and representing a seven-car train, and at the same time showing every style of equipment on our engines, and freight cars; duplex gauges are connected to each brake-cylinder and auxiliary reservoir, giving us every facility for making tests that the Westinghouse instruction car has. I have just concluded a series of twenty tests, which the following table will show the result of, there was a slight variation in the pressures, owing to the inability to draw exactly the same amount of pressure from the train-pipe every time, but they show the general average. All tests were made with a pressure of 50 pounds in auxiliary reservoirs, and a piston travel of seven inches. Under these conditions a full application of brakes (in service notch) required a train-pipe reduction of 17 pounds, and reservoir and brake-cylinder pressure equalized at 35 pounds. A full emergency application gave 42 pounds in brake-cylinder.

The first column shows the reduction of train-pipe pressure, the second the auxiliary reservoir pressure, the third the brake-cylinder pressure (in service), the fourth the brake-cylinder pressure after using the emergency, after the light reduction.

| Train pipe reduction service. | Auxiliary reservoir service. | Brake cylinder service. | Brake cylinder after emergency. |
|---|---|---|---|
| 5 | 45 | 0 | 39 |
| 7 | 43 | 5 | 38 |
| 8 | 42 | 9 | 37 |
| 10 | 40 | 15 | 36 |
| 12 | 39 | 20 | 35 |

Thus it will be seen that there is a gain up to and including a ten-pound reduction of train-pipe pressure before the emergency is used. If the New York Central car does not give like results, it is because there is something wrong with the equipment, or the men in charge are following the instructions that a young man gave in the Westinghouse car on its last visit here. He says, throw the handle to the extreme left and let it stay there until the train comes to a full stop. That kind of an application only gives thirty-seven pounds in brake cylinder, a loss of five pounds over a proper emergency application, and necessarily a tardy release by having to replace the air in train-pipe uselessly wasted.

I have three problems in air-brake practice to submit to your readers. While they may not be new to all, yet if a discussion of them results in helping one air-brake man out of trouble I will feel that my experience has accomplished some good.

1st. When the pump is started all the air flows out the exhaust-pipe fitting of brake-valve. On lap and in the emergency notch air can be held in main reservoir, but in full release or running position it *all* flows out as fast as pumped. What is the matter?

2d. At the slightest touch of handle in service notch the brakes all go on emergency. Where is the trouble?

3d. A pump running a steady and regular stroke suddenly makes several quick strokes, sometimes up and sometimes down. To all appearance a suction-valve has stuck up, allowing the pump to discharge back through suction instead of in main reservoir. The most careful examination failed to find any air blowing back. Three or four quick strokes and the pump resumed its regular stroke again. This occurred at intervals of four or five minutes while the pump was in use. There was not the slightest difficulty in keeping up seventy pounds of air with five coaches down a grade of 120 feet to the mile. Where does the trouble lie?

### Brake Trouble in an Awful Cold Country.

*Editors:*

In this country during the winter the coupling next to main drum freezes and air-pump stops working; in order to start pump again have to apply lighted waste to thaw this out; in many cases this has to be done several times while running over division; would say there is a governor attached to air-pump; before governor was attached this trouble of freezing up did not often occur—in fact, it was very rare to find pump stop on account of above trouble. This summer the whistle signal has been attached. The weather during our winter months has been very severe, averaging from 25 to 55 below zero, with heavy winds, so that it's not a very pleasant job to be getting down at every other stop or so to thaw out this coupling, and again, I have seen cases where pumps would be working all O. K. while at station, and after pulling out have known pump to stop before getting over main line switch, thereby causing extra stop. Can you throw any light on this subject?

F. S. THORNE.
*Brandon, Manitoba.*

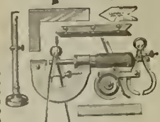
[The trouble mentioned by our correspondent is a serious one on mountain grades in such extremely cold countries as the Northwest Territory of Canada. The pump governor may aid the elements in freezing up the pipe by temporarily shutting off the flow of air and giving the moisture time to congeal. The best cure is provision against moisture in the air as much as possible and in locating the air drum on the engine in such a way as to make the pipes the most direct and where they are liable to keep warm. Drip pockets help in collecting the moisture before it gets to a point liable to freeze, it is almost impossible to keep air pipes from freezing up in such a cold country when the drum is located at the rear of the tender.]

### The Mechanical Department.

*Editors:*

It has often occurred to the writer that the frequent changes in the heads of mechanical departments must be largely due to other causes than simply change of management, and he has quietly tried to find the cause. The old idea was that a man, in order to be a master mechanic, must be all the name applies, *i. e.*, a man who can do everything, and, therefore, supposedly competent to supervise others.

## STARRETT'S FINE TOOLS



For ... workers in metal or wood. Accurate enough for the finest mechanic. Low priced enough for the youngest apprentice. Made on honor, best in finish, latest in design. All warranted. Skilled mechanics prefer them. Live dealers sell them. Ask your dealer for my catalogue. If he cannot give you one send to me.

☞ WRITE FOR OUR CATALOGUE. ☜

That idea has now gone out of date, and the man with the executive ability to properly organize his department and systematize his labor is the man for the position, although he may not have had the diversity of experience in actual work that the old-time master mechanic has had. The *Safety Valve* puts it thus: "The man with the pencil and drawing-board is driving out the man who carries a foot rule in his pocket. The man with the trained mind is usurping the place of him with the trained hand, and the artisan of the future, if looking for promotion, must needs be a student." It does not follow, however, that because a man has a trained hand that he cannot also have a trained mind, for he will be far more efficient if he have both; but if we must choose between them both, give us the well-trained mind, for it must be evident to all thinking men that the man with a business education, including, of course, mechanical draughting and an experience in shop-work sufficient to give him an intelligent understanding of practical methods, is far superior to the man who is simply educated in shop practices alone. In the one case, theory is reduced to practice on a basis of scientific principles, whereas the other has no theory and whose practices are fast becoming obsolete in the light of mechanical improvement.

We do not want to be understood as intimating that a master mechanic must be a graduate of a college, but he must be trained on broad-gauge principles, either in practical mechanical schools or in technical colleges; and the day is coming, and we believe it is not far distant, when every position in our railroad mechanical departments, from fireman to superintendent of motive power, will be filled with men especially educated for their positions. The position at the head of any railroad mechanical department is one of honor, trust and grave responsibility, and it takes a very little difference in material application for a man to save or lose ten times his salary.

There is hardly a shop in the country where the shop methods could not be materially improved, and yet, if you tell the master mechanic so, he pities you because you know so little about his ability to beat anybody in the world for economy. A short time ago the writer was visiting a master mechanic who was bitterly denouncing the general manager who had just sent him a most positive order to reduce his force and cut down expense. He said, "See the work I have to do, and only this handful of men to do it. It is shameful, and I cannot keep my engines up with so little force." The writer went through the shop with him, and was pointed out in detail the work being done, and it is not in the least exaggerating to say that at least one-third of his labor was employed in making specialties that could have been purchased from the manufacturers cheaper, and saved him his labor for far more important work. Our master mechanics are trying to do too much. The great expense of the shop is not only costly material, but costly labor to work it, and it can be summed up very easily if they will only use a little business common sense. Make your shops what they should be—repair shops, and not try to convert them into manufacturing establishments. It is all very easy to show how cheaply you can do your own work, but if ever the general manager goes carefully over the auditor's report, he will soon discover your mistakes, and call on some one else to conduct your department.

Don't cheat yourself by underestimating your cost. Keep up with the procession. Read the railroad papers. Think how it would be if you had to pay the bills yourself. Educate yourself up to your requirements, and become a practical business man as well as a practical mechanic. Our railroad papers have some of the brightest mechanical minds in the country upon their staff, and if you have been deprived of scholastic advantages, take advantage of their learning and practical experience. Read the papers. Don't say you haven't the time. Take time, for it will save your company more than your time will cost them, and make you a more competent man in every respect, for the man who reads and thinks and acts is the coming man. GEO. L. DE WITT.

*Milwaukee, Wis.*

## Young Small's Locomotive.

*Editors:*

In looking over LOCOMOTIVE ENGINEERING I saw a cut of a small engine called the "Little Maryland," and noted her sizes. I have one as a competer, and one that has a record which I will give you in detail. She ran by engagement at Elitch's garden, Denver, Col., four months of last summer every day except one day and a half, which was caused by a washout. The distance made was 1,320 miles. She hauled from five to seven cars. Each car was weighted down 50 pounds to keep from jumping the track while going around the short curves. The track was in a circle of 400 feet. This little wonder was reviewed by from 1,000 to 10,000 people a day during her engagement. The principal dimensions are as follows:

Gauge of track $8\frac{3}{4}$ inches, cylinders $1\frac{1}{4}$ x 2 inches, diameter of drivers 6 inches, total wheel base 28 inches, top of rail to top of stack 20 inches, total length of engine and tender 67 inches; diameter of boiler $7\frac{1}{2}$ inches, fire-box $5\frac{1}{2}$ x $6\frac{1}{2}$ inches; five tubes: three $1\frac{1}{2}$ inches, two 1 inch. Tender holds 4 gallons of water, and boiler 3 gallons. Total weight of engine and tender ready for the road 260 pounds.

I built this little wonder in Jamestown, New York, commenced it 1888 and completed it 1889. I worked on it by odd spells. I made my own patterns, built my own boiler, made of the best steel. Boiler carries 125 pounds steam, tested, when built, at 300 pounds per square inch. My workshop was in our kitchen, my bench a stove box. I borrowed tools to work with. I never served at any trade in a shop. I am now firing on the Union Pacific Railroad. I presented their road with this little wonder at the gardens last summer.

I claim that I have the smallest successful coal burning engine in the United States. This engine hauled five cars with five grown persons. Each car weighing without its passengers 125 pounds, each person averaged 125 pounds, which makes 2,250 pounds the little wonder hauled around this circle of 400 feet.

C. T. SMALL.

*Denver, Col.*

YOUNG SMALL'S LOCOMOTIVE.

## A Reminder from the Drawing-Room.

*Editors:*

I have always noticed that the mechanical papers are forever showing up new designs of locomotives and giving the superintendent of M. P. credit for them. Now I should like to know if the mechanical draughtsmen are not entitled to some credit? As a rule they make all the drawings, and many a useful suggestion here and there, pile on figures and lines and all to scale, and all must be right.

I never hear of them in the way of credit, and it's mighty seldom one gets appointed to the position of master mechanic.

Couldn't you put your pen under and give us a lift out of the mire of obscurity?

ONE OF 'EM.

*Washington, D. C.*

## About Lining Up Guides—Wear on Same.

*Editors:*

On page 283 of your August (1892) issue Mr. C. F. Smith, of St. Paul, "picks me up" on two statements made in my article contributed to your February (1892) issue. The first of these is his exception to there being any rock to a crosshead when first laid on the bottom guides after they have been lined and leveled as closely as possible before the line is removed from the cylinder. Mr. Smith says that after setting guides for fifteen years he has never found this rock. I am very glad for his sake that such is the case, for I have known quite a number of persons (ye humble writer being no exception) who *have* found the rock, and who have spent a few anxious moments endeavoring to unfind (?) it. The other statement to which he takes exception is: More wear being from top guides and top crossheads when an engine is running forward. And after more closely observing this point I believe him to be right when he says "The greater wear is on the bottom guides," under these circumstances, and I take pleasure in thus publicly acknowledging my belief that upon this point he is right and I was wrong, and I wish to thank Mr. Smith for pointing out my error. His is the sort of criticism I like to see.

It is the *truth* and the correct ways we are after more than fame or glory.

L. C. HITCHCOCK.

*Minneapolis, Minn.*

## What Made These Brakes Apply?

*Editors:*

We had a little trouble with our air-brake, and I have no doubt many of the readers of your paper have had the same experience, but for the benefit of those who have not, I will give the symptoms and let them determine what it was, and send the answer for publication next month.

It was nothing serious but very annoying, as the brakes commenced to go on as soon as the brake-valve was placed "on lap." At first I thought there was a leak in the train-pipe, so I got down and looked, but found it O. K. I then placed the valve "on lap," and found that air escaped through the equalizing valve—not enough to make much noise, but enough to apply the brakes. Thinking that there must be a leak in the brake-valve reservoir, I examined it and the pipe and joints between it and the brake-valve, but found no leak. Not having time for further investigation, I postponed the matter a while and afterward found the difficulty, which was soon remedied. What was it?

M. E. WATTS.

*West Nanticoke, Pa.*

## Good Work with Brakes.

*Editors:*

In replying to our Wisconsin friend, would say that I did not wish to be understood as saying that the engineers in question habitually used 12 lbs. of air to stop with, but my idea was to give the maximum, showing what is used in emergency stops, and as a rule such applications are made when there is something on the track or where a very quick stop is required, and I thought this was understood in friend Synnestvedt's statement in the August issue.

I will, however, say that an occasional station stop is made with 3 lbs., and rises accordingly, until, as I have said, it gets to about 12 lbs. for an emergency, and as for telling these engineers they are using too much air to stop with, I believe they

would give lessons on that subject, and that such information to them would be superfluous. For instance, their run is 103 miles and there are four trains handled by three men, and the wheels under coaches are inspected after each trip, and the general foreman of car inspectors has informed me there has not been found a single slid-flat wheel caused by these engineers handling air-brakes for over twelve months and there has been no complaint about their trains jerking. As to pressure equalizing at 12 lbs. reduction, I have found some coaches with 10-inch brake cylinder and 12 x 33-inch reservoir that would equalize with 9 lbs. reduction and others that took as high as 14 lbs., difference I suppose caused by temperature and strength of graduating springs, and I find the average pressure in 10-inch brake cylinders to be 56 or 57 lbs. when equalized through service application and at 4-inch piston travel with 70 lbs. in auxiliary reservoir to start with. Now take a 10-inch brake cylinder in this condition and make a 12-lb. reduction; there would still be greater pressure in the train pipe, namely, 58 lbs., while the equalized pressure, 56 lbs., in the brake cylinder, applied to the wheels as a service stop, would, I believe, stop the train in less distance than a quick-action or emergency stop with the same quantity of air in the brake cylinder.

I have made some experiments on coach, tender and driving brakes to determine what were the average pressures in them while in service, and they give some idea of what a man does when he stops a train without jerking. The American driving-brakes had 12 x 33-inch reservoirs and 12-inch brake cylinders with 5-inch piston travel, equalized at 35 to 38 pounds. Tender with 10 x 24-inch reservoir and 8-inch brake cylinders gave 50 pounds at 7-inch piston travel, while the 10-inch cylinder on coaches with 12 x 33-inch reservoir gave at 4-inch piston travel 56 to 57 pounds on service stop, 59 on emergency and 61 on quick action, and at 8-inch piston travel equalized at 50 pounds service stop, 54 emergency and 57 quick-action, but graduated much better on longer travel.

What is the opinion of others as to a 12 x 33-inch reservoir being a proper size in this case. Does it seem to supply too great a volume of air and take too long to fill on this account, or not?

Now, as for that love-feast, would say I am partial to such things and do not see why, as that one was missed, we could not get up a small crowd and have one of our own, and after some others have been heard will tell what explanation I gave to the engineers.

GEORGE HOLMES.

*Roanoke, Va.*

## Oiling Air Pumps.

*Editors:*

One of the most interesting articles I have read for some time was the one signed "A Fireman" in the November number of your paper, treating of the equalizing discharge valve. It is refreshing to read anything as candidly and tersely put, even if the writer be in error in the position taken. As stated in the editorial note at the end of the article, most of the trouble was undoubtedly the result of intoxicating the pump with such a cocktail.

That it is bad to mix drinks or to drink too much is well known, and the same thing may be very aptly said about the treatment of the air-pump. Give it only one kind of oil (the right kind), and very little of that. One of the most difficult things to teach engineers is the proper care of the pump, and particularly in the matter of oil.

Some men pour in a few drops or more every time they go around the engine to oil up. Some men use black oil, some valve oil, some signal oil, and some a mixture of every oil they can find.

And what seems peculiar, a man who thus doses the lower cylinder is generally very anxious to save oil in the upper cylinder, and will run it almost perfectly dry until it is in a horrible condition, packing-rings all loose, bushings worn hollow, and every stroke blowing like a porpoise. The upper cylinder under the action of the steam requires much more oil than men imagine, and should never be allowed to run, even for an hour, entirely without oil.

Any man who does not give the upper cylinder sufficient oil will find out that before very long he will have to assist the action of the pump with a hammer, until finally even the hammer will not start it, and he will be required to give up his train or run to the end of his division without brakes.

As before stated, the great majority of men give the lower cylinder altogether too much oil, and it is a habit of which it is very hard to break them, largely because the pump seems to be like a toper who suffers when the quantity of his grog is reduced. A pump which has been in the habit of receiving large doses of oil regularly and often, will groan dreadfully if the allowance is cut down very suddenly, so the best way is generally to reduce the quantity gradually and at constantly lengthening intervals. If this does not secure the desired result the pump must be overhauled, after which the proper allowance of oil may be given.

The evils directly traceable in many cases to the use of the wrong kind of oil in the pump or in too generous doses, may be summarized as follows: Heating, pounding, sticking of valves and consequent intermittent or uneven stroke, failure of brakes to set with proper force in graduation, difficulty of moving the engineer's valve handle, gumming up of the train signal valves, especially the pressure-reducing valve, and other troubles too numerous to mention.

The writer is familiar with a case where, for the sake of experiment, several pumps were run for a number of months without any oil in the air cylinder except such as would be sucked down with the piston rod from the upper cylinder in the downward stroke, and a small quantity put at frequent intervals on a swab around the piston rod. When these engines came into the shop for repairs the pumps were carefully examined and found to be in first-class condition, better in fact than many which had been generously fed with oil, and showing less wear.

*Chicago, Ill.* PAUL SYNNESTVEDT.

## Passes in New South Wales.

The question of free passes on railways appears to be exciting the people of New South Wales not a little. Politicians there, as elsewhere, consider themselves entitled to ride free, and they are a little more exacting in their demands than the average assemblyman of America. The members of Parliament obtain a gold badge which serves as a pass on the railways. This badge they consider a perpetual legacy, and ex-members of Parliament are accused of using it after they are no longer members. A movement has been started to deprive ex-members of the badge which entitles them to ride on railways, and there is a feeling of indignation among those concerned at the attempt to curtail their privileges. Meanwhile the government railways are a heavy tax upon the colonist, and hot words are passing between those who think that all citizens should pay their railroad fares and those whom custom has made spungers upon expense. The holding of a pass entitles a man to free transportation over 12,000 miles of railways. The abuse of this privilege is said to have a marked effect upon the earnings of the railways.

In a lecture on ancient railway history by our correspondent, Mr. Clement E. Stretton, of Leicester, England, and reported in the London *Railway World*, the claim is made that George Stephenson was the inventor of the steam whistle. We believe this to be a mistake, and we are under the impression that the steam whistle was invented in this country. Can any of our readers give us information on this question?

## Some Blacksmith Shop Tools.

BY GEO. F. HINKENS.

I am glad to note that your paper is taking up railroad blacksmithing; it is an important branch and one that has been neglected.

I believe one of the troubles has been that blacksmiths were afraid of being criticised if they ventured into print. I am the opposite; I am afraid they won't criticise; let them come, be fair, tell the truth and all will learn something.

Please remember, however, that I am a blacksmith and not a draughtsman, and that I make all my own sketches.

A comprehensive view of blacksmithing is impossible without a knowledge of the different parts for which the work is intended, knowledge that can only be acquired by close and studied observation. Therefore, the first in order and importance to know of iron is, "What service must it render, what special purpose is it best adapted for?"

Mr. Lottes puts the question, "How often do we hear of a side-rod breaking in the welds?" and says nine times out of ten you could blame the material or man that did the forging. Please, Mr. Lottes, what is the cause of the tenth mishap? Possibly the tenth break is the result of a bad weld or poor iron, but the other nine were due to crystallization; now I never saw a side-rod broken in the weld.

However good the weld, it is always the weakest point. At least tests have demonstrated such to be a fact. Consequently, it is a matter of vital significance to locate your weld, keep the weld from the terminus of vibration lest the rod will break before the proper time, and that time will arrive when the constituent particles at the end of shock or vibration become crystallized, due to the molecules of metal becoming intact or in a measure independent of each other.

The question then suggests itself, how are we to avoid crystallization in side rods?

Select suitable material which should be fibrous and hard; fibrous so as to sustain shocks, and capable of yielding to force or pressure without breaking. Hard, because soft iron will crystallize quicker than hard, and after all this precaution is taken don't allow side-rod to be in service long enough for internal disintegration to take place, and when it does take place there is only one remedy—"fusion."

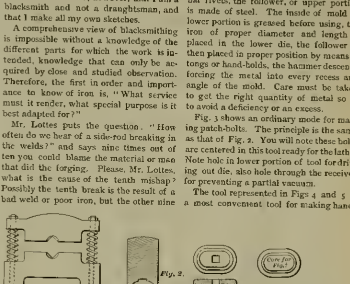
In regard to welding I have reference to welds taken in a smith's fire, in an oxidizing atmosphere. As a matter of course, "if temperature is increased to fusion in a non-oxidizing furnace welding is practically perfect," but I am speaking of welding in its general acceptation.

As to forging there are various methods and for those of your readers that may be interested I will endeavor to generalize a few tools that can be utilized with efficiency under a steam hammer.

Fig. 1 shows a device for squaring stay-bolts cold. A pair of coil springs lift the top die to allow for turning on each quarter. With this process we square 2,240 bolts in ten hours; all heads are central and uniform, and it is without question a valuable tool in a shop not provided with an automatic or belt-power bolt machine. The hole in die is drilled half across the face, the balance is squared for the head. In connection with this tool, we use gauge tongs.

Fig. 2 represents a tool for making crown bar rivets, the follower, or upper portion is made of steel. The inside of mold or lower portion is greased before using, the iron of proper diameter and length is placed in the lower die, the follower is then placed in proper position by means of tongs or hand-holds, the hammer descends forcing the metal into every recess and angle of the mold. Care must be taken to get the right quantity of metal so as to avoid a deficiency or an excess.

Fig. 3 shows an ordinary mode for making patch-bolts. The principle is the same as that of Fig. 2. You will note these bolts are centered in this tool ready for the lathe. Note hole in lower portion of tool for driving out die, also hole through the receiver for preventing a partial vacuum.



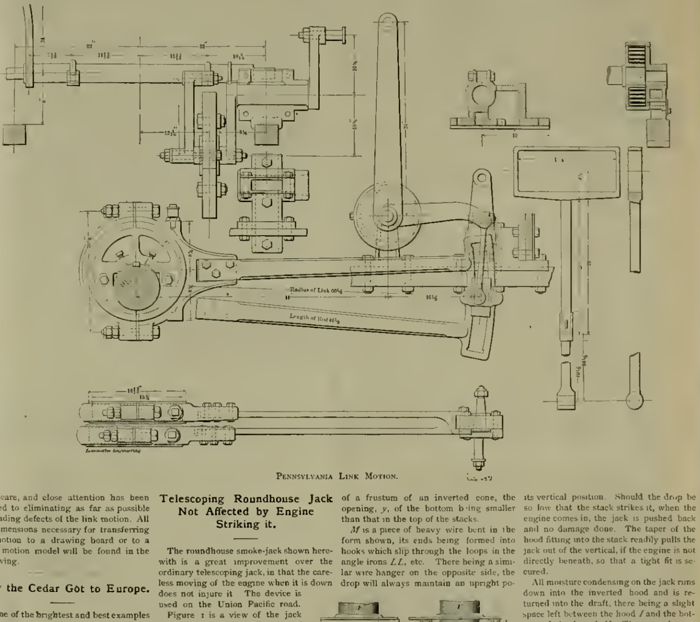
The tool represented in Figs 4 and 5 is a most convenient tool for making hand-hole plates, an article extensively used about locomotive boilers. A solid mold or core, exactly a copy of the work to be produced, is made of steel by hand forging and then finished in the machine shop to the required form as shown in Fig. 7. The bottom or receiving portion of the tool, Fig. 5, is then forged to the general form and core, Fig. 7, is indented into it. In making the top or shearing part as shown in Fig. 4 care must be exercised in giving the proper clearance lest it will bind or drag the metal. The tool now being ready for use the inside of mold, Fig. 5, is oiled with greasy waste, the white-hot iron is placed thereon, the hammer descends upon it, forcing the metal into the mold, thus forming the rib or flange. The next process is shearing it to the required form, which is done by placing the cutter, Fig. 4, over the mold, Fig. 5, thus cutting off all surplus. The last operation is placing punch, Fig. 6, in square hole of Fig. 4, driving it through and making hole for the bolt.

---

A thing about car construction that strikes us as strange is the practice of making short pockets for the stakes of gondola cars and cutting the stake flush with the bottom of the pocket. Why not extend the stake to the bottom of the sill and give the lower part fulcrum hold to resist the leverage of the long end? It is no wonder that there is difficulty in keeping the sides of gondola cars from bulging out.

### Pennsylvania Link Motion.

The numerous class of our readers who concern themselves in the study of valve motion will find in the annexed engravings a valve motion well worthy of close attention. It is the standard link motion for all the locomotives belonging to the Pennsylvania Railroad to which it can be applied. It has been worked out with great care, and close attention has been devoted to eliminating as far as possible the leading defects of the link motion. All the dimensions necessary for transferring the motion to a drawing board or to a valve motion model will be found in the engraving.



PENNSYLVANIA LINK MOTION.

### How the Cedar Got to Europe.

"One of the brightest and best examples of perseverance and genuine love of plants was exhibited by the man who first introduced this species of tree into Europe," again began Jack, pointing to a large cedar growing on the other side of the road behind a lodge gate. "I was only a youth when I first read the story of that French man who, when traveling in Palestine found a little seedling among the cedars of Lebanon. He carefully took it up, with all the soil about its roots, and, for want of a better flower-pot, placed it in his hat. The ship in which he sailed, on its voyage home, met with many contrary winds, and was much delayed in consequence, so much so that the provisions fell short, and all on board were put on short allowance. The captain received only two glasses of water daily, the crew one glass, and the passengers only half a glass. Our traveler, undismayed by its scarcity, gladly shared his half glass with his little seedling, stinting himself so much in that respect that, when the ship arrived at last in port, he was almost dying, and, behold, the little cedar was a fresh young tree six inches high! It required all his persuasive eloquence to convince the Custom House officers that the hat contained nothing more valuable than its tiny roots. He had it conveyed to Paris, and planted in one of the gardens there, where it grew and grew, until it became the largest and noblest tree in all the gardens. When it had attained its hundredth year it was cut down, doomed to make room for a railway, and now, the most potent factor in the civilization of the nineteenth century, 'the god of fire and steam,' shrieks daily over its withered roots."

### Telescoping Roundhouse Jack Not Affected by Engine Striking it.

The roundhouse smoke-jack shown herewith is a great improvement over the ordinary telescoping jack, in that the careless moving of the engine when it is down does not injure it. The device is used on the Union Pacific road.

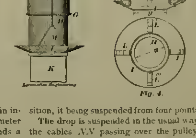
Figure 1 is a view of the jack at right angles to the direction of the track beneath. Fig. 2 is a view of the upper portion of Fig. 1 taken at right angles to it or parallel to the track. Fig. 3 is a section of the drop part of the jack. Fig. 4 is a plan of Fig 3. *FF* are the roof beams of the roundhouse. *E* is that part of the jack which extends above the roof. It also extends down into the roundhouse to a point slightly below the lower edge of the beams *FF*.

The pipe or barrel *O* is made of sheet-iron stiffened at the lower end by the ring *G*, and at the top by the ring *D*. On the opposite side of this ring *D*, are trunnions *AA*, which pass through suitable holes in the straps *CC*, which are fastened with lag bolts to the inner face of the beams *FF*.

The pipe *O* is made slightly larger in internal diameter than the outside diameter of *E*, the lower end of which extends a short distance into it. It will be seen that the pipe *O* swings freely on the trunnions *AA*, in a vertical plane parallel to the track.

In the lower holes of the straps *CC*, are hung the pulleys *BB*. The barrel *H* of the drop on lower part of the jack is made of sheet-metal, its outside diameter being slightly smaller than the inside diameter of *O*, so it will slip inside easily. To the bottom of *H* are riveted the angle irons *LL*, etc. The arms of *LL*, etc., form an acute angle, *x*, with each other. To the other arms of *LL*, etc., is riveted the hood *I*, also of sheet-iron; its form being that of a frustum of an inverted cone, the opening, *y*, of the bottom being smaller than that in the top of the stacks.

*M* is a piece of heavy wire bent in the form shown, its ends being formed into hooks which slip through the loops in the angle irons *LL*, etc. There being a similar wire hanger on the opposite side, the drop will always maintain an upright position, it being suspended from four points.



The drop is suspended in the usual way the cables *NN* passing over the pulleys *BB* and running back horizontally for some distance where they come together and are continued in one cable. This passes over another pulley and comes down the face of one of the posts of the roundhouse. To the lower end is attached a counter weight of the same weight as the drop. The motion of this counter weight is fixed to keep the drop in proper limits.

Figure 1 shows the drop resting on a stack *K*. Should the engine start with the drop in this position the jack swings on the trunnions till it is free from the stack, when it swings back and finally resumes its vertical position. Should the drop be so low that the stack strikes it, when the engine comes in, the jack is pushed back and no damage done. The taper of the hood fitting into the stack readily pulls the jack out of the vertical, if the engine is not directly beneath, so that a tight fit is secured.

All moisture condensing on the jack runs down into the inverted hood and is returned into the draft, there being a slight space left between the hood *I* and the bottom of the barrel *H*. This entirely prevents the water that condenses on the jacks from running on to the engine.

### Inferior Firebox Steel.

I believe that instead of the price of steel for fireboxes of locomotives dropping all the time, it would be for the interest of railroads if it were increased and the increase meant a better article.

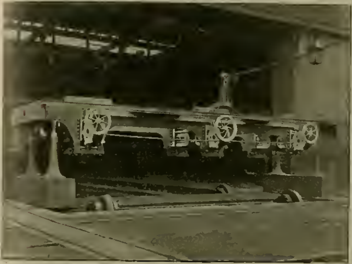
A new boiler costing from $1,500 to $2,000 is put into service, and in ten months is torn apart because plates of an improper quality have been put in which require renewal, while another engine doing similar work has caused no expense to the owners. The steelmakers and the railroad companies ought to agree on a quality of steel that will stand the bad water and not call for the expensive repairs that renewing fireboxes or side-sheets involves. Facts regarding good and bad steel and the comparative results of using them ought to be strongly urged upon the attention of railroad managers.—*J. N. Lauder*.

## The Crewe Shops of the London & Northwestern, the Largest in Great Britain.

[*Editorial Correspondence.*]

The shops of the London & Northwestern road have a peculiar attraction for an American, being, as they are, the largest shops in the country. The road operates 1,700 miles of road and owns 2,620 locomotives—the largest number owned by one road in the world. These engines were built at Crewe.

I had the misfortune to get to Crewe during the August "bank holidays," and found the works shut down, but this was more than compensated for by the kindness and courtesy shown me by Mr. F. W. Webb, the locomotive and carriage superintendent, who personally conducted me about the works and added greatly to the interest of my visit by answering a thousand questions and allowing me to pry into everything that caught my eye.



JAW FACING MACHINE.

The shops at Crewe are strictly locomotive and permanent way shops—the "carriages" and "waggons" are maintained by the shops at Wolverton.

Crewe is all railroad. In 1841 the population of the village was 203, but the next year the shops of the combined roads that make up the London & Northwestern were moved to Crewe, and the census of 1851 showed 4,571 inhabitants. Now, or in 1891, there were over 30,000. There are two small factories here employing female labor, otherwise there is nothing of the town except the railroad shops and the homes of the workmen. The public buildings are good and there are plenty of them, but everything has the L. & N. W. brand on it in some way or another.

### PERSONNEL OF MANAGEMENT.

The first superintendent of these works was F. Trevithick, a son of the noted engineer who did so much toward the development of the steam engine, he was succeeded in 1857 by Mr. Ramsbottom, inventor of the water scoop and the double safety-valves that bear his name, who was in turn succeeded in 1871 by the present efficient officer,—only three men at the head of these great works in half a century.

### EQUIPMENT OF THE CORPORATION.

Some idea of the magnitude of the business done by this corporation may be had when I tell you that last year their earnings were $58,400,000 and the expenses $31,045,000. They employ 60,000 hands, 18,000 being in the locomotive department. They own 2,620 locomotives, 6,000 passenger carriages and 57,000 goods wagons, besides twenty steamships and 3,000 horses and carts.

### BUSINESS DONE.

They carried 63,000,000 passengers and hauled over 40,000,000 tons of goods. There are 800 stations on the line, 1,500 signal cabins or towers and 32,000 signal levers to handle; 17,000 lamps are lighted every night. They burned over one and a quarter million tons of coal last year, and ran 211,000 special trains—or that many in excess of those on the time card.

### THE SHOPS.

The offices of the department are in a very long brick building, probably 800 feet long; this contains the drawing rooms, photo studio, the stores, accountants', running and signal offices, complete suits of rooms for the head of each department. This building is surrounded by green sward and shrubs, and near the end and inside the works is the residence of Mr. Webb.

The shops I shall not attempt to describe; they are substantial brick and stone buildings extending for a mile and a half, and being located in a Y where the different lines converge to form the main stem to London, the works extend over 116 acres of ground, there being thirty-six acres of roof.

The company roll their own rails. I believe this is the only company that does this in Great Britain, although most of them make everything they use. This is a noticeable feature of all English shops; they are manufacturers of everything they want—a hard place for supply men if it was not for the export trade of the country. The rails now used are of the bull's-head variety, being 30 feet long and weighing 90 pounds per yard. The forge shop is unique and a very extensive one. Here I saw my first Ramsbottom duplex hammer. I had heard of these for years. There is a 30-ton machine here and it is said to be very efficient. There are two 30-ton blocks driven horizontally to and from each other by steam. The usual vibration noticed in the ordinary vertical hammer is absent to a large degree in this big machine. There are quite a number of vertical hammers here ranging from 2,000 pounds up to 20 tons.

Mr. Webb's metal sleeper is rolled here, and there is something like 100,000 of them in use on the line, but I must say I don't like them, they are so noisy. It is plainly discernible when the train drops off the wood on to the steel.

Not only are the rails rolled here, but the steel is made on the ground, they have both the Bessemer and Siemens-Martin processes, and besides this make their own crucible steel for edge tools.

Like all the other European roads, they are making many parts formerly made of wrought iron of cast steel, and a large plant is employed.

One of the nicest things about these shops is the power, gas engines are used and each shop and department has its own. No boilers are needed and the space occupied by them and the coal bunkers is entirely saved, besides the room required to handle the coal, etc., the large Otto gas engine in the erecting shop has been in use since 1884, giving the best of satisfaction. One good man can keep up a number of them, and they are easily cared for and are always ready to go to work on a moment's notice without waiting to get up steam. In America we are just beginning to see the advantages of divided power, how much lighter shafting we can use, and how much we can save by transmitting power from one shop to another, the work of Westinghouse, Church, Kerr & Co. is doing much to show the utility and practicability of this plan of having a dozen engines instead of risking everything on one big one.

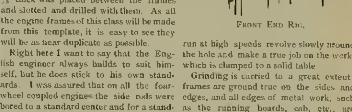
At Crewe the gas works are large, there being forty-nine producers and are located where the least in the way, the gas coming to the works for furnaces and engines in underground pipes.

There are only two parts of a locomotive that Mr. Webb buys, the brass flues and copper fireboxes, they use a half a million flues a year.

The flat plate frames seem awful easy to make, just slabs of 1⅛ steel slotted, they put ten on a three-headed slotter at once, and do the slotting for $1.25 per frame. I noticed they were making the first frames of a heavy eight-coupled mineral engine, and in order to get a template of the frames for future use, a steel plate ½ thick was placed between the frames and slotted and drilled with them. As all the engine frames of this class will be made from this template, it is easy to see they will be as near duplicate as possible.

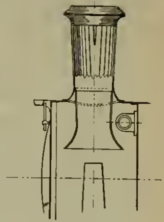
Right here I want to say that the English engineer always builds to suit himself, but he does stick to his own standards. I was assured that on all the four-wheel coupled engines the side rods were bored to a standard center and for a standard pin, and that the side rods on nearly a thousand engines were interchangeable, although the engines varied much in general design.

One of the interesting tools to be seen is the rotary device for squaring up the jaws of frames. Three of these are shown at work on the frame of a six-wheel goods engine. These machines are very simple, the cutting heads being driven by a worm on the shaft, and carrying tools on each side, they are centered by special devices on their frames as shown, and one feed through the jaws cuts both sides. At some places these tools are mounted on wheels and are shoved under engines in repair shops by putting planks across the pit, they are then centered and the jaws turned up. Many roads there do not use shoes or wedges, simply turning up the horn-blocks when worn, it is no great job to replace these blocks on the frame, an American frame is an expensive thing to change much.



EIGHTEEN-INCH GAUGE "DICKIE."

I should like to call attention to the capstan in front of the "Charles Dickens." Many of these power devices are around the works, and are most convenient when it is desired to pull dead engines in or out of the shops, or in moving or loading anything heavy; they can be set in motion any time and cost little or nothing to maintain; they save lots of "pushing." They have a great many special tools that we don't need and some that we might use to advantage. There are a number of sizes of vertical spindle grinding machines, with which they grind out all holes in hardened work. Emery wheels of small diameter



FRONT END RIG.

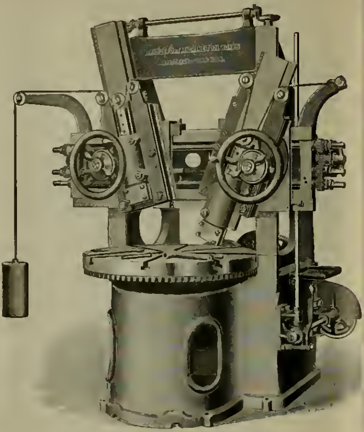
run at high speeds revolve slowly around the hole and make a true job on the work, which is clamped to a solid table.

Grinding is carried to a great extent; frames are ground true on the sides and edges, and all edges of metal work, such as the running boards, cab, etc., are ground and polished. A large room is fitted up with grindstones, where all kinds of work is finished.

Milling is done extensively, and some very ingenious machines are employed to do special work, such as milling around the hubs and between the spokes of wrought-iron driving wheels. They finish a great deal of work that is afterward painted.

I expected to see sawing machines used extensively, but there are not many, and the fabled band-saws that "cut out the throws of crank shaft forgings" were not to be found, band-saws are used on thin sheet metal. Hot saws are used in the forge; one of them seven feet in diameter, running with a periphery speed of 13,000 feet a minute, cuts off the end of a nine-inch axle in thirty seconds.

They have a rotary milling device for cutting out the throw of the cranks. This has two cutting tools in a revolving wheel while the centers turn the axle, forging so



as to feed it to the cutters, making a complete turn around the center of the pins, thus roughing out the throw and forming the pin itself. This is called a "nibbling machine."

All wrought-iron work is annealed and every five years all wrought-iron work such as rods, crossheads, pistons, valve motion, etc., are annealed and rehardened. This prevents crystallization and takes out any strains that service may have put into the parts.

In the erecting shops they have well-made frames so constructed that the engine frames, cross frame braces, horn blocks, etc., are simply put in place without measuring and riveted up.

One of these shops is devoted to the manufacture of signal apparatus, which is very intricate, and there is lots of it. The European roads are run by signals, the engineers rarely or never receiving orders to move their trains; double track lines are controlled by manual, inter-locking signals; single track lines are operated by the staff system—a staff being the scepter of between the trucks and only some 18 inches above the ground; it has seats in the end and is used to hurry pieces for repair, tools and men from any of the shops to the running sheds or any place else.

As so much of the work is manufacturing, there is always large orders of stock going through the works; injectors and brake apparatus are made in lots and special tools provided for them.

Around the works everywhere there is an 18-inch-gauge track, and numerous little locomotives like the one shown herewith are employed in handling material, and wonderfully powerful and handy little helpers they are. The boilers are straight, round shells, the firebox being a tube in the end about as big as a pail; they have a throttle and lever at each end so that the runner can see where he is going; they carry 165 pounds of steam on these. There are five miles of 18-inch track.

In the shops most of the work is done by the piece and "piece work detectives" are employed to keep track of results and cut down the price of work.

brake blocks are used. These were once discarded for iron, but the men petitioned to have them back, and as they cost less than iron, back they went.

Everywhere is the evidence that cast-steel is taking the place of wrought-iron, but it is especially noticeable in the case of wheels for cars and engines. Cast-iron wheels are not looked upon as safe, still their rough-and-ready mineral and coal engines have cast drivers with the old-fashioned I-section spoke.

On the front of the stacks or top of the arch there is a little bracket on which different devices are placed to denote the character of the train; these are pieces of sheet iron cut in oval, diamond, heart or other shape and painted white. These are used to show the signalmen in the towers what trains are important and should not be delayed, and should be run around others, etc. Fish and meat trains are run at a high rate of speed and given the preference over other trains.

On some of these engines a real novelty is to be seen in the shape of solid-ended to get her back. The crew number is fifteen.

Driving axle journals are, as a rule, very much longer than ours and hot-boxes correspondingly less; 12 inches is not an uncommon length, the springs being inside the frame; the boxes bear directly upon the "horn-blocks," and few of them have any provision for taking up wear.

Little attention seems to be paid to making an engine easy to repair; they are made to run. For instance, the front ends are riveted on the arch and all the rivets filed down smooth and flat; nice pieces of work, but expensive to get into shape when once disfigured.

The front flue-sheet is, as on all British engines, larger than the boiler; it is always fastened to the barrel of the boiler by an angle iron; its lower edge is extended down and fastened to the cylinders on the frame; the edge is flanged ahead and the arch fastened to it. This is why all their engines have a smokebox larger in diameter than the boiler.

As every joint about the average Eng-

"Charles Dickens"—A Million-Mile Record in Less than Ten Years.

authority to occupy the line from one station to another. This called for grievous delays where more than one train wanted to move in the same direction, and this brought out the ticket-and-staff system, the most complete system of this kind being an electrically controlled system known as the Webb-Thompson. This device is made in the Crewe shops and is illustrated and described in another column.

Some idea of the size of inter-locking and switch-towers used can be seen from the number of levers in the towers at Crewe and London, the latter having 280 levers and the former 155. One thing I noticed particularly was the use of a ⊓ section of rolled iron for rods instead of pipe; these are very stiff and rigid; the lengths are coupled by a strip inside the recess, bolted through, guide rollers run under and are covered by the flanges of the strip. It is claimed that they are cheaper than pipe, occupy less space and cannot change their length by turning.

The shops are strung out for something over a mile, and to facilitate the handling of men and material they have a couple of locomotives with a long covered car where tender should be; the floor of this car is

THE ENGINES.

A pair of cylinders are usually cast in one piece, with the steam chest between them. This only has a cover on the front end, and the back has two valve-stem holes and stuffing-boxes. The back cylinder-heads are also cast in. This casting is bored in one machine, and at one setting both cylinders and their stuffing-boxes are bored, the front flanges faced, while a small pair of bars are boring the valve-stem holes in the chest.

They are using cast-steel driving-boxes with a shell brass. They babbitt the sides to prevent cutting of hubs of the wheels. These boxes are put on a machine that planes the top sides and rounds out the crown for the brass at one setting. The inside tool is something like the planer tool for this purpose made by Pedrick & Ayer.

They have a number of electric cranes of their own make and use the Thompson electric welder in some of the work.

The fire doors open inside the box, swinging from the top. These are unfinished castings. They make them of steel and chill them. They burn out in from three to four months.

On engines, tenders and cars wooden rods; instead of a brass bush fast in the rod they have a bronze bush *fast on the pin*; this runs in a hardened and lapped hole in the end of the rod; they go two years without serious wear, and the pin is never worn out of true. A new bush restores it to its proper size and keeps the centers the same.

The extension front is unknown. A short front with a straight, open stack is used. All the fronts have holes to let the cinders run out. They have abandoned the torpedo in the nozzle and now extend a pipe from the stack well down into the arch, as shown in the sketch. The nozzle is on a level with the top row of flues and is larger than the old ones. These improved fronts have made the engines steam freer and throw less fire.

In freight engines they use steel packing rings, steel rod bent-up. Three are used on each piston. They are only about one-quarter of an inch wide, but are three-eighths of an inch deep.

On what ought to be the cab roof, and facing back into the tender, there is a small plate with the number of the "shed" or roundhouse to which the engine belongs, so if an engine is sent off her regular beat all know where she belongs and can figure

lish engine is a flange joint, there are lots of flanges to make. I noticed some flanges that were to have four square holes through the flange; these holes were being finished to a standard size by shoving a square piece of steel with teeth cut on each side of it, in a sort of spiral, a smaller size being used to rough out the hole than that used to finish it; this seemed a quick, cheap and accurate way to do the work.

Such parts of the engine as are liable to rust are galvanized; the inside of the tank is thoroughly galvanized as is also the coal space; this requires no paint and lasts three times the life of bare plates.

Slab frames are particularly easy to fit work to, being true and square all over and extending from buffer to back of engine in one straight piece, the frame going outside the cylinders. It would be almost impossible to fasten a slab frame to an outside cylinder of our style and preserve its "get-at-ableness." Their entire frame is made without a forging.

Mr Webb is now using three boxes on

the main driving axle. The center box is fitted between the cranks, and slides up and down in a pair of heavy jaws that are supported by a heavy brace to the cylinders and across the frame; this box bears no load, but it prevents undue bending strains on the axle and will admit of an inside engine being run home on one side with a broken axle.

The oil pipes from cab to chests are run through the exhaust pipe from the large vacuum-brake ejector which extends from the boiler head to the smoke arch on the right hand side. These oil pipes are cased in wood to prevent them from wearing.

The tenders have six large steel-tired wheels set in solid jaws, no trucks; there are extra good steps and hand-holds. The tanks for express engines only hold 1,300 gallons as the road has numerous scooping troughs; even suburban engines with very small tanks will strike bravely out with a big train; they can scoop water almost anywhere.

All the steam-chests are cast on the cylinders, and in most of them the cover to the chest is cast on, the end having another cover through which a machine is introduced to mill out the ports and face the seat.

Some of these inside engines have as big as 19½-inch cylinders, the two cast together, one steam-chest for both and the whole thing weighing less than one of our cylinders and saddles; but when one cracks the whole thing has to be thrown away.

The road uses automatic vacuum brakes, but have an improvement of Mr. Webb's. This is a separate steam valve, connected with the engineer's valve, which can be handled from either side of the cab, that applies the brake on the engine. This steam brake is so arranged that should the vacuum in the auxiliary cylinders under the cars run down below a safe amount, the steam brake is applied and informs. I understand this was done to prevent accidents to the brake from freezing up. It is not an unmixed blessing, for if steam runs down in making a hard run, the jet that keeps up the vacuum will let up a little, and the first thing you know on goes your engine brake, and the only way to get it off is to restore the vacuum, and this takes steam when needed; it may keep things safe, but it prevents a man from "getting there" sometimes when he otherwise would.

Mr. Webb believes that there should be a "breaking piece" in all mechanism; that is, a piece that is sure to break first when a crash occurs from any possible cause. He makes his tenders the breaking piece in passenger engines, so that they can crush with the least loss of life and property. The tank frames are made of creosoted pine.

The company used to give coal premiums and do yet, but the men say the amount has been cut so close that there isn't "baccy" money in it for the best of them.

HISTORICAL LOCOMOTIVES.

The "Charles Dickens" is one of a large class of engines in use, and until the invention of Mr. Webb's compound the standard passenger locomotive of the road. This engine has 6 feet 6 inch drivers, and was turned out of the shop in February, 1882; since then she has run between Manchester and London, doubling the road daily, and on the 12th of September, 1891, completed her 2,651st trip, running 1,000,000 miles in nine years 219 days, in this time she also ran ninety-two extra trips. In making the million miles she burned 14,016½ tons of coal. She is still doing yeoman service.

The "Cornwall" is also a noted engine at Crewe. She was originally built in 1847, by Trevithick, with the boiler under the axle and a wheel 8 feet 6 inches in diameter. She was changed in 1862 by Mr. Ramsbottom and a new boiler placed above the axle; this engine is still pulling express, having been on duty more than 45 years; she has the largest wheel in the world.

Mr. Webb recently constructed a full size model of the "Rocket" just as she was when she won at the Rainhill trial in 1829. The picture of the builder, George Stephenson, was obtained by photographing his statue, while the driver on the foot plate is Mr. Jas Hitchens, the runner who brought the Webb compound out to the United States a few years ago.

THE RUNNING SHEDS.

At all of the running sheds there is to be found a bundle of soft iron wire, about as large as broom straws, and a big "hunk" of wool yarn, this is used as feeders for all oil cups, driving boxes, etc. "Trimmings" the men call them; men get fined for neglecting "trimmings."

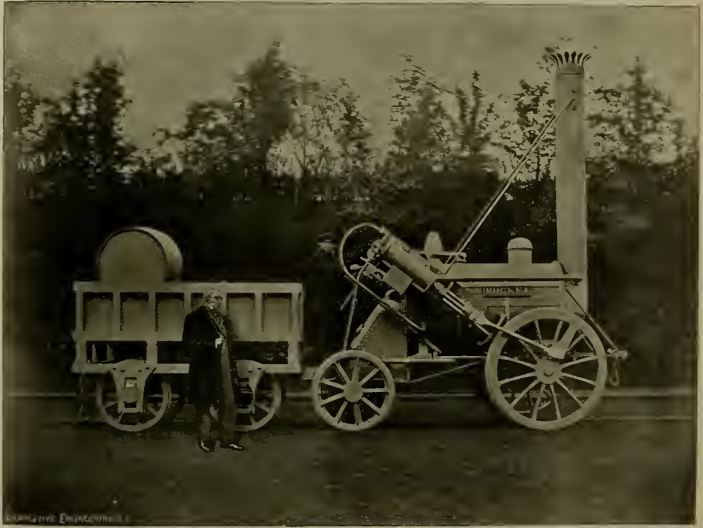
In the running sheds the engines stand on long tracks, one ahead of another; over them extends an inverted trough of light wood; from this, openings are made at every engine or two to the air above, the stacks are very close to these jacks and when the pops go off it blows the boards off the rig, but they have the best of dampers and take care so that a case of popping in the shed is rare, and the man who is responsible for it hears from it.

In these running sheds they have great iron furnaces in which coal is burning; this is used to fire up dead engines, no wood being needed. When a new fire is to be kindled the man who fires up takes his men, about six and each man has a long iron-handled scoop, holding more than the ordinary firing scoop; these they fill with live fire, put the crooked handles over their shoulders and march to the engine, where one mounts the deck and receives the fire, spreads it and covers it lightly with coal. This plan is clean, uses no push-cars for wood and removes the danger of fire in a large pile of kindling. The heat of the furnaces is utilized in drying sand.

THE COMPOUNDS.

Of the compounds I am loth to speak, comparatively, because I know so little about their simple engines; a comparison of their compounds with our simple engines, or *vice versa*, is no comparison at all. Mr. Webb has ninety compounds of his three-cylinder type; all of these are on express trains and the most important ones on the road. Whatever may be said, their inventor does not hesitate to put them on heavy fast trains. I have before me a list of the ninety engines, names, numbers, size of wheel, date turned out, miles they have run and coal they have consumed. The first one, named "Experiment," was sent out April 3, 1882, and has run 440,933 miles and burned coal at the rate of 30.8 pounds per mile, and it is a remarkable fact, that this is the very best record of all the class. The "Alchymist" has been running four years with a coal record of 41.2 pounds per mile—the poorest record—while the average for the class, for a mileage of 21,181,250, is 35.1 pounds per mile. These engines keep well on time and often handle 20 English carriages—very heavy trains.

The latest and largest engine of the class is the "Greater Britain," shown herewith. This engine has a pair of trailing wheels, and a combustion chamber in the barrel of her boiler, using two sets of flues. This engine has 7-feet 1-inch wheels, two 15-inch cylinders and one 30-inch, all of 24-inch stroke. She has 1,505.7 feet of heating furnace. Weighing 116,704



GEORGE STEPHENSON AND THE ROCKET, AS ORIGINALLY BUILT.

pounds, she is a very finely finished engine, and doing fairly good work. She has the latest loose eccentric plan of valve-gear for her low-pressure cylinder, the runner having no control of it; the high pressure cylinders move the axle until it strikes a stop in the loose eccentric, and this drives it for that gear; when the engine is reversed the small cylinders have to move the engine before the valve for the big cylinder changes, this is hard to do under some circumstances. I was riding behind one of the engines when the runner had to get down and shift the loose eccentric by hand before he could start his train; couldn't get slack enough to move it.

## Confession.

I have failed in lots of things which some other fellow working alongside of me would do with ease. I always considered myself the best machinist that ever lived, and when I heard of big wages being paid in some distant shop I assumed, as a matter of course, that all I had to do was to go to that shop and get a job. When I got the job I didn't always get the big pay, but I was too smart to kick much about it. My career as a journeyman machinist was rendered much smoother and more pleasant than usual by my having come to a knowledge one day that I could find better mechanics than myself in every shop I went into. This was a bitter pill, but I swallowed it and it did me good.

I could tell some interesting things regarding my own experience and the experience of others who, like myself, were troubled with the big head for some time before discovering the proper remedy. I know one man to-day who never got more than a dollar and a half a day in his life, and he never was worth more, either, and still that man will tramp from the Atlantic to the Pacific ocean if he hears that good machinists out there are getting two or three dollars a day. He can tell of the many times he has been humbugged by shop-owners, and can tell of many a poor shop-owner who has been humbugged by him. He has tramped this country over expecting to find a man foolish enough to pay him the wages of a good machinist, and I never knew him to work a day for less than he was actually worth as compared with other men.—*Chordal's Letters.*

## The Mertsheimer Variable Nozzle.

The Mertsheimer variable exhaust nozzle is working with remarkable success on the Union Pacific, and has been applied to 150 locomotives. A highly promising feature about this variable nozzle is, that it is remarkably easy to operate and does not get gummed up or corroded. It is formed by two serrated or notched circular plates, the one sliding on the other. When the notches of the upper or sliding plate coincide with those of the lower one the greatest amount of opening is obtained. If it is necessary to reduce the area of nozzle opening, the sliding plate is turned till the projections partly or entirely cover the notches of the lower plate. It is a remarkably ingenious contrivance and possesses the saving merit of simplicity. There is nothing to get out of order and therefore the nozzle is likely to be a permanent success.

The engineers in charge of locomotives having this nozzle speak very warmly about it and they operate it to save coal. When pulling out of a station or on a hard pull they open the nozzle and find it a decided improvement to the working of the engine. They say that the pulling open of the nozzle frequently saves doubling heavy grades.

During a recent extended ramble, in which numerous shops were visited, we noticed a variety of methods employed for transmitting power at an angle from the line of shafting. Some of the methods employed were rather ingenious, but none of them approached in simplicity or efficiency the Almond coupling, which can be seen in the Watson & Stillman shops, East Forty-third street, New York, near the Grand Central station. Parties who wish to transmit power at right angles ought to look into this device before scheming costly substitutes. It is made by the T. K. Almond Mfg. Co., Brooklyn, N. Y.

Where railroads are built into sparsely settled districts it is a fine thing to have a rich government to stand behind any lack of earnings. The people of New South Wales who indulge in the expensive luxury of government ownership of railways, are receiving practical illustrations of the advantages not to say the disadvantages of the system. Out of a total mileage of 12,000 they have ten sections, comprising 765 miles, which are operated at a loss. The roads cost $47,500,000, or $62,000 a mile, and they are operated at an annual loss of $1,555,000. Instead of presidents and general managers the railways are operated by a railway commissioner who is not responsible to the people who pay the bills for shortness of receipts. The railways of South Australia were operated for a time under the commissioner system, but the colony has lately decided to abolish the office.

Almost every large railroad shop in England has one or more small switchers with a crane either swung around the dome or stack, the latter plan gets the crane at the front of the engine but requires the arch and stack to be made immensely heavy. These cranes are operated by steam, handled from the cab and are very handy, as they will go out into the yard and pick up anything weighing less than two tons and place it where wanted, particularly useful in loading pieces on cars.

A subscriber to Locomotive Engineering, who writes on the business paper of a bank, writes us: "I am not now, nor never have been a railroad man, but take your paper because I appreciate the valuable reading matter contained therein." It does not require a railroad man to enjoy reading the paper. Anyone who is conversant with engineering affairs can find interesting and profitable employment in the perusal of its columns.

We understand that the Chicago, Milwaukee & St. Paul have ordered the Walker smoke consumer for twenty-five locomotives.

Webb's Last and Largest Compound.

Some one has patented an invention which consists of deepening the needle beams of cars and making that a seat for the truss rods instead of the usual queen post. The patentee is already after some railroad companies for infringement. He ought to have some difficulty collecting the royalties. It is one of the most impudent patents we ever heard of being applied for. The practice of using the needle-beam as a queen post is nearly as old as car building. We are only surprised that some one does not get a patent on the diamond truck. Some combination could doubtless be devised that would be patentable, and superlative assurance on the part of an agent might lead some railroad managers to pay royalty for the sake of peace and quietness.

The best trains of the Great Northern of Ireland are lighted by electricity, there are four incandescent lights in each compartment. A storage battery system is used.

## Metropolitan Double Tube Injector.

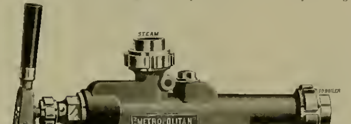
We hereby present to our readers a perspective and a sectional view of the Metropolitan double tube injector. This injector, as the name implies, is a double tube apparatus provided with an independent lifting appliance which, when the injector is working, constantly lifts the water and supplies the forcing apparatus. The benefits of this arrangement are numerous. It enables the makers to provide an injector that will always lift the water, no matter how hot the injector or the suction-pipe becomes, and they have found by experimenting that it never requires over thirty seconds to one minute to bring the water under the hardest conditions. It also enables the injector to start readily at 25 pounds steam pressure and work up to 250 pounds steam pressure without any regulation of the water or steam supply, and no matter how much the steam may vary, the injector cannot drop the water at the overflow. This injector will work hot water, and from experiments made, they find that with a steam pressure of 25 to [illegible] pounds the injector will take feed water at a temperature of 145 degrees Fahrenheit; with 125 pounds steam pressure it will take feed water at 140 degrees Fahrenheit, with 150 pounds steam pressure it will take feed water at about 135 degrees Fahrenheit, and with 200 pounds steam pressure it will take feed water at [illegible] degrees Fahrenheit. These results are wonderful and go to show the great range of this injector. Owing to this great range and the device employed to regulate the capacity, the capacity can be reduced nearly as much at 180 pounds as at [illegible] pounds steam pressure. Another curious feature is that the maximum capacity steadily increases as the steam pressure increases. In other makes of injectors the capacity is regulated by increasing or decreasing the water opening. This is not done in this injector, but instead, they increase or decrease the steam to the lifting apparatus. If it is necessary to decrease the capacity they throttle the steam to the lifting apparatus by means of the regulating valve (part 21; see sectional cut). The result is that less water is lifted, and consequently less water is forced. By employing this means of regulation, the injector will work as steadily when discharging its minimum as when discharging its maximum capacity. There is a stop in the regulating valve which is so set that the operator cannot break the feed by regulating too close.

The operation of the machine is very simple. The lever is drawn back slightly to lift the water, then pulled back as far as it will go. The construction is well designed. There are no outside attachments to break, wear or interfere with the numerous small attachments found in every locomotive cab. By referring to the sectional drawing it will be seen that the tubes are all removable from the back of the machine and can be removed without taking the injector off the locomotive. It will also be noticed that all the *valve seats* are removable and can be taken out for regrinding or replacing, thus doing away with placing the body of the injector in a lathe to turn up the seats. When the injector is working the overflow is closed and the valve is held to its seat by a pressure equal to the boiler pressure, and under no circumstances can the water run out of the overflow, and the engineer is not required to run his head out of the cab to determine whether the injector is feeding the boiler or the water is running out of the overflow.

This injector is manufactured solely by the Hayden & Derby Manufacturing Company, 111 Liberty street, New York.

The makers of this injector write:

"We placed the first one of these locomotive double tube injectors on an engine of the Central Railroad of New Jersey about a year ago, and when they placed the compounds of the "385" class on that road they were equipped with this style injector. These engines have been in constant service, and, as you well know, the service is a severe one for an injector. We are pleased to say that the injectors have given perfect satisfaction and the engineers are highly pleased with them, owing to their reliability and to the fact that at high steam pressure, as well as the lowest working pressure, the capacity can be regulated to suit the requirements of the locomotive for a light or heavy service. We now have about one hundred of these injectors in use."



## Proper Location of Machinery in Shops.

By W. S. Rogers.

The following paper was read at the November meeting of the New York Railroad Club:

Properly locating and arranging the buildings for a locomotive machine shop, where general running repairs and the usual overhauling may be done, and where, if need be, the completed engines may be built, is, beyond question, a work of utmost importance, requiring great care and study. But following the correct construction of the plant comes the proper location and arrangement of the machines and tools necessary in equipment an item of engineering requiring intricate and tiresome planning, tedious in its many small details, and, as a rule, to the progressive mechanic seeking perfection in shop practice and lowest shop expenses annually, very unsatisfactory.

The rearranging of an old plant to cheapen and shorten the production is also a work requiring no small amount of skill and display of mechanical wisdom, and can only be successfully carried out to perfect completion by one who is perfectly familiar with the strength and use of each and every machine and tool in the works, but he must be also acquainted with all the requirements demanded from the nature of the work, studying the methods in vogue and making all alterations and changes with only one object in view, that of cutting down the cost and time of producing finished results.

A battery of planers so placed that their frosted cross-rails and heads appear in perfect alignment from some central point of view in the shop is very pleasing to the eyes of an enthusiast for beauty, and they are also quite an advertisement for their builders, but to the man with practical ideas all harmony of operation is destroyed; he sees no such thing as beauty, for he knows the requirements of those tools in daily output of work, and he calculates the added expense of manual (or brute) labor needed in transportation of materials to and from other machines variously located and involved in finishing the product. Would it not be far better to have those planers distributed about the shop, whereby the heavy work would all be concentrated near machines adapted to it, and make as much saving as possible out of the annual allowance for shop expenses that the motive power and equipment might be the gainer thereby?

The lathes all standing in long lines by the windows or double lines with their backs together make a very imposing array of tools. We see them so arranged at expositions, etc.; but is it not better to disperse them about the shop? A large one in convenient proximity to a heavy planer or slotter, and the smaller ones grouped together in pairs in such manner that their carriages will face each other, thereby making it an easy matter for one man to run two machines without doubling the burdens already on him? Experience has taught the writer that a man can operate a heavy lathe and a planer or slotter satisfactorily and to advantage if the machines are conveniently located, and he also discovered that such combinations bring about the piece-work system in a very desirable manner.

Milling machines are usually grouped together—the idea being that most anyone can run a milling machine and attend to half-a-dozen others at the same time. All of which is about half true, but it takes so long to get the work to and from them, and so much time is lost in changing the machine to all the demands, that it takes really more time getting ready and getting there than it does to do the work. Consequently, much work that should be done on this class of shop equipment goes to other machines.

In some lines of manufacture, such as sewing-machine and gun work, these tools are kept in constant service and on one class of work—thus it is an easy matter for one simple, cheap man to operate several of them. In locomotive work it is different. I know of one machine in a locomotive-building plant that stands idle three days a week, while enough goes to other tools to keep it busy fourteen days a week. The reason being, simply, that it is located in the wrong part of the works. The same line of thought will lead to the proper distribution of the drilling machinery about the shop, also the axle lathe, wheel lathe and wheel press, whereby the materials will all concentrate at the right place and go on to their destination without clash, confusion or useless cost. No machine should be located in any part of a shop simply to fill a vacant space on the floor, or because it is as good a place as any. There is such a spot as the best place for it, and I would say, find that place and put it there if it requires the moving of half a dozen others to make room for it.

Another important adjunct and absolutely necessary evil to all first-class plants is the tool-room. Its importance demands that it should be convenient and easy of access to the employés at all times. The space it requires alone makes it the hardest to locate, and as a general rule it is the creator of more dissatisfaction than any item connected with the whole plant. A friend of mine once asked my opinion about the best place to locate the tool-room in the new plant he had established. I advised putting it in the northeast corner, and he did. Three years later I met him, and in the course of our conversation I inquired regarding the convenience of the tool-room's location. His reply fully illustrated the uncertainty always existing in the mind of a practical mechanic when this department of the shop's equipment demands attention. His answer was: "I have moved it to all four corners of the shop since I saw you, and now have it in the center of the place, and still it don't fit. My general manager suggested recently that I jack it up and run a set of trucks under it and take it out doors next."

I have seriously thought that when it falls to my lot to again locate a tool-room, to divide it up and put four or more smaller ones in as many parts of the plant with the small hand-tools in each necessary for the machines in their vicinity.

Taking, for example, the work on cylinders, planing, boring and drilling are the three distinct operations to be performed. If the planer is located near the boring lathe and in proper position, and the radial drill is also within convenient range, very little transient labor will be required to perform the three operations. We also will find that the man on the boring tool can also push along the planing and oversee the drilling, thus keeping all the machines in operation with the minimum of labor and in equally rapid time as if it was done the old way, with one man to each machine and one third of them waiting for work to reach them, as would be the case if they were isolated.

The important gains made by such methods are almost wholly in time, and if nothing else is earned this alone is money saved. If a piece of work (a set of guides, for example, of four driving-boxes) can be finished in six hours, it is the height of false economy to allow the time to be lengthened out an hour or two longer because the labor element is too busy elsewhere to take it from the machine. Far better will it be to move the machine to a more convenient location.

Following the work on the various machines closely, and having them so placed in positions with reference to the travels of the many parts of work through the shop toward finish and erection, thus avoiding all back-lash, confusion, delays and clashing among employés, means low cost of production, harmony throughout the plant, fewer names on the pay-roll, and large decrease in operating expenses with increased amount of work performed every year.

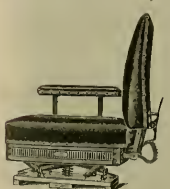
## The New Cab Seat, with Arm-Rest.

Now the boys have got it right! A long time ago the junior philosopher said that ... or any other seat would never be just right until the arm-rest was fast to it, so that when the seat made a sudden dive while the rider's elbow was on the arm-... it wouldn't tear him in two just where the fifth rib is spliced on the main frame

The Brotherhood seat has always been a good one—now it's simply perfect. No matter how one-sided you alight on it, the seat goes down and comes up "square"—no tilt in it.

The adjustable back is nice when you want it, and gets out of sight when you don't want it.

Anyone who cares for an engineer or ...man—and we suppose there are quite a ... who have certain ones they do care for—could not do them a better turn than to drop one of these seats into the lucky fel-



New Cab Seat.

low's Christmas sock, it's something they'd all appreciate, and then the makers, Stannard & White, of Appleton, Wis., are giving a year's subscription to Locomotive Engineering to every one who orders a seat before January 1st.

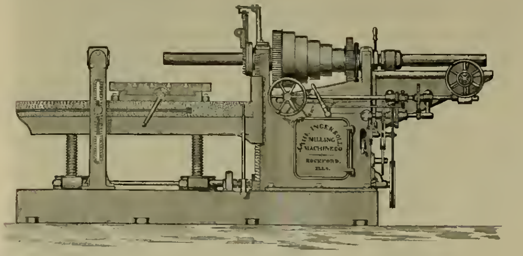
This seat is not expensive, is durable, and one that will save a man's bones many a hard jar

## Sixty-inch Horizontal Boring and Milling Machine.

This type of machine, so well and favorably known to most mechanics, is here shown in a much improved form.

As heretofore built, it was almost indispensable in any shops having accurate boring and drilling to do, the builders aim to make it quite so by excellence of proportion, workmanship and convenience of handling.

The driving cone has five steps for 4-inch belt, range, 8½ inches to 20 inches in diameter. The back gear ratio is 9½ to 1, giving much more power than has heretofore been the custom for this size machine. The spindle is 4½ inches diameter, of high carbon hammered steel. The socket is 3½ inches in diameter and tapered $\frac{1}{16}$ inch per inch. Traverse, 60 inches at two strokes, and is guided through a sleeve 46 inches long; usual quick return is provided. Cross table is three feet wide by four feet long, can be lowered to swing 46 inches, hand and power cross-feed is applied to this table in both directions and hand motion longitudinally, 4 feet 6 inches. The main table is 8 feet long 26 inches wide, provided with bolt slots for use when cross table is removed, cross table is movable by hand and power, and has vertically all the feeds common to the spindle and cross table. Elevating screws 4 inches in diameter. Feed motion of this machine will bear very close investigation. By use of the friction disk a very wide range of feed is obtained; this, we believe, has never been equaled before. The lever shown near the front hand-wheel gives the hand cross feed, hand elevating, hand spindle feed, or power spindle feed in its various positions The clutch lever, which is easily operated from the same position in which a man will stand in operating the lever near the front hand-wheel, controls the power to raise and lower feeds; these two levers being within the reach of the operator at one time control conveniently all the operations of the machine. Feed mechanism commands both table motion and the spindle feed in two directions, and when any one is in use there are no surplus parts revolving idly. The machine is especially adapted for end milling, or slab milling, or rack cutting within its range, and the hand-wheel is graduated to move the spindle by thousandths of an inch for this purpose.



New Horizontal Boring and Milling Machine.

The set of cutters illustrated show one of the many intricate forms in which our patent cutters have been made for milling special work. The slab milling machines are especially adapted for railroad work Any one interested in milling can obtain from the manufacturers of these machines, The Ingersoll Milling Machine Co., of Rockford, Ill., some very interesting data in regard to the time in which they will guarantee machines to mill a certain number of such pieces as crossheads, driving-boxes, truck-boxes, shoes, wedges, valves, etc.

They make a milling machine 36 inches wide to mill 8, 10 or 12 feet long, and are glad at any time to give any information which is within their power about this machine and appertaining to milling

## The Standard Electrical Dictionary.

A popular dictionary of words and terms used in the practice of electric engineering. By T. O'Connor Sloane; published by Norman W. Henley, 150 Nassau Street, New York. Price, $3.00.

The most progressive science of modern times is that of electricity. Every man connected with the operations of applied mechanics is every day being more and more brought into practical contact with electrical appliances. The discoveries and inventions relating to electricity are so numerous that it requires a diligent student to keep informed on electrical progress, and ambitious mechanics and engineers with other duties to attend to cannot burden their memories with the immense mass of details. But they can keep books of reference that will supply, when needed, all the information required

Among the numerous books offered to keep people informed on electrical matters we have rarely seen anything that equals in value the Standard Electrical Dictionary. The name does not describe the book properly, for it is more of an encyclopædia than a dictionary, since it gives detailed information about nearly every phrase and device connected with electricity

Professor Sloane, author of the book, is one of the most accomplished teachers of electricity in Europe, and his explanations are always reliable, besides being expressed in plain language that ordinary people can understand. The telegraph operator who interests himself in his business will find in this book facts well worth knowing about batteries, instruments, and all apparatus connected with transmission, the electroplater will find information relating to his art, the man with electric bells in his house can, by a little study, learn to detect the cause of failure to ring, and the man in charge of an electric lighting plant will find the dictionary the most valuable kind of a hand-book. Railroad men who are ambitious to post themselves on the science which is now operating so many railroad appliances will find the book a most valuable source of reference.

## Horizontal Radial Car Borer.

This machine is the latest in the line of boring machines. It will bore all kinds of straight or angle holes for car and bridge work, with the greatest rapidity and ease for the operator.

The column is one single column with the main roller frame resting on and bolted to the same. The vertical part of the column is made to revolve, the center of which is the center of the mandrel. It is also made to move in and out on the main column and also carries the spindle and slide moving up and down.

The rolls are 6 inches in diameter, all driven by gearing and friction operated by foot power. These rolls can also be driven by hand at the will of the operator.

The mandrel is of the best quality of steel, of large diameter, and has a vertical stroke of 26 inches, and a horizontal stroke of 24 inches.

New Horizontal Radial Car Borer.

The countershaft is placed above and provided with a new device, to allow the spindle to be driven at any position without any changes being made

For further information address the builders, The Egan Company, Cincinnati, Ohio.

## A New Tire Remover.

Hank Colvin sat down behind the president the last time he called at the Ananias Corner, and listened attentively to the liar who was telling how he ran an old Hinkley 400,000 miles without turning the [illegible] and to the secretary as he related how he used to weld up broken tire, etc., at country blacksmith shops, but Hank can't listen long without saying something.

"Reminds me," said he, "in '56, when I was on the Lackawanna, we had a continual circus with the old wrought-iron tires, breaking, getting loose and being shimmed. They fixed up all kinds of schemes to heat tires, and at last one of the shop men thought of putting clay all around the 'fire pan' to keep from burning the nice red paint on the wheels, and also to make the fire 'draw.' The first rig of this kind was in full operation on the old 'Secaucus,' when in stumbled Sandy McPherson with about three gauges of sheep-dip in him. Sandy stopped beside his engine and looked at the clay for a minute, then he called up to his fireman in the cab: 'Hey, Jock, lad, coom doon 'ere, I'm a coo if they 'aint got to drawin' em off wi' poultices.'"

## Didn't Know Where He Lived.

On one of the Western lines Terrence Cunerty got on as engine house crew caller with the idea of some day running the engine of the day express.

Terrence wasn't much on the read, and it often took him a long time to spell out the names on the board and get his list made out.

One night train, 29, was marked up for 1.30, with Ames engineer and Stuart fireman. In the evening an order came to abandon the train. The foreman was in a hurry. He made a swipe at the names on 29's line, got only the fireman, and hurriedly wrote "Aband"—a common abbreviation.

Terrence came in here and scrawled "29 Ames" in his book, and then slowly spelled out the "Aband." several times. Terrence had got his job upon his oath that he knew where every railroad man in town lived, but "Aband" was a new one on him, so he went to the boiler washer and complained.

"Say, Bill, this ain't no fair show, some one is tryin' to down me; here's a new smoke shoveler put on and nothin' said to me about where he lives, but I'll fix him, blast his skin, I'll call the extra man, that's what I'll do. When they git the best of me they'll git up early in the mornin'. See?"

## A Satisfactory Excuse.

Superintendent Vreeland of the New York & Northern has a hard time keeping the cranks among his commuters in good humor when delays happen to Elevated trains that lead to the missing of connections. One day the express trains on the Elevated were late and some of the cranks who expected to meet trains from the city were indignant because the orders were given to start New York & Northern trains without waiting for the express.

"Why don't you hold your train?" exclaimed one of them to Mr. Vreeland. "I have friends on the city train, and it is shameful not to wait for them."

"Didn't you hear of the big children's parade at 145th street?" asked Vreeland. "You would not want the express train to run through that crowd and mash up the youngsters, would you?"

"O, I forgot about that," said the faultfinder, and he walked away satisfied, without reflecting that the children were in the street twenty feet below the express train.

## Novel Way of Keeping the Ports Closed.

"Speaking about the way of fixing up broken down engines," remarked Brother Casey, "there was a plan tried by Hiram Jones on the Michigan Southern & Northern Indiana that made some talk at the time.

"It was away back in—Oh, well, when the big strike happened on that road. Hiram just squeezed through as an engineer of a saw-mill engine, and when the strike happened he made up his mind that it was time to bloom out as a locomotive engineer. He got a trial easy enough and started out with an old Rogers engine. He did not go far when the crosshead on one side broke. He looked the engine over leisurely and decided that he could fix her to run on one side. The main rod was taken down all right. Next operation was to close the ports. This he did by pinching the engine till the rocker-arm stood in the right position. How to keep in that position was a mystery at first. Reflection brought forth a bright idea. He got a chain and with it secured the rocker-arm to the pump, taking care that it was firmly enough fastened not to move. Then he was ready to start the train.

"When Hiram got back to his saw-mill he spent a long time considering how it was that the rocker came to break off that pump. After years of thought he came to the conclusion that it was because the pump was too weak."

## A Railroad Men's Fishing Party.

When flowers were still in their bloom, you or one of your correspondents suggested that an article on deep-sea fishing would be seasonable. About the same time you gave particulars of a convention of master car builders and master mechanics that was held at Galveston, Tex., for the purpose of settling questions of interest in the movement of cars. There may not appear to be any intimate relation between the discussion of interchange of cars and deep-sea fishing, but things are not always as they seem, and it does not appear that your correspondents told all there was to be said about what was done when the M. C. B. and M. M. of the Sunny South met to settle their differences.

After the business session was over some evil-minded person persuaded the railroad men to enjoy the questionable pleasure of spending an afternoon in a deep-sea fishing expedition. With light hearts and jocund faces the whole party boarded a yacht of much sail and small beam and were soon scudding down the bay before a spanking breeze. Joy reigned supreme till the party got clear of the jetties, and then the tumultuous waves that smiled with the sunshine glitter, but tossed the craft with merry bounds, took the sense of fun and pleasure out of the thorough landsmen comprising the party.

A burst of laughter that rose from a group listening to one of Colonel Meehan's stories was checked by Frank Rearden suddenly jumping up and thrusting the upper portion of his person over the rail. "Smoked that strong cigar of McGee's a little too long," was the explanation given. Talk was scarcely resumed when Hancock nearly threw Siddons overboard in his mad rush to the rail. While he gazed in distress at the deep blue waters of the gulf he protested that Galveston oysters did not set well on his stomach. Mirth was now no more. The rail was quickly crowded with anxious faces poring into the briny deep and groans loud were uttered and many sighs that expressed a longing for the dusty shore.

Leeds, the big-hearted man whom everyone knows him to be, was leaning in sympathy over Player, who was trying to turn himself inside out.

"Do you feel bad, John?" asked Leeds. Player looked around with an injured air and asked: "Do you think I am doing this for fun, Pulaski?"

By this time Campbell was lying in the scuppers with Burke for a pillow, and Groves was urging Galbraith to try a swallow of salt water. The only difference in the condition of the company was that some were a little worse afflicted than the others.

While the captain of the yacht was roving about to give his cargo a full taste of the pleasures of "A Life on the Ocean Wave," the tide turned and the wind fell away. In vain he tacked and beat against the breeze. The more he tried to get back the further he drifted away from land, and there were good prospects of the party remaining all night "Rocked in the Cradle of the Deep." This was more than flesh and blood were equal to, and a steam-tug was engaged to put the party ashore on the extreme end of the jetty. The jetty is composed of rough stones with a narrow rail on top. It was now dark, and the shades of night covered the stumblings of this sad band as the party crawled along amidst many pitfalls in the three miles' journey to the city. None of the party carried home a single fish story.

M. C. B.

## Disposition of the Cow.

Mr. W. P. Brady, who is superintendent and general agent of the Mississippi Racine road, is very particular about having full reports of all stock killed, so that settlement may be made with the owners. A rule of the company requires that the section foreman shall report all stock found killed or wounded on his section and calls for detailed particulars. A cow was killed at Morse some time ago and the section foreman's report was very meagre. Mr. Brady wired:

"Patrick Dugan, section foreman, your report gives no particulars about the disposition of the Morse cow killed."

In reply to this Mr. Dugan answered: "The disposition of the Morse cow was very kind."

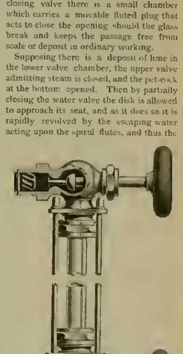
An improved form of safety-valve has been patented by Amos P. Kinney, Boston, and assigned to the American Steam Gauge Company. It is a combination of safety-valve with a valve-seat provided with an annular groove in its under side. Means are provided for pressing the valve to its seat against the pressure of steam beneath. A ring surrounds the valve and a pair of vertical rods extend upward through the casing and are connected on top by a yoke making a very compact and strong form of safety-valve.

## Ashley's Automatic Water-Gauge.

The annexed engraving illustrates a new form of water-gauge which possesses several features that commend it for use on locomotives. It will be found particularly adapted for the numerous roads that use feed water heavily charged with solid impurities, for it is designed to automatically clean out the lime deposits which so quickly choke up gauge-cocks. It also closes in case of the glass breaking, an arrangement that is very useful for locomotives.

In appearance the fittings are not unlike those generally in use, but behind each closing valve there is a small chamber which carries a movable fluted plug that acts to close the opening should the glass break and keeps the passage free from scale or deposit in ordinary working.

Supposing there is a deposit of lime in the lower valve chamber, the upper valve admitting steam is closed, and the pet-cock at the bottom opened. Then by partially closing the water valve the disk is allowed to approach its seat, and as it does so it is rapidly revolved by the escaping water acting upon the spiral flutes, and thus the



deposit is cut out all the way to the seat by gradually opening the valve. The gauges are highly spoken of by engineers who have used them. They are made in various sizes by the Ashley Engineering Company, 136 Liberty street, New York City, a full stock being carried.

A full edition of the Martha Washington Cook Book, 320 pages, well bound and illustrated, has been published by the Cincinnati, Hamilton & Dayton Railroad and is given away for 10 cents a copy. Send that sum in stamps to E. O. McCormack general passenger agent C., H. & D., Cincinnati and you will receive the cheapest book of the season. There are some new recipes in it for dishes that will make the Christmas dinner a memorable event.

A patent has been granted to D. H. Nichols, Boston, for a method of lighting cars by electricity. Two electric lights are set opposite to each other, at opposite ends, but at the same side of the car. There is a circuit for the lamps and two switches in the circuit. Reflectors are employed to distribute the light where it is wanted.

If you want a first-class watch of the best make and can't afford to spend the money, we will supply it for overtime. See the rear pages of this paper.

The Pennsylvania have started the Baldwins at work on forty-five new class "R" engines, consolidation.

## SUMMARY.

| | | | |
|---|---|---|---|
| 33 Compound Engines, | aggregating | 5185 | H. P. |
| 35 Standard | " " | 1180 | " |
| 30 Junior | " " | 1160 | " |
| TOTAL, 98 ENGINES, | aggregating | 7525 | H. P. |

(108) R. C. Buffalo, N. Y., says

In an engineering book I read lately, the expression vis-viva is often used. What does it mean? *A.*—It means the mechanical or "kinetic" energy of a body in motion.

(109) Inventor, Pittsburgh, Pa., asks

How much saving of fuel do you think I could gain by putting a jacket around the smokebox and smoke-stack, and leading heated air from there to the ash-pan. *A.*—None.

(110) J. B., Chicago, asks.

Why is it that one can start a screw with a long screwdriver when you cannot move it with a short one? *A.*—With a long screwdriver the inclination off the perpendicular gives increased leverage.

(111) J. E. T., Chatham

What course do you recommend to fit a boy leaving school as a first-class mechanical engineer, either for railroading or other purposes? *A.*—Go into a shop and learn the machinist trade, and then attend the classes of a good engineering school.

(112) F. H. R., Philadelphia, writes

I claim that George Stephenson, the inventor of the locomotive, was the inventor of the Stephenson link motion, but some of the men in the shop say I am wrong. We decided to refer the dispute to you. *A.*—The link motion was invented by an apprentice in the Stephenson works at Newcastle, England, named Williams, and put into practical shape by a pattern-maker named Howe, in the same works. It was applied experimentally to one of the Stephenson locomotives and to the surprise of the leading engineers of the time, it was a great success from the first. Stephenson had no hand in the invention. It is a mistake to speak of George Stephenson as the inventor of the locomotive. He was merely a prominent improver of the engine.

(113) J. S., Jackson, Tenn., writes:

We have several Rome engines and the point in suspension of the saddle-pin is $\frac{11}{16}$ inch out of center. The radius is 100 inches, plade-pin holes $11\frac{1}{2}$ inches apart. The engine uses more steam in back end of cylinder than front. I would like to know the rule by which they get the pin set back $\frac{11}{16}$-inch. We take half the distance between the centers for the saddle-pin. *A.*—The correct location of the saddle-pin to insure an equal cut-off in both strokes is a much more complex problem than our correspondent realizes. A variety of parts of the engine's machinery influence the location of the saddle-pin. Among these might be mentioned the ratio of crank to length of main rod, the radius of link and the location of the blade-pins, the length of the link-hangers and the location of the tumbling shaft. Besides these the angular advance of the eccentrics and the travel of the valve have to be considered. Full particulars of this problem may be found in Meyer's "Locomotive Construction" or in Sinclair's "Locomotive Engine Running."

(114) J. D., Chicago, Ill., writes

One authority asserts that it requires from $3\frac{1}{4}$ to 4 pounds of air per pound of coal for perfect combustion, while another claims that it takes 12 pounds for perfect combustion and 24 pounds as it takes place in the locomotive. Who is right? *A.*—Combustion is the chemical union of carbon and oxygen and the combination of 12 parts by weight of carbon to 32 parts by weight of oxygen. It takes 4.35 pounds of atmospheric air to supply one pound of oxygen, so it will take close on 12 pounds of air to provide enough oxygen to combine with one pound of coal. In the rapid combustion of locomotive fireboxes, the burning fuel has to be saturated with air, and it is calculated that complete combustion cannot be maintained unless from 20 to 24 pounds of air is passed into the fuel for every pound of coal burned. 2. Do different kinds of coal require different quantities of air? *A.*—Yes. The quantity of carbon or hydro-carbons present in one quality of coal may require more or less air than coal with different constituents. There are also certain qualities of coal of a refractory nature that seem to need a hurricane of air blowing into the mass to effect combustion. 3. What percentage of the air that is admitted to a firebox escapes through the stack and what percentage is consumed during the operation of combustion? *A.*—The coal that burns enters into combination with oxygen in the proportion of 12 to 32, or 12 to 16 if the supply of air is restricted. All the air not deprived of its oxygen by combustion in the proportions mentioned passes out through the stack.

(115) John Strouse, Bellwood, Pa., writes

Could you inform me if a Baldwin four-cylinder compound, high-pressure cylinder 13-inch, low-pressure 22 x 24-inch stroke, is equal to a simple engine 20 x 24 inch, both of same general dimensions? *A.*—In reply to this and several others of the same character, we append a letter from the Baldwin Locomotive Works on this subject. "The formula is the same in principle as that for calculating the tractive power of a single expansion locomotive. The formula for single-expansion cylinders is the square of the diameter of the cylinder multiplied by length of stroke multiplied by the mean effective pressure on the piston and divided by the diameter of the wheel. The result is the tractive power. For example: The tractive power of a 20 x 24-inch cylinder with 48-inch wheel and 100 lbs. mean effective pressure would be $\frac{20^2 \times 24}{48} \times 100 = 20{,}000$ lbs.

"For a compound locomotive a formula on the same principle is used, as follows: Assuming the diameter of high-pressure cylinders as 13 inches and that of low-pressure cylinders as 22 inches, we have

$$\frac{13^2 \times 24 \times \text{M.E.P.} + 22^2 \times 24 \times \text{M.E.P.}}{\text{diameter of wheel}} = \text{tr. p.}$$

The diameter of piston of driving-wheel and the length of stroke are to be expressed in inches. The mean effective pressure in the low-pressure cylinder must be arrived at empirically, and experience has shown that it may be taken at

$$\frac{\text{M.E.P. in high pressure cylinder.}}{2.7}$$

In designing the engine, however, the diameter of the high-pressure cylinder is found by allowing a ratio of 3 to 1 in the proportion of the squares of the diameters of the pistons as near as even sizes will permit."

## Recent Express Locomotive Practice in England.

By Hugh Sharp.

It is curious to note that English and American express locomotive practice is each year becoming more divergent. About twenty years ago it seemed as if the two types were losing their distinctive features and were approaching a common standard. In England the bogie was extensively introduced, outside cylinders were increasingly employed, large single driving-wheels were generally replaced by coupled wheels of more moderate diameter with equalizing beams between the springs, and although the characteristic slab framing was never departed from it was generally placed inside the wheels, which was not the usual practice before 1870. But the modifications here noted were mostly made under protest rather than from conviction. This especially applies to the coupled driving-wheels. English designers have always had a strong predilection for single drivers, but the increasing weight of trains demanded increased locomotive power. The single engines which were usually employed for express service in 1860-70 lacked adhesion; nor were heavier engines of the same type admissible, for the comparatively light iron tracks of those days were unequal to carrying a greater load concentrated on a single pair of wheels. A coupled engine was the logical outcome of these conditions, and although such engines had existed in England, they were now employed almost exclusively. In the meantime great improvements were being made in the manufacture of steel. Steel rails soon became as cheap as the iron rails with steeled surfaces hitherto employed, besides being far more durable. The principal railway companies began to relay their tracks with steel rails of a considerably heavier grade than the iron ones they replaced. The greater strength of the improved roads afforded an opportunity for the re-introduction of the favorite single engine with its driving-wheels more heavily loaded than heretofore, and from the table given further on in this article it will be seen that this type represents the most recent practice in England except where the grades are unusually heavy.

It has been said that the bogie came into extended use in England about 1870, but during the last decade there has been a marked reaction in favor of a rigid wheel-base. On inferior tracks, even where the curves were not severe, the bogie had been found to greatly assist the easy running of the engine by solidifying the tracks for the drivers to follow on. With the improved tracks this advantage disappeared, and the bogie is only retained now where a flexible wheel-base is necessary to prevent the excessive wear and tear on the leading tires in passing round curves at high speeds, with the additional risk of derailment. Nor had outside cylinders been employed from any conviction that this position was the better, but simply to avoid the expensive and, at that time, unreliable cranked shaft, which latter quality was becoming increasingly apparent with the greater demands made on it by higher pressures and larger cylinders. There, again, the improved manufacture of steel applied to these shafts as it had to rails. They became cheaper, and failures were rare, so inside cylinders were again adopted where they had been discarded, just as the single drivers had again replaced coupled. (In connection with inside cylinders it should be remembered that all engine sheds and repairing sheds in the old country are very completely equipped with pits, and dealing with inside motion under these conditions is not inconvenient.)

The drift of English practice seems to be toward a locomotive with a single pair of driving-wheels between 84 and 92 inches in diameter, and a pair of 50-inch leading and trailing wheels (rigid) with outside journals. The Great Western engine is thoroughly characteristic of modern English practice and represents the class employed for working the celebrated "Flying Dutchman." This engine has outside journals throughout, double slab framing of unusual depth, weighs in working order 100,000 pounds, with 40,000 pounds on the drivers, the working pressure is 165 pounds, and the total heating surface 1,440 square feet.

Express Locomotives with Single Driving-wheels in 1892.

Great Western—Cylinders, 20 x 24 in., driving-wheels, 92 in. Six-wheeled engine with inside cylinders and rigid wheel-base.

Great Northern—Cylinders, $18\frac{1}{2}$ x 26 in., driving-wheels, 90 in. Six-wheeled engine with inside cylinders and rigid wheel-base. Previous type had outside cylinders, single driving-wheels and leading bogie.

Northeastern—(Compound. Worsdell and Van Borrie's patent)—Cylinders, 28 x 24 in. and 18 x 24 in.; driving-wheels, 92 in. Eight-wheeled engine with inside cylinders and leading bogie. Previous type was a simple engine with coupled drivers and a leading bogie.

Midland—Cylinders, 19 x 26 in., driving-wheels, 90 in. Eight-wheeled engine with leading bogie and inside cylinders. Previous type was otherwise similar, but had coupled driving-wheels.

Northwestern (Webb's patent)—Cylinders, 15 x 24 in., 15 x 24 in. and 30 x 24 in., driving-wheels, 86 in. This engine, the "Great Britain," has two pair of disconnected driving-wheels. The leading pair are actuated by the single low-pressure cylinder placed inside frames beneath smokebox. The second pair are actuated by the high-pressure cylinders, which are outside the frames. There is one pair of carrying wheels with radial axles beneath the smokebox, and a second pair behind the firebox, with straight axles.

These five companies probably have a greater mileage to their credit than any other ten in England, and their practice may therefore be taken as representative. During the last decade, the writer knows of no company, except the Great Eastern (not in the above list), which has substituted coupled wheels for single. Of course, all these companies use coupled engines extensively, but it is a noticeable fact that, for their fastest and heaviest traffic, single engines are employed.

Compounding is losing headway in England. It has been experimented with extensively, but at this time only two companies, the Northeastern and the Northwestern, continue to build compound engines. The locomotive superintendents of both these companies are the patentees of the respective systems of compounding employed on their railroads.

The writer has purposely refrained from drawing any comparisons between American and English practice. It is beyond the scope of this article. But in conclusion one reference to this subject will be made: The conditions, as regards speed, gradients and weight of trains, are practically similar on the New York Central, the Great Northern and the Great Western railways, whereas the English and American engines employed for these services are about as dissimilar as they can well be.

---

Considerable attention was excited at the last Master Mechanics' convention in a piece of steel exhibited by Mr. W. Smith, superintendent of the Chicago & Northwestern. The steel had been in a firebox for twenty years and had shown no tendency to crack. The makers of crucible steel claimed that it was their product. Mr. S. Wellman, of the Wellman Steel Company, has lately investigated the matter, and gives plausible reasons in support of the belief that it is open hearth steel.

## Locomotive Running Among the Bushwhackers.

BY OLD SOLDIER.

About the latter end of 1863 the government sent to Nashville what they called a stray dummy. I think they got it from the Pittsburgh & Fort Wayne road. Well, it was used for a kind of an inspection car. I was assigned to run it as engineer and conductor We had a porter, cook and waiters

General Grant and some of his staff came aboard, and we started for Chattanooga on a tour of inspection, but we did not get any further than Bridgeport, and we were three or four days making that place on account of inspecting. After arriving at Bridgeport the General and staff proceeded to Chattanooga.

I had better tell you here why I did not get through. It was because the Johnnies held the road from Bridgeport to Chattanooga—a very good reason for not pulling General Grant on their road.

I remained there at Bridgeport for four or five days, when he came back and got aboard of his car and we proceeded back to Stevison. The Memphis & Charleston road crossed us there. This run on the military roads the boys used to call going around the "Horn," as this run was from Stevison to Huntsville, and over the Nashville & Decatur road to Nashville. The run was almost always from Nashville, over the Nashville & Chattanooga road, to Stevison, then over the Memphis & Charleston to Huntsville, then down the Nashville & Decatur road Well, as I said before, the General went down the Memphis & Charleston road and about seventy-five miles down the Nashville & Decatur road, and then back to Bridgeport. There I left him and he proceeded on to Chattanooga and Knoxville. I returned to Nashville with my dummy. I had the car full of sick officers. We arrived at Nashville at night.

This car was a great curiosity to the natives and the negroes. I gave it up on my arrival at Nashville and took the passenger train to Chattanooga. This passenger run I considered the best run on the road, as we did not have to go around the "Horn." I almost forgot to mention here that in cold, wet winters both armies went into winter quarters. The bushwhackers enjoyed themselves more in the winter than in the summer, as then they raided the country and captured both wagon and railroad trains and made it a point to keep both armies in hot water.

The railroads had about the same business while the army was in winter quarters as when on the march in active service. After General Grant made his inspection of the Army of the Cumberland and left it in command of General Sherman, he went to Chattanooga, Knoxville and Atlanta In the meantime the Rebs had sent a brigade to hold the Nashville & Chattanooga road between the Tennessee River and Chattanooga for, although we had Chattanooga, they kept us from operating the road. I think General Grant was ordered to Washington City to take command of the Army of the Potomac and he telegraphed the superintendent to have me with my engine to take him from Stevison to Nashville on a special. I met him with one baggage car and a coach. Old Jesse Cinceebaugh was conductor of the train. We got orders that all trains would be side-tracked for us, and as far as possible we would have clear tracks.

I should have told you in the start of my reminiscences that the Louisville & Nashville road was the first military road opened out of Nashville. While we operated both ends of this road the Rebs operated the middle, but we soon cleared them out and got the whole road At the time that General Grant went South the L. & N. had been turned over to the company, and it was operated by the company, and only in case of danger was it in any way used for the military excepting carrying government stores. No military orders went on the road. They were running regular passenger trains.

The morning train left at 7.30 A. M. General Grant and party, with myself at the throttle, left Stevison about 11 P. M. It was at about this time Cumberland Mountain was a hot country for sharp-shooters. We left with orders to make it as quick as we could, and to be sure and make connection with the L. & N. train at Nashville. Well, I had a good, old-time Roger engine, 15 x 22, with 5½ foot wheel, only two cars, and about fifty soldiers for guard. I suggested to General Grant before we left Stevison to get from prison some rebs and sit two on each side of the tank, so that I might have some protection for myself and fireman, but General Grant said "No, Mr. Engineer, we do not want to freeze prisoners to death in that way."

Now do not imagine that I am heartless because I mentioned this idea. I knew the night was so cold that no man could stay out all night and not freeze, especially while running I wanted them for company and would have taken them in the cab, as I felt almost sure we would be captured, and I so expressed myself to General Grant. He said that was the fate of war, and if we were captured we could sell our lives dearly unless we were ditched and crippled. I answered him that I was not afraid, for if I was I would not be there.

This talk all happened while we were waiting for orders When we got them, away we went My engine was good for two coaches up the Cumberland Mountains. They always kept a pushing engine at the foot of the mountain to push trains up, and of course the mountain was pretty well guarded at this time, but no extra guard on account of this train as no one knew we were coming except the operators, and they did not know it was General Grant. All they knew was they had orders to hold all trains and clear the main track, so it was kept very quiet about General Grant going over the road on a special, and I guess it was a good thing it was kept quiet, as almost any Johnny would have tried to capture him at this time, although none of us knew he would be made a full General and then President, as you all know he was afterwards.

When I arrived at the foot of the mountain all trains at that point were side-tracked. Of course I struck all side-tracks with train under control. We did not have the air-brake as we have now. When I found track all clear I pulled out. I was very short of wood in my tender, and I knew she would chew it up pretty fast going up the mountain. I knew where I had passed a good cedar-wood pile, going down the mountain. The fireman told me that all of our wood was gone excepting what was in the fire-box. I told him she would make the pile I expected to get, and so she did, but when I got to where it had been the wood was gone. I knew of another pile about two or three hundred yards ahead of that, but I could not get another car length on that mountain as my fire and steam both were low

Old Jesse and the porter came out in order to throw on wood. He claimed I stopped in the wrong place. I told him I began to think so, too, as there was no wood there, but I told him there was a pile there the day before but some one had gotten it I told him there was another pile about two or three hundred yards ahead, and that if I could cut the engine loose I could make it. Then the Captain of the guard jumped out and said we could not cut the engine loose unless General Grant said so. I told him to go back quick and ask the General, which he did, and he was told "not to let us cut loose"

General Grant himself came out. I told him the situation, and he said we must not cut the engine loose, but suggested we back down the hill.

I told him we could not do that as other trains had left at the foot of the mountain.

"Well," he says, "what can we do in this case?"

I told him we could run the empty engine up and get the wood.

He said, "No."

"Well, then," I says, "send the train guard, or some of them, say about ten men, and let each man bring an armful of wood."

He told the Captain to take the men up and get the wood for the engine I told him I would go along with them, but he said no, I must stay with the train and engine I told him all right, I would stay, and so would any of you if you had been in my place, because he was not a man to hold an argument with. At this time he took particular pains to examine and see where I showed the place for the wood-pile to have been, and if he had not seen the stakes and bark off the wood, I am afraid it would not have fared well with me at that particular time

I pulled up the stakes that had racked the wood up and carried them up to the engine and threw them in the firebox. I had two tank-boxes made of wood and I took them also. I told the General that I had burned up all the household furniture and that was all I could do That kept up fire and steam until the first soldier got to us with an armful of wood. The soldiers came in pretty fast, as we all wanted to get away from that place, and I have often thought since that if the Johnnies had thought of General Grant being there at that time of night they would have risked their whole army to catch him, and I think General Grant thought so too. I was very well acquainted with him, and that was the first time I ever saw him nervous. He remarked a couple of times that it was a hard looking place. You could not see bottom below, nor could you see the top of the mountain We were about three-quarters of a mile from the mouth of the tunnel. The guards were stationed at the tunnel, but patrolled the track on the mountain. Of course I knew this and told the General of it, which I think made him feel better, for he remarked that if we were captured, his chances were better than mine, especially if Dick McCann or Forrest got us. I did not think that Forrest or Dick McCann was on that mountain, and they were the only Johnnies I feared.

Well, I got a good tank of cedar wood, and then I told the General I would have my way clear now, if I did not go in the ditch. My delay there must have been about one hour, so I had to hustle to make the connection, and you just bet that little old Roger engine flew after I got my side of the mountain. All the telegraph offices were asked about the special and they answered that something had just flew by which they guessed was the special. Well, we made the connection at Nashville, but not much time to spare. I took him across the trestle to the L & N. depot. If the General were living to-day he could describe this trip better than I can. The night was bitter cold.

There is one little instance I forgot to mention. Coming down Raines' cut, near Nashville, the water, which had been falling for nearly a month, ran over the rocks and froze solid. I was running as fast as I could when the coach the General was in swung over and struck the ice. This so frightened the General that he jumped up and declared that the coach had turned over, when the brakeman ran up and told him she had only swung over and struck the ice and that all was safe Well, as I said before, when he came to me in the L. & N. depot at Nashville and bid me good-bye, he congratulated me on my safe trip. I told him I thought our safe trip was owing to the extreme cold night. He gave me a bottle of good brandy and a $5 gold piece and a good cigar. He did not tell me what he was going to Washington for, and I doubt if he knew himself at the time, as he said that if he came back to the Army of the Cumberland he would look me up if I remained there You all know he never came back to the grand old Army of the Cumberland, but I guess Lincoln and Stanton thought they placed him in charge of a grander army, well, perhaps it was, but I cannot think so. I have been told that the engineers in the Army of the Potomac had their cabs iron-clad. We had none of this, but ran our engines with open cabs. I do not tell this to brag, nor to say that we were braver than the Eastern military engineers As for myself, I never took an engine that I did not notice the thickness of her dashboard, and always made it a point to keep as little wood in the tank as possible, and never to allow a fireman to build a very high fire-rack, for the well of the tank was very good breast-works for bullets.

I never saw General Grant but once after that trip, and that was when he was on his Southern tour in this country. Then I could not get up to speak to him, everybody and anybody turned out to see him We have a few cranks in the South, as you do in the North and East, but not quite so many. I could have seen and talked with him that night, but one of those cranks kept me from it, as well as a good many old vets. I will not explain here, as a good many people might misconstrue my meaning and cast reflection on the Southern people, who, I assure you, are among the noblest works of God's people.

The night that General Grant spent in this town he was guarded closer by the old rebel vets than by the Federals.

You can all rest assured of this, for I was there and know of what I speak. The hotel where he stopped was guarded by rebels and Yankees as long as he remained. This was all caused by two cranks of this town that never smelt powder, and I think General Grant left here none the wiser that he had been guarded while on his visit.

## Early Railway Traveling.

The first regular train service in England commenced on the Liverpool and Manchester Railway on Friday, September 17, 1830, two days after the opening of the line. It was not on a very ambitious scale, three trains each way on week days and two on Sundays were deemed quite sufficient. The novelty of the thing, however, at first and very soon its proved safety and efficiency, led at once to a much larger traffic than had been anticipated, and as soon as the company could obtain more rolling stock the service was increased.

For a time people who had ventured to risk their lives by the new mode of conveyance were the objects of admiration for their courage or of contempt for their foolhardiness, but one by one the coaches had to be taken off the road, and everybody went by rail.

The time occupied in the journey was at first seldom more than two hours and often less, the distance being thirty-one miles, but even this rate was too fast for some people, for a gentleman, writing about six weeks after the opening of the line, says the speed was too great to be pleasant and caused him to feel somewhat giddy.—*Cornhill Magazine*

---

We found a very ingenious and useful practice in shop whitewashing followed by Master Mechanic McKenzie, of Oakland, Cal He mixes the whitewash in an old air drum, passes a perforated air-pipe through the mixture, puts on a good pressure of air, and leads a hose from the top with a perforated cap. This is directed toward the parts to be whitewashed and a thin spray of the mixture is applied. Any one wanting to use this remedy for soot-covered walls and ceilings can obtain full particulars from Mr McKenzie The work is done quickly and at small cost.

## The Best Shop I Saw in England.

[EDITORIAL CORRESPONDENCE.]

If Crewe is the largest railroad works—you never say shop in England unless you mean a store—those at Horwich are the most modern and the best.

Horwich is a little mite of a village, about nine miles from Manchester, where the Lancashire & Yorkshire road have located their main sho—works

ERECTING SHOP LANCASHIRE & YORKSHIRE RAILROAD, HORWICH, ENGLAND.

These shops run lengthwise down a green little valley, a mile or so to the side of the main line, and being new and very extensive present a fine appearance.

The buildings are of red brick with stone trim, iron truss roofs, etc. They are arranged in three rows, each row being one building harmonious in size, etc., on the outside

The office stands at one corner of the large inclosure with a little park in front of it, beyond this is the stores and paint shop; further along at the back of the inclosure, and fronting on its end, the erecting shop stands, and a grand one it is. This splendid building is 117 feet wide and 1,500 long, of course it has several fire-proof partitions, but it is a beauty to the eye of the railroad-shop man.

This shop is served by the best specimens of rope-driven cranes I have seen, a good view of which is had in the illustrations shown herewith; they were built by Hetherington & Co., of Manchester, and there are enough of them to prevent delays in so big a shop.

Our front-page picture was taken at one end of the shop and shows just half its width; the style of roof and iron structure that carries the cranes are well shown.

As can be seen, between the two pit tracks there is a central track for the temporary storage of wheels and other parts of engines undergoing repairs, the cranes having head room enough to swing a locomotive over anything placed on this center track; beside the pit tracks there runs an 18-inch gauge for little engines such as described in article last month on the Crewe works

You will note chalked on an axle in the center track "Bent Axle", it is the custom when dismantling an engine to mark defects that might possibly be overlooked. The picture on page 3 shows the other end of the shop, looking at the front of the engines. Note the row of vises down the left side of the building I couldn't help noticing the great number of vises in all European shops, and all of them say as plain as A B C, "hand fitted"—you might as well brand the engines so—it means scraped joints and ground seats and reamed and lapped holes and filing—ah, it makes one's arm ache just to think of it

Immediately behind the paint shop, but back about 300 feet, running parallel with the erecting shop, is the machine shop, this shop is 110 feet wide and 110 feet from the erecting shop. It contains most of the machine tools, is served by overhead cranes, but has all through it that great convenience so seldom found in an American shop, the traveling jib crane. This device travels on a single rail, only occupying 18 inches of aisle room, it is supported by a girder rail above and driven by a rope. The operator sits on the frame and by handling one wheel runs the crane forward or back, swings the jib and lifts and lowers loads of moderate weight—as heavy as any piece about a locomotive except the boiler This crane is often called a "walking crane."

A great many manufacturing operations are going forward in the machine shop, for Horwich, like all the other British main works, makes pretty nearly everything the road uses.

They don't roll their own rail, but they do roll the merchant-bar and some plate, they make their own track chairs, frogs, switches, signals, etc., cut their own nails, make their own screws, build their own telegraph instruments, etc., etc.

One hundred and ten feet from this shop stands another building some 1,300 feet long and 110 wide, this is divided from the end toward the office as follows: boiler shop, smithy, forge, and foundries.

The steel foundry is a large and important part of these works, and the L. & Y. engines contain more pieces and more pounds of cast-steel than any other in the world!

Mr. Aspinall, the locomotive superintendent, is a progressive man (he comes to America once in a while to see how we do things), and has paid a great deal of attention to cast-steel.

His first experience was in "boughten [illegible] and while some pieces gave the [illegible] there were many failures. [illegible] up his mind that if *some* steel [illegible] could be made that were good, [illegible] them could with care. He built a [illegible] foundry and experimented, the result [illegible] that they are getting uniformly good [illegible] and there is hardly a forging to be found on the L. & Y. engines of recent build. All the wheels are cast-steel, the [illegible] plate, which has something like our [illegible] except that it is inside the [illegible] supports the guides, is slotted for the [illegible] and carries the guides to the [illegible] — the motion-shaft for Joy-[illegible] ng-shaft for links, all the [illegible] saddle, brake rig, levers, [illegible] are cast-steel.

[illegible] the secrets of sound castings [illegible] to be enormous gates and lots of [illegible] a 42-inch wheel will have three on [illegible] and one at the hub, all bigger than [illegible] part below them. These are cut off with saw.

All castings are rough-turned or planed, where they are to be finished, and then placed in an annealing furnace for forty-eight hours. The result is strong, tough working parts.

I noticed in the machine shop several big millers on heavy work, but in the tool room Brown & Sharpe millers, from the well-known Providence, R. I., works, are employed.

They use a great many multiple-drill machines in which one or more drills can be thrown out; on these tools they drill mud-rings, which, by the way, are also made of cast-steel.

I couldn't help but notice the stationary engines made of old locomotives; the inside engine makes a very neat and small double-cylinder upright when stripped and the crank-shaft lengthened.

The hydraulic lift in the boiler shop can handle a 30-foot shell over the riveter.

In one part of the shop there is set up four car-brakes—automatic vacuum—the same as in use; these are operated automatically, the brake going on and off every few seconds day after day; a counter tells just how many applications are made. This is used for testing sacks, hose and cylinder packing.

One very interesting machine is a huge hydraulic press over an immense table moving like a planer; this is used to straighten plate frames.

THE ROAD.

The Lancashire & Yorkshire is the only considerable road in England running east and west; it spreads out like a spider net over the northern part of England. It is only some 500 miles long, but has 700 signal towers. It is double tracked, heavy steel rail laid in 56-pound chairs (see them in the cut)—by the way, they make these at the rate of 2,000 a day; one man makes 3 per minute, 440 being his day's work; he uses a half of a machine—one that he runs by hand, but it withdraws the pattern. These chairs are held down by screws, spikes and round wooden pins. There is a machine for making these pins,—it sort of molds them, saturating them with something like creosote and making the pin hard.

THE ENGINES.

Like all the other roads the L. & Y. have a distinctive color for their engines—theirs is dark blue—and boiler and all are painted that color.

Most of them have the Joy valve motion, and all are inside-connected. The engine shown to the left in the first engraving is a saddle-tank switcher, the one on the right being a suburban engine, and a very good one, having six wheels connected and a radial truck and some sort of excuse for a cab. They have many eight-wheelers for passenger service, and freight is hauled by the standard six-wheeled truckless machine made just as plain and straight as a Puritan Sunday.

The top of the driving-boxes have two places for oil; one has a wool wick in it—a "trimming"—the other has cold tallow that can run only when the box gets hot. These boxes have a metal cover to which is riveted a lining of felt; this prevents wear and insures a tight joint.

The cylinders have common cups on the heads, as a rule, but they have a large brass cup on the engineer's side of the cab (or what ought to be the cab), and pipes run from this to the chest—you remember there is only one chest for both cylinders—there are no glass feeders on this lubricator, but there is a force pump in it with a pump-handle hanging out; when the bold engineer—no driver—wants to get a little slipprication to the valves, he wiggles the pump-handle. This is safe and cheap, and I believe well liked by the men.

The injectors are of the self-contained type, check, starting valve, lazy cock and injector, all in one piece on the boiler head. They have in use a few exhaust injectors; they are rather awkward looking affairs.

The blower-cock is simply a packing-nut and a handle on the boiler-head. The pipe goes directly through the boiler; no pipes outside.

The vacuum brake is used, and there are several plans of locating the big ejector. One is to cast it as part of the nozzle-stand, the ejecting jets being ahead of the nozzle and aimed up the stack.

No gauge-cocks are used, but there are two water glasses.

They use a device that we ought to adopt in this country at once, and that is a cylinder for raising and lowering the water-scoop. Theirs is operated by vacuum, but air could be applied easier. The fireman takes water by simply turning the handle of a three-way valve. There is no room taken up in the gangway, and no danger of injury if the operative forgets where the end of the trough is, their water-scoops having small rollers that prevent their ruin if the scoop is left down too long. The suburban engines have a scoop that has an opening both ways and is used when the engine is running in either direction.

They were building sixty of these tank engines for local trains and suburban work during my visit. They have 17 x 24-inch cylinders and weigh 44,000 pounds.

These inside-connected engines have a partition in the exhaust nozzle but four inches high. The nozzles are set on a level with the top row of flues.

The boiler fronts are beautiful jobs—smooth, clean, all rivets cut off and filed down flat, nice joints, but hard to repair if struck.

There is a large man-hole right over the crown-sheet. This man-hole ring and its cover are of cast-steel. The crown-bars and roof arches for stays are cast-steel.

The domes are welded up, not a rivet in them.

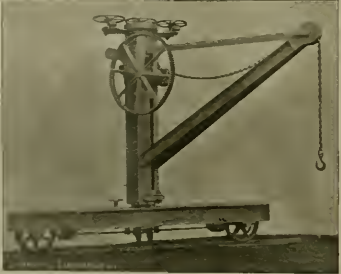
In some of their solid-ended rods they use a cast-iron bush, in others a bush made entirely of babbit.

There is no hose between the engine and tender, but a slip coupling combined with a ball joint is used. Just such schemes were in use in this country forty years ago.

They use a radial truck, the single pair of wheels being kept in the center by stiff springs.

I was shown some brass valves on which they had tried to make the Richardson balance strips work, but without success. It was evident that the strips were not deep enough, and perhaps the metal had something to do with the failure, or the slots may have been milled instead of planed. Good cast-iron valves are a success when properly fitted with this device. Nice work is done on ash-pans, and the dampers are tight, the operating rods are screwed up and down. In fact, an English locomotive is operated by screwing something all the time. The driver operates his reverse-gear by a screw and a hand-wheel, those on the L. & Y. being located just where the driver ought to sit down, and the place where the screw ought to be is vacant.

They cast steel crossheads with about a foot of 5 or 6-inch metal where the rod ought to be. This is drawn out under a hammer into a piston-rod; as the taper fit in the piston-head is larger than the rod, and the crosshead occupies the other end, the gland has to be put on in halves. This style of crosshead and rod seem to have had quite a run of popularity in Britain, but Mr. Aspinall, as well as several other locomotive superintendents, told me that they should make no more; when the rod is worn out they have to throw away a lot of work on a crosshead that would run for years.



WALKING CRANE.

INGENIOUS TEST.

I was quite interested in the way they look for cracks in crank-axles. An axle having two immense cranks in it is very liable to develop almost invisible cracks. When an engine comes in for overhauling, her crank-axle is cleaned, right down to the iron, bright and dry; then the pair of wheels are rolled sharply against another pair or any other stationary object. This sets up considerable vibration, and if there is a hidden crack anywhere the oil will come to the surface and expose it. When this does occur a clean paper is pressed upon the part, which takes an exact print of the fracture, in oil, and its location is defined exactly. This is filed away in a book with the age, kind, size and previous condition of servitude, all noted down for future reference.

J. A. H.

**Punctuality of Trains.**

One of the best threshed themes of discussion that a traveler hears constantly ventilated in the smoking-rooms of sleeping cars is the want of punctuality of trains. The average drummer is not inspired with much patience when delays of trains interfere with his business engagements, and he loves to air his woes to fellow travelers and to indulge in a little wholesome abuse of railroad companies.

We have frequently borne the infliction of late trains without Christian resignation and used uncomplimentary expressions toward those responsible for bringing in trains behind time. We wish now to make a general retraction and bear testimony to the punctuality of American railroad trains as a rule.

Two months ago we went out to view the extent of the country, and made a very long tour and gained much experience of traveling, even though moving about the world was no new proceeding. We sat behind some of the New York Central flyers to Buffalo, and the Lake Shore train took us at satisfactory speed to Cleveland, where Big Four's power whirled us to Cincinnati. The same line landed us in Chicago. By the handsome cars of the Chicago, Milwaukee & St. Paul we journeyed to Cedar Rapids, Iowa. The Burlington, Cedar Rapids & Northern took us comfortably to Burlington, and we did not get suffocated quite in the dirtiest car we have seen for many a day, which took us on the Chicago, Burlington & Quincy from Burlington to Fort Madison.

At that point we went upon the Atchison, Topeka & Santa Fé and rode upon it for about a week on all sorts of trains, from limited to way freight. We went from Fort Madison to El Paso, Texas, and back to Albuquerque, New Mexico. It was really the same fine road that took us from Albuquerque to Los Angeles, California. The Los Angeles Terminals Company conveyed us to view the Pacific Ocean and the great orange groves and fruit orchards of Southern California. Next we joined the Southern Pacific lines and traveled on them for about a week, finally transferring to the Rio Grande Western at Ogden. This line took us to Grand Junction, Utah, and delivered us to the Denver & Rio Grande, which conveyed us to Denver. The Union Pacific took us to Cheyenne and Omaha, and the Chicago, Rock Island carried us comfortably to Chicago.

In all that long journey over the numerous roads we were not once an hour late in reaching the destination or meeting point. The trains were not by any means run slow, and many of them made as good time as the express trains of lines east of Chicago.

After reaching Chicago we went to Cincinnati, and landed two hours late, the most of the time having been lost in the first 100 miles. From Chicago we went to Pittsburgh, and got in there one and a half hour late. After remaining in Pittsburgh a couple of days we started for New York with the evening train, and got in three hours late. Nearly an hour was lost in the last fifty miles with hot boxes on a car. Two of these got hot on different trucks. That was the first hot box we had seen attended to the whole tour.

## Directions for Setting Valves on a Locomotive.

BY PRACTICAL MACHINIST.

I will speak of an eight-wheeled, two pair drivers connected, 17 x 24-inch cylinders, 5-foot wheel, indirect valve motion, that is one with a rocker arm between eccentrics and valves. Valves have $\frac{11}{16}$ of an inch outside lap, $\frac{1}{16}$ of an inch inside lap, $\frac{1}{16}$ of an inch lead; eccentrics have 5-inch throw, link-saddle set back $\frac{5}{8}$ of an inch.

First see that the shoes and wedges are up to their proper place, the main rods the right length so the clearance will be the same at each end of cylinders when piston is at end of stroke, the rocker arms are the same length on each side, that is, the two lower ones are the same, and the two top ones are the same. It is not necessary that the top and bottom arms be the same length; the link-hangers are the same length, the arms on tumbling shaft are both the same length, and at the same angle from reach rod arm on tumbling shaft, notice that the eccentric blades lead to the links properly, that is, the forward eccentric blade is connected to top of link, and backward eccentric blade to bottom of link.

In this class of engines the eccentric that moves the valve follows the crank-pin both in forward and backward motion.

The throw of eccentric will be set as much less from right angles to crank-pin as the sum of the lead and lap

Lead is the amount the steam port is opened when the piston is at end of stroke.

Lap is that part of valve that extends over the outside edge of steam port when valve is on center of valve-seat.

You will find in some build of engines that the lower rocker arm is not in line with the top arm. It sets back a little. That is, the center of valve-stem pin, the center of rocker shaft, and the center of link block in lower arm, will not be in line. This is to make a uniform motion, the top of rocker being at right angles to the valve stem and the bottom at right angles to the center line of motion in mid-gear. In most engines the link saddle-pin is set back. The object of this is to overcome the error caused by the angularity of main rod. This can be better understood by referring to Fig. 1, $A$ is center of main axle, $B$ center of cross-head pin when piston is in center of stroke, $C$ and $D$ center of crank-pin when on forward and backward centers, $E$ and $F$ center of crank-pin when at top and bottom quarters. The distance between $A$ and $B$ is length of main rod. Using this length as the radius, the circumference of the circle will not reach the points $E$ and $F$. This shows why the crosshead and piston travels farther for the crank-pin to move from the forward center to the position where crank-pin is at its lowest point, or bottom quarter, than it does for the crank-pin to move from that point to back center. The crosshead and piston travels less for the crank-pin to move from the back center to the position where crank-pin is at highest point or top quarter than it does to move from that point to forward center. To overcome this difference of travel in crosshead and piston so that nearly the same amount of steam will be taken at each end of cylinder, the link saddle-pin is set back—one defect counteracted by another.

Examine rocker arms and see that they are both the same distance from main axle.

Before marking the valve-stems to show the port openings, see that the valve-yokes are a good fit on the valves If not, it is a difficult job to get your engine to sound "square," as the valves are set as the cylinders begin to take steam and the engineer hears her as she lets go of the steam or exhausts.

When everything, as rocker-boxes, arms, eccentrics and blades, links and hangers, valves and yokes and arms on tumbling shaft, are all right, it is not a very difficult job to get an engine "square." When one is wrong, as is frequently the case, then it is a more difficult job.

A good way to mark the valve-stems, is, if engine is all put together, to let the front end of one eccentric blade where connected to link, on each side down, then put a piece of tin in the steam port and move the valve up to the tin, then with a tram that has one point longer than the other, put the short end in center, punch mark on steam chest stuffing box at Fig. 2, and with the long end of tram make a mark on valve-stem as shown at $B$ Fig. 2, then move tin to the other steam port on same side and mark that one the same as shown at $C$, Fig. 2, you then have the two points, $B$ and $C$, Fig. 2, that give the position of valve when it begins to admit steam; mark the other side the same way. The distance between these two points is the lap on both sides of the valve. It is a good idea to get the center of these two points so that you can tell when the valve is covering both steam ports.

A person cannot be too careful in getting the port openings, I would here suggest that you be careful in getting the centers, and all work in regard to setting valves should be done with a great deal of care and attention.

I said use a tram that had one end longer than the other on account of valve-stem being lower than the stuffing-box on steam-chest, so the tram will stand at right angles to your stem, or you can mark the stems, using a center punch mark to move on top of cylinders; when you do this, there is no chance for the marks to move when the steam-chest cover is put down, as there was when using mark on stuffing-box.

It is not necessary to start at any particular point when getting dead centers, any center will do.

Starting with the right crank-pin a little below the back center the crosshead will be near the end on the back stroke, put one point of the tram on wheel cover at $D$, Fig 2, and make the mark $E$ on tire of driving-wheel, put one point of tram on back guide block at $F$, Fig. 2, and make a mark on crosshead at $G$, then move drivers over the center until the tram point reaches the mark $G$ on crosshead again, stop moving the drivers and make the mark $H$ on tire of driving-wheel, using the same tram and point on wheel cover used in making mark $E$. Get the center of these two marks $E$ and $H$ which is $I$; put reverse lever in back notch of quadrant, then move the driving-wheels back until tram will reach between the two marks, $D$ and $I$; the engine is now on back center in backward motion; make a mark on guide where end of crosshead comes, do this at each end of guides on both sides. When marking guides on front end use front end of crosshead, when marking guides on back end use back end crosshead. These marks to be used when running engine over in cut-off. With the valve-stem tram put one point at $A$, Fig. 2, and with the other point of tram make a mark on valve-stem; move the drivers still more back until all lost

THE BEST RAILROAD SHOP I SAW IN ENGLAND.

motion is taken up, then put reverse lever in front notch of quadrant, move driving-wheels forward until tram point reaches point I again, this is back center on forward motion, put one point of valve-stem tram at A, Fig. 2, and make a mark on valve-stem. Move the drivers forward until the crosshead on left side is near end of stroke, stop moving the drivers and make a mark on tire of left main driving-wheel same as done on right side, get the dead center and mark the valve-stem same as done on right side. For forward and backward motion, continue this until all four dead centers have been obtained, always moving the drivers both forward and backward, so as to take up all lost motion. When marking the valve-stem let the marks for forward motion be from the center of valve-stem to outside, and the marks for backward motion be from center of valve-stem to inside, so as not to get the marks for forward and backward motion confused.

Fig. 3 represents the left valve-stem, after getting the centers, and marking the valve-stem, A is front steam port, B back steam port openings, C shows for forward motion front end, valve 1/8-inch blind, D back end 1/16-inch lead, E backward motion front end 1/16-inch blind, F back end 1/8-inch blind. The distance between A and F is the lap on both sides of the valve. Holding valve-stem tram one point in center punch mark on steam-chest stuffing-box, the other point at A, the steam port for front end is just opened, when tram point reaches between the points A and B the valve is blind, outside the points A and B the valve has lead.

Get all the eccentric blades the right length first, then move eccentrics on axle to give the proper lead.

Valve stem on right side shows for forward motion on front end 1/4-inch lead, back end 1/8-inch lead, to make that eccentric blade the right length, make it shorter, one-half of what the lead it has in front end more than it has at back end, 1/16-inch, that will make the front end 3/16-inch and the back end the same, as it takes 1/16-inch off the front end and puts it on the back end.

Backward motion for right side shows on front end 1/8-inch lead, back end line and line, to make that eccentric blade the right length, make it shorter, one-half the lead it has on front end as the back end is line and line, that takes 1/16-inch off lead in front end and puts it on back end, so that will now show 1/16-inch lead on both ends. The right valve stem will now show for forward motion 3/16-inch lead and for backward motion 1/16-inch lead.

Valve stem on left side shows for forward motion on front end 1/8-inch blind, back end 1/16-inch lead, to make that eccentric blade the right length, make it longer, one-half the sum of what it is blind on front end and the lead on back end, 3/32-inch, taken off front end, leaving that 1/32-inch blind and putting 3/32-inch on back end, which takes 1/16-inch lead off and makes it 1/32-inch blind, same as front end.

Backward motion for left side shows on front end 1/16-inch blind, back end 3/16-inch blind; to make that eccentric blade the right length, make it shorter, as it is more lead on back end than on front end, so that blade is shortened one-half the difference what it is blind on back end more than on front end, taking 1/16-inch off back end and putting it on front end, leaving that 1/8-inch blind on front end, and same on back end. The left valve-stem shows for forward motion 1/32-inch blind, and for backward motion 1/8-inch blind.

It is a good idea to go over this the second time, beginning at the first, getting the marks on valve-stem and the dead centers. If any changes are needed, make them. It is seldom you will find everything right on going over them again, for by changing either of the eccentric blades to any great amount it changes the other one on that side a little, so it is best to always go over them the second time.

When there is more lead on front end than on back end, shorten eccentric blade; when more blind on front end than on back end, lengthen eccentric blade; when more lead on back end than on front end, lengthen eccentric blade; when more blind on back end than on front end, shorten eccentric blade. In the above rules the eccentric blades are to be shortened or lengthened one-half the excess lead, or what it is blind for either forward or backward motion. When there is lead on front end and blind on back end shorten eccentric blade one-half the sum of what it is blind and the lead, when there is lead on back end and blind on front end, lengthen the eccentric blade one-half the sum of what it is blind and the lead. All the above rules are for forward or backward motion.

The eccentric blades are now the right length, eccentrics are now to be moved on axle so as to give the proper lead, which is 1/16 inch on both forward and backward motion.

Put reverse-lever in forward notch in quadrant, move engine forward until crosshead is on right-front center, the valve-stem shows 1/8 inch lead, move the forward motion eccentric away from crank-pin until valve-stem shows required lead 1/16 inch, fasten that eccentric, put reverse-lever in back notch in quadrant, move engine forward to take up all lost motion, then move engine back to center again; valve-stem shows 1/8 inch lead, move the backward eccentric away from the crank-pin until valve-stem shows required lead

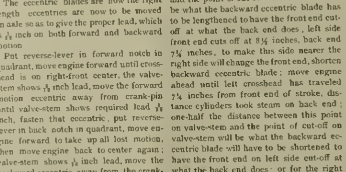


Fig. 2. Fig. 3. Fig. 1.

1/16 inch, fasten that eccentric, then move engine back until crosshead is on back center on left side with reverse-lever in back notch of quadrant; valve-stem shows 1/32-inch blind, move backward eccentric toward crank-pin until valve-stem shows required lead 1/16 inch, fasten that eccentric; put reverse-lever in forward notch of quadrant, move engine back until all lost motion is taken up, then move engine forward to center again, valve-stem shows 1/4-inch blind, move forward eccentric towards crank-pin until valve-stem shows required lead 1/16 inch, fasten that eccentric. It is best to go over this work again, for moving one eccentric to any great extent changes the lead for the other one on that side. Remembering moving eccentrics towards crank-pin, gives valve lead, and away from crank-pin makes valve blind.

The engine is now supposed to be "square" in the corners, or working steam nearly the full stroke, as the engine is worked at that point only when getting a train under headway, or on a hard pull, it is best to go over the valves when the reverse lever is hooked back, so engine will not work steam so far on each stroke.

Put the reverse lever up near the center of quadrant, any notch of quadrant will do, move engine ahead, holding tram on valve stem with one point at A, Fig. 2, another point on valve stem, watching valve stem, when mark C gets to point of tram stop moving engine, when that point is reached the steam is cut off from that end of the cylinder; measure the distance from front end of crosshead to mark on guide at front end of stroke, the mark made when the dead centers were obtained which is 5 inches, mark it on top of the guide the crosshead traveled over, this distance is length of stroke the cylinder was taking steam, the balance of the stroke the steam will expand in cylinder; move engine forward and get point of cut-off on the front end of left cylinder, and that shows the cut-off at 8½ inches, mark that on guide, get the point of cut-off for back end of right cylinder, that is 6½ inches; get the point of cut-off for back end of left cylinder, that is 7¼ inches; the left side front end cuts off at 8½ inches, back end at 7¼ inches, right side front end cuts off at 5 inches, back end 6½ inches. To have the front end on right side take steam same distance as back end, will lengthen the backward eccentric blade, with the reverse lever in the same notch in quadrant it was when cut-off was got; move engine ahead until right crosshead has traveled 6½ inches from front end of stroke, distance cylinders took steam on back end; one-half the distance between this point on valve stem and the point of cut-off on valve stem will be what the backward eccentric blade has to be lengthened to have the front end cut-off at what the back end does, left side front end cuts off at 8½ inches, back end 7¼ inches, to make this side nearer the right side will change the front end, shorten backward eccentric blade; move engine ahead until left crosshead has traveled 7¼ inches from front end of stroke, distance cylinders took steam on back end; one-half the distance between this point on valve-stem and the point of cut-off on valve-stem will be what the backward eccentric blade will have to be shortened to have the front end on left side cut-off at what the back end does; or for the right side lengthen the forward motion eccentric blade, and that would have let cylinders take steam longer on front end and less on back end, for the left side shorten the forward motion eccentric blade, and that would have let cylinder take steam longer on back end and less on front end.

When an engine is "square" in the corners and lame hooked up, you will have to sacrifice either the backward or forward motion, when working steam full stroke, unless you can discover what is wrong, then make the change at that place; it is at times a difficult piece of work to locate the defect, as it may be in various places, and at times a more difficult job to change after it is located.

The engine is now supposed to cut off on right side front end, at 6½ inches, back end 6½ inches; left side front end, 7¼ inches, back end 7¼ inches, will change one side so it will cut off nearer to what the other side will raise the tumbling shaft box on the long or left side, or shorten link-hanger on same side, or do the opposite on the right side, lower the tumbling shaft box or lengthen the link-hangers. To find how much to change the tumbling shaft box or link-hanger so that both sides will cut off the same, will change the right side, which is the shortest. With reverse lever at same notch in quadrant as it was when points of cut-off were got, move engine ahead until crosshead has traversed 7¼ inches from front end on right side, with a surface gauge make a mark on tumbling shaft as shown at P, Fig. 2, then move reverse lever until valve has cut steam off from that end of cylinder, as shown by valve stem tram, then make another mark on arm of tumbling shaft. The distance between these two marks on arm of tumbling shaft will be what the tumbling shaft box or link-hanger will have to be changed, as it is, the short side, to be changed, will lengthen the link-hanger the distance shown on arm of tumbling shaft, or lower tumbling shaft box the same distance.

Raising tumbling shaft-box is the same as shortening link-hanger—makes valve cut steam off earlier on the stroke, and lowering tumbling shaft-box is same as lengthening link-hanger—makes valve take steam longer on the stroke.

It frequently happens that after an engine has had general repairs the reach rod is not the proper length; to find out how much to change it so it will be the proper length, put reverse lever in forward notch of quadrant, move engine ahead until forward motion eccentric is at its full travel in front, crank-pin will be a little in front of the bottom quarter, make a center-punch mark on side of firebox near reach-rod, or any point that will not move, make a mark on each rod as shown at L, Fig. 2, put reverse lever in back notch of quadrant, move engine back until backward motion eccentric is at its full travel in front, crank-pin will be a little in front of the top quarter; make a mark on reach-rod as shown at M, Fig. 2, using same center-punch mark on side of firebox used before, then disconnect the back end of reach-rod from reverse lever, and raise the link up until bottom of link strikes the link block, and then make another mark on reach-rod at M, the distance between these two marks, the front ones on reach-rod, is clearance at bottom of link ⅞-inch, then put the link down so top of link block strikes the top of link then make another mark on reach-rod at L; this distance is clearance at top of link, it is ¾-inch, this gives clearance on right side, try the left side the same, so to get clearance at the top and bottom of that link. The difference between the clearance at top and bottom of the link on right side is ⅛-inch, so shorten reach-rod one-half the difference, 1/16-inch, then the clearance will be the same at both top and bottom. Have changed the reach-rod on the supposition that left link had same clearance as right one, if clearance for left link had been different from right, would have changed reach-rod to correspond with both links.

Better results will be obtained when running the valves over if the engine is in same condition as when in service that is, has water in boiler, and under steam have engine hot, so all parts affected by heat will be expanded.

The engine that I have been trying to explain to you how to set the valves on, is now supposed to be square in all points, or as near as can be, without making other changes. I have endeavored to make it plain, so it could be understood by all.

In setting valves there is much to be learned by practice; it is practical experience only that will make a person perfect in setting valves on a locomotive.

*Portland, Ore.*

---

Locomotive Engineer J. Puffenberger, of the N. Y., O. & W., is a candidate for the position of United States supervising inspector of boilers at Washington, D. C., and his division, No. 292, has unanimously indorsed him for the job. "Puff" is a well-known engineer, and has represented his division in several international conventions, and a host of friends will be glad to hear of his success. We don't suppose there is any law, if there is a precedent that prevents a man who has actually had charge of boilers from becoming an inspector. Should "Puff" get there his folks would not be in the hysterical condition that is attributed to the wife of Mr. Thompson when he was appointed Secretary of the Navy. "Oh, dear," said she, "I'm so scar't; somethin' will happen. Mr. Thompson's appointed to the navy *and he can't swim a stroke*."

---

The C., St. P., M. & O. have but twelve engines out of service for general repairs out of a total of 266, which speaks well for the machinery department.

### A Remarkable Wreck.

The reproduction from a photograph on this page was sent us by a friend, and is a striking illustration of what can be done by slamming two trains together real hard.

As is plain, it was a winter wreck, and it looks as if a passenger engine was being assisted through the snow when they collided with a freight train.

As the two consolidations met on even conditions as to size and weight, they clinched, welded their heads together, and froze up.

The passenger engine was lighter, and after throwing her big leader's tank over on the said leader's back, and collecting a pile of trucks to climb on, started up in the air, aided by the weight behind her. It looks as if the consolidation that played it alone against the combination had stood her ground well, but that her tank had been thrown more than sixty feet ahead of where it belonged. The work done in lifting about 100,000 pounds of locomotive eight or ten feet in a second is considerable.

Wrecks always have and probably always will occur as long as men railroad, but something can be learned from each and every one of them.

We know nothing of this wreck, nor the fate of the crews that "got together" on this occasion, but we hope they escaped injury.

We don't believe in being one of the kind of heroes that "grasp the throttle and die to save their trains" when they can just as well put on the emergency and jump for a snow bank.

### Tragic Times on the Atlantic and Pacific.

In the early days of the Atlantic & Pacific locomotive engine running was a terribly difficult and perilous occupation. The feed water was so densely charged with solids that it required skill to keep water in the boilers; gauge cocks would choke up solid in a few hours, and there were very limited facilities for doing work on the engines. All sorts of inferior men were hired and their blunders and mismanagement made the position of others more difficult and uncomfortable. Quite a number of English and of Reading engineers were hired. Few of these men understood running on train orders or how to avoid other trains that were scheduled. The result was numerous collisions. It is a grim fact that the engineers who had not been brought up on Western roads were quickly thinned out by getting killed in collisions caused by their own ignorance. On some divisions of the road there is scarcely a mile that does not show the scene of a tragedy with the blotting out of more than one life. Natural selection has left a highly efficient set of engineers on that system. Mistakes in train orders are very rare nowadays.

---

The *New South Wales Railway Budget* is worried to know what "double-header" means, it seems they don't put a pair of smokingines on one train over there. We notice their railroaders have the trade habit of inventing phrases—they call a delay a "nap," not so bad, *eyether*.

### Off in Figures.

There has been some agitation in Victoria lately about the pay of engine drivers in the colony, and there is some inclination to make out that these men are too well paid as compared with other railway employés. One of the leading papers of the colony recently had an editorial on the subject in which the stand was taken that the engine drivers were the best paid class of men in the world, and that their duties were not more responsible than those of guards (conductors). A high-favored class among these engine drivers receive 15 shillings or about $3.75 a day. Others receive 13 shillings, but the most common pay is 11 shillings a day. People who write about this being the highest pay in the world for engine drivers, do not know what they are discussing. The highest pay quoted is the common figure in America, and there are many of our locomotive engineers who earn more than twice the Victoria rate. With continuous brakes in use there is no comparison between the responsibility of the engine driver and the guard.

---

Last month an Erie freight train stalled and delayed the limited, No. 8, and the irate super. telegraphed the well-known and ominous words to the engineer "What was the cause of that delay to No. 8?" The freight man is a distant relative of Shakespeare, and wired back

"The wind was high, the steam was low,
The train was heavy, and hard to tow,
The coal was poor and full of slate,
And—that's why we held No. 8."

---

An English government official lately made a statement explaining why such locomotive works as Baldwin's could build so many engines at low cost. He said that Americans only had two types of locomotives, and that consequently they could be turned out like sewing machines, new drawings and patterns never being needed. The facts are that Baldwin's people have built about 1,500 different kinds of locomotives, and the orders that come from abroad nearly always call for diversity of design.

---

A leading railway company in England which experimented extensively with lighting passenger coaches with electricity, abandoned the light on account of its cost. There was no difficulty in the manipulation of the electrical appliances and the system of lighting was regarded as an entire success except that it was much more expensive than gas or oil.

---

There has been a great deal of agitation among the people who expect to visit Chicago during the World's Fair to compel railroad companies to carry passengers at the lowest possible rate. Railroad fares are not the only expenses connected with a visit to the Exhibition. The hotel keepers and caterers of Chicago are looking forward to the reaping of a golden harvest from the great influx of visitors. We second the *Railway Age* in a suggestion made that part of the public energy devoted to squeezing down railroad rates be bestowed upon the people who are most noted for fleecing travelers.

A WRECK THAT WAS A WRECK

### Tools for Repairing Compounds.

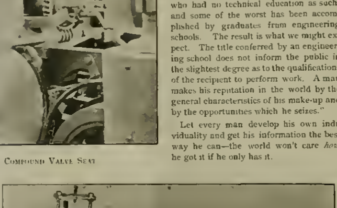
It is remarkable how soon a demand is filled in the machine field There were some mechanics who wondered how in the world they were ever going to re-bore the valve bush of Vauclain's compound when it needed it, especially those located inside and below the frame

A very simple boring bar has recently been devised that will go almost any place and can be used in any of the Baldwin compounds built Our upper engraving shows it at work on the valve seat of a large compound, where the low-pressure

Boring Bar for Vauclain Compound Valve Seat

cylinder is below the high-pressure The second engraving gives the details and the lower one shows the bar in a difficult place to get at, it also shows the valve of a Baldwin compound.

This tool can be made cheaply, or the Baldwin Works offer to furnish them when the user prefers to buy rather than build



Details of Boring Bar.

### Chemists Differ.

During the course of the investigation of iron and steel by a committee of the Master Mechanics' Association last year, analyses were made of specimens of steel by different chemists, and the results obtained gave serious offence to some steel-makers and no doubt did their product injustice. It appears now that chemists differ as much in their analyses as doctors in their diagnoses. At an engineering meeting lately, Dr. Dudley, chemist of the Pennsylvania, read a paper in which he said

"I have recently seen a series of, I think, sixteen determinations of sulphur in a piece of pig iron, supposed to be the same iron, that differed from each other from 0.005 up to 0.02 per cent., or the extreme results (I am giving these figures from memory) were about as 1 to 4. Now, obviously, while the amount of sulphur is excessively small in this case, not being a matter of very great importance, yet, as bearing on the accuracy of chemical work, the result is something appalling I have seen a series of phosphorus determinations recently, made by six or seven chemists, where the extreme results differed 0.03 to 0.04 per cent, in a total of about 0.10 per cent. I have a friend, who, for a number of years, was manager of a large furnace, who some four or five years ago sent out borings from some pig iron to eight or nine different chemists for phosphorus determination, and when he got the results back, no one of the chemists knowing that any other was working on them, they differed almost as 1 to 2, and, in his nervous, energetic way, he said 'I said, in my wrath, all chemists are liars'" Perhaps it is not necessary to mention any more discrepancies, I might, however, give one more instance. In a recent analysis of bronze, we obtained in our laboratory a trifle over 9 per cent of tin; another chemist, working on what was supposed to be exactly the same metal, being half of the same pig, got over 10 per cent., the discrepancy being about 1½ per cent. Now, obviously, there is something wrong somewhere"

The cause of the discrepancy he holds is the different methods of analysis employed, and he proposes to establish standard methods which he thinks will produce uniformity when the same conditions exist.

### A Dangerous Safety Device.

There has been considerable discussion in Eastern papers about an accident which happened on the New York, New Haven & Hartford, in which a dining-car was burned up and several trainmen injured. The accident was caused by the vicious rule that permits a conductor to stop a train by pulling open the escape air valve in the car instead of signaling the engineer. The passenger train to which the accident happened was running at night and had passed a point where a fast freight train had the right to start three minutes afterward Shortly after passing that critical point the conductor discovered that the dining-car at the hind end of the train was uncoupled and was pulled by the safety chains. Instead of displaying the judgment that would have prompted him to reach down and shut the air off the uncoupled car so that it would couple itself the first time the engineer shut off steam, the conductor pulled open the air-valve in the car and stopped the train. The margin of three minutes appeared to have passed before the flagman started out, and the freight train came thundering on with almost no warning of the danger ahead. The air having been all drawn out of the train-pipe, there was not sufficient volume in the main reservoir to enable the engineer to release the brakes, and they held the passenger train fast while the freight train plunged into the rear car.

The practice of using the conductor's valve for anything but accidents should be discouraged. More than one bad accident has happened of late because this valve was opened and not closed again and the engineer could not release his brake.

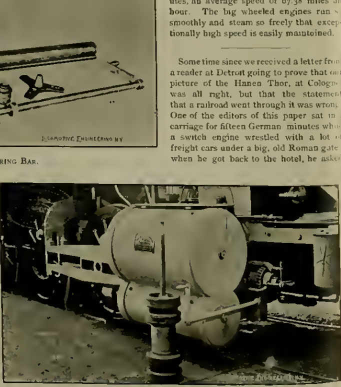
Whoever was responsible for the removal of the old conductor's valve, that closed itself by a spring, and the substitution of the plain straight-way cock, made a mistake. The old valve might have leaked a little, but when the excited conductor or passenger did let go of them the engineer could get his brake off. Just as many accidents can be prevented by taking the brake off at the proper time as in putting it on

### Some Plain Truth.

Mr H. F. J. Porter read a paper before the Mechanical Engineers' Association in this city last month, in which he said

"Some of the best engineering work of the country has been accomplished by men who had no technical education as such, and some of the worst has been accomplished by graduates from engineering schools. The result is what we might expect. The title conferred by an engineering school does not inform the public in the slightest degree as to the qualifications of the recipient to perform work. A man makes his reputation in the world by the general characteristics of his make-up and by the opportunities which he seizes."

Let every man develop his own individuality and get his information the best way he can—the world won't care *how* he got it if he only has it.



In a Tight Place Low Wheel Engines.

### Wrong Material in Car Repairs.

One of the most fertile subjects of conversation in the offices of master car builders and superintendents of railroad machinery is the unreasonable and unjust acts done in the interchange of cars. It appears that men who are otherwise of high character lose all sense of fairness and justice when trying to get the advantage of their connecting lines in disputes about the repair of cars. We heard particulars of a fairly representative case lately. A car belonging to A got damaged on the B line, and had to have new sills put in. The original sills were of an odd size, and the repairing road put in those they had in stock, which were about half an inch thicker than the old ones. When the car got home a charge for new sills was made upon the repairing road on the ground that wrong material had been put in, and Rule 19 was quoted as authority for the charge. The officer under whose charge the work was done protested that the cars were better than they would have been had the original size of sills been put in, but the owners insisted on their pound of flesh. Word was then sent to return the sills that had been put in and the charge would be allowed. The owners of the car made no answer to this request, and the claim was dropped.

### The Fastest Long Run.

There is nothing more common nowadays than the hearing of passenger trains on our leading lines being run at speeds varying from sixty to eighty miles an hour for a few miles, but it is still a novelty to find a train running over 100 miles at higher speed than a mile a minute On November 8th the Empire State Express broke the record for long continuous speed by running 115.76 miles in 110 minutes, an average velocity of 63.14 miles an hour The train consisting of four cars, pulled by engine No. 893, Engineer Chase, left Syracuse thirty minutes late and made up twenty minutes in the run to Albany There was a stop of three minutes at Utica. For two miles out of Syracuse station the speed had to be held down below twenty miles an hour, but after that the train was spun along in great style, for the run from Syracuse tunnel to Utica, 51.67 miles, was covered in forty-six minutes, an average speed of 67.38 miles an hour. The big wheeled engines run so smoothly and steam so freely that exceptionally high speed is easily maintained.

---

Some time since we received a letter from a reader at Detroit going to prove that our picture of the Hanen Thor, at Cologne was all right, but that the statement that a railroad went through it was wrong One of the editors of this paper sat in a carriage for fifteen German minutes while a switch engine wrestled with a lot of freight cars under a big, old Roman gate when he got back to the hotel, he asked the porter—who knows everything—what gate it was, and was told the Hanen Thor Again he asked the photo dealer for a picture of the gate with the railroad and was given a Hanen Thor again. Since receiving the letter we wrote to the manager of Thos. Cook & Son, at Cologne, and he informs us that the road enters through the Pantaleans gate. As long as it came in decorously through a gate we don't care which gate it was, but if there had been any fence climbing we should have resented it.

### Progress of American Transportation Facilities.

At the recent State Fair of California, held at Sacramento, the Southern Pacific Company made an exhibit that attracted a great deal of attention; it was intended to show the stages of transportation facilities in the Golden State.

The first stage was represented by a set of Indian tepee poles; these, as is well known, are tied on each side of a pony, one end dragging on the ground, and loads of scanty household furniture carried thereon.

The second stage was represented by a cumbersome Mexican "caretta." This was introduced into the State when the Mexican superseded the Indian on the fertile coasts of the Pacific. The specimen shown is a splendid one from real life; the wheels are simply disks sawn off a log, with a heavy wooden axle and wooden linch-pin—not a scrap of iron about it.

Then they exhibited the first locomotive they owned, the "C. P. Huntington, No. 1," with one of their latest and best 10-wheeled passenger locomotives.

One of their cars of fifteen years ago and one of their latest furniture cars—about twice as large.

A passenger car of two decades ago stood up beside one of our modern 62-foot coaches.

The old style scoop-plow was shown together with the latest Rotary steam-plow.

The Southern Pacific Company have only been operating a road for some twenty-four years, and the improvement in that time is best told by the object lesson of this exhibit.

The fine illustrations of the different exhibits were made from photos taken on the ground.

First Stage, Indian Tepee Poles.

Second Stage, Mexican "Caretta."

The First and the Latest Locomotive.

Snow Bucker—The Latest and the Oldest.

New and Old Style of Freight Car.

Modern Coach and Old Passenger Car.

The Baker Car Heater Works have removed their machinery to their new factory at Hoboken, N. J., and have opened an office and show-room at 143 Liberty street.

We want to call every reader's attention to our new heading, head-letter and dress. We think the typographical get-up a great improvement.

The Locomotive Engineering calendar for 1893 is ready for delivery—just right for the cab—sent to all who ask for it.

Wm. H. Owens, who has been for some years an engineer on the Buffalo division of the P. & R., has been appointed road foreman of engines on the line between Manchester and Sayre, including the Ithaca branch. The appointment took effect December 6th.

Mr. J. J. Ellis, master mechanic of the C., St. P., M. & O., at St. Paul, has all eccentrics of his engines put up in two pieces, the smaller part of the cam being made of wrought iron. Mr. Ellis has found that eccentrics so put up wear well and there is not the tendency for smaller part of cam to break in the event of heating, as heretofore, when both parts were made of cast-iron.

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK

Address all communications and make all orders payable to

LOCOMOTIVE ENGINEERING,
3 Beekman Street, New York.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } *Editors and Props.*
JOHN A HILL, }
J W CURRAN, *Mgr Advertising Dept*

### Subscription Price.

$2.00 per year $1.00 for six months, postage paid to any part of the world Single copies, 20 cents.

### Special Notice.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock department of Railroads*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper This will be done without charge, and without reference to advertising considerations*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits The reading columns will not be sold*

*Correspondents must give their names and addresses, but not necessarily for publication*

*Mailing address can be changed as often as necessary, always give old and new address, and if you subscribed in a club state who got it up*

*Please give prompt notice when your paper fails to reach you properly*

Entered at Post Office, New York, as Second-class mail matter

For Sale by Newsdealers Everywhere.

W Williams, 21 Fink's Bldg, Melbourne, Australia.

### Notice.

Our reserve for binding, 100 copies, is now ready for delivery We have forty-two bound volumes of 1892 on hand and about thirty complete volumes, unbound. When these are disposed of there will be no back numbers of LOCOMOTIVE ENGINEERING for 1892 We will enter the orders as received, first come first served. We do not propose to do a back-number business. We will bend all our energies to the making of an interesting paper each month—and nothing else. We shall try to keep enough papers to insure the complete year to every subscriber, if wanted, but no "year before last" business.

ANGUS SINCLAIR,
JOHN A. HILL.

### Our Birthday.

Five years ago this month the first LOCOMOTIVE ENGINEERING, *neé* LOCOMOTIVE ENGINEER, was issued It was a little 16-page, 3-column infant, but it yelled lustily, and—most important of all—lived.

Its editorial policy was unlike most other papers in the field, and its aim was more to interest and instruct the rank and file in the railway motive-power and rolling-stock departments rather than to cater entirely to those high on the ladder.

This policy has done enough good to make the paper the favorite one among progressive railroad men high and low, has increased the page to 4 columns, the number of pages from 16 to 48, and the monthly mail-bag from a few hundred pounds to *more than five tons.*

As we do not blow our own horn in the reading pages but this once a year, we may be excused for having our little New Year's say and feeling good because there are plums in our birthday cake and peanut candy on the frosting

Last year the great enlargement of the journal and the doubling of the subscription price was going to ruin the paper—so we were told

But the LOCOMOTIVE ENGINEERING nurses had experience, and felt assured that the railroad men of this country would not drop a good paper because it had been made twice as good—and charged for accordingly.

This year the report of our old club-raisers from far and near are that they will increase their lists, and from every part of the country come applications for permission to get subscribers—the circulation is assured

Advertisers know a good thing when they see it, and the doctrine that a big circulation is a bad thing for advertisers is not making converts to any alarming extent.

During the year we have spent a great deal of time and money to make the paper interesting and instructive, and for the next year propose to fill its pages with such matter as will confirm and, well, sort of "rub in" the words on the seal of public approval "Most Interesting Railway Paper Published"

LOCOMOTIVE ENGINEERING starts out on her sixth year with new head, new dress, new ideas and new courage She sends a greeting to one and all, old friends and new, and wishes them a Happy New Year

ANGUS SINCLAIR,
JOHN A. HILL

### Exhaust Nozzles.

Those who have enjoyed opportunities of watching the working of locomotives in foreign countries are nearly always struck with the light exhaust of the engines compared to the violent noises caused by the steam passing from the exhaust pipe of American locomotives. Why there should be such a distinct difference is not readily apparent. American locomotives, as a rule, are required to do much heavier work than most of those abroad, but when a foreign engine is seen pulling with maximum power, the sound of the exhaust is weak compared to the ringing detonations that shoot from the smoke-stack of all our engines working at the same rate. Why this should be so is well worthy of investigation

The noisy exhaust proclaims that, in passing from the cylinders, the steam is performing laborious work against the atmosphere, and that in consequence the capacity of the cylinders for doing the useful work of pulling cars is reduced This fact that a noisy exhaust means a weakened engine is not so well recognized as it deserves to be There are many persons influential in the care and handling of locomotives who believe that a noisy exhaust means a powerful engine, and this fallacy, no doubt, has something to do with the prevalence of contracted exhaust openings. Various causes make it necessary that many of our locomotives should use exhaust nozzles that are too small for economy of fuel or for free working of the engine, but others suffer from contracted nozzles that would steam better were the exhaust openings enlarged.

Small nozzles and the noisy exhaust resulting therefrom came into fashion through the use of boilers that were too small for the cylinders and had to be constantly forced to supply the steam required. The small nozzles would make a sharp blast that burned coal rapidly and, of course, created much heat for steam making. The small nozzles would also prevent the free escape of the steam, leaving part of it in the cylinders, thereby in a small way decreasing the quantity to be drawn from the boiler. Another practice that encouraged and demanded the use of small nozzles was the obstructing of the hot air passages with spark-arresting appliances Cones and diaphragms, and all sorts of deflectors and nettings, would be put in the way of the exhaust gases for the purpose of stopping sparks, but with the added effect of nearly stopping the draft or of offering much resistance to the full movement of the gases This action is very much of the same character as that of a miller who attempts to make the water from his wheel run up hill There is a correlation between the forces of nature that demands compensation if one is thrown out of balance When the smoke-stack or smoke-box is obstructed, the gases must be forced through with a greater velocity or there will be reduced generation of steam. Reduced nozzles is the usual resort for overcoming the restrictions put upon free movement of the exhaust steam and gases of combustion

Small boilers and spark arresters are necessary evils that have to be made the best of, and the use of contracted nozzles becomes the smallest in the choice of evils. There are, however, defects in locomotive construction that entail the use of small nozzles when changes could be made at very small expense which would remedy the evil Foremost amongst these is the use of grates that have not sufficient opening to admit air freely. A designer schemes with great care and ingenuity to provide as large a grate surface as possible for an engine, and then another man spoils the thing by making grates that make nearly a solid bed of metal under the fire. Men who do this sort of thing fail to understand the true relations that exist between fuel-burning and steam-making An engine has a certain size of grate area and a certain weight of coal must be burned per square foot to supply the heat necessary for steam making. Each pound of coal requires a certain volume of air to convert it into heat-gas, and unless this air is supplied the heat will not be generated. If the grate that the coal is resting on contains 50 per cent. opening the air will pass through much more freely than it will when the openings only amount to 25 per cent There are no mechanical difficulties in the way of making the openings amount to half the grate area, but it is much more common to find the spaces left for air to pass through only about one quarter the area. Here the superfluous metal of the grates performs the same part as the obstructions in the smoke-stack The restricted opening must be compensated for by increased velocity of the gases, and this is brought about by contracting the nozzles. One of the most successful master mechanics in the country lately remarked "Opening the grates leads to opening the nozzles, and no other light repair change can do so much to improve the engine"

An insuperable obstacle in the way of enlarging the nozzles of locomotives on most railroads is the diverse character of the coal supplied. Some qualities of coal are of a free burning nature and readily combine with the air passing through the incandescent mass. This kind of coal makes steam with a comparatively small supply of air Other coals are of a refractory character and require a strong gale of air to maintain combustion. The supply of air that would generate steam freely with the first mentioned coal will be found entirely inadequate with the latter. As the refractory coal has to be burned sometimes the nozzles must be made small enough to supply a sharp blast that will draw the necessary volume of air Owing to this, the nozzles of most locomotives are made small enough to cut the worst quality of coal, although the worst kind may not be supplied once a month. A few railroad companies have found it a good plan to establish uniformity in the grades of coal supplied with the result that the draft appliances of the engines are regulated to suit the coal, and decided saving of fuel is secured. Nearly all railroad companies could improve their practice in this respect without increase of cost in coal handling if only attention were directed to the matter. But to the greater part of the men who regulate the purchase of coal there is understood to be no difference in the product of different mines, and no attempt at uniformity is ever thought of.

On some railroads it would be highly inconvenient to make the coal supplied of uniform quality. In such cases we do not see why expanding nozzles cannot be employed so that the draft may be regulated to suit the quality of coal supplied. There is a strong prejudice against variable exhaust nozzles because so many forms have been tried and abandoned as worthless. This does not prove that all the expanding nozzles tried were impracticable, for many things that are now successfully used in connection with railroad rolling-stock were condemned when first tried. There is great demand among railroad managers for a reduction in fuel bills, and all enterprising master mechanics are striving to meet the call for increased economy of fuel. This has led to the introduction of compound locomotives upon many lines. From what we have seen of the working of good variable exhaust nozzles we are inclined to believe that great saving could be effected by their use. To make them successful care and energy are requisite, but the gain to be made is worthy of the effort.

### Dissensions in Car Interchange.

The principal railroads running into Cincinnati entered into an agreement about a year ago to handle freight cars by joint inspection, but it is not working well and there is great likelihood that the arrangement will soon be abandoned. Some of the railroad companies are perfectly satisfied with the working of joint inspection, and the officers admit that the plan facilitates the movement of cars, but others are strongly opposed to it. We listened to a rather heated discussion of the joint inspection plan at a meeting of railroad officers, and the impression received was that the men who are most vigorously opposed to joint inspection are actuated by unfair motives. They want to get the best of their connecting lines and joint inspection does not encourage this. There is also an inclination among some of the superintendents to establish rules for their inspectors that do not harmonize with the M C. B. rules of interchange. This is a very unsatisfactory state of affairs.

The formulating of rules indicating the condition in which cars are safe to run naturally belongs to the car department. The interests of railroad companies would be promoted by leaving the control of joint inspection in the hands of the man best able to understand the merits of disputes that will arise in the best regulated interchange yards. Obedience to the spirit of the M. C B. rules of interchange of cars is the only way in which the business between connecting roads can be carried on with any degree of harmony. When an inspector is responsible to authority that he concludes cares little for the M. C. B. rules, he only follows the weak dictates of humanity in frequently ignoring the plain dictates of the rules. If a railroad company is not prepared to place the joint car inspectors under the officers whose voice and counsel have been instrumental in perfecting the M C. B. rules of interchange of cars, it would be wiser to withdraw entirely from the Association, for rules that are not enforced become forms for enabling unscrupulous men to follow dishonest practices

A committee of the Master Mechanics' Association has sent out a circular calling for information about wheel centers and tires. There has been so much increase in the size of driving-wheels since the standards were established that it is considered necessary to make additions to the list The standard centers at present range from 38 to 66 inches, the upward steps being by 6 inches. There ought now to be standard centers as large as 84 inches, and many master mechanics believe that a step smaller than 6 inches should be made between the standards. Those who are interested in this important subject ought to give the benefit of their views to the committee.

At a recent meeting of the New York Railroad Club it seemed to be the general opinion that there was no real reason for using flangeless tire on any class of locomotive. Men who had run consolidations for years with all tire flanged, spoke in their favor.

### Rights in the Word "Engineer."

At the last meeting of the American Society of Mechanical Engineers the oft-ventilated grievance was again aired of the injury and disrespect endured by mechanical engineers on account of the men running locomotives being called locomotive engineers. The graduates of engineering schools are particularly exasperated that men who never heard of the differential calculus or of the adiabatic curves should be called engineers. The proposal was made that railroad officers should call their locomotive engineers runners, engine-drivers, or enginemen, in the hope that that would lead the general public to give the appellation of engineers to those who carried a certificate from some school dubbing them engineer. The proposal did not meet general support, and no one was able to devise a satisfactory solution of this stupendous difficulty.

We are afraid that it is beyond a remedy and that the exclusive-minded college graduate, who very often knows nothing of real engineering, will have to endure to hear the high-sounding honor of engineer borne by men who handle locomotives. The change has been proposed too late in the day. The popular voice has decided to call the men who handle locomotives locomotive engineers, and the talk of mechanical engineers' societies and technical school societies about changing the practice will have as much effect as the old woman's efforts to sweep back the ocean with a broom. One or two of our contemporaries began years ago to sedulously avoid calling locomotive engineers by any term except runners, and the practice has been religiously maintained, but we never saw any indications that a single convert had ever been made to the use of the "reformed" expression.

The man with a piece of parchment in his pocket solemnly certifying that the bearer is an engineer deserves some compassion in the dilemma where he is placed. We once saw one of these gentlemen introduced to a lady as an engineer, and his face was a study when she sweetly inquired what kind of an engine he ran? That indicated the extent to which the ordinary mind goes on bearing the term engineer. The nomenclature of the people on this continent terms the man an engineer who handles an engine. There is no decided impression among the public as to the term that mechanical engineers should be known by. If this class of men are aggrieved beyond remedy on account of being classed with greasy engineers, they might devise some other term for themselves, and there is a possibility that the public would learn to call them by their chosen appellation. Unless they agree to do something of this kind, they will have to endure for all time the mortification of hearing others called by the name they think sounds so sweet.

### Learning to Detect Broken Stay-bolts.

The hammer test for ascertaining the condition of stay-bolts appears to be highly satisfactory on some roads, while on others it is not considered worth using. From what we have seen and heard about locomotive boiler inspection we are inclined to believe that no test is positively reliable, but that the hammer test is valuable if made intelligently by men who practice it enough to become expert. The Pennsylvania railroad people, who have devoted particular attention to the inspection of boilers and practice the hammer test, made some curious experiments to find out its value. They had a boiler about to be cut up They invited the boiler inspectors from all over the road to attend at a certain shop and try the hammer test on the boiler All the stay-bolts were numbered, and the inspectors were required to report on a blue print each carried the condition of the stay-bolts. The boiler was then taken apart and the stay-bolts examined. None of the inspectors had detected all of the broken stay-bolts, and they all reported bolts to be broken which were found to be intact. It was said that a deaf boiler inspector came nearest being correct.

The men were sent home and told to keep on with the hammer test but to try to acquire more skill in detecting broken stay-bolts. After a time a second boiler was to be broken up and they were invited to come again and try what they could find out about the condition of the stay-bolts. When the boiler was taken apart and the broken stay-bolts compared with the reports of the inspectors, it was found the latter had greatly improved in their efforts at detection. After another interval of time the inspectors were called to examine a third boiler that was about to be broken up, and they all detected all the stay-bolts that were broken. This is a striking illustration of the value of training and it is well worthy of imitation by railroads generally. There is a vague idea prevailing that any boiler-maker can detect broken stay-bolts by the hammer test, but a boiler-maker has to learn this special part of his art by careful practice and study, just the same as any other man. Nearly all roads have to renew their fireboxes frequently. It would be a good plan to examine those to whom are intrusted the work of inspecting boilers by having them test the stay-bolts of a firebox about to be removed. This would show whether or not the inspectors were reliable

Broken stay-bolts are such a serious source of danger that no reasonable means should be neglected to insure their detection.

### Malleable Iron for Driving-boxes.

There are very few driving-boxes made of malleable iron, but we believe that this material would be a remedy for the breakages of driving-boxes that cause so much annoyance on many locomotives. The prevailing increase of speed, the practice of putting larger driving axles into old engines, and the harder work done all tend to make the driving-box a weak point The size cannot be increased in all engines, so that a stronger material is urgently in demand. Steel has been found objectionable on account of its tendency to cut the wheel hubs and the wedges. Malleable iron does not have this objectionable character. In fact, there is good reason to believe that malleable iron to cast-iron would cause less cutting and wear than cast-iron to cast-iron.

The experience of many people using malleable and cast-iron in machinery tends to prove that they work exceptionally well in contact The latest illustration of this we have noticed was in the construction of the Chapman jack. The small jacks of this kind were first made with screw and base of malleable iron. When the jacks made in this way were put into service it was found that they did not wear well. This induced the makers to look for a remedy, and they tried gray iron for the base. This combination has proved so durable that no other base is now used in the small jacks.

We have known some cases of eccentric straps being made of malleable iron, and they display extraordinary wearing qualities. Those who are annoyed with the breakage of driving-boxes and eccentric-straps would do well to try the use of malleable iron.

### Preventing of Grievances.

The trainmen of the Fall Brook railroad were treated to an agreeable surprise last month in the shape of an announcement from General Superintendent Brown, who stated that all would be paid for overtime when delays kept them on duty beyond certain hours.

A committee of the engineers presented an address of thanks to Mr. Brown in which they say

"We are agreeably surprised to learn that the company has voluntarily granted pay for overtime. We appreciate the company's kindness and consideration for their employés in this and many other instances.

"The increase means a good deal in the way of additional comfort to ourselves and families. We desire to thank you sincerely for your efforts in our behalf and request that you convey our thanks to President Magee.

"We shall endeavor to show by our work, as we have in the past, that we appreciate the company's desire to meet its employés fairly in all reasonable requests. We are solicitous in common with the officials to maintain the high reputation the Fall Brook railroad has won in comparison with other roads for its methods of doing business."

---

There appears to be agitation among the railroad telegraphers all over the country to obtain concessions from their employers in the shape of increased pay There have been several strikes lately as a means of emphasizing the demands of the men, and in every case that we are aware of the railroad companies were the victors in the fight. The real trouble with telegraph operators is that their business is too easily learned, and that it is a genteel occupation which numerous young men who aspire to always work with a starched shirt on are glad to enter. The grim law of supply and demand makes the supply of telegraph operators excessive, and the natural result is that the competition for positions keeps the pay low Telegraph operators at railroad stations perform highly important duties, yet railroad companies generally pay the lowest remuneration and get the poorest operators in the business. The men are striving by combination to compel the companies to pay them living wages, but they do not appear to have been very successful this time. Unfortunately railroad companies have never displayed any inclination to pay according to the value of the services performed unless compelled to do so by labor organizations. The telegraph operators may be beaten all along the line this time, but the blind policy of railroad companies will strengthen the cause of organization so that the men will become sufficiently united to win in the long run.

### BOOK REVIEW.

TIPS TO INVENTORS. By Robert Grimshaw, Ph.D., M.E., etc. Published by the Practical Publishing Co., 21 Park Row, New York Price, $1 00.

This is another neatly bound book by Grimshaw So far as we are able to see, there is not a line in it of any value on earth to anybody. It is small and divided up into subjects—Electrical, Metallurgical, Railway, etc.—and under these headings it tells the professional and the amateur inventor what to invent. Under the heading, "In Railway Lines," he advises inventors to get up a brake that takes hold of the rail, and says there is a chance for inventors to change our whole system of train-braking. We think so, too—a slim chance. He wants some one to get up a typewriter that you can see the last letter printed—there are several good ones on the market. He says there is room at the top, and also cash for the inventor who "gets there," with jet propulsion for vessels. Grimshaw's advice about taking out patents is all good enough, but his "tips" are about as good as race-course tips in the evening papers—and no better.

CAB AND CABOOSE By Kirk Munroe G P. Putnam's Sons, New York, publishers. Price, $1 25.

This book is one of a series of books for boys recently put on the market. The young hero of the tale, "Rod. Blake," does almost everything, possible and impossible, saves people from all kinds of disasters, catches train robbers, runs locomotives, etc., etc., and ending up as private secretary to the President. The story is interestingly told, and exciting enough for any boy, and the author seems quite familiar with railroad operations and railroad phrases.

### PERSONAL.

Mr. J. S. Turner, master mechanic of the Mexican Central at Jimulco, has resigned.

Mr. M. M. Reid has resigned the position of master mechanic of the Savannah, Americus & Georgia

Mr. Robert Walker has resigned as master car builder of the Missouri, Kansas & Texas, on account of ill health.

Mr D D. Sewall, formerly general manager of the Consolidated Car Heating Co., has been elected vice-president of that company.

Mr. J. F McElroy, formerly mechanical superintendent of the Consolidated Car Heating Co., has been appointed consulting engineer of the same company.

Mr. W. S. Wakefield, one of the oldest master mechanics on the Chicago, Rock Island & Pacific, has retired. He rose from the foot-board and ran the first engine that went over the road in 1857.

Mr. C. C. Keenan has been appointed general foreman of the shops of the Western New York & Pennsylvania, at Olean, N Y. He was formerly connected with the Pittsburgh Locomotive Works.

Mr. Samuel Irvin has been appointed master car builder of the Missouri, Kansas & Texas, to succeed Mr Robert Walker, resigned. Mr. Irvin was long master car builder of the Missouri Pacific, at St. Louis.

Mr J H. Sewall, formerly assistant general manager of the Consolidated Car Heating Co., with headquarters at Chicago, has been appointed superintendent of construction of the same company with headquarters at Albany.

Mr. F W Sargent, formerly engineer of tests of the C., B. & Q., and for some years general agent for the Congdon Brake Shoe Company, has been appointed superintendent of the latter company's brake shoe and iron department.

Mr. J. H. Berry, master mechanic of the Cincinnati division of the C. C. C. & St. L., has had his jurisdiction extended over the Sandusky division, his headquarters remaining at Delaware, Ohio. This division was formerly in charge of Mr. J S. Porter.

Mr A. W. Quackenbush, lately superintendent of machinery of the Chicago & Alton, has not long remained out of harness He has accepted the position of master mechanic of the St Louis, Cape Girardeau & Fort Smith road, with headquarters at Cape Girardeau, Mo.

We have received a paper containing a lengthy account of the success achieved by Mr. G. A. Haggerty, mechanical superintendent of the Canadian Pacific at McAdam Junction, N B. From what we have seen of Mr. Haggerty's management we can indorse all the kind things said about him.

We have been informed by Mr. F. D. Casanave, superintendent of motive power of the Pennsylvania lines west of Pittsburgh, that they are building seven more of the class X engines at Fort Wayne. The engines of this class already in service are reported to give entire satisfaction in pulling heavy trains.

Mr H G Bechhold has resigned the position of general foreman of the Chicago & Erie at Huntington, Ind., and gone to be general foreman of the Cleveland Frog and Crossing Co., at Cleveland, O. Before leaving Huntington he was presented with some substantial presents by the men who had worked under him.

Mr. D. H. Neale has returned to the editorial staff of the *Railroad Gazette* and is engaged preparing a new edition of the

"Master Car Builders' Dictionary," work for which he is peculiarly well fitted Mr Neale has been mechanical engineer of the New South Wales railways for several years and left there to take his old position on the *Gazette*.

W G Nugent, roundhouse foreman of the Iowa Central, at Marshalltown, has lately been appointed acting master mechanic, *vice* M. C Wheeler resigned Mr Nugent is a young man of more than ordinary ability and above all an excellent organizer His early training was under John Player, as an engineer

Mr Leonard Crossman, who was once master mechanic of the Central Railroad of New Jersey, died at Elizabeth N J, last month Mr Crossman went to the road in 1855, with an engine called the ..., built at Taunton and ran it till he was made master mechanic, a position he held for eighteen years, being succeeded by William Woodcock

Mr Thomas Smethurst, master mechanic of the Mexican Central at Guadalajara has been transferred to Jimulco, to succeed Mr J S Turner, resigned Mr C E Thackford has been transferred from San Luis Potosi to Guadalajara to succeed Mr Smethurst and Mr D M Haynes, recently general foreman in the shops in the City of Mexico, has been appointed master mechanic at San Luis Potosi, in place of Mr Thackford

A number of changes have recently been made in the organization of the West Milwaukee shops of the Chicago, Milwaukee & St Paul Mr Elijah Fairbairn, master mechanic of the shops has resigned and has been offered another position Amos E Allcutt general foreman, Joseph Corner, foreman of the erecting shops and other foremen have resigned Mr C A Place, who has been paymaster since 1861, will retire on January 1 with a pension

Mr Matthew Ellis, formerly master mechanic of the Chicago, St. Paul Minneapolis & Omaha, died at St Paul last month. Mr Ellis had to retire from active service about two years ago owing to ill health Mr Ellis was born in England and worked for a time in the Stephenson Works at Newcastle. He came to America about 1860 in company with the late Mr Lowrey, of the Chicago, Milwaukee & St. Paul, and several other young mechanics, who became mechanical officers of American railroads

We have to acknowledge a very pleasant visit from Mr. T F Rotheram, locomotive superintendent of the New Zealand railways, who is visiting this country while on his way to Europe Mr Rotheram is naturally very much interested in our railroads and in our methods of operating He sees many things to admire, but on the other hand is a keen critic of some practices that are common here. He is a man remarkably free from insular prejudices and will doubtless profit by what he has seen in this country.

J N. Lauder, of the Old Colony, is fixing up an exhibit for the World's Fair He is putting into first-class shape the last inside-connected engine, built by Geo S Griggs twenty-three years ago for the Boston & Providence road, now a part of the Old Colony system This engine is the last of a class of famous early engines built by Mr Griggs, she has 17 x 22-inch cylinders An old English passenger coach, that has been carefully preserved since the '40s, is also being fitted up This car will have its original wheels, body and brake

Mr Cecil Gabbitt, who made a miserable record as general superintendent of the Central of Georgia, has been appointed by the receiver general manager of the Savannah, Americus & Georgia. Mr Gabbitt is inaugurating his rule on this road by turning out the principal operating officers This is the policy so often followed by small men who do not understand their business. It is the most certain way to achieve failure Men of sense always understand that the old men on a road will do better than new ones everything else being equal But Mr Gabbitt is an old track man and evidently thinks that men suitable for superintendents are as numerous as men suitable for track foremen

Mr H Stanley Goodwin, general superintendent of the Lehigh Valley Railroad, died very suddenly at Bethlehem, Pa, on Christmas morning. Mr Goodwin was one of the best known civil engineers in the country He began engineering work in 1852 as a rodman on the Delaware, Lackawanna & Western, and eight years later, after varied experiences in his business, he attained the position of resident engineer of the Pittsburgh, Fort Wayne & Chicago Three years afterward he became chief engineer of the Northern Central In 1882 he was appointed superintendent of the Lehigh Valley railroad. He was considered one of the best authorities in the country on railroad engineering problems

For the last month there have been rumors that owing to incompatibility for pulling in harmony with the purchasing department, Mr E P. Lord, superintendent of motive power of the Big Four had been asked to send in his resignation The tendency of the mechanical chief of this road to be out of harmony with the purchasing agent is nothing new That the management would be willing to sacrifice their remarkably able superintendent of motive power upon this altar of discord we were inclined to doubt, and we now have reason to believe that the rumors of a change originated with those who were anxious to see one made A change is badly needed on this road, but not in the head of the mechanical department The real cause of trouble is that the striker imagines himself to be captain of the boat.

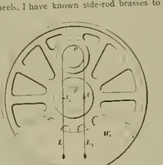
Mr Eugene Chamberlin, the well known master car builder for the New York Central, has resigned and accepted the position of superintendent for Rood & Brown, wheel-makers, Buffalo. We are very sorry to see a man like Mr Chamberlin leaving railroad service, for he is a man of commanding ability who would be a credit to himself and to his employers in any line of business. He is a persuasive public speaker and was a power in the Master Car Builders' Association By power of argument and by sagacious management he several times carried the convention to adopt measures that seemed to have no support till he became their advocate Besides this he was an exceptionally good officer, and has few equals as a shop manager There are very few first class railroads in the country that would let a man like Mr. Chamberlin go to a private firm

One of the most popular of our supply men appears to be making an unqualified success as a railroad manager. About six months ago, Mr J. K. Bole, of the Otis Steel Company, was appointed receiver of the Valley Railroad, at Cleveland The road was a complete wreck and Mr Bole devoted a little of his well-known energy to regenerating the concern, and he has already got the road in good working order on a remarkably small expenditure of money He is putting in new ties, new rails and new rolling stock, as fast as the limited means at his disposal will permit. Trains can now be run over the road at fifty miles an hour safely Four months ago it was jeopardizing the lives of all concerned to run trains faster than fifteen miles an hour They did not require to hold trainmen down to schedule speed They were frightened to hold up to it, but there is a very decided change now

## Roundhouse Work.

BY OBSERVER

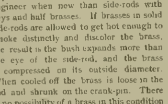
Practical machinists who have had experience in filing rod brasses will have noticed that the connections will often warm up after filing, and wear rapidly until they accommodate themselves to the oscillating of the driving-wheels of the engine The rougher the track the greater the change in the length of engine's side-rods, and the greater the movements of the driving-wheel's centers. After the rod brasses have accommodated themselves to the different movements of the driving-wheels, I have known side-rod brasses to



run for months with but little additional wear if the engine is kept continuously on the same run. It is not always good practice to file side-rod brasses when they show a little loose on crank-pin

Solid side-rods with brasses pressed in require a little more attention from the engineer when new than side-rods with keys and half brasses. If brasses in solid side-rods are allowed to get hot enough to smoke distinctly and discolor the brass, the result is the bush expands more than the eye of the side-rod, and the brass is compressed on its outside diameter. When cooled off the brass is loose in the rod and shrunk on the crank-pin. There is no possibility of a brass in this condition to run cool again until it is taken off and refitted to rod and crank-pin. Solid side-rod brasses ought to be fitted loose on crank-pins. Do not let them get hot enough to smoke and you may expect good results. This, I am sure, is the general experience with solid side-rods. Keyed side-rods are adjusted to accommodate the driving-wheels, but driving-wheels must be adjusted to accommodate solid side-rods.

A great many derangements of the locomotive can be attributed to poorly adjusted connecting rods. Bolts are sheared, keys are lost out, crank-pins sprung and



cut, rods bent, finally axles of driving-wheels bent and driving-wheels twisted on axles Those are derangements that are not in a general way early determined by the ordinary roundhouse machinist Crank-pins can be tested in various ways, but more quickly and correctly by using gauges made for the special purpose. For bent driving-axles in the ordinary way, caliper between treads of driving-wheels. If the treads are parallel with each other the axle is not bent. To determine if driving-wheels are twisted on axle, the operation as illustrated on accompanying engraving will demonstrate. With a pair of dividers inscribe circle on end of driving-axle equal in diameter to collar of crank-pin, as marked *c c* Hang a double plumb-line with double plummet over collar of crank-pin. Pinch engine backward or forward until double plumb-line cuts circle of same diameter as collar of crank-pin on end of axle, marked *l l*. Wedge the driving-wheels so they remain in position. On driving-wheel on opposite end of axle inscribe circle equal in diameter to collar of crank-pin. Place straight-edge on collar of crank-pin, cutting circle of same diameter as collar of crank-pin on end of axle. Make straight-edge fast to driving-wheels with clamps, and apply plumb-rule, *P*, to parallel straight-edge. If the driving-wheels should be twisted it is determined at once by the plummet, *B B*. This operation can be gone through in a short time

The cost of maintenance of the vacuum-brakes on the New York Elevated Road is an interesting item to those in charge of suburban railroads. General Manager F K. Hain recently made a report on this subject in which he says "The cost of material and labor for the maintenance of the Eames vacuum-brake on 1,043 passenger coaches and 310 engines for the year ending September 30, 1892, was $6,339.84, an average of $4.68 for each of the 1,353 pieces of equipment for the year; 83,000 stops are made daily." It would be very hard to beat that record.

Many members of the New York Railroad Club gave evidence at a recent meeting that there was no practical reason why consolidation or mogols should have blind, or flangeless tire, men were present who have run locomotives with 15-foot-8-inch rigid wheel base for years on crooked track with flanges on the four pair of wheels The practice seems to be to make the forward and back flanges from ¾ to ⅝-inch short of gauge and those in center of the wheel base up to gauge.

In answer to a correspondent, who writes to show how much will be gained by the increase of ten seats in the Chicago Elevated cars, we have to say that his figures have been wasted. The cars on the Chicago road seat 48—just the same as the N Y. Elevated—and we fail to see how double doors will move the crowds quicker, because the gates are the same. It's a good deal like putting in 30-inch ports and leaving the nozzle 3¼.

We have received notice that F H Coolidge and R. E. Meehan have gone into new quarters in the Equitable building, Atlanta, Ga. Mr. Coolidge is southern agent for the Westinghouse Brake Company and Mr. Meehan handles the products of Paul S. Reeves Smelting Works. Mr Meehan is son of Mr. James Meehan, of the Cincinnati, New Orleans & Texas

The American Waltham Watch Company has recently completed, ready for delivery, watch movement No. 6,000,000 It took twenty years to make the first million watches, five years for the second, four years for the third, three years for the fourth, two years for the fifth, and about eighteen months for the sixth.

The work of the American Railway Association has increased the car mileage of the country from ten miles per twenty-four hours to seventeen miles It hardly seems possible that our freight cars only average seventeen miles a day.

How many of our readers will find in Cy. Warman's touching little poem on page 11 a case much like one they have known

The C., B. & Q. are in the market for some additional power variously stated to be from fifty to seventy-fifty engines

The Norfolk & Western have let 1,000 freights to Pullman and 2,000 will probably be built at Roanoke.

The Schenectady Locomotive Works have an order for three moguls from the Maine Central.

### A Successful Absurdity.

Readers of Chordal's letters will remember that the author speaks in an amusing strain on the mechanical paradox illustrated in the working of a locomotive. In expert evidence given in a law suit, a few months ago, Mr. James W. See, author of the book mentioned, has this to say about locomotives

"A railroad locomotive on a steam railroad contains many elements of absurdity in general principles. Its tractive power is due only to its weight, and its own weight is a dead weight to be carried along with the paying train. If each wheel of a railroad train were animated, then every pound of freight or passengers carried would become traction weight and the absurd locomotive could be suppressed. The electric locomotive is as absurd as the steam locomotive. The axle of the paying car is the place to apply the tractive power."

---

In the course of a conversation with Mr. Bissel, general manager of the Wagner Car Works at Buffalo, we learn that they are extremely busy preparing for the exceptionally heavy business expected next month. They are employing 1,800 men, and this large force has to be worked overtime. Orders have been given to further increase the force this month. All of the old cars are being overhauled as fast as they go into the shops, and new cars are being turned out rapidly. The company has, during the year, added about $40,000 worth of improvements.

Some parties connected with the New York, New Haven & Hartford Railroad Company have got a practical illustration of the adage that "'twixt the cup and the lip there is many a slip." They had prepared to swallow that goodly morsel of railroad property, the Connecticut River Railroad, and a meeting of directors was called so that the parties most interested might participate in the feast. When these gentlemen got together it was found that the Boston & Maine, otherwise the Philadelphia & Reading, had carried off the game.

A startling accident happened with a tire in the shops of the Rhode Island Locomotive Works, at Providence, R. I., last month. A set of Midvale tires had been applied to the double-ended Johnstone engine built for the Mexican Central Railroad. The usual allowance for shrinkage was made. Some hours after they were put on, one of the tires burst into several pieces. The owners of the locomotive are very thankful that the accident was not delayed till the engine was at work above the giddy precipices common on the road.

---

Messrs. John Wiley & Sons, New York, report that their popular books of the season are "Modern Locomotive Construction," by Mr. J. G. A. Meyer, associate editor of the *American Machinist*, and "Mechanical Drawing," by Professor McCord. Both these books are first-class works, original productions by men expert in the lines they are writing about. We are glad to learn that the real honestly written books are crowding out the fraudulent compilations which have been so importunely forced upon the engineering fraternity of this country.

At a meeting of the Consolidated Car Heating Co., held at Albany, December 6th, a number of changes in the officers were decided on, the particulars of which will be found in our personal column. The Vice-President and Treasurer reported that the business of the company had averaged $1,000 a day for eighteen months.

We are printing 25,000 copies of this number of LOCOMOTIVE ENGINEERING. A pretty healthy pile of papers. When piled up, one on top of the other, they would make a monument 166 *feet and eight inches high*. This is the kind of a monument we want.

### HERE COME THE CARS!

By Cy Warman.

How often at night, when I'm rocked o'er the rail,
 And the little stars shine overhead,
My mind wanders back, over memory's trail,
 And I think of the days that are dead.
The red locomotives we had for our toys,
 The coaches so gaudy and gay
How we played together, Bill, when we were boys,
 And again I can hear you say

"Chuchu!! Chuchu!! here comes the railroad!
 I'll be the brakeman and open the bars."
Big bell a-ringing,
Somebody singing
 "Chuchu!! Chuchu!! here come the cars!"

And here, where your sleep is so dreamless and still,
 In this silent city I stroll.
O, send me some signal, or speak to me, Bill,
 How is it, old friend, with the soul?
I fancy the loved ones who went on before,
 Away from the world and its care,
Knew when you were coming, and on the bright shore
 Were waiting to welcome you there.

How is it up there on your heavenly railroad?
 The moon for a headlight, for white lights the stars.
The glad bells are ringing,
The angels are singing
 "Chuchu!! Chuchu!! here come the cars!"

---

When cars for the moving of grain begin to get scarce, Kansas City is nearly always the first place to proclaim the existence of a famine. There are two causes for this. Kansas City is a center through which large numbers of cars are drawn for loading with farm produce; then the people of that region are so energetic in pushing business that their howling is heard from ocean to ocean when their peace is not bought by supplying their wants as soon as they arise. Kansas City at this hour of writing, two days before Christmas, is reported to be 6,000 cars short of the demand, and the citizens are rending the air with their complaints in a manner that will disturb the peace of Christmas in divers railroad households. We pity Kansas City, but we pity more the victims to whom the complaints will be made.

The committees of investigation appointed by the Railway Master Mechanics' Association are displaying unusual activity this season. Four circulars of inquiry have already been issued and several of the committees that are collecting information through direct investigation and personal correspondence are reported to be actively at work.

At the last meeting of the New York Railway Club, Mr. Dolbeer's paper on the "Proper Time to Destroy a Locomotive" was well received and discussed. Mr. Dolbeer's belief is, that more old engines should be scrapped, and he showed some interesting figures to prove that an engine eight years old would cost more to maintain for eight years longer than it would to scrap it and buy a new engine. The plan recently adopted of sending blanks to members to fill out, asking the club to take up some certain question, succeeded so well that the members voted to dispense with a paper at the January meeting and discuss ten of these topical subjects in order to clear the docket.

Out in New Zealand there are four or five systems of railroad in different localities, not yet connected. There are nearly 2,000 miles of road of 3-foot 6-inch gauge, all under the management of the government. This is a good deal of railroad for a country so sparsely settled as the little continent in the South Sea--they only have 600,000 people. For £10, or, practically $50, your can buy a season ticket, good for a year, and you can ride on any road in the colony as long as you want to.

### Some English Steel Tests.

One rainy day last August the writer put in some hours at the plant of the Leeds Forge Co., Ltd., Leeds, England, the works of Sampson Fox, who made fame and fortune by the introduction of the corrugated furnace tube.

I won't attempt to describe these works, yet there is an impressive lesson to be learned at every turn, and one of the most impressive is the advantages of a specialty—the developing and improving of one thing.

When Fox first started his works he rolled iron and steel of varying qualities to meet the different prices and the different classes of trade, but as soon as he got into the pressing of steel, flanging and corrugating, he discovered that his reputation depended entirely on results, and, like the keen business man that he is, he decided that only the best material should be used for the new line of work.

The way to insure good material was to take all the poor material out of his place, remove all the furnaces and processes for producing it, buy nothing and make only the best. This he did.

No coal fires are used in the works, gas or water gas being the only flame that comes in contact with metal to be worked.

The writer was particularly struck with the care used in inspecting plate. They were making up stock for carriage frames, trucks and boilers for one of the Indian roads, and off of every sheet of boiler steel *twelve* test pieces were cut—six for their own standard tests and six for the inspectors.

A heavy steel ingot is heated and drawn out under a hammer, and about a third of its upper end cut off and thrown away. Every steel-worker knows that the bottom end of an ingot is always the best steel, the top is uneven and filled with bubbles that, if rolled out, make a *pipe*.

When a plate comes out of the rolls it is laid on the cooling floor, and a man gets into position where he gets the proper light on the sheet, and if it shows a dark spot or spots in cooling, these places are chalked. It is usually found that there is a lamination there; the sheet being virtually double it cools quicker than the solid parts.

In flanging the back-head of a locomotive boiler, for instance, that part of the sheet that was made from the bottom of the ingot *must* go at the top—better metal for the flange—they have discarded sheets that were flanged "wrong end up."

All pieces that have to be flanged or pressed are operated upon at one heat—a frame for a 6-wheeled tender on a truck is made at a single heat.

Metal is never worked unless it is hot enough in every part to ignite a piece of hard wood.

After flanging or pressing a piece it is annealed and then straightened and trimmed cold

They were making "goods-waggon" frames for India, the sides, sills, cross and end sills were of pressed iron of a U or trough form, the sides and ends folded up, some of the angle-braces were not over 4 inches wide; the ends folded on an angle and the work done so as to thicken the metal wherever it bent. All the pieces of this frame have the edges trimmed on shears and then ground true on emery wheels, and the holes drilled in jigs.

One of these frames was set up in the shop on horses, but instead of being riveted up, there were taper pins driven through the holes to keep it together. This was the first frame and the standard.

Every piece made for the several hundred wagons in the order, had to be a duplicate of the one in the standard frame, and the inspector had a perfect right to order any part that don't seem to "jibe" to be tried in the standard frame, if it don't fit to a T, without drifts, or bending, or anything else, it is laid on the ground and a hole punched through it with a sledge, on one end of which is a punch—the inspec tor of the road is paid to hunt for these things and he hunts.

Many of the English, rather British, roads are using a considerable number of pressed steel trucks similar to ours, and for some classes of cars they are slowly creeping into favor

The big presses here are a wonder to a mechanic, one of them has two 36-inch cylinders and six 12-inch cylinders, capable of getting a 200-ton squeeze on a sheet On this press they flange the lower half of a 14-foot marine boiler-head with the outer flange thrown one way and the flange for the three furnaces the other This press also takes in a 6-wheeled truck frame, flanging the whole edge one way, the three jaws another and oval openings, to lighten the plate, flanged the same as the edge In such work the big parts are taken care of by the 36-inch cylinders and the other parts by the smaller cylinders, each operation following in such a way as to prevent the "crimping" or folding of the plate and insuring that each corner will be thicker than the flat part of the sheet

The latest production of the works was a car axle box of the American pattern for passenger service a floating box This was folded up with flange in front and back, places on the sides for the jaws, etc , looking just like a cast box it weighs only 21 pounds as against about 60 or 65 for a cast box. This box is now being duplicated at the Fox Works at Joliet, Ill., an institution, by the way, of which Mr Fox is very proud He says that if two such hustlers as Jim Hackney, in the shop, and Jim Brady on the road, don't make a success of pressed steel in America he misses his guess.

The machines for welding up furnace tubes 4 feet in diameter and 8 long are very ingenious and elaborate, the tube is slipped over a long heavy arm that carries a pipe terminating in a fire-brick burner about a foot or 15 inches long, another arm

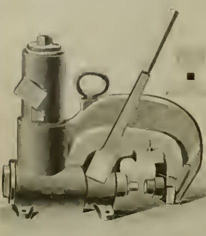


Fig. 1

extends out above this, carrying a similar burner and two heavy flames of water gas soon heat a long section of the lapped edges of the tube When this is at the proper heat it is moved out over an anvil and steam hammers weld it down. They were welding up some locomotive domes this way when the writer was in the works

The corrugations are rolled into furnace tubes after they are welded

In the shops they were making some moderate sized square fireboxes for torpedo boats, the two sides and crown sheet being in one piece and put up without stays. These boxes were expected to stand a pressure of 160 pounds.

In these works it is not necessary to make new dies for every piece wanted. They have a system of segmental dies that can be built up into varying shapes and sizes All round corners are of a standard radius for several sizes, ovals and circles can be formed, etc , so that a change in centers simply means the dropping into or taking out of the die of another segment.

All work is done on the piece work plan.

J. A H

## Some Modern Hydraulic Tools for Track.

Watson & Stillman, of this city, have recently put on the market two efficient tools for track work that have distinctive advantages. Fig. 1 shows a hydraulic punch for making the bolt holes in the web of rails It is light enough to be handled by an ordinary section gang and can be used without removing the rail from its place.

By the use of a quick acting lever, shown in the middle of the cut, the ram may be worked in and out a distance of 2 inches without the loss of time and labor of pumping. In mounting the die in a sliding bolster, which latches it in position an additional opening is obtained without the extra weight, which would be necessary to get a 4-inch movement and also a reservoir of sufficient capacity A guide is placed at the top of the jaw which once set for any pattern of rail, will cause all holes to be punched at the same height. In returning the punch to the cylinder the pumping socket must be brought down against the head lug before the quick-working lever can be used.

Two sizes are made, the one for 70-pound rails weighs 225 pounds and uses a pressure of 50 tons, while the one for 90-pound rails weighs 300 pounds, but uses a pressure of 120 tons

Fig. 2 is an adaptation of the hydraulic punch, for the purpose of punching the spike slots in the base of heavy rails for regular railroad service, as is frequently desired on switches and curves, and is the first tool of the kind which is convenient, expeditious and reliable, making a clean cut slot The body of the punch is somewhat longer than in the regular style of punch, and is cut out in front to bring the center of the punch to the proper position. The punch may be brought down to the work without the labor of pumping, being both raised and lowered by the lower lever

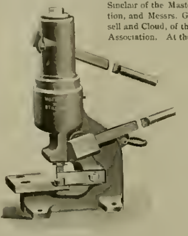

Fig. 2

shown in the illustration. The head is of the same construction and size as in the corresponding sizes of the regular make of punch. The No 2 with 1½-in. jaw, weighing about 90 pounds, has sufficient power to punch the [illegible] x [illegible] slot in the side of the base of 90-pound steel rail Guides are placed on the side for determining the depth, and also act as strippers.

## The New York Air-Brake.

The New York Air-Brake Co is rapidly coming to the front. The company have made some recent discoveries that give grounds for the assumption that the younger company has been making more progress in the art than its older competitors, and if results in practice bear out recent experiments in the shop, the railroad world may prepare itself for some surprises in the science of air-braking

Stockholders in the New York Air-Brake Co are feeling enthusiastic, and believe the New York Air-Brake Co. will yet eclipse all others.

The New York Air-Brake Co is now filling orders for the New York Central & Harlem Railroad, which road has begun the equipment of its old cars.

The works of the company at Watertown will be rapidly enlarged to a capacity of 250 car equipments per day They are now turning out 100 a day and are crowded with orders

The pump of the New York Air-Brake Co. is claimed to be rapidly replacing others, as its superiority is conceded.

## A Novel Cutter.

The illustration herewith shows a novel form of their patented milling cutter for

circular work, such as rod-brasses, recently put on the market by the Ingersoll Milling Machine Co., of Rockport, Ill.

## Meeting Place of Railroad Conventions.

On December 13th, a meeting of the Joint Committee of the Master Car Builders' Association and the Master Mechanics' Association was held at Hollenden Hotel, Cleveland, for the purpose of deciding on a place of meeting for the next conventions.

Mr. John Hickey was elected Chairman, and Mr. John W. Cloud as Secretary of the meeting. There were present, Messrs. Hickey, Garstang, Blackall, Stewart and Sinclair of the Master Mechanics' Association, and Messrs. Grieves, Casanave, Bissell and Cloud, of the Master Car Builders' Association. At the call of the Chairman, Mr. Sinclair explained the objects of the meeting.

The expressed desire at the last conventions that the coming conventions should be held near Chicago was carefully considered, and careful attention was bestowed upon the accommodation available at different places near Chicago. Various gentlemen were invited to express their views about suitable places of meeting, among them Messrs. Freeman, Sewall and Richardson, the Committee of the Supply Men. The accommodation available at Waukesha, Milwaukee, Detroit, Cincinnati, Cleveland, Lakewood on Chautauqua Lake, and Saratoga were discussed very thoroughly. After this was done, a vote was taken which resulted as follows Four for Lakewood on Chautauqua Lake, N Y., two for Saratoga, two for Cleveland, one for Old Point Comfort. Another vote was taken to decide on the second place, which gave Saratoga the preference. A sub-committee, consisting of R. C. Blackall, Chairman, representing both Associations, T A. Bissell, representing the Master Car Builders' Association, and Angus Sinclair, representing the Master Mechanics' Association, was appointed to determine whether Lakewood would be suitable or not and to settle on one of the other places if it was not.

This committee met the hotel-keepers of Lakewood, at New York, on the 15th, and an agreement was made by the committee that Mr. Sinclair meet Mr. Freeman (the latter for the Supply Men), and go to Lakewood and examine the hotel accommodation. This was done, and the accommodation being satisfactory, arrangements were made to hold the conventions at that place.

## The First Railway Master Mechanic.

We have received from Mr. T. Hackworth Young, general foreman of the Chicago, Milwaukee & St Paul at Chicago, a memoir of his grandfather, Mr. Timothy Hackworth, who is called the father of the locomotive. Those who are familiar with the history of locomotive engines will remember that Mr. Timothy Hackworth entered a locomotive built by himself for the famous Rainhill competition, where the Rocket of Stephenson came out victor Many of the leading engineers of that day believed that the "Sanspareil," as Hackworth's engine was called, was the best in the trial, but one of the cylinders failed on the day of the competition and that proved fatal to the engine

Mr Hackworth was the first man to make the locomotive a commercial success through his invention of the exhaust blast Before he introduced this improvement the locomotives on the Stockton & Darlington Railway, where he was master mechanic, were more expensive to operate than horses, and there was strong likelihood of their being abandoned, when the simple act of passing the exhaust steam through the chimney gave them such increase of boiler power that the future success of this form of engine was assured.

The Stockton & Darlington was the first railway regularly operated, and Mr. Hackworth being the first man in charge of the machinery of that road, was the first railway master mechanic in the world.

The Pennsylvania Railroad Company last month made some experiments with a train equipped with a re-enforcing brake intended for use at unusually high speed. The New York Air-Brake Company made experiments of the same character with a train on the New York Central.

We are frequently asked to recommend draughtsmen and graduates of technical schools to parties looking for that kind of help If men of this class looking for work will send us their names and addresses we will be glad to put them on a list which we keep and recommend them when the opportunity comes.

Parties using the Butler attachment for car drawbars say that the device is a perfect preventive of the loss of draft springs, and on that account alone it pays to use the attachment.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING CO , 607 & 609 Sansom St., Philadelphia, Pa.

SINCLAIR & HILL.

### Johnstone's Double-Ended Compound.

The double-ended locomotive shown in the annexed illustration is one of three built for the Mexican Central Railroad by the Rhode Island Locomotive Works, after designs prepared by Mr. F. W. Johnstone, superintendent of machinery of the road. The engine, as will be readily seen, is an extraordinary form of a locomotive. It looks like two moguls fastened cab to cab, but it is structurally a good deal more than that. The purpose of this odd form of engine is to provide an exceptionally powerful motor for climbing the steep mountain grades of the Mexican Central Railroad, and with flexibility sufficient to go round the very sharp curves with the least possible frictional resistance. The flexibility is obtained by securing the driving-wheels in a truck which is free to move in a line different from that followed by the main frames. In the Mason bogie engines the drivers are grouped in a flexible truck which carries the cylinders. In the Johnstone engine the cylinders and boiler are carried on the main frames separate from the driving-wheel truck.

As the cylinders are not in line with the driving-wheels in passing curves, it is necessary that a special method of transmitting the power from the cylinders to the crank-pins should be employed. This is done in a very ingenious way through levers that transmit the power and compensate for the varying distances between the pistons and the crank, due to the swiveling of the driving-wheels. But for this compensating arrangement it would be necessary to give the engine so much cylinder clearance that the loss of steam would be very great. The power transmitting levers are seen at the back of the cylinders, connected at the top by a short link and the bottom ends pinned to the front end of the main rods. There are two of the latter, one connecting with a crank-pin, the other with a return crank. The piston transmits motion to the back one of the two levers, and that gives motion to the front lever, which is fulcrumed securely to the frame near its center. We must delay giving our readers an analysis of this motion until we receive drawings of the levers and connections.

The engines are compound with annular cylinders, the high-pressure cylinder being in the middle and the low-pressure cylinders outside. The high-pressure cylinder is 13 inches diameter and the low-pressure 28 inches. The stroke is 24 inches. It is calculated that the cylinder capacity of each pair of cylinders is equal to a 19 x 24 simple engine.

The boilers are of Otis steel, 9-16 inch diameter, and carry 180 lbs. of steam to the square inch. They are 54¼ inches diameter and have 201 2-inch tubes, 15 feet 9½ inches long. The fireboxes are of the Belpaire type, 56 inches long and 56 inches wide.

The arrangement of working is that the valve motion of the two engines is operated by one screw reverse lever. The engineer is located at one side of the cab with all the apparatus for working the engines within his reach, the fireman is on the other side and applies the coal through side doors. A coal passer is employed to help the fireman.

This is the heaviest and most powerful locomotive in the world. The weight, in working order, is about 130 tons.

Double-Bogie Compound for Mexico

---

The Brooklyn Union Elevated Railroad people are in the market for about twenty coaches. They want to secure a delivery for May.

---

The Buffalo, Rochester & Pittsburgh R. R. are just receiving the last of their recent order for 850 cars, all equipped with the New York air-brakes.

---

A St. Louis inventor is reported to have received $50,000 for a patented brake which is designed to grasp the rail. The inventor was more fortunate than the purchasers are likely to be.

---

The Brooklyn Elevated Railroad is in the market for about ten locomotives. The manager talks of ordering some more compounds. He has three Rhode Island compounds now on the road.

---

Owing to increasing demand for the Lunkenheimer brass and iron specialties, the company has been compelled to double its capital for the purpose of increasing the manufacturing facilities.

---

The Schenectady Locomotive Works have received an order for sixteen locomotives for the Chicago & Eastern Illinois, and three freight engines for the Maine Central, all to be equipped with the New York air-brakes.

---

The increasing demand for Coffin treated material for axles, cranks, pins, etc., has necessitated an increase in the already extensive turning and forging facilities at Johnstown. Some six or eight roads are added to the list of users of this material.

---

The largest single order for car-heating material ever given for new stock was received by the Consolidated Car Heating Company, on December 15. This order was for the equipment of 100 New York Central standard coaches. The Gilbert Car Manufacturing Company, of Troy, N. Y., are building these cars.

---

The Northern Pacific intend to build many of its freight cars in the Edison shops, Washington, in future. Lumber is so much cheaper there than it is in the East, that the cars can be built cheaper, although labor is slightly higher. As a start on the new policy, the shops named have received an order for a large number of logging and lumber cars.

---

Spon & Chamberlain, New York, have lately issued "The Practical Polish and Varnish Maker," by C. Standage. This is a book that all progressive railroad painters ought to have for ready reference. The book is by a practical painter and contains receipts and formulæ for the manufacture of polishes, lacquers, varnishes and japans of all kinds for workers in wood and metal, with directions for their use.

---

The Empire State Express, on December 21st, was detained by reason of a freight breaking in two, which occurred on the Hudson division. The train left Peekskill late and ran from Peekskill to Albany, a distance of 101 miles, in 96 minutes, an average running time of over 63 miles an hour. It ran the distance from Hudson to Albany, 28.43 miles, in 25 minutes, slowing down to 20 miles an hour over the Stockport bridge, an average running time for this distance of over 68 miles an hour.

---

The Dixon Crucible Co., of Jersey City, N. J., are putting the fifth story to their lead pencil factory, the floor being 175 x 75 feet. One would think, to see the improved machinery in this place turn out lead pencils, that a week's run would glut the market of the world. The pencil department is only a small part of the works, yet its business is so large that they will build in the spring a brass-shop and a rubber-shop just to supply the millions of little pencil tips of various designs that they make.

---

Not a long while ago we reported in the pages of *Hoisting* that a locomotive crane was doing duty in a quarry as a switch engine, shunting cars from the quarry to the siding on the main track. We have since seen a locomotive crane employed to pull a small train of cars out of a machine shop, for the purpose of getting them out of the way. Shunting cars and switching trains is not exactly the prime purpose for which a locomotive crane is built or purchased, but the above uses serve to indicate the general adaptability of a movable crane with self-contained power to the necessities of the shop or yard where it is used.—*Hoisting*.

## Two Examples.

The master mechanic sat in his big revolving chair and put question after question to the nervous fireman who was being examined, to see if he knew enough to take charge of the handles in the cab of a switcher.

"Now, my young friend, there are two things I want to impress on your mind, and they are as follows, to wit, namely:

"R-u-n s-l-o-w and

"D-o-n-'t d-r-i-n-k!

"Now, you can see examples every day of the work done by drink—

"Yes, sir; I'm the master mechanic."

This was said to an old man who opened the door with an inquiry.

"Come in, sir."

The old man came in; he was six foot, had a keen eye, snow-white beard and hair, an elastic step, sharp, well-preserved and impressive. He had called to get the address of his grandson, who was an engineer on the line.

"I think, sir," said the M M, while the fireman drew into the background, "I think you are one of the finest examples of well-preserved manhood I have ever seen. Might I inquire your age?"

"I'm 86, sir."

"Eighty-six years! Well, I believe you are as hearty as I am, and I'm not quite half that."

"I rode twenty miles on horseback this morning, sir. I can't see but that I am just as good a man as I was forty years ago—never sick a day in my life."

"Remarkable, remarkable," muttered the M.M. "May I ask, sir, to what you attribute your health? Do you use tobacco?"

"No, I never used it."

"Nor liquor?"

"Never a drop of the stuff has passed my lips."

"Ah, I thought so. I was just talking to my young friend here about temperance. You are an example for him; let's see, your name is—"

"Wood."

"Ah, yes; why, your grandson is out in the roundhouse now—step right through that door and you will find him at the engine numbered 186."

"There is an exam—

"Yes, sir; come in."

Another old gentleman, as hale, as hearty, and, if anything, better preserved, stepped in.

"Excuse me, gentlemen, I expected to find William here."

"You refer to an old gentleman with white beard, like yours?"

"Yes, sir, he is my brother."

"You are the younger, I see."

"Oh, no, Bill's two years younger than me."

"A remarkable family, sir, a sermon on temperance."

"Temperance! Why, you ought to hear Bill preach on temperance; he's a teetotaler; I do all the drinking for the family."

"You may take a drink now and then, but you know enough not to abuse it."

"Well, I don't know, I've been drunk weeks at a time, my boy, whole weeks, and since I was nineteen years old Sunday night has never seen me sober. I enjoy life, I do. Why, my dear sir, I have drank enough whisky right in this town to float the biggest man-of-war Uncle Sam owns. I'm huntin' Bill now to borrow $10 to get a demijohn to take home. Temperance is good enough for women, but I don't propose to let my whistle dry up as long as my name is Wood."

The M M. looked out of the window as the sprightly old drinker mounted his horse.

"How do you account for that fellow's health, sir?" asked the fireman.

"Well, Jimmy," said the M.M., turning his paper-weight over and over, "I guess that the old rule stands good, and that says, 'To preserve *wood*, you must keep it either very *wet* or very *dry*'—but mark ye, boy, to preserve the crown-sheet of the 18 you keep it wet, and to preserve your job you keep *your own* crown-sheet dry—dusty dry, boy!"

## The Crown-Sheet in Danger.

"Everybody on the Pacific Coast," writes a correspondent, "has heard of the late Hank Smith, as good an engineer as ever turned a brake handle—but wet, decidedly convivial. Some time before his death, while the ultimate result of his sickness was yet in doubt, his physician positively forbade the use of liquor.

"Swearing off was about as hard on Hank as dying, in fact it was about the same thing. About the time that the order stopping liquid supplies had been issued, some one asked young Smith how his father was. The young man knows something about an engine himself. He answered:

"'Well, they've made the old man stop drinking and he's burned his crown-sheet. They don't know yet whether it'll fall in on him or not.'"

## The Cinch on McCormick.

"A long time ago," said the old-timer, stopping to tamp down the cut-plug in his cob pipe; "A long time ago, when I was on the South Park road, we were having a good many wrecks.

"Most of these were caused by runaways, the stock was equipped with straight vacuum, and it wouldn't suck wind for a cent—'cause they didn't take keer of it.

"We had a superintendent then of the name of McCormick, who was a holy terror on the fire, he'd discharge a man just on suspicion; new men come and went on almost every train.

"Every few days there'd be a runaway, and McCormick would fire the whole crew—just to keep up the discipline.

"One night, Sam Black's Mason-Fairlie—we always called 'em 'jim-crows'—got away from him on Kenosha hill, and Sam and the whole crew were killed.

"The news came early, and a lot of us gathered at the little depot at the foot of Larimer street, Denver, to meet No 2 and help carry the remains of the boys home. McCormick was pacing up and down the platform with his hands behind him.

"Whilst we were waitin', sorter quiet-like, each man kinder thinkin' how near it come to him, and feelin' sorter sober, I happened to notice an old Irishman sitting on the edge of the platform smoking a clay pipe and watchin' a little ant hill between the ties.

"Pretty soon another old fellow, of the same nationality, came along with a spike maul over his shoulder, evidently he did not know the reason of the gathering. He jerked his head cornerways at his friend and said:

"'Mornin', Jimmy.'

"'Good mornin', Moike, did ye see MeKor-mick?'

"'Oi did not.'

"'MeKor-mick is cryin' this mornin'.'

"'Sure, phwat's the matter ave him, Jimmy?'

"'There does be foive min comin' in that he can't discharge anny more—bad cess til him.'"

## The Brake and the Boiler.

When railroads were first experimenting with the Westinghouse air-brake there was considerable mystery among train men as to the working of the apparatus.

A railroad company in Ohio was negotiating with the view of adopting the automatic brake, and an experimental train was provided to show how well the brake worked. This train started out in charge of Conductor Meyer, who had been carefully instructed as to how the thing worked. Among the information given to the conductor was an explanation of the working of the conductor's valve. By pulling the cord attached to the valve, he learned that the train could be stopped at any time without signaling the engineer.

The train started out and Meyer was delighted with the way the braking was done—all the effort of stopping applied from the locomotive without the least help from the brakemen. It was a great invention, but still Meyer was nervous about it.

When they had got about half way over the division, a friend of Meyer boarded the train, and, of course, the extraordinary air-brake was the leading topic of conversation.

"Do you mean to tell me," inquired the friend, "that you can stop the train by pulling that cord without the engineer shutting off steam?"

"Yes," replied Meyer, "at least, that is what Morris Sellers said. He is the brake company's agent, you know."

"I would believe that readier if I saw it done," remarked the friend, skeptically.

"Well, we can easily prove it," said Meyer. They were standing near the door of the car and Meyer pulled the valve rope. The sudden pull of the brakes sent the friend's head through the glass door. When the extra strain was suddenly put upon the locomotive, the packing of a gland blew out, enveloping the engine in a cloud of steam. At this time Meyer looked forward, and seeing the steam, exclaimed:

"It's just as I feared it would be. Putting on the new-fangled brake has busted the boiler of the engine."

## Lost an Exhaust.

Road Master Mike Sullivan, of the B., C. R. & N., always had an idea that locomotive engineers were a trifling class of men and that they were constantly scheming to cause embarrassment to the road department. Controlled by this fixed idea, Mike kept a sharp eye upon the movements of the engineer when he had an engine doing construction work.

One summer he had an old Grant engine pulling a ditching train, and Frank Davis was the engineer. The engine needed a great deal of nursing to keep her alive, and Frank took his time.

"Frank Davis, yez be the shlowest mortol in loway," Mike would say. "Phwy didn't yez hev that owld kittle sowdered up before ye left the Rapids? Git a move on yez or divvil a load will we git out this mornin'."

One morning there was greater delay than usual, and Mike found Frank inside the smokebox. The eccentrics of the engine were chronically loose, and were always slipping. One of them had moved without loosening the set-screws, and Frank thought that the trouble must be in the smokebox. The position of the eccentrics was a good deal of a mystery to him anyway.

"Phat 'n the divvil's the matter now, Frank Davis," demanded Mike, in an irate tone, "don't yez see that ye are shtoppen the intire operation av this railroad?"

"I can't help that," grunted Frank, "I've lost a go-ahead exhaust and I am trying to find out what's the matter."

"Lost a go-ahead exhaust; divvil take you, you are always losing somethin'. But I'll find an exhaust for you."

Mike hurried back to the nearest station and wired to the master mechanic:

"R. W. B. Please send a new go-ahead exhaust for the 26 with the first train."

## A Startling Disclosure.

Teddy Cunerty was sweeper in the roundhouse, and had gotten the job, so the boys said, by claiming that he had got a touch of rheumatics from helping the boiler-washer so long.

When the company appointed a doctor there was considerable talk over the long bulletin notice, and Ted was anxious to know what it said, as he had neglected to study "readin'" at school.

A waggish wiper read it all over to him at noon-time, and added:

"All employés not examined by the company doctor before the 20th will not be able to draw their pay until such examination is made"—and this was the 17th.

The next morning Ted appeared with his "store clothes" on under a clean suit of overclothes. He was going to see the new doctor at noon so as not to lose time.

By this time the stove committee got on to the "job," and one of them had interviewed the young surgeon.

Ted came back looking rather doleful and with a decided limp. He went right for the roundhouse foreman.

"Mister Grane, Oi must lay aff for a few days and take hot sulphur baths."

"Why, Ted, what's the matter?"

"Well, sor, I knew Oi had touches ave the rumatics, but I never suspicioned before, till the dochtur tould me, that me constitooshun were bein' undermined wid de *ippecure's gout*."

## Against Gas-lighted Cars.

A very large volume of the immense suburban business of New York City is carried by the Delaware, Lackawanna & Western. This business grew up against the wishes of the company, which gave particular attention to freight traffic, and very little was done for years to develop the carrying of passengers. Among the drawbacks complained of by the passengers was badly lighted cars. Of late a new and more progressive policy has been adopted by the company, and among improvements introduced has been the lighting of the cars with Pintsch gas. Only part of the cars have yet been equipped with the gas-lighting apparatus, but the indications are that the whole of them will, in the course of time, be provided with this admirable light.

We are among the travelers on this road who appreciate the use of a light which enables a person to read his evening paper with comfort. It was then with surprise that we lately heard a conductor growling:

"These darned Pintsch lights are a nuisance. I wish they had never been put into our cars."

"What is the matter with the Pintsch lights?" we ventured to ask.

"Matter? There's everything the matter. Don't you see this car so full that people are standing in the aisles? Now look back at the oil-lighted cars and you will see empty seats. As soon as they get off the boats the passengers just run to get into the gas-lighted cars and pack themselves so that I can scarcely get through. Plague upon the gas, I say."

The Thirsk railway accident in Scotland, which we commented on last month in connection with the capability of American cars to safely sustain the severe shocks of a collision, appears to be exciting our British friends to investigate the merits of our style of car. London *Engineering*, which is always ready to supply information on all engineering subjects, has lately illustrated the style of framing used in American cars. In connection with that the explanation has been given of how European cars with side doors must necessarily be weaker than cars that have continuous side framing that forms a strong truss.

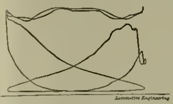
## A Puzzle Diagram.

*Editors*:

Being a constant reader of your valuable paper, and taking considerable interest in the so-called puzzles, I thought I would have you get the opinion of some of the



indicator-expert readers of your paper as to what caused the peculiar end on this inclosed diagram. F. S.

*Kaukauna, Wis.*

## Front Brasses Fitted Open.

*Editors*:

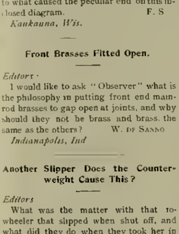
I would like to ask "Observer" what is the philosophy in putting front end main-rod brasses to gap open at joints, and why should they not be brass and brass, the same as the others? W. DE SANNO.

*Indianapolis, Ind.*

## Another Slipper. Does the Counterweight Cause This?

*Editors*:

What was the matter with that 10-wheeler that slipped when shut off, and what did they do when they took her in the shop? It was three or four months ago, and I never saw an answer to the question. We have an 8-wheeler, 15 x 22 inches, driving-wheels 4 ft. 10 in., that will slip on a damp rail on down grade shut off, and would tear herself to pieces if not stopped with the driver-brake. She will slip on level track shut off if the rail is wet or a few leaves are on the rail, at any speed above twenty miles per hour, or even eighteen miles per hour. Twice in a



few weeks she has been brought in with her side-rods bent out near the center, and bolts in straps partly sheared. The counterweight in her wheel has three panels cast solid the full thickness of the wheel, but on examination we find one panel, although flush on the outside, is not flush on the back side of the wheel, it being less than half the thickness of the other two.

This engine is used as spare, and every engineer and fireman dread to go out on her. I inclose a rough sketch of the wheel on this engine. Who can tell us what is the matter? J.

*Pontiac, Mich.*

## The First Locomotive for America.

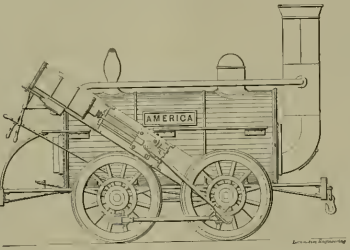
*Editors*:

In looking over the back numbers of your paper I cannot find any diagram of Stephenson's first engine for America, named "America," 1828. It was sent from England at the end of the year 1828 by the sailing ship Columbia, and arrived in New York, January 15, 1829. It was the first locomotive for a railway in America.

CLEMENT W. STRETTON, C. E.

*Leicester, Eng.*

[Diagram of the *America* is here reproduced from drawing sent by Mr. Stretton. The *America* might have been the first ordered, but she was not the first to run in America. Horatio Allen went to England in 1828 to investigate steam railroads, and while there ordered three locomotives, two from Stephenson, one of which was probably the *America*, and one of Foster, Rastrick & Co. This last engine, named the *Stourbridge Lion*, was sent to



Carbondale, Pa., on a canal boat, and there, on August 8, 1829, ran on the rails under steam—the first in America.]

## Some Difficulties in Keeping an Engine Clean.

*Editors*:

You see and hear a great deal about firemen keeping clean engines. At some times and in some places this can be done with pleasure and profit, but, let me tell you how encouraging it is here on the B., C. R. & N.

It means about twenty-four hours on freight to make a 100-mile trip, and after this the fireman shows up to clean and draw his supplies.

He has to go over the jacket about twice with a broom before he can use waste—because the clinker men and ash-pan cleaners don't use the blower. Then he blacks his front end and stack, wipes up his paint, cleans his windows, plumbagoes the boiler-head, scours his brass, fills his lamps and oil cans and lubricators and otherwise puts in from six to eight hours—for which he receives nothing—and goes home believing that he has done his whole duty and that the old girl looks as good as any of 'em. The next morning he comes up ready to go out, and see how his work is appreciated.

The cab brass, windows and paint are smoked so that you can write your name anywhere, the men who fired her up have left the door open.

The hostler has taken her out and done it so artistically that she looks as though a flock of blackbirds had roosted over her. Then he took her to the coal chute, and filled her tank, forgetting to lower the curtain; this helped the chance to write your name.

The tank is full of coal about the size of the door, the water pail is gone, the night machinists have emptied part of the oil cans, the new shovel has been exchanged for an old one, a window glass broken and perhaps the broom gone.

While you are standing up to your knees in disgust, wondering whether it would be best to kill some one or commit suicide, along comes a man of authority and wants to know why you can't keep that engine looking decent.

This is no imaginary picture—it is our regular daily ration, ask any B. C. R. fireman. A. STOKER.

*Cedar Rapids, Iowa.*

## A Blow; Where Was It?

*Editors*:

I have a kink or puzzle I should like to submit to the consideration of your many readers.

I was running some time ago an 8-wheel coupled or consolidated engine on the C. & E. I. Ry., the next to last pair of drivers being the main ones.

While switching one day, and in the act of starting ahead, a heavy blow occurred. I ran the engine ahead a few hundred feet, and watching the crosshead on the right side found the blow occurred as it started from the front of the guides. I opened the cylinder cocks, but they showed no indications of the packing blowing, the blow did not occur while the crosshead was returning.

There were some thirty to thirty-five cars coupled on behind the engine, and not wishing to block main track, started to back them on the side track. The engine was all right backing up, there being no blow. I then thought that valve had been cocked, but on moving ahead again I found the blow was still there.

I was pretty well puzzled by this time, and after examining eccentrics, blades, links, rocker-box and arms, and finding them all right, I was more puzzled than ever.

I took up the right steam-chest cover and found the valve-yoke broken in front of valve. I couldn't think how that would cause such a blow, but the seat being pretty dry thought that the yoke sprung open and allowed the valve to cock.

I blocked the valve and disconnected engine and took her to the shop, where the yoke was repaired, and I was called to leave at 3 30 A. M. I arrived at roundhouse before engine was taken out and found the blow as bad as ever when she was moved from the house, and, as she was badly disabled, was held in. I waited until the day foreman and several engineers and machinists had looked at her, but they were as badly puzzled as I was.

The engine was put back in the roundhouse and the right steam-chest taken up and the packing out of both cylinders, but there was nothing out of the way. The eccentrics, links, rocker-box and arms, etc., were examined, but were all right. Where was the trouble? C. G. B.

*Danville, Ill.*

## Some Points on Tramming—Talking Shop—Getting Pointers—Some Questions.

*Editors*:

While traveling through the South I visited a railroad repair shop, and there noticed a young man who was engaged at

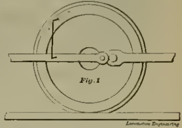


Fig. 1

setting the slide-valves of a ten-wheel engine which, having undergone general repairs, was about ready for service. While watching this man work I noticed that in marking the dead-center points on the rim of the main driving-wheel he trammed from a prick-punch mark on the side rod, which brought the tram nearly into the position shown by Fig. 1.

I asked the young man why he trammed from the side rod, his reply was, "because we can't tram from the main rod." Said I, why tram from either rod; do you not think that it would be correct to tram from the wheel-cover? He replied, "I don't know, we have always trammed from the side rod, and that settles it." Of course that put an end to farther conversation with him on the subject, but it did not quite "settle" to my satisfaction that his method of tramming was correct. I was very sorry that the young man was so short with me, for I desired very much to ask him a few questions with the sole object of gaining information.

The questions I had in mind are the following, and I shall feel obliged to him, or any others among the many readers of LOCOMOTIVE ENGINEERING, for an expression of their opinions upon this subject through this most excellent paper.

1st. While using the tram in the manner shown will a person not be subject to error owing to the lateral motion on the pins of the side rod from which he trams? This motion might be all taken up toward the outside while making one mark on the wheel, and toward the inside when the other mark was made, in such a case

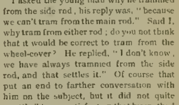

Fig. 2

would the dead-center mark be in the proper place on the wheel rim?

2d. When a tram is used in a nearly perpendicular position, as shown in Fig. 1, will not every irregularity in the track be more noticeable than where a person trams from the wheel-cover, and the tram is used in a horizontal position as shown by Fig. 2? And in the latter position it strikes me that all the lateral motion a person would have to contend with would be that of the forward drivers, and this he would have to contend with in either case. I can readily see that while tramming from the side rod a slight movement of the driving-wheel is

more perceptible at the upper tram point than where you tram from the wheel-cover and hold the tram horizontally, but is not this advantage more than balanced by the disadvantage mentioned?

Now, while I readily excuse the young man for his short answer to me (he being very busy at the time), would it not be to the advantage of any young mechanic to talk intelligently upon such subjects, disregarding the question of which method was correct, for by thus talking these matters over we all gain information and get new ideas? Would this not be better, I say, than to snub a person who desires to have a little friendly conversation with you? And I wish to say for the benefit of the younger readers of this paper, that I have yet to hear of a case where a person was in any way injured by showing a proper amount of courtesy to strangers.

I also wish to state that the young man in question does not work for the E. T., V. & G. road at Selma, for here in the shops, offices, and on the road will be found as nice a lot of men as can be met anywhere. L. C. HITCHCOCK.

*Selma, Ala.*

## Those Richmond & Danville Drawings.

*Editors:*

I note in your last issue that Mr. H. K. Griffith, of the Richmond & Danville, devotes twelve lines to defending his drawing of that cab-bracket and the other fifty-two lines of his article to delivering us a sketch of his mechanical career.

Suppose, now, that we analyze those drawings and see just how they do look. Fig. 1 is the sheet just as it comes from Washington. We find the plan *B* in the center, and *A* is a view of the curved end or front looking horizontally, while *C* is a view the reverse of *A*. Now, is *C* essential to make matters clear? Does not *A* explain and show all that we find in *C*? Removing *C* or *A* from the sheet, could we not just as well construct our pattern? I guess yes. Owing to its reversed condition, does not *C* tend to bring forth a question of uncertainty in the mind of the "wood-carver"? If we make two things when one is a plenty, does it not take more work and thought? Then is not this a case of "needless labor and waste of brains"?

The proper way to have made this drawing I illustrate in Fig. 2. A plan same as in Fig. 1, and a section through line *xx*, showing in bold, unmistakable outlines just how the component parts of the pattern are grouped together, shutting off all questioning on the part of the pattern-maker and putting him *en rapport* with the designer. But Mr. Griffith says, "We will readily see that a section would be very awkward to make." Well, if we have no conception whatever of the rules for projections, and can form no idea of how the object will look from all sides, nor have a perfect brain photograph of what we are trying to design, then I will admit it is "awkward," and our best way out of the dilemma is to make it a little mixed and throw the responsibility on the poor constructor.

Again let us analyze those drawings, taking Fig. 2, which is Mr. Griffith's made clear. It is composed of six pieces, two flanges, two straight ribs, one curved rib and a web so designed that they must go together slowly and carefully. Draft has to be worked out on both sides for the molder, and still it is a mean thing to get in and out of the flasks in the foundry. All this inconvenience to the men who have to work with their hands compels them to slow up. Slowing up means loss to employé and employer both.

Now suppose we make it as shown in Fig. 3, as has been done by others. The flange and web are all in one piece with ribs easily glued and nailed to it. Draft is all one way and we easily "follow-board" it and the molder jerks it in and out of the sand in "half-past-two" time.

We do find that the form shown in Figs. 1 and 2 are almost 6 per cent. stronger than that shown in Fig. 3, but practically this small amount is unworthy of consideration in a cab-bracket; while the latter form will save four hours in the pattern shop and as many more in the foundry, adding nothing to the comprehensive draftsman's time or labor.

Probably those cylinder drawings would confuse me. That is the great trouble with some professors of mechanical design. The more "confusing" they get things the more science they think they display, and never dream of the reversed blessings invoked upon them by those who have to bring order and results out of their chaotic work, nor the thousand and one little molecules of time thus wasted for their employers.

## Running a Railroad on Percentage.

*Editors:*

I have been railroading thirty-five years and for many years at the head of a department, but have only recently found out how to run my end of the thing economically.

An oil man recently offered to guarantee me a saving of 30 per cent. if I used his lubricant; the next day a grease man promised 15—he was modest.

It was not long before an extension-arch fellow offered to run us on 20 per cent. less coal if we used his device.

Every improvement seems afflicted with the per cent. fever. The injector saves some, the air-brake more, the compound locomotive is going to bite off all the way from 15 to 45 per cent., while if you only care for a paltry 10 per cent., why, just buy metallic packing, cylinder lubricators, revolution counters, chine whistle, or a pee-wee valve.

The way I am fixed here galls my ambition and gives me no chance to show what is in me—I am hampered by the powers above.

What I want is a position as general manager. I will buy all these per cent. savers, have coal to sell, operate the road for nothing, and pay 98 per cent. dividends. I can do it if figures don't lie, and who dares say they do?

Don't you think there is something in this plan of mine, or do you think that lying is getting a regular place in trade, or that this mark % is being overworked?

*Houston, Tex.* OLD RAILROADER.

## Marks Is Scared About the Revolution in Locomotives.

*Editors:*

It haz bin sum time since I last wrote you regardin' the advent of the elektrik lokomotiv, as wuz predikted by our frend Marks and Prof. Bell, but as that day hasnt yet arriv I am still hangin onto my old job and waltzin ther same old skrap heap over the road on time five days in ther week.

But there is more danger ahead fur us old runners who aint so nimble jointed as we was wunce and who may not be able to do the flyin trapeze act in quick enuf time fur ther new inventions.

Ther latest skeme fur paralyzin time and gettin ter New York and back before breakfast is now on exhibition on Arch street in ther village called Philadelphy. But I warn all ther boys not to go there unless they wear neck ties and look as though they wuz preachers or other stock holders, as this is not bein exhibited fur information, but ter sell stock; at least that's what they told me when I wanted ter see the masheen run. This arrangement is patented, I believe, by two men from the wild and woolly West, and besides bein' wild and woolly it duz seem as though they wuz "rare"—sort of underdone like, not thoroughly baked, as they sometimes say.

The names are Holman and Caldwell, and for pure, unadulterated "genius" they outrival Keeley himself. Ther plan of operatin (?) is sumthin like this. Ther engin is much like any engin on ther road, but it is jacked up on two sets of trucks run under ther drivin' wheels, so as ter make the drivin wheel tire run on the truck axles and ther upper story of ther truck play ther same game with the basement tenants of this double-decked arrangement.

Even an old back-woodser like me can see that when ther drivin wheel revolves once ther upper trucks will turn more than once, and this iz agin multiplyed in ther lower trucks, so that it seems clear as mud that ther engin will travel a whole heap faster "goin at ther same speed" as they do now, I mean they will run over more ground when the drivers are runnin the same as now, and their seems no limit to the speed with this arrangement. Ther great beuty is that (as must seem perfectly clear to all) it takes no more power to run ther engine too turns a minit when she is up on stilts than if she was on the rail, and yet (as must also be clear) she will cover a grate deal more ground than when built on the ground floor plan as at present.

As ther loads will be no heavier and it takes no more power ter turn ther wheels at this same rate, which moves ther engin over double the ground, it shows that by simply adding this patent double geared friction truck ther speed of ther train is doubled and yet no power is consumed. Uv corse this dont seem exactly possible, but as we can see that the doublin uv travel takes place with ther same speed of drivers, it cant take eny more power as I can see, and ther thing *must go*. Now if this was some elektrikal duck who talked about volts, watt meters and gas meters and ther like, I shouldnt think anything uv it, but set him down as a crank and know it wouldnt work anyhow, but here it is, a plain every-day locomotive (sumthin like my old skrap heap), only with a two story "apartment house" truck shoved under ther drivers and truck wheels, doublin ther speed and only takin ther same power, as must be plain ter eny-one, and how can I dispute ther workin of it. I can now see the folly of Fontaine

and his "upside down friction wind-mill." Ef he had only put those friction wheels *under* ther drivers instead of *over* them he would have had things "by the neck" as the boys say "and had a down-hill pull." Then too if he had only put in two sets of extra wheels in place of one he might have made the engin howl more than she did. But what iz worryin' me is not thet ther engin will go but thet I may hev to run one of ther animals instead of my old skrap Now I'm not stuck on my engin at present, but as I never wuz an akrobat think I would rather hev her than wun of their new ones fur several reasons

Not bein a hod carrier by professhun I dont like ther idea uv climbin up several flights of stairs to reach the top story of thi family hotel, namely ther cab. then agin if the wheels should bee damp and greasy sum of these mornings I dont fancy livin over such a grist mill or thrashin masheen as these two story truck wheels and ther drivers on top will keep goin after they get started on a good slippin match if I saw a train ockupyin ther same trak I wuz on, and wuz runnin one of this kind of mill at ther high speed they would run it seems to me thet I should stop ter calkerlate whether it woud do more damage ter let her run than ter try ter lap on ther emergency air. Thrashin masheens at startin or slippin wouldnt kompare with ther circus broke loose when this happened. Just imagin all ther wheels in all ther double decked trucks etc. tryin to go both ways at once and think of stayin up over this bedlum and "hangin on ter throttle to ther last et cetera." Might just as well tho fer you wouldnt get more than half way down from your perch before ther engin would hav covered several miles or so But for genuine akrobatik performances you want ter run this mashéen on sum of ther mountain roads where the kurves dont seem morn six foot radius when your runnin at good speed; and imagin these cartload of truck wheels chasin each other round these kurves with ther drivers all ther while trying ter climb over them all.

It may be thet Im gettin too old for the railroadin of to-day and if this is ther engin of the future I shall be thankful thet I lived before they bekame popular, but it isnt the high speed thet I kick against as it is carrying around a load of truck wheels in order ter fool ther steam into doin twice as much work as now without knowin it. Ther piston would be travellin just ther same as usual and yet ther engin would be bumpin itself over the ground in a manner that must make ther steam dizzy and ther engineer sea sick especially if ther trucks are not covered from his view. Now while I dont believ in Takin such unfair advantage of ther steam and also throwin fireman out uv work, if this iz to be done and called fair why not do it up brown and put three four or five sets of trucks under ther engin insted uv two and so get more speed, or if you dont want to go so fast, to reduce ther size engin rekwired to do ther work. If your goin ter tell a lie it might jest as well be a whopper as a small one, and its no worse ter fule ther steam into doin four times as much work as now than doin twice as much, and it seems ter me (fer havin seen the engin *I know it will do all they klaim fur it*) thet if they only get truck wheels enuf they wont need eny boiler on ther engin, but if they can get some good talkers, auctioneers, hammer blow men or sumthin of ther kind to just talk into a cylinder, the engin could run like the wind, for all they need is "wheels." So that if ther wheel foundries only hold out we kan expect ter see engins with no boilers but only wheels—wheels on every side.

Unless you kan find another job fer me shall hav ter go inter training in ther gymnasyum and also go ter sea, so as ter learn not ter get sea sick and then perhaps I kan tackle ther new animal when she comes on ther road

## Fires, Tuyeres and Points for Workers of Tool Steel.

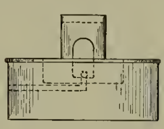
*Editors:*

I will continue on steel at present and fall back on iron in the future. In a recent letter in LOCOMOTIVE ENGINEERING I somewhat criticised some of our steel-makers

Now, it is true that good steel properly worked is among the most useful of man's productions. You may say it is used by every man and woman on earth, and is consequently taking the place of iron, wood and tin. Now you stop and think of the large percentage that is spoiled in working it up. Nearly every workshop in the country has a different way of working it, and still the different grades are all made about the same and ought to be worked about the same, and if worked right there would at least be a saving of 25 per cent. on an average of steel, besides the labor.

Did any of you toolsmiths ever figure up the amount of tools you spoiled in tempering every six months—just those you have cracked and broken, besides those you

*Fig. 1*

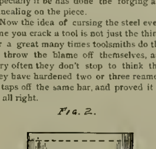


FRONT VIEW.

have let go into machine shop, boiler shop and car shop? If you have not, stop and do this and it will surprise you. Now a great many say it cannot be helped. This may be true in some cases, but ninety-nine times out of a hundred it is the toolsmith's fault when he cracks a piece in hardening, especially if he has done the forging and annealing on the piece.

Now the idea of cursing the steel every time you crack a tool is not just the thing, for a great many times toolsmiths do this to throw the blame off themselves, and very often they don't stop to think that they have hardened two or three reamers or taps off the same bar, and proved it to be all right.

*Fig. 2.*



SIDE VIEW.

Now when the toolsmith cracks the fourth one, it is almost a clear case against him, for there is not one bar out of a thousand that is poor on one end and good on the other—that is, difference enough to cause it to crack in hardening

I mail you a sample of Crescent steel drill rod, hardened as steel ought to be hardened. You will see that the outside is so hard that it cannot be scratched with a file, while the center is soft enough to drill.

This kind of hardening can be done with any good steel that will refine, and a tap or reamer hardened in this way will stand a lot of abuse because your center is perfectly soft while your edges are perfectly hard, refined, and you need not draw the temper on a tap or reamer hardened in this way enough to change the color

The first thing to do in order to accomplish this, is to test your steel and see if it will refine and is pure of phosphorus, sulphur, silicon and other impurities. The

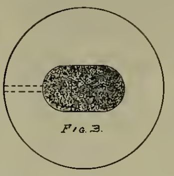


*Fig. 3.*

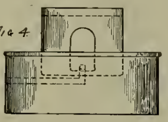
TOP VIEW.

next is your fire and the fuel you use in it, both for forging and tempering, then the the faculty you have for forging which must be taken into consideration. A forge fire as represented in Fig. 1 and 2 is the best that I have tried or seen, for getting a long heat, either for forging or tempering, as the top can be made of old tank iron any size you want it, the full length of

*Fig 4.*



FRONT VIEW.

the diameter of your forge, by having your tuyere iron the same length as your top, as shown in Fig. 2 Fig. 3 represents the top filled with coal, which I generally fill within $1\frac{1}{2}$ inches from top, so that I can throw a bucket of water on occasionally so as to keep the opening about the same size. Fig. 4 is a similar top, with the opening cut in the sides, and the long tuyere iron left out. This I find to be about as good a forge fire for general work in the line of a hollow fire as I have heard of, or seen, because there is very near as much heat from the top as from the bottom.

This fire can be built on an ordinary forge in fifteen minutes by first building your fire level with your forge; then start your fire with charcoal; then take and set your top so that the center of it will come

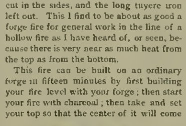


*Fig. 6.*

over the center of your tuyere iron and take a few sticks of wood long enough to reach clear through your top where your opening is represented in Fig. 1 or Fig 4. then fill your top with coal and tamp it down with a hammer, and by the time your wood is burned out your coal will be coked enough to hold itself up, this will only take from ten to fifteen minutes.

A fire of this kind will last you ten hours and will give you coke enough for the next day, while a fire as represented in Fig 6 will last five hours, but makes a very good open fire.

I will try and explain the benefit of these in a future letter.

## The Retaining Feature in Air-Brakes.

*Editors:*

This is a subject that I feel should have the strict attention of each and every inspector and repairer of air-brakes.

If this feature is worthy of being placed upon a car, it should certainly be looked after and kept in good repair.

Now, the retaining-valves are to be used only on such gradients as are prescribed by the rules and regulations of the road using them, but they should receive the same rigid inspection at repair shops on divisions which have no use for them as they would if they were repaired at shops in a mountainous country where they were continually used

I find that it costs an enormous amount of money to keep this feature up, as the valves are continually getting knocked off and lost, or if they be of brass they are stolen by petty thieves and sold for old brass.

Now the question naturally arises, which is the best valve to use?

In the first place, I think they should be of cast-iron, and in the second place they should be made heavy enough to stand the knocks and jars to which they are constantly subject.

I believe the new pattern of the W. A B. Co. to be the best for this reason, viz. It is made larger and heavier and can be fastened to the car with lag-screws, whereas the old valve was merely tacked or fastened to the car with the common wood screws.

Of the old pattern, I think that those cast of brass are preferable to those of iron, as the lugs on the iron ones are so frail that a slight wrench or blow will break them

As this is a weighted valve there should be more care taken in placing it upon the car. They should be placed in a perpendicular position.

I find them reclining at all angles, and have found a few that were fastened in a horizontal position under the end sill.

The train crews should receive a little instruction as to the usage of this valve, as there are a number of them that sometimes make costly errors by wrong usage.

As an illustration I will cite the following

"A train has pulled into a station, and a brakeman in passing along the train discovers air blowing from the retaining-valve, said leakage probably due to an imperfect emergency-valve or other defect in the triple-valve. He immediately sets his brain to work to ferret out a scheme whereby he may stop this leak without cutting out the car. After thinking a while he decides to break that little pipe at the triple-valve and stop up that hole with a plug. Sure enough, he stops the leak, and they are ready to proceed. (They are running on a time order.) They make one stop at a crossing, and in starting again the engineer feels something dragging.

He throws his valve-handle into release position again, but it does no good, and he finally drags on to siding at the next station "with four pairs of flat wheels" under the car with the plugged exhaust port.

I find many such cases as this, although the wheels are not always slid flat, but as I said in my illustration, I have seen four pairs of wheels taken from under a car for this reason.

By taking an interest in these minor details an employé goes a great ways toward saving a heavy expense for the railway company, and at the same time makes himself invaluable to them.

Giving one's views and having comments passed upon them, and receiving other's ideas in exchange, must surely be conducive to good results, as it assists each one to elevate himself in his craft.

CHAS. S SHALLENBERGER.

**Calendar for 1893 Free.**

The Chicago & Northwestern Railway has just issued an attractive calendar for 1893, which is one of the best we have seen for practical use in the business office as well as the home. A copy of this desirable calendar will be mailed free upon sending your address with a two cent postage stamp to W. A. Thrall, G. P. & T. A., Chicago.

### Common Air-Brake Disorders.

*Editors :*

The equalizing discharge valve is all right if properly cared for and properly handled. The men who use them are responsible to a very great extent for their condition. One of the principal causes of annoyance to me is the gum that accumulates in the valve, the result of too much oil in lower cylinder of pump. I sometimes get out of "sorts" trying to convince the men that the air cylinder of the pump requires but very little oil, for too much is worse than none. I find that the substance we call gum gets under or between rotating valve and its seat on the part having the greater surface. This causes the valve to wear uneven, and leak under, sometimes bad enough to prevent excess pressure in the drum as well as letting off brakes when the valve is on lap.

SAND IN TRIPLE VALVE.

Another cause of valve working bad, and which many times causes an emergency application of the brakes, is the sand that is deposited in chamber 18, under piston 17. Men will wonder how sand could get in their brake-valves and triple-valves. I think it easy to explain how it gets there. It gets there by letting the hose on tender and on cars hang down while running over the road; the couplings catch up the sand, and when they are coupled up again the circulation of air takes the sand direct to brake-valve and triple-valves. It don't require much of an effort to hang up a hose in its proper place, but it does save a great deal of trouble sometimes.

SUDDEN APPLICATION OF BRAKES.

I have often had engineers come to me and say: "I tried to set my brake to-day by service application until I reduced the pressure on train line twenty-five or thirty pounds, then all at once it would go 'bang.' What was the trouble?" Well, the trouble is that piston 17 gets gummed up and sticks, and instead of reducing train line pressure, the pressure is reduced on top of piston 17, and to that extent that when the piston moves up it moves very suddenly, causing such a sudden reduction of train-line pressure as to make an emergency application Now all of this trouble and annoyance can be obviated by the exercise of a little judgment on the part of engineers and trainmen. Engineers and firemen, don't put so much oil in the air cylinder of your pump.

HANG UP THE AIR HOSE.

Trainmen, hang up the air-hose on cars when not in use; if you do this you will find that the brakes will work better because the triple-valves and engineer's brake-valve will be kept in better condition The heads of most all departments of railroads have organized themselves into associations, which is of great benefit not only to themselves, but also to the companies by whom they are employed. What's the matter with air-brakemen forming an association? Speak out my brother dispensers of wind.

*Syracuse, N. Y.* W. F. RELYEA.

### Early Locomotives.

*Editors :*

A great deal has been said from time to time about old locomotives and their builders. While the names of Baldwin and other famous builders have become household words, we must not lose sight of the fact that many good engines were built by men whose names never appeared in print, and of whose existence a great many readers of railroad literature are not aware. In speaking of early locomotives we must keep in view the early productions of builders who afterward became famous, and notice the improvements made from time to time.

Our scenes are laid on the old Philadelphia & Columbia Railroad, at that time owned by the State of Pennsylvania, at present the Philadelphia division of the Pennsylvania Railroad. This road was a double track road from the beginning, and is understood to have been operated by horses at first, being eighty-two miles long. Who built it, or where the first engines were built, deponent sayeth not, but I used to hear the old-timers often speak of the "crabs," referring as they did to the "grasshopper" class, and have often heard the "John Bull" spoken of and have seen the name-plates of "Gray Eagle" and "Black Hawk" lying around the shop where I served my time; wish I could get hold of one of them now, also two old headlights, one to burn candles, the other for lard oil, with an immense flat wick.

The earliest locomotives coming under the writer's notice were the little two-wheeled machines, without cab, pilot, sandbox, headlight or cylinder-cock rigging. Some of these early engines are well shown in the Joseph York reminiscences in the July number of LOCOMOTIVE ENGINEERING. A majority of the engines were the Baldwin half-crank type, inside connected, drivers in rear of firebox, the main rod passing between the side of firebox and inside of drivers, the whole machine being surrounded by an outside frame of wood about 4 x 10, covered with iron. These engines had a single fixed eccentric, one on either side, with a top and bottom drop-hook but no starting bars, only a reverse lever. The Norris engines were outside connected, with the drivers forward of firebox and with a wrought-iron frame. By this arrangement of the drivers more weight was carried than by placing them in the rear of the firebox, putting the drivers forward of the firebox was adhered to by all the builders except three engines built by Eastwick & Harrison, of Philadelphia, and Baldwin of same place. The E. & H. engines had a fixed eccentric connected to rocker by rod and strap, the reversing being produced in the steam-chest. These engines had two reverse-levers, or one for each side of the engine. They were flyers in forward motion, but not much account backing up.

All the other engines had two eccentrics and the ordinary drop-hooks and starting bars on the foot-board. There were about a dozen of the Baldwin engines, five or six Norris, three Eastwick & Harrison, two Campbell (built in Philadelphia I think) one or two built by Pennell, Leonard & Harmon, of Lancaster, Pa., and one or two by Dotterer & Co., of Reading, Pa., and one or two with no builder's name on them. These old engines had the dome type of boiler with a smaller dome on the top of the large part, over the throttle. These small domes were made of copper or cast-iron, and polished. The boiler had no jacket, but was lagged with tongue and grooved, beaded strips painted alternately green and black, with flat brass bands, and looked very neat when clean.

Amongst the early Baldwin engines were two outside connected with wrought iron frames and cast-iron jaws. In speaking of drop hooks, they must not be confounded with V hooks; of course they both served the same purpose, only the V hooks did not require starting bars to have them engage with the rocker, they were simply jammed down, and when the throttle leaked they were jammed hard. Any of the readers of LOCOMOTIVE ENGINEERING—and they are legion—who have had experience with hook motion engines know how it is themselves.

The business of the road began to grow with the building of the P. R. R., and heavier engines were required.; then Baldwin built the first multiple connected engines on the road, six-wheelers (no trucks), and with balloon stacks. Then Norris sent the first four-wheel connected engine (no cabs) with independent cut off (hook motion), these were followed by Baldwin with two four-wheelers with independent variable cut-off (hook motion). These, again, by some fine engines from Paterson, New Jersey, built by John Brandt, with the link motion, the first on the road; it was a long time before the writer could understand the connecting of the forward and back motions eccentric rods together; but when it came to taking up lost motion by fitting new dies in the old hook or yanking our arms off on a solid link-block we choose the books.

What a change on that part of the road between the past and the present! Then there was no time card for freight trains—burden trains they were called—and they did not run at night. Two passenger trains left Philadelphia (8th and Market) every day, and two left Columbia. Switching was done with horses. Through freight between Philadelphia and Pittsburgh was carried over the road in canal boats, or section boats, as they were called; if a burden, or freight train, got on a passenger train's line, the passenger came up and pushed the freight until a switch was reached, when they could run around the freight.

This early road had a Jonah, as all modern roads have, or in other words, an engine that was always in trouble or breaking down. She was one of the Baldwin half-cranks, called the Octorora; this engine would break more crank axles than all the rest of the engines put together. But these are all things of the past.

W. DE SANNO.

*Pan Handle Shop, Indianapolis.*

### Blacksmithing and Crystallization.

*Editors :*

I saw in the last paper an article by G. F. Hinkens, of Gladstone, Minn., on blacksmithing, in which he says that he believed that blacksmiths were afraid of being criticised if they entered into print, and that he was of the opposite sort,—he was afraid that they would not criticise. Now, it is a great deal easier to criticise than to inform, and if you just keep on trying to inform you need not lose any sleep fearing that you will not be criticised. Now, Mr. Hinkens wants to know what is the cause of the tenth mishap; now, if an engine rolls down an embankment, or strikes a car on a side track that did not clear, or gets into a collision and breaks a side-rod, would you blame the man that did the forging, or the material, or either? Or would you lay it to crystallization? You say you never saw a side-rod broken in the weld. I have, and more than one. I put the question: "How often do we hear of a side-rod breaking in the weld?" I did not say anything of those that break from crystallization.

You say, "However good the weld is it is always the weakest point; at least tests have demonstrated such to be a fact; consequently, it is a matter of vital significance to locate your weld. Keep the weld from the terminus of vibration lest the rod will break before the proper time, and that time will arrive when the constituent particles at the end of shock or vibration become crystallized."

Now, when you get a broken side-rod to weld, do you weld it where it was broken, or do you cut out a piece and put in a new one so as to keep your weld from the terminus of vibration?

You put the question · "How are we to avoid crystallization?" and answer "Select suitable material, which should be fibrous and hard; hard, because soft iron will crystallize quicker than hard iron."

Now, how would you go to work to crystallize a piece of good nail rod, which is certainly a soft iron, to any great extent, or a piece of Norway iron, which is more apt to crystallize than the nail rod?

Wishing you A Happy New Year, and hope you will accept my criticism as I do yours—as a favor. W. G. LOTTES.

*Madison, Wis.*

### Why Did this Engine Limp When at Work?

*Editors :*

A new locomotive from Pittsburgh Works is taken out on trial, is all right without any train, but with a full train is so lame she will not handle the train. This is an 8-wheeled engine, the eccentrics are keyed on shaft, the blades, links, rockers, valve-stems, valves, tumbling-shaft, reach-rod, reverse-lever, quadrant and everything pertaining to the motion work is as good as it can be made. This engine is always square when working without train and always lame with a train; where and why the trouble? TOBY.

*Vandalia, Ill.*

### That Lame Exhaust Puzzle.

*Editors :*

In your December number I notice a lame exhaust puzzle.

Traveling Engineer says he examined the valve motion carefully, and also the exhaust nozzles, and found all O. K. He does not say he examined the valves or the tram marks on valve stems, but taking it for granted that he did and found everything all right from the eccentrics to the valves, the only place left would be for a broken tram ahead of the main jaw which would act the same as a slipped eccentric or a slipped eccentric blade.

*Topeka, Kan.* A MACHINIST.

*Editors :*

Answer to lame exhaust puzzle If valves and gear were all right, I should expect to find piston-rod broken and piston forced to front end, showing steam passage. If there were three clear exhausts, I don't think it was necessary to examine nozzle. If three exhausts could escape all right how could the nozzles stop the fourth? The trouble would necessarily be in the passages or cylinder, providing valves and gear were all right.

*Cleveland, O.* S. WOOLMINGTON.

*Editors :*

In answer to Traveling Engineer, from San Francisco, California, regarding a lame exhaust, would say that I would not have given up as soon as he did. Before doing so would have removed cylinder-head to see if packing was all right. My impression is that if it was not a solid piston-head with snap-rings, that the follower-head had become loose, rings displaced and that the steam from the initial end was going through and out with the exhaust of other end of cylinder. If this was not the trouble it was in steam-chest between the point trammed and the valve.

W. H. APPLE, M.M.,

*Ashland, Ky.* A. C. & I. R. R.

THE ANSWER.

*Editors :*

The engine that had the lame exhaust was afflicted with a loose lifting-arm on the tumbling shaft. This let the engine work square when down, but when working cut-up close, the arm moved up and down causing the limp.

TRAVELING ENGINEER.

*San Francisco.*

### Kellogg's Air-Brake Puzzle.

*Editors :*

In answer to H. W. Kellogg's puzzles 1 and 2, December issue, page 441

First—The reason he could not keep pressure in main reservoir while in running or release position was because packing ring on piston 17, was left out when valve was put up.

Second—Air-passage, between chamber D and equalizing reservoir, was choked, or there was a blind washer put in pipe connection, consequently his brake acted like lightning.

M. C. GLEME.

*Wilksboro, N. C.*

### Watts' Trouble.

*Editors :*

I should say there was a leak some place in the gauge-pipe or pipe to small drum or the space above piston in engi-

neer's valve itself. This would reduce the pressure when brake-valve was on lap and apply the brake. JOHN STEADMAN.

*Waco, Texas.*

THE ANSWER.

*Editors:*

In answer to my letter that was published last month, would say there was a leak in one of the small pipes that lead from the brake-valve to the air-gauge This reduced the pressure above the piston in brake-valve, allowing it to raise, thus reducing pressure in train-pipe and applying brakes M. E WAITS.

*West Nanticoke, Pa.*

A shocking railroad disaster happened on the Great Northern last month by which eight men were killed and several others severely injured. As most of the victims of this accident were laborers we are not likely to hear much indignation expressed about the carelessness that caused the disaster. A very heavy freight train with no power brakes on it was flagged on a descending grade to stop on account of a wrecking train being on the main line. The train could not be stopped and crashed into the end of the wrecking train with the result noted The press dispatches make the comment that the accident was due to the carelessness of the men in charge of the wrecking train. We do not wish to condone the carelessness that neglects flagging, but in this case we think that the blame was not confined to the trainmen referred to. All the transcontinental lines except the Great Northern have the greater part of their freight cars equipped with air-brakes. The Great Northern is the most conspicuous example of one-man management in America, and that man is James J. Hill, the president. The principal cause of the accident was want of air-brakes and Mr. Hill alone is to blame for that means of safety being absent. Mr. Hill ought to be held responsible for the death of these men.

We want to call especial attention to the interesting article on war-time engine-running by "Old Soldier." Of all the interesting things he has told us, the incidents related in this number are the best. As is shown by the present paper, "Old Soldier" is Mr. E. A. Campbell, general master mechanic of the H., E. & W. T. road at Houston, Tex. Last winter, while the junior philosopher was on a visit to Texas, he saw the original orders and many other interesting war-time papers at Mr. Campbell's home. At the time Mr C. writes about he was a young married man, and had and still has one of those kind of wives that won't stay at home when her husband is in a dangerous location—wherever Campbell went she went also. On every pretext and on every occasion he would send her North out of the lines, but just when things got interesting she showed up again, bag and baggage, rode on the engine, kept house in a box-car, or slept on the ground. Mrs. Campbell's reminiscences are as interesting as those of any soldier at the front.

Regarding the question that appeared in LOCOMOTIVE ENGINEERING as to who was the inventor of the steam whistle, Mr. R. J. Dill, Grand Island, Neb., writes "A man by the name of John Lodge, of Magnolia, Kent Co., Del., was the inventor. I do not know if he patented it or not, but he was the inventor of it. He was a little bit of a hunchbacked fellow. He got drunk and gave his invention to some fellow for a pint of whiskey. I knew him well, he was a foreman and lived a half-mile from us. He is dead now, I think"

If there are any technical school graduates who are anxious to enter railroad service they might obtain employment from Mr Johnstone, mechanical superintendent of the Mexican Central Railroad. Mr. Johnstone is anxious to employ a few well-educated young men who would be capable, after a time, of filling official positions.

### Thatcher's Dumping Car.

The engraving herewith was made direct from a photo, and shows the Thatcher car in dumped position on each side of the track

As is plain, the air-cylinder shown in the center of the car lifts and dumps the car. When it is desired to dump on the other side the car is turned around.

There is a small air-cylinder that locks and releases the car automatically, so that there is no danger of its dumping in transit, nor can it be dumped by an ignorant or malicious person releasing the lock This must be done from the engine.

The cars shown will carry ten cubic yards of dirt.

They are built by the Thatcher Car and Manufacturing Co. of this city.

### A Good Blow-Off Valve.

One of the worst things on an American locomotive, or any other kind, is the common taper plug-valve used as a blow-off cock.

They leak and fill up and stick; in anything like bad water you must loosen the set-nuts on the plug before you can use it, and then it gives you a shower bath when you try to close it up again. This well-known fact prevents their being used a good deal too often.

On many of the Southern roads they are using an improved valve that has many merits and is just as cheap as the plug. We do not know just who originated it, but it is in use on the L. & N. and several other roads. We got our drawing from the South Carolina road.

This cock has an internal opening valve much like a whistle valve, and operated in the same way, as plainly shown in our engraving. The body of the valve is a straight plug with a pair of lugs to carry the operating bell-crank, and a hex head for turning it into and out of the boiler, the outer end being threaded to attach a pipe to carry water and steam away from the engine.

The valve has a long-winged stem with a recess for the end of the lever, as shown, the stem is partly cut away next to the valve, so that this shall be the weakest part, and if the plug should get knocked off the stem would break there, leaving the valve in place, held there by the pressure.

One advantage of this valve is that it must be held open, it cannot be left open, and when you let go it shuts itself.

### From Start to Finish.

BY EUGENE V. DEBS.

I am persuaded, from such information as I have been able to obtain, that LOCOMOTIVE ENGINEERING is read chiefly by practical men. I know that the publication is owned, controlled and edited by men whose ambition prompts them to disseminate that kind of knowledge which will aid men who toil to accomplish the most satisfactory results. In reading LOCOMOTIVE ENGINEERING, as I am in the habit of doing, I discover little that is speculative or theoretical, the fanciful and imaginative being discarded to make room for bed-rock facts and principles upon which to rear fortresses, in the construction of which, reason, logic, common sense, argument, more enduring than granite and iron, furnish an impregnable retreat for thousands who by their brain and brawn are required from start to finish to build their own fortunes or die poor and obscure. The name, LOCOMOTIVE ENGINEERING, is eminently suggestive of practical problems which only sturdy men care to wrestle with. The sentimental namby-pambyisms, whims and crotchets of the period, of which there is a superabundance, are not lassoed and corralled for exhibition in the pages of LOCOMOTIVE ENGINEERING.

I am not unmindful of the fact that to say "The locomotive is a wonderful machine," and that "It is revolutionizing the world," are exceedingly trite expressions, long since worn threadbare, notwithstanding the fact that the first locomotive was built within the memory of men now living, and not so far advanced in years as to be retired from active pursuits, and yet to multiplied thousands the locomotive remains a mystery, an explained enigma, and strange to say, a truth stranger than friction, there are thousands of men known as "runners" to whom the locomotive has never yielded up its secrets I am aware that the plea is put forth that locomotive engineers and those who aspire to the responsible position, are not required to know as much about a locomotive as its builder, that their business is to run and not to build engines. I do not care to engage in much controversy, except to say that the more an engineer knows about a locomotive from start to finish, the better he is equipped as a "runner," and when assertions to the contrary are made, their effect, if they exert any influence at all, is in the line of promoting and perpetuating unfortunate conditions. And this leads me to say that when men at all capable survey the field of railroad employment, they discover at once that the supreme need is incentive to studious habits, that there may be more mind development, larger brain growth and grasp, in the ranks of the men who operate railroads.

Of late years we hear much about physical education, and our colleges and universities are devoting great attention to the subject Every institution of learning of high degree has its gymnasium where students are trained in athletics, it being acknowledged that a healthy, vigorous body is essential to the achievement and maintenance of high intellectual development, but it so happens that with railroad trainmen, firemen, engineers, conductors, switchmen and brakemen, whose *alma mater* is the railroad cab, caboose, yard or car, find a gymnasium all along the line, the development of their muscular manhood being a concomitant of their employment, their vocation affording them all the athletic exercise which health demands, hence I am not required to discuss physical education with regard to the requirements of trainmen, to whom reference has been made.

Shakespeare is credited with saying

> There is a tide in the affairs of men,
> Which, taken at the flood, leads on to fortune

And that

> There is a divinity which shapes our ends,
> Rough hew them how we will

Such expressions, no doubt, are im-

mensely poetic, and are accounted by many as the acme of wisdom. I do not doubt that there is a tide in the affairs of men; indeed, I am confident there are in human affairs numerous tides—flood and ebb—which lead on to fortune or down to unpleasant conditions. I object to the intimation of the one flood-tide which must be caught, else, by a decree of fate, all is lost. I prefer the kindergarten philosophy;

> If at first you don't succeed,
> Try, try again.

I do not believe that the first or the second failure settles a man's destiny; such is not the logic of experience. Nor do I take stock in any end-shaping divinity, if by the term "divinity" the man himself is to be denied the privilege of participating in the discussion which shapes his ends, his destiny. In such matters I am in favor of free speech, a free ballot and a fair count; of anything and everything that educates men up to the exercise of all their faculties, to win and maintain their independence, and I antagonize any creed or dogma that so much as squints at any interference with man's high prerogatives to start right, to advance along the main track and finish his career crowned with success. Anything else reduces men to mere machines to be operated by millionaire divinities, who have "wipers" forever wiping engines, and firemen forever breaking and shoveling fuel, and brakemen forever at the brake, and engineers forever at the throttle, unable, if they would, to take any tide at its flood, because some divinity had shaped their ends, put them in a hole from which they could be extricated only by a miracle.

Taking the world as we find it, difficulties arise when one is required to determine what conditions are really the most fortunate under which a youth may start in life and finish his career crowned with victory over "the world, the flesh and the devil." Dismissing extremes of great poverty and wealth, I am convinced the grandest achievements in human affairs are to be credited to those who were born neither very poor nor very rich, but occupied at the start that happy medium where there was an imperative demand for the exercise of the faculties to secure success. Still, instances are numerous and luminous of men starting far below the average and rising by virtue of their own efforts to independence and distinction. It is the testimony of all history that progress, such as the world may boast of, should be credited to men who have started in life neither the victims of squalor, nor yet the inheritors of riches; but rather those who were required by the exigencies of conditions to be self-reliant at the start and to work out their own emancipation from embarrassing environments by their own brain and brawn, by a miserly husbanding of their resources of time and opportunities, by habits of study, close application to duty, rising above temptations and their debasing influences, and with steadiness of purpose advancing, regardless of obstacles, along the line of success.

I could, were I so inclined, and space would permit, enter all the domains of human endeavor and name men who, starting at the bottom rung of the ladder, finished their career by standing securely at the top. These examples of obscure starting and victorious finish would be found in every profession and vocation, and in every instance the propelling forces would be found to have been practically the same, always from start to finish hard workers and laborious students, always broadening their mental vision and strengthening their mental grasp. They did not go up like a rocket, flame and fall; with them it was years of patient toil. The world admires such exhibitions of pluck and perseverance, but few there are who know or care to investigate the silent but potent forces to which society is indebted for all its progress.

I confess to profound admiration for such men. My historical readings, such as they are, lead to the conviction that the useful, the ornamental, the luxurious things that mankind has possessed since the dawn of creation, have been the product of the world's toilers, its wage workers. They were the builders of the seven wonders of the world, aye, of the seventy-seven thousand wonders, from the pyramids to the Columbian Exposition buildings. All of the cities, buried and above ground, from the first which Cain built, to Chicago, are so many monuments of their skill and toil, and should their brains and hands be paralyzed, the earth would be remanded to pre-historic conditions, when man was something less than a savage.

Taking this view of the subject, we come down to the present and inquire if men who build all the monuments of our civilization are true to themselves? At the start they have before them the problem, what shall the finish be? I do not believe that in the past there was such an inquiry. Workingmen, like the coral, have built and died. Others standing upon the graves of their predecessors worked on in the old grooves. There is a new dispensation for those who seek to comprehend its mission. Skulls are no longer the raw material with which to build thrones and steps to thrones. Man is something superior to a machine, if he so determines. It is a great mistake to find fault with an inheritance of work. Work, as an inheritance, taken into consideration with the elevating, redeeming, emancipating power the humblest possess, is a benediction, if, at the start, the finish is considered, if the worker reflects that he and he alone, is to be the architect of his fortune and that it will be in vain for him to call upon others to supply the material with which to build the superstructure. Starting poor and obscure, he will remain the victim of poverty and seclusion at the finish, provided he elects to let his mental faculties remain inert. If, however, he resolves to be a student in the line of his work, the gates to all the avenues of progress and high ambition will swing wide open at the touch of the charmed key he carries. Day by day, as the years speed on, he determines what the finish shall be. No toiler on the rugged road leading to final success must "lay the flattering unction to his soul" that chance, a flood-tide, some fortuitous circumstance, is to make the finish to his career such as is wrought out only by the faithful employment of mental and physical faculties in holy alliance to win victories from the iron jaws of fate; anything else is a vagary, a will o' the wisp of the brain, always and inevitably leading to disaster.

The times in which we live are fruitful of illustrations of such conclusions, and in no development of industrial enterprises are they more numerous than in the railroad service of the country. They include, at the start, office-boys, switchmen, firemen, brakemen, conductors, telegraphers, engineers, clerks, etc. Their name is legion. They start poor and obscure and by degrees win positions of influence, power, independence and opulence. They were in every instance and in the best sense of the term, students. Their motto was work, watch, study. The fortunate tide came every day to move them on toward the goal of their ambition. Their zeal, their fidelity, their ever-increasing knowledge, were divinities that shaped their ends and sent them forward to achieve victories, each in proportion to his talents, but all moving on an upward grade to goals of success.

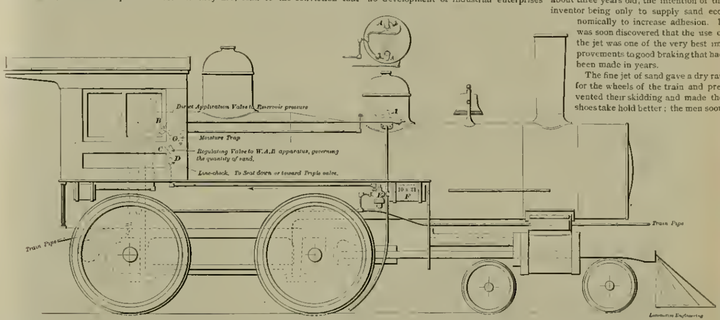
It would be in the line of supporting the argument to introduce notable examples of men now living and at the head of great railroad systems in the United States, as for instance, Mr. S. H. H. Clark, president and general manager of the Union Pacific system and vice-president of the Missouri Pacific system of railways. He began his railroad work on a New Jersey gravel train and advanced steadily to his present offices. As also, Edward Turner Jeffery, president and general manager of the Denver and Rio Grande Railway, who started at the very bottom and is finishing his career, as is Mr. Clark, with the most eminent distinction. There are numerous other instances of living men who are now in active employment, who started poor, obscure and unknown, whose equipment was brains, strong bodies and willing hands; who saw the need of vigilance, the study of books, men and their chosen calling; who placed a proper value upon time and opportunities and who shaped their ends to meet emergencies, so that when a man was wanted for a higher position, they could say, "Try me!" Thus it will ever be. The industrious, the studious, the alert, the courageous, who from start to finish are always adding to their equipment, will always be found moving on an upward grade to stations of greater power, influence and usefulness in the world, while the sluggards, the victims of ignorance and apathy, with stolid indifference and unconcern, will stand aside and see the procession, keeping step to the music of progress, march on to still higher achievements.

### An Automatic Sand-Feeding Attachment.

It is wonderful how a new invention finds other uses than the inventors sought, and how one improvement brings out another.

The air-jet sand-feeding device is only about three years old, the intention of the inventor being only to supply sand economically to increase adhesion. It was soon discovered that the use of the jet was one of the very best improvements to good braking that had been made in years.

The fine jet of sand gave a dry rail for the wheels of the train and prevented their skidding and made the shoes take hold better; the men soon came to use the jet as much for this purpose as to help start their trains.



Charles W Sherburne, of 53 Oliver street, Boston, Mass., has recently patented a device for automatically starting the air jets when the brake is applied. he does this without any new parts, simply using a Westinghouse air-brake auxiliary drum and a plain triple.

These he locates as shown in the cut, the triple acting with the other valves in the train, but instead of sending air to a brake cylinder the air goes through a pipe to the jets.

In the illustration the jets are in the base of the sand-box at *A*, the old hand-feeding valves being still there and ready for use. All the other valves are marked and their use told on the plate.

The engineer can use his old "free-for-all" valve, he can start the air-jets and let them operate as long as he wants to, or he can set the automatic sander and then regulate the amount of air it shall supply.

All the pipes are ¼-inch in diameter, and all the Westinghouse equipment used is a No. 1 triple-valve (Plate D 19) and an auxiliary reservoir (Plate D, 20).

Sand-feeding jets are a great improvement in service; they save tire, prevent slipping and stalling, and insure better braking and are economical of sand, at no time supplying enough to have the wheels throw it over into the link motion and other bearings.

### In Krupp's Steel Works.

[EDITORIAL CORRESPONDENCE.]

It is hardly fair to say that Krupp's works are located at Essen, Prussia; Essen is located at Krupp's works.

All there is of importance is owned by Fried Krupp, the third head of the concern and the grandson of the founder. There is no company or corporation, shares, or stock—it's all Krupp's.

It would be entirely impossible for me to describe the works; they are very large and extensive and somewhat different from anything in America.

As a rule the buildings are good, the machinery is good, that in the gun works being especially fine.

Some idea of the magnitude of the place can be had when I tell you that in the works alone they employ 16,000 men and in the mines 8,000 more. There are employed about the works sixteen standard gauge locomotives and twenty-four narrow gauge ones.

The product of the Krupp works represents almost everything made in steel.

Guns, the largest in the world, wheels, many kinds, tires, building material, armor plate, parts of men-of-war, springs of all kinds and sizes, tool steel, etc.

When I went through their works early in July, I saw the inner tube of the great gun that is coming to the Chicago exposition. In the gun shop they were making cannon for many countries and the foreign inspectors in their uniforms looked rather unique. There are only three countries of any size that Krupp has not made heavy arms for, these are France, Great Britain and the United States.

They have an immense shop for turning off and boring out car wheels, and hundreds were being thus made ready for service.

All European countries use wrought-iron car wheels of large diameter, and plans for forging these are numerous.

I was much interested in the process of making the Krupp No. 1, or "Ribbon" wheel; the center of this wheel is a plate, but it is made by rolling up a strip of metal as you would roll up a tape line.

This is done by powerful machinery, but the metal rolled is not thin like a ribbon; the center is composed of three pieces of metal of different sizes welded together; one end, which forms the rim, is heavier than the center; the whole not over 15 feet long. After being rolled up red hot, the coil is placed in a furnace and heated almost to the melting point and then welded into shape between huge dies on an immense steam hammer.

But Krupp makes excellent cast-steel wheels, and these are coming into use very fast, although they say they can not be produced cheaper than wrought-iron wheels.

I saw some of these wheels tested under a hammer; some were set on edge and the wheel flattened out—they were spoked wheels—until the rims were only 3 inches from the hubs, the spokes distorted and bent, enlarged in some places and stretched in others, and yet showing no cracks.

Then they blocked up under the rim of a wheel and drove the hub down, forming a cone of the entire wheel; no break in material. Another wheel was hammered into a twist and without a flaw in the metal being developed.

At Krupp's they don't cast steel that can not be forged, and all have some part that is finished in that way. I saw an immense casting weighing many tons—this was the beak or ram of a man-of-war, it was to be forged into finish.

The most interesting part of the plant to me was the tire-making shop. And to watch a tire from ingot to lathe room tells you the reason why Krupp's tires are so uniform. Poor metal can't stand that test.

In the first place a piece is cut off the bottom of the ingot; this is done under a hammer and in such a way as to leave a round chunk of metal.

This is heated properly and placed under a hammer and flattened out—looking for all the world like a small cheese.

It is now inspected, and if the edge has cracked under the flattening-out process it is thrown away. If it stands it is reheated and a pointed punch driven through it, forming a rough ring—again it is inspected; if it has stood this test it is considered good tire steel, and it passes to the hammers, where it is drawn out by slow hammering all around. One hammer has an overlapping die and bead that form it into the correct shape, with flange; the hammering is done very close to size, the rolls merely taking out the hammer marks.

This is a slow way to make tires, but it is pretty sure to get good ones.

The gas works are as big as you will find for many cities, and beside these there is an immense electric-light plant.

A uniformed fire brigade are on duty all the time.

Everywhere you notice the number of men; they seem to be in the way of each other.

In the spring department they were making hundreds of long, half-elliptic car springs, every process being a hand one.

They make crucible steel for tools, and make the finest and largest crucible castings in the world.

The workmen average less than $1 per day, and, I thought, did about 75 cents' worth of work. They are faithful and sure, but they plod; they plunk around in their wooden shoes and do their tasks mechanically. Herr Krupp employs mechanical engineers, chemists and specialists to do the thinking.

Near the center of the works is carefully preserved a little stone cottage, once, nearly a century ago, the humble home of the parents of the founder of the great works. Here he experimented, here his first forge was erected, and here he first made steel. This little seed, from which grew the greatest steel works in the world, has been cared for by the great and the rich Krupps, and it is said that they are proud of their humble origin and the brains and energy that made them a name and a fame as wide as the world. In a country where people are supposed to be born either with blue blood or canal water in their veins, this was refreshing to me, and I went away from Essen with far more respect for Herr Krupp than for the Kaiser,—or anyone else. J. A. H.

The useful books on "How to Run Engines and Boilers," and the "Corliss Engine," by E. P. Watson, the accomplished editor of the *Engineer*, are now handled by Spon & Chamberlain, New York.

Remember we pay cash commission to club-raisers.

### The American Balance Slide-Valve.

The engravings shown herewith will serve to make clear the details of construction of a balanced slide-valve that is making some friends in the West, it being a Californian invention and for some time in use there.

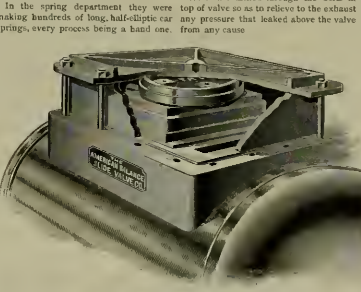
There is no balance plate, packing strips or springs used. The balancing device is simply bolted to the top of an ordinary slide-valve and the inside of the chest cover faced off for the packing-ring to wear against.

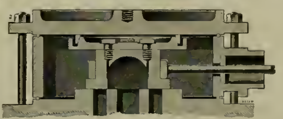
A circular disk is bolted to the top of the valve and on top of this disk there is a beveled boss, upon the outside of which a beveled packing-ring sets.

This ring is cut square across, but has a joint strip on the outside.

The pressure of steam in the chest tends to compress this ring and this forces it up against the cover. Any tendency of the valve to lift also tightens the balance packing; still the valve can lift.

Holes are drilled through the bolts in top of valve so as to relieve to the exhaust any pressure that leaked above the valve from any cause.





It has been found that the proper angle for this packing-ring depends upon the size of the circle and the pressure, and a number of angles have been worked out for the different sizes.

Where the chest is too short for one large plate two smaller ones are used. The general office of the company making these valves is in San Francisco, with a branch office in Chicago.

### Test of Turnbuckles.

An interesting test of four of the leading types of turnbuckles was recently made by Professors Gray and Brown at the Rose Polytechnic Institute. The four buckles tested were the Providence, the Cleveland, the Brooklyn and the Brazil. In tensile strength the Brooklyn proved to be the weakest of them all, breaking at 53,600 pounds. It failed by splitting open at the thread at the end. The Providence buckle broke at a strain of 62,000 pounds, the failure occurring at the bend. The Cleveland buckle, when subjected to a strain of 68,000 pounds, broke on one side. The Brazil turnbuckle, manufactured by the Central Iron & Steel Co., of Brazil, Ind., stood a strain of 85,000 pounds, and then the steel stub ends which were screwed into the buckle for the purpose of testing were broken without any apparent damage to the buckle itself. We do not know the size of the turnbuckles used in testing, but all the buckles were of the same size and took the same size rod.—*Railway Review.*

### No Cranes Needed.

"Speaking of appliances for transporting heavy weights," remarked F. W. Johnstone, superintendent of machinery of the Mexican Central, "I found some methods in Mexico that surprised me. You know that all the laborers we employ about the works are Mexicans, and good laborers they are. One day we had a consignment of anvils, each weighing over 600 pounds, that had to be taken to a place about half a mile from the shops where there was no track. I directed that barrows be used to carry the anvils on, and some of them were conveyed that way, but the men did not seem to take naturally to wheeling barrows. Presently one of them got an anvil on his shoulders, resting on a pad they use for bearing heavy weights. He started off with this enormous load and soon was followed by several other laborers, each with an anvil on his shoulders. All the anvils were transported in that way. If a load is under half a ton the average Mexican laborer will prefer taking it on his back to loading it on a wheelbarrow."

The Central Iron and Steel Co., of Brazil, Ind., are not complaining of trade being slack. On the contrary, they say that orders are keeping them as busy as their capacity is equal to, but they are hustling to increase their means of production. They are adding new wings to the rolling mill, one part being 35 x 222 feet, the other 56 x 170 feet. Into this they are putting a new engine, gas furnace and bolt-cutter made by the National Machinery Co., of Tiffin, O. There is also a new train of 8-inch rolls, a heavy steam hammer of the Morgan Engineering Co.'s make. Another addition to the works is a nut, bolt and rivet department, which comprises a forge room 55 x 96 feet, a screw-cutting room 55 x 75 feet and a boiler-room 30 x 40 feet.

Through the courtesy of Mr. William Smith, superintendent of motive power of the Chicago and Northwestern, we have received a statement of the iron ore shipped from Escanaba during the year passed, and carried there by the Chicago and Northwestern trains. The total amount is 4,008,900 tons. This ore-hauling business is very systematically done by the railroad company handling it. Special ore cars are employed that have air-brakes and vertical plane couplers. The cars carry from 25 to 30 tons each. The quantity of ore named would fill 160,356 cars with a load of 25 tons. If each train consisted of 25 cars, the business would call for over 20 trains a day for 300 days of the year.

The genial general superintendent of the New York & Northern, H. H. Vreeland, has been promoted to the position of general manager. Vreeland is said to be the best natured railroad officer in the country, yet he is a hustler in his line. His friends will all be glad to hear of his lift. He came up from the ranks, and has not forgotten how it seems to sit out on a box-car all night with his hand on a brake-wheel and his eagle eye full of cinders.

Among the railroads that have had compound locomotives lately built by the Baldwin Locomotive Works are Central of Brazil, New York, Lake Erie & Western, Philadelphia & Reading, Pike's Peak, Richmond & Danville, Norfolk & Western, Jacksonville, Tampa & Key West, Missouri, Kansas & Texas, Lehigh Valley and several others.

### Baldwin Mountain Climber for Italy.

Baldwin's have recently built the locomotive shown herewith for Count Telfener, of Florence, Italy.

As can be seen, the engine is for a rack railroad. She has cylinders 11 x 16 inches, and her toothed driving-wheel is 37.59 inches in diameter, total wheel base but 8 feet 2 inches, and total weight 33,000. The gauge of the track is 3 feet 3⅜ inches.

This mountain road is about six miles long (8 kilometers), having very sharp curves; one-third of the road has a grade of 8 per cent. one-third is 8 to 18 per cent.,

Mountain Climber for Italy.

and the other third averages from 18 to 22 per cent.

The engine has a brake on the crank wheel, as shown; a hand-brake on the leading axle, and the La Chatelier water-brake on cylinders.

### To Make Men Loyal and Contented.

BY SAM SHORT.

Ever since General Manager Wartmouth intimated to me that my services as master mechanic of the N. & Y. were no longer wanted, we have been good friends and he frequently gives me orders for supplies. The real trouble between us was that Mr. Wartmouth likes to be his own master mechanic, just as he persists in being the chief engineer, and road master, and train master, and train dispatcher. When either of these officials does not quietly agree to the general manager stepping in and running the details of his work on any and all occasions, there is going to be a change in the office.

I have always believed that Mr. Wartmouth had a covert admiration for the decided way in which I objected to his interfering with my department. The day that I told him I would not tolerate his going into the shop and dictating to my foremen, and he retorted that my resignation could not be sent in a minute too soon, ended a fight that had been going on for two years.

Every time I go there now Mr. Wartmouth is eager to tell me about the tanks of wrath which he has been pouring upon something. His road is dominated by the Brotherhoods, and it is torture for him to deal with any power which interferes with his strong, sour will.

"Railroad interests are going to the dogs; hounded to hell by unions," mildly remarked Mr. Wartmouth, after passing the courtesies of the day on my last visit.

"What is the latest agony in this line?"

"Why, I've been for the last three days wrestling with a set of fools all because I dare to run my own business in my own way."

"What were the particulars of the trouble?"

"Well, it was this way. The flyer was pulling through the yards at Smiths and that lunkhead, Bill Warner, whom you sent back to switching because he could not read train orders, pushed some cars so they did not clear the main line. Jim Wantz, who was running the 73 on the flyer was gaping along, not attending to his business. He was close to the cars before he saw they did not clear, and tore the side off five first-class coaches. It was by the greatest good luck that nobody was killed."

"I don't see why that should give you very much trouble."

"You don't, don't you? That's because you don't realize the villainy of Brotherhoods. You may not call it trouble, but I was never so near having a strike on my hands."

"I can't see how the men should want to strike about that accident. None of them were much to blame as far as I can see."

"None of them to blame, eh? I just consider they were all to blame, and bounced the whole of them, the whole of the switching crew and Wantz and his fireman."

"That is what I would call indiscriminate guillotining. Did poor Warner push the cars without orders?"

"No; of course he pushed the cars by the switchman's signals."

"Do you give orders now that a switching engineer will go back to see that the main line is clear when a train is due?"

"No, but discipline must be maintained."

"Weren't you a little severe at Wantz pulling that train you are so particular about making time, through a crooked yard filled with cars, and no signal to protect anything?"

"I don't look at it in that light. If you let these fellows ram into trains every time they feel in a reckless mood, the road could not meet the repair bills."

"What kind of trouble came out of the case that has given you so much annoyance?"

"These fellows were not satisfied with the way I am running my business. They all came and protested that they had been badly used, but I gave them a piece of my mind. That did not close the matter, for the miserable Brotherhood took it up and threatened to strike unless the men were reinstated without loss of pay. You know that the chairman of our board cares more for Wall street influences than the dignity of his subordinates, and I had to make the best settlement I could."

"Was that the putting of the men back to work?"

"Yes; but give these fellows an inch and they compel an ell. They put a toil to that part of the settlement and said that since they were about it they must have an agreement that men shall not be suspended without investigation."

"Don't you think that is fair?"

"No; it's an imposition. Something must be done to prevent labor organizations from interfering with the management of railroads. The country is going to ruin anyway, but a little good management could save it."

"What would you propose doing, Mr. Wartmouth?"

"I am not ready to announce my plan just yet. We must arrange it so that men cannot strike on the least provocation without being losers themselves. I have a scheme of a mutual benevolent association, into which every employé must pay so much a month. He will be cared for during sickness and will receive a pension after so many years' service. That would make the men interested in the welfare of the company, and is my remedy against strikes."

"How do you think treating the men fairly all the time would work? Take care, for instance, not to punish a man unless he deserves it, and you will have no trouble."

"Why, Short, you must be turning Socialist. You know that no men could be better treated than those on the N. & Y."

"I don't know anything of the kind. You are accustomed only to seeing things as they are done on your own road. You have your own notions about discipline, and believe that what you think is right must be fair. But I am in the position to compare your ways with the ways of other managers. I know that rewards and punishments have always been given in an indiscriminate fashion under your system, and also know that the road is honeycombed with discontent and disloyalty, although you pay more than roads where men are contented, harmonious and loyal. On roads where this state of good feeling exists, the officers are not constantly on the watch for excuses to punish men. Punishment is looked upon as a necessary evil and never indulged in recklessly. On these roads the officers do not require to sit up nights forming schemes of benevolent associations that will keep their men in subjection. On some of these underpaid roads you could not drive the men into a strike because they realize that the management is treating them as well as circumstances will permit."

"You astonish me, Short. I must look into this thing. No man is more anxious to be fair than I am, but I may have made mistakes. I don't like the way you talk, but you may be right. Good-day, Short; you always liked to make a man feel that he was a ruffian. Don't apologize, for I know you mean to make the case as black as you can. That's all right. I shall specify your goods for the new locomotives."

---

A correspondent writes "J. A. H. I notice you were made a member of the French Society of Inventors and was offered the medal. I was also *offered* the *gilded* medal *for ten dollars*. Men claim distinction in the late war. I claim the distinction of doing the *last work* on the first *Monitor*. It was some work to her turret engine, about two weeks before she was lost. Was detailed from my ship, the new *Ironsides*, for that purpose."

### Local Etiquette.

In some parts of Texas the people are intensely particular about forms of etiquette. There may be rudeness, not to say brutality rampant in some departments of the social fabric, but every white female must be called a "lady." The division superintendent of a certain railroad operating in Texas was looking after the erection of a new depot in a small way town and through ignorance of the social rules of the place he put the word "women" on the lavatory of the ladies' waiting-room. Now these natives were as touchy about the significance of the word "woman" as was Mr. Bardell in the famous case Bardell vs. Pickwick. A deputation of citizens immediately waited upon the superintendent and requested that the offending word be changed to "ladies." The superintendent was from the North and was obstinate. He intimated that the building belonged to the railroad company and he had the right to put anything on it that he pleased. The following day another department waited upon the superintendent provided with a rope and other conveniences for giving offenders against the habits of the place short shrift. They invited the superintendent in their most cordial fashion to accompany them to a convenient telegraph pole and form the principal figure in an act that was popular in the region. The superintendent was now ready to come to terms. The terms offered were that he decorate the telegraph pole or quit the country. He went North and stood not on the order of his going.

### A Hose on Wheels.

In a French engine-house I watched a little, bow-legged boiler-washer walk off eighty or a hundred feet with his hose following him, and he did it so easily as to call to my mind the picture of our boiler-washers pulling and dragging a 3-inch rubber hose on the floor.

The French hose was made of 8 or 10-foot sections of 2½-inch pipe mounted on casters, as shown in sketch; these pipes were connected by pieces of leather hose 1 foot long, the nozzle end of the line having 12 or 14 feet of hose. I have given the dimensions of the wood-carrier and casters; the block has to be long enough to

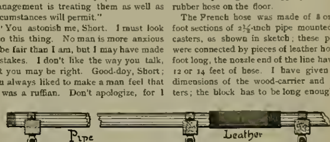


Fig 1.

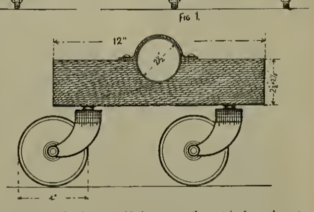

prevent the cart it forms from tipping over every time it makes a turn.

It is remarkable how much of this kind of hose a man can pull around, and how it must last as compared to rubber hose dragged over the pits, scrap-iron, etc.

On the asphalt streets of Paris a hose of this kind is used to sprinkle with, and each section of the street is cared for by a man who sprinkles all the time. There are lots of places in our shops where this little kink could be used to advantage.

J. A. H.

---

G. H. Fairchild, engineer of the N. P., has been promoted to the position of road foreman of engines.

### Improved Brake Apparatus.

The Westinghouse Air-Brake Company have effected improvements on several of the brake appliances. We illustrate the new air-pump, engineer's brake and equalizing valves and the governor.

NEW PUMP.

The principal features of this pump, as differing from those of the 8-inch pump, are as follows:

*First*—The 8-inch pump was designed at the time when very much lower steam pressures were used in the boilers than at present, and, in order to insure a sufficient pressure of air at all times, the steam-cylinder was made 8 inches in diameter while the air-cylinder was but 7½ inches, so that the area of the air-piston was only ¾ that of the steam-piston. Since that time, the steam-pressures of all locomotives have been so much increased that, in designing this new pump, the steam and air-pistons are of the same diameter, *i. e.*, 9½ inches each.

*Second*—In order to make the air-valves more accessible, they have all been placed in separate chambers, and to avoid the necessity of carrying a stock of different sized valves, but one valve is used, and all the air-valves are thus interchangeable, the lift of the valves being regulated in such a way as to permit this.

*Third*—The steam-valve gear has heretofore been placed in the steam-cylinder casing, necessitating the removal of several parts in order to get at the steam-valves. In the designing of the new pump, this objection was avoided and the steam-valve gear much simplified by placing it all in the upper cylinder-head in such a manner that the valves could be removed without the removal of the head; or the entire valve gear may be taken off by removing the upper cylinder-head and put into repair without removing the pump from the engine or disconnecting the steam and air-pipes, as has been necessary with the former pumps. The same form of reversing valve, No. 72, is employed as formerly. The valve controlling the admission of steam to the steam-cylinder of the pump, is now also a slide-valve (No. 83) which is operated by the differential pistons 77 and 79. Steam enters directly between these pistons, forcing them to the position shown. The pump piston then rises until the washer, 69, strikes the shoulder, *j*, of the reversing stem, when it moves the reversing-valve, 72, upward, admitting steam through the passages, *s* and *g*, to the chamber, *D*, at the right of the piston, 77.

Chamber *E* is always in communication with the exhaust passage. Piston 77, then having steam pressure on both sides, and piston 79 having steam pressure on the right side only, the differential pistons move to the left, carrying the slide-valve, 83, with them and thus reversing the pump. The piston then moves down until the washer, 69, reaches the button at the lower end of the reversing-valve stem, carrying the reversing-valve down to its present position, where the steam is exhausted from the chamber *D*, and causing the differential pistons to move back again to the position shown in cut.

The advantages claimed are, briefly, simplicity of construction, greater accessibility of both air and steam-valves, greater ease for repairs and an increased capacity for furnishing air, of about 60 per cent over that of the 8-inch pump in the same length of time.

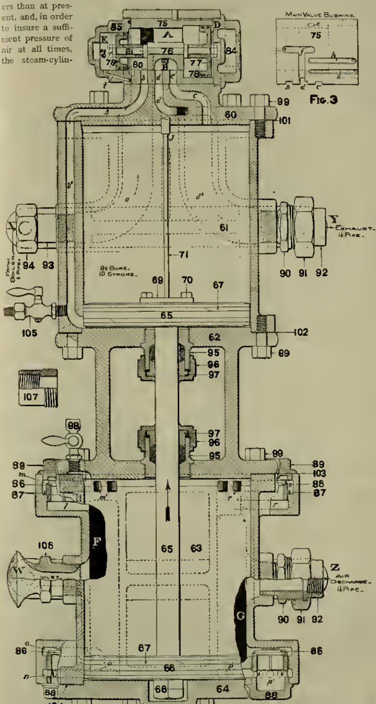

Fig. 1

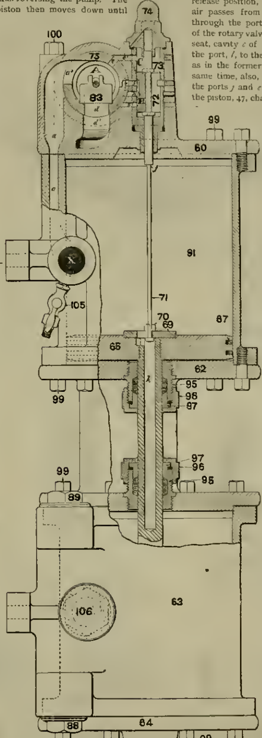

Fig. 2

IMPROVED ENGINEER'S BRAKE AND EQUALIZING DISCHARGE VALVE.

Several advantages are claimed for this valve. Its operation is, generally speaking, the same as that of the former construction, and the construction of all that portion shown in the lower case, 34, is unchanged, the piston, 47, and its functions remaining the same.

In the operation of this valve the brakes are released by placing the handle in the release position, No. 1, by which the air passes from the main reservoir, through the port *A*, the supply port *a* of the rotary valve, cavity *b* of the valve seat, cavity *c* of the valve (Fig. 4), and the port, *l*, to the train pipe—the same as in the former construction. At the same time, also, the air passes through the ports *j* and *e* to the chamber above the piston, 47, charging the small reservoir connected thereto.

When the handle is brought to the running position, air passes to the train pipe, from the main reservoir, only through the port *j*, the port *f* (Fig. 3), under the valve 63 and thence, by the dotted feed port *i* (Fig. 2) to the port *l* leading to the train-pipe.

When the pressure in the train-pipe has attained the maximum (70 pounds), such pressure upon the upper face of the diaphragm 72 (Fig. 3) forces the piston, 66, downward, compressing the spring, 68, and allowing the valve, 63, to seat itself and prevent further passage of air from the main reservoir to the train-pipe. The other functions, of applying the brake, both for service and emergency stops, are precisely the same as with the older form of construction.

The essential difference between the operation of this improved valve and the old one is the use of the feed-valve attachment, consisting of the valve 63, piston 66, spring 68, and diaphragm 72, instead of the excess-pressure valve formerly used and shown as it may be attached to this style of construction (instead of the feed-valve) in Fig. 5.

It will be observed, therefore, that the only difference in the operation of the two valves is when the handle is in the running position. With the old valve, when the handle was placed in the running position, after having been in the release position, the air could not flow to the train-pipe from the main reservoir until the pressure in the latter had become greater than that in the train-pipe, by such an amount as is necessary to open the excess-pressure valve 77 against the spring 79. This spring was so adjusted as to require a pressure in the main reservoir about 20 pounds in excess of that in the train-pipe. The objection to this form was that upon long trains the brakes of the forward cars

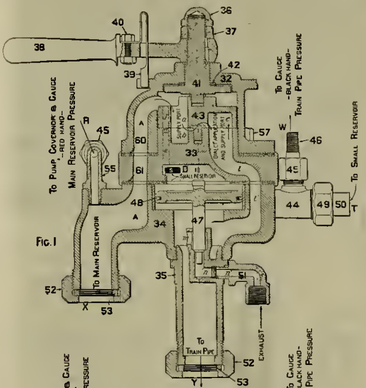
might apply slightly upon the removal of the handle from the release position to the running position. This is due to the fact that, in releasing the brakes and recharging the auxiliary reservoirs throughout the train, the friction which the train-pipe presents to the flow of air through it is not inconsiderable, and also to the fact that the recharging of the reservoirs, at the forward end of the train, is reducing the supply of air in the train-pipe as it passes toward the rear end of the train. The result was that the pressure at the rear end of the train-pipe was somewhat lower, at such times, than at the forward end of the train-pipe, especially upon long trains. When, now, the handle of the brake-valve is then brought to the running position, the train-pipe is cut off from communication with the main reservoir until the excess pressure is pumped up; in the meantime the air pressure in the train-pipe becomes equalized, feeding into the auxiliary reservoirs at the rear end of the train, until the train-pipe pressure is below that of the forward auxiliary reservoirs, thus causing the brakes to apply at the forward end of the train. The construction of the feed-valve attachment is such as to obviate this difficulty.

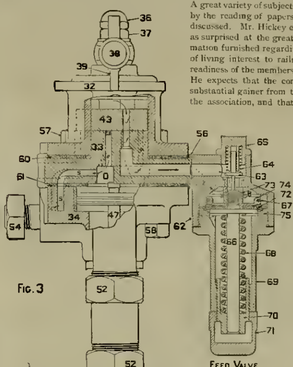
When the handle of the engineer's valve is brought to the running position, the air of the main reservoir has still access to the train-pipe through the feed-valve, 63, which is held open by the spring, 68, and thus the train-pipe is supplied with air until the pressure reaches 70 pounds, when the feed-valve gradually closes, so that equalization throughout the train-pipe takes place before the feed-valve is fully closed.

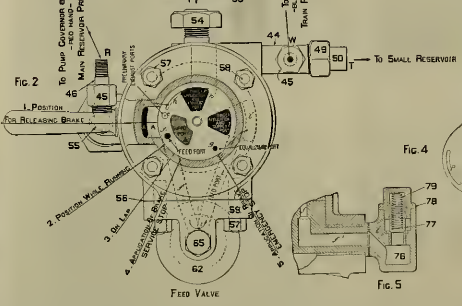
The new construction, therefore, removes the source of the only legitimate excuse for the very bad and too largely prevailing habit of leaving the handle in the release position while running. A small port, not shown in the drawings, is now also provided, so that, when the handle is placed in the release position, there is a small escape of air, producing a hissing sound, which calls the engineer's attention to his negligence to return the handle to the running position. The noise from this warning port will be a sufficient reminder to the engineer who is simply neglectful, and will make it disagreeable for the engineer who insists upon leaving the handle in the release position, in violation of his instructions.

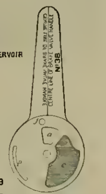
The advantages in construction are as follows. The case of the engineer's valve, instead of being made in two pieces, with a cap screwing in at the top, as formerly, is now made in three parts. The lower part, 34, has all the pipe connections, so that the valve may be easily taken apart and cleaned without disconnecting the lower case, 34, from its fastening, or disconnecting any of the pipes, also, the upper portion of the case, 32, may be removed, leaving the portion 33 exposed, and thus offering ready access to the seat of the rotary valve, 43. It was, with the old construction, necessary to reach down into the case to scrape this valve-seat, which is now readily accessible; also the valve, 43, is of brass, while the seat, 33, is of cast iron, instead of brass as formerly, so that the wearing surfaces are brass upon cast-iron instead of brass upon brass.

A description of the new pump governor will be given next month. We will say here, however, that, with this new engineer's valve, the governor is connected to the main reservoir, while with the old engineer's valve, with the excess pressure valve, the governor is connected to the train pipe.









Chicago suburban railroads are beginning to experience some of the tribulations that owners of stock in the elevated railroads in New York have suffered for years. The Supreme Court of Illinois has awarded damages to a property owner for the nuisance of noise and smoke caused by the trains of the Chicago, Milwaukee & St. Paul Railroad. There has been no end of fraudulent imposition put upon the New York elevated railroads on this kind of pretense, and we know no way in which a rogue can so successfully steal from railroads. Surface railroads will next become victims.

### Northern Pacific Mechanical Association.

We have been informed by Mr. John Hickey, superintendent of motive power of the Northern Pacific, that a highly useful Mechanical Association has been formed on the Northern Pacific system. The members are composed of master mechanics, master car builders, shop foremen and road foremen of engines. Mr. Hickey had just returned from a meeting of this association held in Tacoma, Wash., and he described it as being as good as the meetings of the Western Railway Club in its best days. The meeting lasted five days. A great variety of subjects were introduced by the reading of papers, and thoroughly discussed. Mr. Hickey expressed himself as surprised at the great amount of information furnished regarding topics that are of living interest to railroad men and the readiness of the members to discuss them. He expects that the company will be a substantial gainer from the work done by the association, and that the benefits will be indirectly shared by the members. There are similar associations on the C., B. & Q. and a few other roads.

We have frequently heard the question asked, during the last few years, What is the use of the Eastern and Western Railroad Associations? The critics keep saying that the associations are sink holes into which the railroad companies throw a great deal of money and receive next to nothing in return. We are not informed of any good that railroad companies have derived from belonging to the associations named, but we have a firm belief that certain men interested in the associations find the connection very comfortable and lucrative.

When sheriffs' officers are after train robbers it is wise not to stand on etiquette in making arrests. The soundness of this advice was illustrated lately in Montana. A sheriff, with a posse, found gambling in a saloon six robbers who had gone through a Great Northern train, and committed other depredations. Instead of overpowering the men and equipping them with handcuffs, the sheriff began reading a warrant for the arrest of the robbers. Instead of quietly yielding the robbers jumped for their rifles, and the sheriff's posse was at once the pursued instead of pursuers.

The lighting of railroad cars with Pintsch gas is making very rapid progress. It is the cleanest, clearest and safest method of lighting cars that seems practicable, and it is highly popular with the people who ride in railroad trains. Within the last few months new plants for the manufacture of Pintsch gas have been established at Kansas City, Council Bluffs, Chattanooga, Philadelphia, Toledo and Buffalo. This indicates that railroad managers are abandoning the dangerous oil lamps as fast as they can.

*The Railway Carmen's Journal*, official organ of the Brotherhood of Railway Carmen, has gone into magazine form. It looks much like the *Firemen's Magazine*, and is a big improvement over its former self. It is printed at Minneapolis, Minn.

# Car Shops and Car Builders.

### A Long Freight Car.

The engraving shown herewith is from a photograph of a 60-foot freight car, one of an order recently turned out by the Mt. Vernon Car Manufacturing Co. of Mt. Vernon, Ill., for the American Car Co. of St Louis, builders of street cars.

This is a very strong car despite its great length; it has 20-inch sills and stiffened by eight 1¼-inch truss-rods.

As it will be used for carrying empty street cars there is not much danger of overloading.

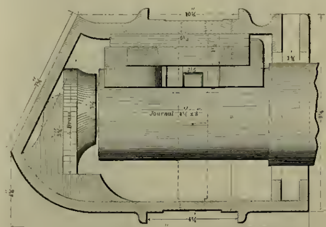
### New Draft Timber Arrangement.

The sketch shown herewith illustrates a form of draft timber recently patented by the firm of Rover & Rover, of Lima, O.

As will be seen, no bolts are required to secure draft timbers to car body.

With this plan of draft timber a broken draft gear can be taken out of a loaded car without any trouble, as all the nuts are where they can be reached.

The device has been in use some time on the C., H. & D. road.



### Colorado Midland Oil Box.

The annexed engraving shows the form of axle-box designed by Mr. A. L. Humphrey, master mechanic of the Colorado Midland, and used very successfully on the cars and tenders of that road. The Colorado Midland is about the crookedest railroad on this continent, and the cars are a great part of the time running on such a steep angle that collars cut with amazing rapidity and cause no end of annoyance from heating. The ordinary end-stops in use were too weak to stand the heavy thrusts put upon them on sharp curves, and Mr. Humphrey devised the form shown, which proved a perfect success. It is a simple form of stop, easily made and very durable.

### Philosophy on a Car's Running Gear.

In giving testimony in a law-suit at Cincinnati involving patents on electric motors, James W. See, the well-known engineering expert, author of Chordal's Letters, gave the clearest evidence we have ever seen of the operation of an electric motor. In the course of his evidence he thus describes the relation between a car and its running gear

"The two axles of a car must be capable of all manner of motions with reference to each other. As a car rounds a curve, the two axles must tend to take a position somewhat radial to the curve instead of parallel to each other. Railroad tracks are never in a true plane, and the action of the two axles with reference to each other as the car proceeds over the inequalities of the track, is as if two mighty giants, each at one end of the car, were seeking to twist the car into the form of a rope. The movements of the car axles are small, but of almost irresistible power. If the two axles of a car were mounted unyieldingly with reference to each other, the car would be hammered out of shape, past all possibility of maintenance. Therefore the two axles of a car are always arranged for perfect freedom of motion with reference to each other, and care is taken that the rigidity of the car body shall not negative the desired condition."

### Playing with Fire.

The excitement that existed a few years ago in regard to the danger of cars getting set on fire in railroad accidents and burning up the passengers stimulated railroad companies to adopt safe methods of car-heating, and all first-class railroad companies have now adopted steam or hot water for the purpose filled by the cast-iron stove only a short time ago. This change has made railroad travel decidedly safer, and the agitation has effected a reformation that might never have come had the railroad companies been left to follow the bent of their own inclinations.

One of the most horrible accidents that can be conceived is the burning up of shattered cars and the cremating of unfortunate human beings, dead and alive, trapped in the debris. The winter months, when accidents are most common and when the causes of fires are most actively in operation, naturally turn our attention to the sources of danger which are still present in passenger cars. Traveling will not be so safe as the public reasonably requires as long as lamps with huge fountains filled with highly inflammable oil are hung in the middle of the cars. Many persons whose views are entitled to consideration and respect maintain that the oil lamp has always been more dangerous than the stoves that are now so rapidly disappearing.

It is certain that the mineral oil sprinkled over the splintered wood-work of cars has done much to quicken the conflagrations that followed numerous collisions made celebrated by their fatal records. While the stove was there to start the fire, little blame was directed to the lamp that fed the flames. A change has taken place now and the lamp will have to bear its own blame when a cause for reproach comes round. If new lessons are needed to place before railroad managers the lamp in its true and dangerous light, we hope that the lesson will not be pressed in the emphatic fashion that the lesson of the car stove was put upon railroad men and travelers alike.

When the dangers of the car stove were under discussion and the agitation was going on for a change, we noticed that railroad companies generally abandoned the dangerous practice of packing the opening between the timbers with shavings, and that mineral wool and other non-combustible materials were specified for that purpose. We regret to notice that in some specifications lately sent out for new cars the safe material is not mentioned, and car builders are left to apply what they choose. This, of course, will be cheap inflammable material. It looks as if some railroad companies would never profit by experience.

### How I Lay out Boiler Work.

BY JAMES HERON.

Figs. 21 and 22—*A* shows how to lay out dome, when placed on one side of boiler; the sheet-iron worker is often called on to make a piece like this. Draw the radius of the boiler or pipe, as the case may be; describe the diameter of dome in the required position; describe the semi-circle with radius of dome; divide semi-circle into any number of equal parts—I use eight parts—square lines down from points of division. I never use a square, but put small center marks at points of division on semi-circle and take distance of spaces with compass and transfer distance found to line marked *H* 8, working both ways

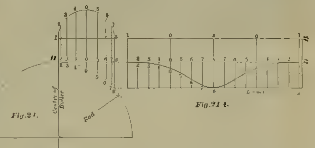


Fig. 21. Fig. 21 A.

from center of dome; then strike lines with short straight-edge, cutting all lines to radius of boiler. Now, take the plate of which dome is to be formed as Fig. 21 *A* and square plate to length required, allowing for laps at ends of plates. Strike a line the full length of sheet; distance from top of sheet must be the same as from 1 to *H* or 8 to 8, Fig. 21, and as at *BB* Fig. 21 *A*. Divide plate into four equal parts from center of holes at ends of plate, quarters are marked 1 0 8 0 1. Divide quarter into same number of parts as shown on semi-circle, Fig. 21 Now, by setting your compass at points marked 8–8, 7–7, 6–6, etc., and transferring lengths found at these points on Fig. 21 to points with corresponding numbers Fig. 21 *A*, or flat plate; this will give you your line of curvature. You must now allow for flange and your job is complete The rule to lay out Figs. 21 and 22 is the same as shown in last paper, Fig. 18 and 19, and I would not have gone into such lengthy details but I got mixed up in numbering the pages in last paper and got the cart before the horse. Note where it reads, "Now roll up a plate to form a dome with all edges square with each other, and put it on top of boiler." Now comes the mistake. To

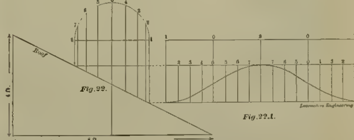

Fig. 22. Fig. 22 A.

make this read properly you must go down the column to where it reads, "square sheet at center of boiler, plumb the sides, etc.," and you will solve the mystery.

Figs. 22 and 22 *A* are the methods I use for laying out jack for roof or man-hole on sloping water tank.

The general railway agents of Lukens Iron and Steel Co., Messrs. Coolbaugh & Pomeroy, report a steadily increasing railway trade. The Penna. R. R. have been furnished steel by this company for twenty-five engines. It is also specified on the seven Fitchburg engines building by the Rhode Island Locomotive Works. Orders have recently been booked from several new roads. There are forty-one roads using this material.

# ? A. What You Want to Know. ? A.

**Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.**

(1) J. J. T., Buffalo, N. Y., writes

Please say in your next number how much the slide-valve of a perfect engine will move by throwing the reverse lever from full gear forward to full gear backward when the engine is on the dead center? *A.*—It will not move at all.

(2) Apprentice, Huntington, Ind., writes

Suppose an engine runs 400 revolutions per minute and you want your main shaft to run 120 revolutions. Please give rule for size of pulleys. *A.*—We answered this question from the same man on page 339 of last year's paper.

(3) B. P., St. Louis, Mo., writes

In a book that I was reading lately mention was made of the Le Chatelier brake as if it were a successful thing. Where is the brake in use, and who was the inventor? *A.*—Le Chatelier brake is the water-brake in use on some of our mountain roads. The inventor was a French scientist.

(4) M. A. S., Milwaukee, Wis., asks:

How is the horse power of a revolving shaft measured? A transmits power to a shop by a cable, and there is a question of how much power is transmitted. *A.*—The best way to measure the power is by using a Prony brake. This is a device which is clamped to the shaft and shows by a lever and weight how much power there is exerted in revolving the shaft.

(5) R. M. Y., Elizabeth, N. J., writes

I find that some locomotives have the rocker arm made with one end out of line with the other. I see no sense in the thing; why not make the two arms in line? *A.*—The offset is on the lower arm, and is made to put the lower arm at right angles to the center line of motion. The adjustment of the valve-gear requires this arrangement in some engines.

(6) L., Chicago:

Asks a variety of questions mostly relating to the proper procedure with compound locomotives in cases of failure. *A.*—We have repeatedly given notice that we will not answer communications that have not the name and address of the sender. The names are held confidential, but we must receive them. People who write anonymous letters do not deserve attention.

(7) Learner, Sioux City, Ia., says

I should like to get a plain definition of a heat unit on a practical basis. *A.*—A heat unit is the amount of heat required to raise one pound of water at its greatest density one degree Fahrenheit. If you light a spirit lamp and put it under a glass flask containing one pound of water, and it is found that the temperature of the water is raised five degrees Fahrenheit every minute, the lamp has practically a capacity of five heat-units.

(8) L. W. T., Nashua, N. H., says

Suppose an engine stood on the forward center with the steam-chest off, and the valve showed a port opening of $\frac{1}{16}$-inch. Now, if I file off $\frac{1}{16}$ more, not moving anything, and I do the same thing on the other end, and afterward move the eccentrics to give the engine the original $\frac{1}{16}$-inch lead, what will the effect of the change be? *A.*—You have reduced the outside lap $\frac{1}{16}$-inch, which will slightly reduce the scope of the engine for working steam expansively.

(9) Mr. G. A. Griffin, Biddeford, Me., asks:

How the air-gauge is arranged for the black hand to show one pressure and red one another, and this with one pipe. I have "Sinclair's Locomotive Engine Running and Management" and "Forney's Catechism," but cannot find it in either? *A.*—There are two gauges in one case and a pipe to each.

(10) M., Frankfort, N. Y., writes:

1. Will you inform me if there is a rule for locating the pin of the link-saddle, or must we cut and try? *A.*—There is no rule. When the motion is laid down on the drawing-board the proper point of suspension for the link is found by trial. 2. Why will an injector not throw water against its own pressure of steam when the water is below the check? *A.*—The injector will throw water against the pressure of steam when the water is below the check. That it will not do so is a common delusion.

(11) A. B., Sydney, N. S. W., says:

1. What lubricating oil is mostly used in the United States? *A.*—Mineral. 2. How is it applied, by worsted trimmings or needle feed-cups? *A.*—Needle feed-cups. 3. What is the Beaumé scale? *A.*—This question was answered in LOCOMOTIVE ENGINEERING a year ago as follows: The gravity or weight of oil is reckoned by the Beaumé scale. In this water is put down as 1, and as all oils are lighter than this, their specific gravity is a decimal of 1. Oil of 32° gravity has a specific gravity of .8641 as compared with water. The degrees are established arbitrarily.

(12) W. O. M., Chicago, asks:

Can you give me a short rule for calculating the weight on the drivers of an eight-wheel American engine? I don't mean the weight necessary for a given size cylinder, wheel, etc., but when certain dimensions are given on a drawing how to find how much weight the engine has. You understand, the weights now-a-days are somewhat in excess of what is absolutely necessary to keep the drivers from slipping under ordinary circumstances. *A.*—There can be no *rule* for guessing at the weight on drivers of a locomotive. The usual practice in eight-wheeled engines is to put about two-thirds of the weight of the engine on her drivers. We do not know that the last statement is true.

(13) D. O'B., Mancelona, Mich., writes:

Being a constant reader of your most valuable paper, I concluded to ask for information through your columns. 1. Why is it that steam of 150 pounds pressure, when cut off very early in the cylinder, does not expand enough to fill the cylinder and destroy the vacuum when it is claimed to have a volume of 169 times that of the water from which it is made. *A.*—If you mean locomotive practice, there is no vacuum to destroy. If you mean a condensing engine, the vacuum is on the opposite side of the piston from the entering steam—in other words, the exhaust is open to the condenser instead of the atmosphere. 2. What is the cause of drumming in an locomotive? *A.*—Believed to be caused by miniature explosions in the fire-box, when the conditions are exactly right for it—the supply of air, etc. Nothing very accurate known about it.

(14) C. H. M., Joliet, Ill., writes

I have been trying to study out the working of compound engines and I can not get it through my head how they work. If you exhaust steam from cylinder *A* into cylinder *B*, the back pressure will be sufficient to obstruct the piston in *A* cylinder to the extent of the positive work done on the piston of *B* cylinder. Where is the gain? *A.*—The piston in the low-pressure cylinder has from two to three times the area of the piston in the high-pressure cylinder, which permits the exhaust steam to perform a margin of useful work after the drawback of back pressure is considered. For instance: The high-pressure cylinder exhausts steam at 90 pounds. The area of the high-pressure piston is 314 square inches, so we have $90 \times 314 = 28,260$ pounds pressure against the piston. The low-pressure piston has an area of 707 square inches. Then $90 \times 707 = 63,630$, the positive work done by the low-pressure piston, giving a margin of 35,370 pounds after the amount of back pressure is deducted.

(15) A. E. H., San Marcial, N. M., asks:

1. Can or cannot the brakes be released on a train when the 10-pound pressure cock or retaining-valve is in use? *A.*—No. The brake can be released *except* the 10-pounds which the pressure retaining-valve prevents from getting out. 2. After making a service application of the new W. A. B. engineer's valve, what effect does it have to place the valve around to emergency, say when having used 10 or 12 pounds at service application, and why does it have the effect? *A.*—The only usual result is to apply the brakes full. Sometimes the emergency will work, but if the application is made before the pressure in the brake-pipe is nearly restored the service application with a 12-pound reduction will have used so much air from the auxiliary that the further reduction will not move the piston of the emergency-valve. 3. What is the difference between a direct and indirect engine—I mean engine, not valve motion? *A.*—An indirect engine would be one not connected directly from the cylinder to the crank—one with a rocker, for instance, like the recent engines built for Pike's Peak. 4. Where is the center of motion of a locomotive? I do not mean the center line of motion we hear so much about. Also, where is the center of motion of a stationary and the center of power of each when working? *A.*—We don't know what you mean by center of motion. We should say that the center of *power* was in the boiler.

## Bad Feed Water.

The cause of the deplorable condition of the water supply of many railroads is very plainly set forth by Mr. William McIntosh in a paper read before the Northwestern Railroad Club. He said:

"During the construction period water syphoned from a slough or borrow pit is regarded as all sufficient. As the line progresses permanent water stations are established about every twenty miles, and their location is largely determined by the cheapness by which an abundant supply of water may be obtained regardless of its quality. Deep wells are often sunk at stations which supply water highly charged with incrusting matter, while but a few rods farther on is a running stream of much purer fluid. The expense of pumping the latter to the station would not be thought of, yet the advantage of using the better water might run into thousands in one year. The departments responsible for the establishment of water tanks, wells and reservoirs as a rule have no direct interest in the motive power department, and are apt to think that the best interests of the company are served when a sufficient supply of water is obtained at a nominal outlay. And it is only after the water at a certain point has proved notoriously bad by years of injury to boilers, that the adequate pressure can be brought to bear to effect a change. Those answerable for the maintenance of locomotives in sections where the water is comparatively free from incrusting matter cannot realize the advantages they have over those occupying similar positions in the bad-water regions of the West where the best water contains as much as 2 pounds of incrusting matter per 1,000 gallons, and the poorest as high as 20 pounds. This will give six pounds and 60 pounds per ordinary tank of 3,000 gallons. It was necessary to use the last mentioned water for years before it was possible to provide a better quality."

The remedy proposed by Mr. McIntosh was the well-known methods of feed-water purification, mechanical and chemical.

## Dressing Cold Chisels.

BY OLD JOUR.

In your November number I saw an article on "Tool Steel, Smith and User." Two machinists bring one chisel each, and the tool-smith dresses and tempers them carefully, but he makes a distinction in the temper—he forecasts the users. One chisel is tempered to a purple, or a dark straw, the other is left a low blue. Both men work on the same class of work, with very different results.

The two machinists, I think you will find, grind their chisels like the accompanying sketch. The machinist who cannot get a chisel dressed to suit him grinds his chisel a little concave, which is a common way for such men to grind them. He strikes the chisel one or more blows with the hammer. Both corners are gone off the chisel. He concludes at once that it is the tool-dresser that is at fault. The other machinist grinds his chisel a little convex. The strain on his chisel is al-

ways toward the center of the chisel. He can chip with it all day. The tool-dresser can dress a chisel for the last-named machinist, but there is no tool-dresser this side the Golden Gate can dress a chisel for the concave chisel grinder and expect it to last more than three or four blows.

We have received from the Consolidated Car Heating Company, Albany, N. Y., part 4, which is the first issued, of their new catalogue. It deals principally with the multiple circuit system of car-heating, and is an excellent treatise on that subject, well illustrated. This catalogue, when completed, will form an exhaustive compendium on car-heating. The many men interested in the care and handling of car-heating apparatus will find this catalogue a most useful object of study, not only for details of special apparatus, but of the broad principles on which the successful system of car-heating are founded. The catalogue can be obtained free on application to the company.

We have received the Columbia Desk Calendar for 1893; it is a very neat and handy affair, having a memoranda for each day; it sells for 20 cents, and can be had of the Pope Manufacturing Company, Boston, Mass.

### A Real Telescope.

Once upon a time a consolidation and a mogul met "by chance," and the mogul being slightly the smaller of the two shoved her front end inside that of the larger engine.

The pilots, buffers, front frames, cylinders, etc., were crushed, and the two big shells shoved together in the manner shown. So well was this job done that they could not be pulled apart, and were actually hauled to the shops in this firm embrace.

A REAL TELESCOPE.

A local poet thummed the following verse (after Tennyson) on the dust of one of the jackets.

> "They met as friends who meet in pain,
> And, meeting, hope to part again."

### Promotion by Seniority.

A correspondent on the Pacific coast writes us:

A line or so in the September number of LOCOMOTIVE ENGINEERING attracted my attention. It related to the promotion of firemen according to seniority, and the resulting consequences as seen by an S. P. fireman. Well, he is partly right and partly wrong. The rule of seniority is strictly enforced on this road—by agreement with the Brotherhoods. The same rule prevails on all far western roads, not by any means from the desire of the companies. Promotion according to time of employment, in any given service on any particular division, is strenuously insisted upon by all the Orders. I know one case where a strike was barely averted because a proposed schedule said promotions should be made "according to seniority, *with the approval* of the *master mechanic*." This final clause was looked upon as a loop-hole for favoritism. In another case the schedule read, "Promotion shall be according to seniority, other things being equal." The latter phrase was always a dead letter. In still another case a deputation of "old" men in the service of the company went to the general manager's office with a request for the discharge of "new" men during the dull season. To the spokesman of the party the manager expressed surprise. "If you don't want to work, why don't you quit? Why do you want me to discharge you?"

"I don't. I want the 'new' men laid off. I've worked for the company five years."

"Oh, yes," said the manager, "on the southern division, but you have been *transferred* to this northern division since these other men were hired. According to the schedule, you are the youngest man on this division." The new men weren't "laid off" that time.

The men argue clamorously that absolute seniority, without exception or limitation, is their only protection against partiality and "pulls." However, I notice that when a director's relatives are promoted over their heads, they generally submit to the inevitable.

On the other hand, master mechanics and superintendents, at least so far as my knowledge goes, are strongly in favor of some sensible limitations of the "seniority rule." They are willing to submit to some restriction of their own authority, but they point to long lists of cases where rigid insistence on the rights of the "oldest" man had a disastrous or ridiculous ending.

I would not like to subscribe to all the complaints your correspondent may have made about promoted firemen on the S. P., for that company has been in the business for twenty years or more, and some of its oldest and best men were "made" here. Seniority does not put the worst men always at the head of the list.

We had a funny illustration here of the "rights" question. After eight years' service on the S. P., an engineer quit (not by request) on account of his health and went North, where he "ran" most of the time on mountain divisions. On returning to the service of the S. P. this fall, he ranked, of course, as a "new" man, and an engineer of *three days'* experience promptly put in a "kick" against the "new" man getting any "rights" over *him*. Now, according to the agreement with the company, this fireman (or engineer?) is perfectly right, but the impartial public is likely to think such agreements detrimental to the service.

I heard an old grievance committee man from the East expound his way of enforcing the rule of seniority. It was a pretty good way for a compromise, too. He said he insisted always on the "oldest" man being given a fair trial, then the master mechanic's man; a comparison of results to decide, and the best man to take the run.

---

The East Tennessee, Virginia & Georgia people have converted one of their consolidated engines into a compound of the Pitkin type. The engine has cylinders 20 and 30x24 inches. One of their ten-wheelers is in the shops undergoing the change to the compound pattern. This engine had cylinders 19x24 inches and the only change to be made is putting a 28-inch cylinder on one side and adding the intercepting valve. Compound locomotives are highly popular on the East Tennessee, Virginia & Georgia and those in use show a decided saving in fuel.

### Improvements at the St. Paul Shops of the C., St. P., M. & O. Ry.

A new carpenter shop and storage room, 50x150 feet, was erected this summer just south of the main machine shop and office building, and an addition of 60x100 ft. made to the boiler shop, as well as ten new stalls being added to the roundhouse, which closes up the circle entirely. All of the above buildings are built substantially of brick, to correspond with the other buildings, all being covered with slate roofs. The boiler and carpenter shops have skylights to add to the numerous windows, which make them rate with the best lighted shops in the country. The power for the carpenter shop is received from the main-line shaft in the machine shop, communicated to a main shaft between both shops. This shaft is supported by an iron truss, 33-ft. span, and is run by a 14-in double belt, which transmits power enough for a circular saw, cut-off saw, dimension planer, band saw, jig saw, mortiser and boring machine, lathe and grindstones. A novel feature of the pattern storage room is the shelving, which runs 20 ft. high, with galleries between the shelves every 7 ft. 6 in., so that any pattern can be reached without the assistance of step-ladders. This room is especially built so that changes in the atmosphere will not affect its contents (which is the great trouble with all pattern rooms) in warping and pulling apart the glue joints. It has an elevator to run the patterns up to the top gallery. The carpenter shop and pattern room is separated by a brick wall with iron door, making pattern room fire-proof.

The boiler shop has an overhead crane which runs over the engine pits, and can lift any of the largest boilers and carry or turn them in any position for working upon. A large reverberatory furnace is built in the new addition, 12x20 ft., so that all boiler sheets can be properly treated after they are finished, to put into their place; a convenient gib crane swings the sheets from the flange fire to the flange-block, or into the furnace.

All the new buildings are heated by the hot-air process, in a convenient place; the exhaust fans and radiators are placed so that the old method of steam-pipes being placed in the pits and around the walls is done away with. A large 35-ft. drop pit has been added to the machine shop that will take in the longest engines with dispatch. All the buildings are lighted mornings and evenings with the Edison incandescent system, and the yard outside is lighted with the arc system, a separate engine furnishes the power for the dynamos. It is anticipated to put a dynamo on the transfer table, and smaller ones in other places, for a cheap and convenient portable power.

All the power at present is centered at the boiler house, where a new 72x16-in. return tubular steel high-pressure boiler has been added. This, like all of the improvements, have been constructed by the company themselves.

SUMMIT OF PIKE'S PEAK—SHOWING IMPROVEMENT ON MODE OF TRANSPORTATION.

### On Top of Pike's Peak.

Our illustration gives a view of the very summit of Pike's Peak, in the Rocky Mountains, showing the government signal station, a pack "burro" and the engine and train of the new rack-rail road.

## Locomotive Running Among the Bushwhackers.

BY OLD SOLDIER.

After pulling General Grant to Nashville I got a couple of days' rest and resumed my old run on passenger without any very serious mishaps. About this time we had some changes in the machinery department, but do not remember the dates. Elijah Benjamin took charge of the motive-power department. He brought Harry Elliott with him as assistant; he also brought Ace Daniels and James McCormick. Daniels and McCormick were made division master mechanics, Daniels being located at Chattanooga and McCormick at Stevison. I think he was sent from there to Huntsville.

I will here have to relate a little story connected with Mr. Elijah Benjamin and myself which occurred in 1859. Mr. Benjamin was then master mechanic of the New Albany & Saline road, which had shops at New Albany, Indiana. E. Brooks at that time was master mechanic of the Ohio & Mississippi road at Cackron, Indiana. I had been working for Mr. Brooks, but hearing so much said about young men learning so fast under Mr. Benjamin at New Albany, I pulled up stakes for New Albany and applied for a job to work under instruction; I got it and went to work for "Ben," as the boys called him. I found my rabbit-foot, and never was there a place where one could learn so fast. M. T. Carson was an apprentice there; he is now superintendent of motive power and machinery of the Mobile & Ohio road and a man of considerable reputation.

After I had been to work for Mr. Benjamin some four or five weeks, I found out they did not have any pay-day but that all men who were discharged could get their pay. Well, I worked along about four months. I had spent all the money I brought with me for board and washing, and tried every way I could think of to get some money, but it could not be done, nor could I sell my time, so one day an idea struck me and as I was a young man I put no particular valuation on my reputation. I had fired three and a half years and had run an engine about a year. I concluded to give up shop work and hunt other fields, and so I carried my plan out and lost the respect of Mr. Benjamin, never thinking I would ever encounter him again in a business way; but, boys, don't any of you do the same thing, but always command the respect of your bosses.

I did nothing very serious, but it was enough to condemn me in the eyes of any master mechanic or foreman. I was working on a little old dome-boiler engine called the "Tippecanoe." She was an old hook engine and had two bearings for her rocker-boxes. She had an outside frame the out end was held in a box with two small brasses I was closing them up by filing them off I had a parallel vise which was quite well worn on the jaws; it would not hold good, so I screwed it up as tight as I could. I then took a big stick for a lever, put it in under the bench and came down on it and broke the brass. I stooped down and picked up the two pieces, stuck them together, looked at them a little, ripped out a big word and threw them through the window. Mr. Benjamin was standing behind me and saw the whole performance. He stepped up, tapped me on the shoulder and told me to go to the office and get my time.

I never expected to see him again after I left Albany, but I did, for he was made master mechanic of the military road where I was a passenger engineer. I was out on the road about seventy-five miles from headquarters when I heard of it. I was a married man then, but I telegraphed in my resignation to him at Nashville; he did not answer me, but came to the depot and met me on the arrival of my train. He came up to the engine and shook hands with me and asked what I meant by that telegram.

I told him I did not want to get discharged, as I knew he could get plenty of men to take my engine.

He said "No, no; I have heard all about you and I feel proud to know you have built up a reputation, and your job is good here."

He then handed me back my telegram and told me to tear it up—and I did, and kept my run. He made no changes in the running department of the roads but did change a good many petty bosses.

As I had been considered a very faithful servant, Mr. Benjamin thought I deserved a better job, so I gave up my run.

The government concluded they would build the Nashville & Northwestern road so as to connect Nashville with the Tennessee river, which was about ninety miles of road. This road was contemplated to be built before the war, and the company had several boat loads of iron at the river end; they intended to build from both ends, so the government carried out this idea. Mr. Benjamin told me I could have the job at $150 a month, so I took the engine and train down the Cumberland River and up the Tennessee River and built up from that end. This iron had been buried by the rebels when they retreated ftom the river. Colonel Floyd, of St. Louis, was sent down ahead of us with his regiment. He was colonel of the first Missouri engineer corps of sappers and miners; he built eighteen miles of this road with his regiment. I ran the engine that did the work. Jack Johnson was the conductor. Wilson Davis and his brother Mike ran the engine and train that built the other end, Bill being conductor and Mike the engineer. In this chapter of my military career I could relate a great many little incidents and scares that happened but it would take up too much valuable space and my time is too much occupied by my old scrap heaps, so I will try and confine myself to the important parts.

A man named Huff was sent down to take my engine and I was ordered back to Nashville. This man Huff had just been on my engine about one hour when he had eleven bullet holes put through him. He was killed on the engine; the bushwhackers made up their minds that we could not run this road; they killed about six engineers and three or four firemen and several train hands before the government got it stopped. Of course many trains were wrecked. I was down there four months building the road and I was only fired into three or four times; my fireman was killed on the engine; he was a colored man that in slave times belonged to the Nashville & Chattanooga road. He went by the name of Bill Marshall. About this time we were ready for the last spike.

I went to Nashville as ordered and reported to Mr Benjamin, master mechanic. He told me to report to Mr. A. Anderson, who was superintendent at this time. Col. D. C McCullom was general manager. Now, some time ago I saw a discussion in your paper about a machine shop at Columbus, Ky., on the Mobile & Ohio road. There was a machine shop there and I here send you a copy of my orders to remove it. I have the order well preserved and can forward it to you if necessary. The order reads like this:

UNITED STATES MILITARY ROADS,
OFFICE OF GENERAL SUPERINTENDENT,
MILITARY DIVISION OF THE MISSISSIPPI.
NASHVILLE, May 26, 1864.

*Mr. Engineer:*

SIR—You will proceed at once to Columbus, Ky., attend to taking down, packing and shipping the engine, shafting and tools in the railroad shops at that place to Nashville. You will come with the articles or send some reliable man in charge. The tools to be brought away are those only which are moved by power; all hand tools will be left. On your return you will report in full what has been done. Inclosed is a copy of an order for the removal of the machinery for the information of those whom it may concern.

Yours respectfully,
(Signed) A. ANDERSON,
*Gen'l Supt. U. S. Govt. Rail Roads, Mil. Division of the Miss.*

This letter with my orders will convince the most skeptical that there existed a machine shop at Columbus, Ky., at this time, because I employed the men working in those shops to pull down the machinery and load it aboard of government transport boats to take it to Cairo, Illinois, then I had it transferred to a packet boat and took it to Nashville, and from Nashville it went to Chattanooga. I took all the men that wanted to go to Nashville. I think they worked about thirty-five or forty men; about one-half of them went to Nashville with me; on my arrival at Nashville, I staid there about one month.

I had orders to report to A. Anderson's office every morning, which I did, but he seemed to have nothing for me to do except running on the road, and I made up my mind I would not go on the road any more as I had been honorably relieved, and I told Mr. Benjamin so. About this time the government located and set up thirteen saw mills at the Tennessee River. The terminal of the Nashville and Northwestern road was call Johnsonville, and it was a great point for distributing supplies to the army of the Cumberland and Tennessee, as the Tennessee River is navigable all the year. A lieutenant by the name of Cherry was put in charge of this post as assistant acting quartermaster. In July, 1864, he came to Nashville and requested me to accept the position of master mechanic. Well, of course he did not have to pull any buttons from my coat to get me to accept it, so I went to Johnsonville and took charge of all saw mills and machinery in the master mechanic's department. We built a warehouse 600 feet long and 400 feet wide for government stores. We had tracks running down to the river and little cars to unload the boats, but we never got it into good operation. I will explain later on why we did not.

Lieutenant Cherry and myself went up to Nashville to get the machinery. They did not run any passenger train on the Nashville and Northwestern road, all the people that travelled on that road had to travel in the caboose and they only ran one train a day each way. Mike Davis pulled one of those trains with his brother Bill as conductor. Mike also ran an eating-house eighteen miles below Nashville; he had stopped off on his up trip at his eating-house and got some one to run his engine to Nashville. The train left there at 7 A. M., but Mike's man failed to put in an appearance, so I was asked to run the eighteen miles, and then Mike was to take her, which he did. Lieutenant Cherry rode on the engine with me to the eating-house and seemed to be overjoyed with his ride. We all went into Mike's house and ate dinner, but do not imagine we had pie and cake or that we lingered long eating fruit or cracking nuts. Mike told us that beans and salt pork were good enough for people traveling in those times.

After we finished eating we all got on board and started for Johnsonville; all of us reached there except Lieutenant Cherry. When we came out of the eating-house, Mike asked me to come on the engine as he wanted to talk with me, so Lieutenant Cherry went back in the caboose. There were a couple of ladies in there and one of them had a six-months-old baby. Captain Coleman, Lieutenant Tanner and Lieutenant James Newhart and Private Fredmann were in the caboose. About fifty boxes of cartridges were in it, and the tops of the box cars were full of private soldiers. Everything went smooth until we got eleven miles from Johnsonville, I was sitting behind Mike, on his side, when I felt the train jerk; we had about thirteen cars. I looked back and saw the cars turning over and soldiers and guns flying in the air in all directions. I hollered to Mike to shut her off for God's sake and to reverse; we were making about twelve or fifteen miles an hour. I jumped off the engine and ran back; the first sight that met my eye was Lieutenant Cherry laying on the dump with the upper part of a side-door frame holding him down. He was a portly man; he was literally cut in two about the center of his body; I grabbed and raised his head, he tried to look up but could not, and only said, "Oh! my poor family!"—the last words he ever spoke. The two ladies and baby were unhurt, but one of the ladies had her dress nearly torn off. Captain Coleman was seriously hurt; his collar bone and three ribs were broken. Lieutenants Tanner and Newhart and private Fredmann and about twenty-five or thirty soldiers were badly hurt. When the end door was opened the little baby was lying down in the lower corner of the car on its little back, kicking up its heels and laughing as loud as it could. We had to pry up the car to get Lieutenant Cherry out. Nothing but the flesh held the two parts together as his back was broken.

That was a horrible sight to witness, but as this was only one among the many I had to see I could well stand it.

This car wreck was caused by the car next to the caboose dropping a brake beam which threw the caboose off on a fill, and it turned over and carried five other cars with it before we could stop. We gathered up the dead and wounded and took them to Johnsonville.

Captain B. F. Coleman was post commander at Johnsonville, and Lieutenant Cherry was post assistant acting quartermaster, so I was left without a boss until such time as they could send a man. I carried out the work as we had planned it, and it seemed to please all who had any connection with it, but it never did the government any good, for about the time we got it completed the Johnnies came in and whipped us out, burned down the warehouse after we had laid up about $100,000 worth of army stores, and now comes a pretty hard yarn for some of my Yankee brothers to swallow, but nevertheless it is true.

We had about 2,000 men at Johnsonville, and three gunboats, seven transports, and five canal boats for Chicago loaded with pork. The rebels came in there one night about 800 strong, with some six-pound cannon, and cleaned us out. We had one regiment of colored soldiers, and this is one time when the colored troops did not fight nobly, but they ran splendidly—you bet they got away that night. Everybody seemed to be on the lookout for himself, so we all got away as fast as we could. Now remember, they captured those three gunboats, burned them up with the seven transports and the government warehouse and all my saw mills, and now you can readily see how this good job of mine went to pieces. I left on the last train. When we were about ten miles from Johnsonville, the engineer, conductor and agent cut the engine loose and left us at this place. I had my wife's little brother with me. I had put him in the caboose and went back to bring some of my effects, which I did not get; this boy was about fourteen years old, but had gone through lots for one of his age. I had to run back to the caboose to catch on; just as I got up in the side door a six-pound cannon ball struck the end of the car, but we were standing on a fill and their battery was on the other shore, so the ball passed up through the roof of the car. I lost my hold and fell. I thought at first I was struck by the ball, but I was not, nor was I hurt; but, oh, Lordy! when I found out that the engine had gone and left those cars my heart went down into my boots. I just bought an old mule and saddle and bridle from an old negro, got my boy on behind, and away we went for Nashville; but in the meantime I saw the engine that had cut loose coming back with three other engines and trains bringing troops to drive the rebels out, which they did.

---

# LOCOMOTIVE ENGINEERING

A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK.

VOL. VI, No. 2. NEW YORK, FEBRUARY, 1893. 20 Cts. Monthly. $2.00 Per Year

## The First Consolidation Locomotive.

The picture here shown was sent to us by a friend of the paper to add to our collection of historical locomotives.

The only remarkable thing about this engine is that she was the first of a class that has since become the most popular locomotive for heavy freight service.

This engine was designed in 1866 by Mr. Alexander Mitchell, now Superintendent of M. P. of the Lehigh Valley Road, then master mechanic of the Lehigh & Mahoning road—now a part of the L. V.—at Delano, Pa. Mr. Mitchell has tried a great many experiments with locomotives, and is the man who first designed the "Decapod," or ten-coupled class.

The name "Consolidation" was suggested by the consolidation of the Lehigh & Mahoning with the Lehigh Valley, that had just then been consummated. Little did her designer think he was naming a class that would be known the world over.

The old half-stroke pump will be a curiosity to many of the younger enginemen, still they are not all extinct yet, and were, all in all, a better pump than those run from the crosshead.

From the original drawings at the Baldwin Works we get the following dimensions, which, for twenty-six years ago, was very large and nearer the present dimensions than any other engine we know of built so long ago.

Boiler, wagon-top, with waist 50 inches diameter.

Firebox, 108 inches long and 34 inches wide; combustion chamber, 16¼ inches long.

One hundred and seventy-nine flues, 2 inches diameter, 11 feet 11 inches long.

Cylinders, 20 x 24 inches.

Driving-wheels, 48½ inches diameter.

Driving-axle journals, main, 6½ x 8 inches; others, 6 x 8 inches.

Feed-water, two iron pumps, and one No. 5 injector.

Engine truck, a Bissell plan, with 30-inch wheels and journals 5 x 8 inches.

Tender, 2,000 gallons capacity, on eight 28-inch wheels, with journals 3¼ x 5½ inches.

The weight was about 90,000 pounds, which is rather light for the class.

THE FIRST CONSOLIDATION LOCOMOTIVE.

## Slamming Car Doors.

The New York, New Haven & Hartford, the Old Colony, and several New England railroad companies are putting automatic door closing devices upon all their passenger cars. This is an improvement which ought to be adopted by all railroad companies. We do not know of a single reform that would conduce so much to the comfort of passengers. The slamming of car doors that goes on in some trains is simply torture to all the passengers who have nerves or ears. In certain kinds of weather every passenger who enters a car takes care to slam the door with all the force possible, and the door crashes like the report of a pistol. We have watched nervous persons sitting near the door who would recoil as if struck with a whip every time the door was slammed. The cost of closing cylinders is trifling and ought to be incurred by every railroad company taking any interest in the comfort of patrons. We should imagine that the outlay would soon be returned by the saving in locks and other fittings that get destroyed prematurely by door-slamming.

## Jim Skeevers as Traveling Engineer.

Bolton, the regular man, took a ninety-days' leave awhile ago to go East, and Jim Skeevers was appointed traveling engineer, *pro tem*.

Skeevers' principal duty seemed to be examining firemen for promotion and going out to buck snow.

They have a new general superintendent and he is a terror on examinations. He ordered all the engineers, old and young, examined on time-card, and if one of them wavered he sent him to the master mechanic for a mechanical examination.

Finally he turned this around and ordered Skeevers to examine all the engineers, and if any of them wavered in the mechanical line to send 'em to him.

The day after the order came out the Stove Committee were discussing it, when Skeevers came through the roundhouse.

"Skinny Skeevers fired for me ten years ago," said Si Lapan, "and I don't guess he'll monkey examining me much." Here he saw Skeevers and continued

"Say, Skinny, do you intend givin' us

old timers the same questions to answer you do these young ducks?"

"Yes What's the use of doing a thing 'less you do it right? If you know the answers better than the young fellows, so much the better for you "

"It's all poppy-cock, ain't I run here twenty years?"

"Yes, but the new management have made many changes and are going to adopt a new book of rules, trains are getting thicker we have some signals we're using joint track, and, all in all, a fellow has to be pretty well posted to keep out of trouble The fault with you old fellows is that you don't keep posted—you learned how once but never kept track of improvements '

"I'll bet you I kin answer more questions than you can, come now."

"Oh, I'm not setting myself up for an example You will pass on your merits no doubt Now there has been two dozen young fellows examined, and the same question is asked 'em all first You don't keep track of the run of things, and I'll bet you can't answer it now "

"Bet you the cigars "

"All right for the crowd, Si "

"For the crowd "

"Well Si What is a time card '

"Oh Lordy What's a time card? Why, wal a time card is a—well, it's the thing to run trains by "

"No it isn't '

"Well it's the thing that tells the first-class and second-class trains apart and which has the right of the road and where to meet and where to stop and when."

"Not much, you're thinking of the book of rules, we're talking about time card only

"Well, it governs the running of trains."

"Say, Si, if you were out here at Dodd's on No 1 and 22 wasn't there, what would you do '

"Go ahead, No 1 has the right "

"Suppose you were on 22 "

"Well, if I couldn't get there, I'd lay back at Somers "

"Yes, but the time card makes you meet No 1 at Dodd's "

"But if you couldn't get there—"

"Then how does it govern the running of trains? The book of rules does that. Si, you don't know Well, I'll tell you, as this is no regular examination. A time card *is a list of the stations and the time at which it is proposed to have the trains arrive at or leave such stations.*

"I smoke *Perfectos*, don't you, boys?"

There is a certain class of men at large who bear the outward stamp of respectability, but are given to habits which unfit them for surroundings more polished than the walls of a back-country barn Such men are sometimes thrown out of their natural sphere far enough to be found riding in sleeping cars instead of hog cars, and then they are a nuisance to all who come near them They chew tobacco and miss the cuspidors when expectorating their cud. They annoint seats and floors with the drippings from their jaws They leave the dirty water in the basin after washing, and they scratch the glossy mahogany panels in lighting matches There ought to be a separate compartment provided for the hog traveler, furnished in rough boards, and carpeted with three inches of sawdust.

The mechanical department of a railroad that intends trying some locomotives with Wootten boilers has proposed that the firebox be changed to the Belpaire form That is, they will use the Wootten to give the great increase of heating surface and grate area and the Belpaire form to strengthen the firebox as a whole. Skillful mechanical engineers are engaged working out the details

Some railroad companies are using a modification of Baird's stay-bolt cutter to good advantage in the cutting up of old cars.

## Biographical Sketch of E. D. Worcester—The Man Who Once Owned the New York Central Railroad.

The annexed engraving is an admirable portrait of Mr E. D. Worcester, Vice-President of the Lake Shore and of the Michigan Central railroads, and an officer of most of the Vanderbilt lines. Mr. Worcester was born at Albany, N. Y., sixty-four years ago, and belongs to a family that came from England to Massachusetts in 1640 His father was a lawyer, and the first work done by the boy was in his father's office, copying law papers. Those were days when American boys had to begin work early, and Mr Worcester was no exception to the rule His father died when he was fourteen years old He knew what work was before that time Then he went into the store of an uncle in Albany The boy had the characteristic American sympathy for me-

E. D. Worcester

Once Owned the New York Central Railroad

chanical pursuits, which was not gratified in his first occupations But the tendencies asserted themselves later, and when he was nineteen years old he entered a foundry and machine shop, to learn the business. Two years later the gold fever of California drew away the manager of the shop, and although he was not yet twenty-one years old, Mr Worcester was put in charge The position was highly responsible, the mechanical and clerical business of the firm falling upon the young manager.

He appears to have gained a high reputation for ability at this early age, for three years later he was appointed discount clerk of the Commercial Bank of Albany. About a year after he accepted this position, Mr Corning, who was the leading railroad magnate of the day, attempted to consolidate a number of small railroads into the New York Central There was no precedent for the organization of large railroad companies, and great difficulty was experienced in putting the affairs in manageable shape Mr Worcester had devoted great attention to accounting, and he was called in by Mr. Corning to put the business of the consolidated company into proper shape, and the work was done satisfactorily. Mr. Worcester, by cautious, tentative efforts, formed the system of railroad accounting now generally in use He was appointed treasurer of the company and was closely associated with the principal railroad men of the time.

From 1853 to 1867 the New York Central had a chequered career, but Mr Worcester held on as treasurer and had unlimited faith in the future value of the property. He displayed his faith by putting his all in the company, and fourteen years after entering the service of the road he was the principal stockholder and was practically owner of the most important railroad in America

As it was highly important that the Central should have part of its stem reaching to New York City, Mr. Worcester in 1867 sold enough of his interest to give Commodore Vanderbilt control of the road. Mr. Vanderbilt was previously the principal owner of the Hudson River road. This connection led Mr. Worcester into very close relations with Commodore Vanderbilt, which continued until the latter died. His relations with the son and the grandsons of the old railroad magnate have been the ties of friendship and personal regard united to business interests

Mr. Worcester took a leading part in carrying out all the most stupendous financial operations performed for the New York Central & Hudson River Railroad. He conducted the negotiations with the government that resulted in putting on the first special train for mails between New York and Chicago, and went to Cleveland practically in charge of the first train.

The present agitation for improved rapid transit in New York City recalls similar agitation twenty years ago. In 1872, the New York Legislature having granted to Commodore Vanderbilt a charter for the construction of an underground railroad from City Hall to the Grand Central station, the details of the enterprise were put in Mr Worcester's charge and he devoted years to the work. Local opposition, and the terror so marked among the politicians of New York City that a corporation might receive benefit from the enterprise, prevented the scheme from being carried out although it had been the Commodore's expressed intention to present the plant to the city when completed.

Mr. Worcester is a thoroughly representative American. He has risen to fame and fortune by his own unaided exertions His success in life has been achieved by the means which every young man ought to emulate. His methods have been industry and strict integrity guided by sagacity, foresight and keen intelligence What he has done is within the reach of every young man in this country who starts in life with the same natural qualifications and directs them to the attainment of the same high aims. He is to-day an active, vigorous gentleman, with beautifully clear complexion and bright blue eyes. He takes a very warm interest in mechanical matters, and is always ready to discuss railroad machinery of the most modern type, or to give reminiscences of the forms in use when the railroad age was in its infancy

## Death of Isaac Dripps.

Isaac Dripps, the man who first bore the title of Superintendent of Motive Power on an American railroad, died in Philadelphia on December 28th.

A portrait with a sketch of this old veteran's life appeared in this paper for January, 1892.

Mr. Dripps was born at Belfast, Ireland on April 17, 1810. He was the first man to run the "John Bull," the first engine to go into regular service in this country. He made the first single propeller for steam boats. He built the first diamond truck for freight cars, and was the first master mechanic in the country.

Long years ago, when Mr. Dripps went out to Fort Wayne, Ind., to take charge of the motive power of the P., Ft. W & C road J. N. Du Barry, late fourth Vice-President of the P. R. R., was employed as assistant superintendent, and H. Stanley Goodwin, late General Superintendent of the Lehigh Valley, was resident engineer of the line. These three men were the heads of their respective departments and stayed to see the road become one of the principal lines in the country. It seems remarkable that all of these men died within ten days of each other. Mr. Du Barry, who was born at Bordentown, N J and was but eleven years old when Isaac Dripps ran the "John Bull" on her first trip in that town, died on the 17th, Mr Goodwin on the 25th, and Mr. Dripps on the 28th.

If there ever lived a railroad mechanic in America who deserved a monument, that man was Isaac Dripps.

A company has been formed at South Bend, Ind., for the purpose of manufacturing locomotive whistles of a novel and unique design, patented by Mr B F Stockford. The whistle gives the time of day or night when it is blown and also records the stopping and starting of trains It is particularly designed for use in accidents, where cases of litigation arise, to indicate whether the whistle was blown on time or at all

The Old Colony Railroad people are putting the Fox pressed-wheel truck under a number of freight cars This truck is giving much satisfaction under cars belonging to the New York Central.

## The Finest Two-Cylinder Compound in Europe.

The handsome engraving shown herewith was taken last summer, just as this fine engine was ready to leave Edinburgh for Newcastle with the famous "Flying Scotsman."

This engine is one of ten of the finest that Mr. Worsdell has turned out, and, freight engines and all, he had built at Gateshead shops 259 compounds up to the time the writer visited the works last August.

This compound has a 20 and a 28 inch cylinder and a single pair of drivers 7 feet 6 inches in diameter.

The boiler dimensions were not given us, but the pressure is 175 pounds.

There is more cab than on any other engines in England, but Mr. Worsdell was once on the Pennsylvania, and probably took the notion home with him. There is no glass in the openings of the cab, however.

This engine carries about 19 tons (2240) on her single drivers and uses a very small driving-box, as compared to other engines in that country, being only 9 x 7 inches.

One of these engines pulling eighteen passenger carriages, at eighty miles per hour on a dead-level line, developed an indicated horse power of 1,068. The average coal consumption for the class, ten engines, last year was 28½ pounds—a remarkable showing.

The engine has the Craven steam sanding jet, the air-pump exhausts into the water tank, and she is fitted with Joy valve-gear.

In order to get between the frames two such large cylinders, they had to place one slightly above the other and somewhat over it. One cylinder inclines back from the front toward the axle, and the other up from the front toward it.

Both cylinders, both chests, both chest covers and both back-cylinder heads are cast in one piece. The chests have two small covers each, as shown, one in front and one on the side.

If one part breaks the whole thing has to be thrown away. Indeed, there was one of the class getting a new set of cylinders when we visited the works, on account of a broken flange on one of the cylinders.

This engine has to have a special design of frame to allow them to use side steam-chests, and putting in a new pair of cylinders means just about taking the engine apart and re-assembling it.

The engine is finished splendidly, a great deal of bright iron about her and lots of green paint.

The tank holds 3,900 gallons of water, something unusual there, but this road does not use scoops and track tanks. There is what they call a "well tank" under the main frame and between the wheels; this comes down within about 8 inches of the axles and holds a great deal of water, allowing the use of a shorter tank with a bigger coal space, and the weight of water is better distributed on the wheels than usual.

The engine and tender—ready for the road, just as shown—weigh 87 tons (2,240) or 194,880 pounds.

THE FINEST TWO-CYLINDER COMPOUND IN EUROPE.

---

The great ocean racer, the "City of Paris," uses forced draught to make the furnaces generate the vast volume of steam used up by the engines. When the vessel was built an English blowing plant was put in, but it proved unsatisfactory. This has now been removed and a plant made by the Sturtevant Co., of Boston, substituted. This gives entire satisfaction.

An item of news which we recently noticed in a daily paper was that the Norfolk & Western had ordered the construction of 400 *copper-bottomed* cars.

## "To Improve the Locomotive Engine Service of American Railroads."

The heading of this article is at once the motto and the object of the Traveling Engineers' Association, organized in the editorial rooms of this paper on January 9th. If that motto does not enlist the sympathy and support of every railroad officer in the country it will be because that officer ought to go off the road and into the ice business.

The new association is modeled after the Master Mechanics', the meetings being open, the discussion free but limited to the work of the members. We publish in this number the complete constitution, which is brief, simple and to the point—a mighty good thing in constitutions.

The meeting lasted three days, the first day being given to the adoption of the constitution and other routine work. The election of officers resulted as follows

*President*—C. B. Conger, C. & W. M. Railway.

*First Vice-President*—J. W. Sheldon, P. R. R.

*Second Vice-President*—W. R. Davis, Ill. Cent. R. R.

*Secretary*—W. O. Thompson, L. S. & M. S.

*Treasurer*—W E. Miller, Vandalia Line

The above officers, together with the following members, constitute the Executive Committee A. S. Work, Nickel Plate; J. D. Vantwood, Mil., L. S. & W. Ry.; W. T. Hamar, E. T., Va. & Ga. R. R.

The association starts off with fifty-three charter members; this membership will doubtless be made 100 before the regular annual meeting, which will occur in Chicago on Tuesday, September 12th.

The second day was mostly given to discussion about the objects and aims of the association and informal talk on road and locomotive subjects. After the meeting the members visited the works of the Nathan Manufacturing Company, by invitation.

The third day the discussion turned entirely on mechanical matters, and was lively and interesting on the subject of front ends, poor steaming engines, hot box delays and the examination of firemen.

The president announced the following subjects for discussion at the annual meeting in September.

"The Economical use of Oil and Supplies." Committee—M. M. Meehan, D. S. S. & A. Ry.; J. S. Bauder, L. S. & M. S. Ry.; W. E. Miller, Vandalia Line.

"Examination of Firemen for Promotion to Engineers, and Examination of New Men for Employment as Firemen." Committee—J. D. Vantwood, M. L. S. & W. Ry., N. M. Maine, C., M. & St. P.; W. A. Murdock, C. & N. W. Ry.

"How can Traveling Engineers Improve the Service where Engines are Double-crewed or Pooled?" Committee—W. T. Simpson, C. & G. T. Ry.; D. R. McBrain, M. C. R. R., W J. Anthony, C. & N. W. Ry.; J. W. Sheldon, P. R. R.; W. T. Hamar, E. T. Va. & Ga. Ry.

"What are the Best Methods for Instruction of Men for the Safe and Practical Handling of Air-Brakes in all Kinds of Service?" Committee—J. E. Goodman, N. P. R. R.; M. M. Dodd, Seaboard Air Line; Geo. H. Brown, C., M. & St. P.; J. W Shannon, Westinghouse Brake Co.; A. S. Burditt, N. Y. Brake Co.

The president also stated that he should announce other subjects by letter later on, and that he should be glad to hear from members about subjects for discussion.

The infant association is fortunate in its selection of officers, all are good, but the president, C. B. Conger, of the Chicago & West Michigan, is a bright engineman and a worker. W. O. Thompson, the secretary is the father of the association and has been for the past three years carrying on a correspondence and "sub-soiling" for the crops. These two men will never rest while there is work to do to further the ends, increase the membership and broaden the influence and standing of the association.

Traveling engineers are made from what the head of the motive power departments consider the best engineers, as a rule. These men are in constant contact with the work and the men; they know better than any one else just what can and cannot be done with the power, they know the road, they know the men. We have always contended that the men on engines could show more economy than any compound, if they try. And we honestly believe as well that a live, progressive, fair traveling engineer can show more saving of dollars to his company than any other officer; he does it by improving the service, by watching for and rectifying small troubles that lead to worse ones by being the eyes and ears of the department and standing up for honest service from the crews and fair treatment for them; he decides when engines need repairs, prevents waste—and takes a goodly share of the "kicking."

The new association does not propose to decide on the merits of this or that invention, to adopt standards of power or what not; they propose to discuss the subject of doing the best and most economical work with the appliances at hand, and they deserve credit for their energy and all encouragement from the master mechanics and superintendents as well as the enginemen—the T. E. often stands between them and injustice—they have been in the ranks and know the right from the wrong.

For a long time enough men have been interested in forming this association, there was strength but lack of a foothold—the largest ship is useless without a dock—ways and means for a start were needed. LOCOMOTIVE ENGINEERING furnished these, got the meeting called and saw it housed. The future is assured, a good start is half the race.

On the evening of January 9th the association were the guests of the paper and a banquet was served at the Engineers' Club, and a neat souvenir of the occasion distributed. The constitution of the new association will be found on another page.

PORTION OF THE D., L. & W. RAILROAD WHEN BEING OPERATED AS A KINDLING WOOD FACTORY.

### Dirty Shops.

You do not act up to the principle that "cleanliness is next to godliness," we remarked to a master car builder, as we stumbled with him to and fro about an establishment that was macadamized with fragments of timber, bricks, greasy waste, worn out air hose, tatters of cushions, broken bolts, old brake shoes, dilapidated axle-boxes, lumps of broken wheels and no end of other litter. "The company is too poor to employ men to clean up the place," was the answer and it looked to the writer as if the condition of that shop alone was enough to help the company rapidly toward the hands of a receiver.

When we see an establishment remarkable for its untidiness and squalor, we are always sorry for the man in charge because the place is bearing testimony to his incompetency. Where shops and their surroundings are strewn with litter that ought to be converted into some useful purpose instead of obstructing the operations of workmen, it may safely be concluded that the whole establishment is in the condition of confusion. "A place for everything and everything in its place," is the condition under which all successful shops are run. The finding of places for everything and seeing that they are kept there is an essential element in the make-up of a good foreman or manager. When this practice is not followed we find workmen searching all around the shop for tools and mining through strata of rubbish for bolts or some article wanted which has no established resting place. The loss of time that results from this unorderly way of running a shop largely increases the cost of work and would often pay the cost of cleaning up ten times over.

Another objection to squalor in and around a shop is that it seems to demoralize the workmen. There is a listless, lazy air about such a place that imparts itself to most of the men coming within its influence. If you stand and watch the men in a clean, orderly shop you will notice that all hands are active and all minds devoted to the work on hand. There is vigor and energy in every movement. In the dirty shop the reverse picture prevails. Filth seems to dissipate the magnetism which spurs men to exertion. It is not hard to understand why men in charge of shops run on the never-pick-up-anything plan come to imagine that the company is too poor to bear the expense of cleaning up. The first operation in reform ought to be on the man in charge.

### Gas Lighting of Trains.

The following extract from the Report of the Railroad Commissioners of New York State shows where they stand on the car-lighting subject:

"Success has attended the effort to light passenger cars by gas. Last year the Board set on foot inquiries as to the practicability of the various systems in use, and the answers were assuring in both respects. Indeed so practical, and so successful are the systems, and so widely have they been adopted that a car in one of the first-class or limited trains lighted by oil, would be regarded as a relic of a past age. A sufficient reason why every passenger car, whether palace car or ordinary coach, should not be lighted by gas, cannot be given. Economy should not be the prevailing consideration. Aside from the increased security from fire, the annoyance of dripping oil from the lamps is avoided. The lighting of all passenger cars by gas is in line with the progress which has led to heating by steam instead of by stoves, and which is leading to automatic couplers instead of the link and pin, coupled by hand, and automatic brakes set from the engine rather than by men on the tops of cars at the risk of their lives. The prohibition of the use of oil by legislative enactment is desirable."

At the January meeting of the Western Railway Club Mr. G. W. Rhodes read a highly interesting paper on wheel flanges. He thought that there was too much expected of the small rim of iron constituting the wheel flange. It performs the required duty with extraordinary success, considering all the abuses to which it is subjected, but sometimes too conflicting work is put upon the flange and then it is liable to cause derailment. The existence of two gauges of track puts fearfully hard work upon wheel flanges. He considers that the M. C. B. Association made a mistake when they established the present standard of 4 feet 5¼ inches between the backs of the flanges of wheels and allowed a variation of ¼-inch. When the distance between flanges was the maximum allowed and the flanges happened to be cast a little thicker than the proper size, it made the gauge of the wheels so wide that the flanges could not pass a switch or guard rail without danger.

The Q. & C. Company have got control of the Standard Cattle Guard, one of the best of the pitless guards that have lately come into favor.

### Invention of the Barometer.

A correspondent asks us "What is the Torricelli tube and what is Torricelli?" The answer necessarily calls for particulars about a great discovery and a highly important invention.

The ancient belief was that water rose in a pump because nature abhorred a vacuum. About the year 1640 a deep well had been sunk in Florence, Italy, and it was found that the pump would not raise the water from a depth greater than thirty-two feet. The celebrated astronomer, who was then a teacher in Italy, was called upon to explain why nature displayed no abhorrence of the vacuum when the water got more than thirty-two feet below the pump-valve. Although Galileo had first established the value of the vibration of the pendulum as a means of measuring time, and had discovered the law of falling bodies and made other scientific discoveries which entitle him to be regarded as the father of modern scientific methods, the failure of a pump to raise water more than thirty-two feet was beyond his comprehension.

The investigation of the mystery was then taken up by Torricelli, a friend of Galileo's. To experiment conveniently he employed a long glass tube and used different fluids, and discovered that the height of the column depended upon the specific gravity of the fluid. He closed the tube at one end and filled it with mercury. Then he placed his finger on the open end and dipped it in a basin of mercury and, holding it vertically, permitted the contents of the tube to settle. It was then found that a column of mercury 27½ ins. stood in the tube. On comparing the height of this column of mercury with the height of the column of water raised by the pump it was found that the heights agreed in an inverse ratio of the specific gravities of water and mercury. It was then natural to reason that both columns were suspended by the pressure of the atmosphere.

Further experiments proved that the height of the column diminished when the apparatus was taken up a mountain, and also that it varied slightly with changes of weather. The inference of the latter was that the pressure of the atmosphere varied at the same place. To show this varying condition Torricelli made a barometer of a glass tube charged with mercury. This is the Torricelli tube. It is closed at the top and open at the bottom end, which is immersed in a cup of mercury. All barometers are modifications of this invention.

---

The freight agents of the railroads leading out of Pittsburg, have lately been wrestling with the puzzling question, what is a steel billet? Steel billets are rated low for freight on account of being a sort of raw material, and certain parties have been shipping finished iron and steel under the denomination of "billets," and thereby obtaining cheaper transport. There is no doubt at all about what a steel billet is, but freight agents trying to "deceive" for competition's sake may display great density of comprehension about the meaning of the word.

---

The Chicago, St. Paul, Minneapolis & Omaha have ordered five locomotives from Schenectady.

### A Glimpse of the Swiss Alps and the Brunig Railroad.

The handsome engraving on this page gives the reader a scene at the summit of the Brünig pass.

The Brünig railroad is one of the many rack railroads in Switzerland, built principally for tourist travel.

The road starts from Lucerne, climbs to the summit of the pass, and then down to Interlaken. The heaviest grade is 1 in 10, but most of the line is a much easier grade.

The scenery is grand, as the road skirts the side of the mountains, and magnificent views of green valleys below and white peaks above greet the sightseer at every turn.

The road is exceptionally well built, the bridges massive and the road bed as permanent as rock will make it.

SUMMIT OF BRUNIG PASS, SWISS ALPS. GRADE 1 FOOT IN 10, OR 528 FEET PER MILE, ALTITUDE, 1,064 FEET.

---

The Great Northern has recently put in service four new dining cars.

### How they Keep Down the Surplus of Men.

The report of the Interstate Commerce Commission for 1891 is ready for delivery, and contains a great deal of information. Under the head of "accidents" we cull the following

"The casualties during the year ending June 30, 1891, are greater than in any previous year covered by reports to the Commission. The number killed during the year was 7,029, and the number injured was 33,881. Of these totals, the number of employes killed was 2,660 and the number injured was 26,140. The number of passengers killed was 293, and the number injured was 2,972. A classification of casualties according to the kind of accident shows 415 employes were killed and 9,431 injured while coupling and uncoupling cars; 598 were killed and 3,191 injured falling from trains and engines, 78 were killed and 412 were injured from overhead obstructions; 303 were killed and 1,550 were injured in collisions, 206 were killed and 919 were injured from derailment of trains, 57 were killed and 319 were injured from other accidents to trains than collisions and derailments already mentioned; 20 were killed and 50 were injured at highway crossings; 127 were killed and 1,427 were injured at stations; the balance which makes up the total of 2,660 killed and 26,140 injured, is due to accidents which do not naturally fall in the classification adopted for report. Referring to passengers, 59 were killed and 623 injured by collisions; 49 were killed and 837 injured by derailments, 2 were killed and 34 injured by other train accidents; the balance, making up a total of 293 killed and 2,972 injured, being assignable to accidents at highway crossings and at stations and to other kinds of accidents. Not only are the accidents of the year covered by this report greater than those of previous years, but, when compared with the increase in employes, it is observed that they are relatively greater than those of the previous year. Thus, during the year ending June 30, 1891, 1 employe was killed for every 296 employes, and 1 employe injured for every 30 men in railway service. The corresponding figures for the previous year are, 1 man killed for every 306 employes, and 1 man injured for every 33 employes. This same fact is also presented in another manner. The increase in the number of employes killed during the year covered by the report over the previous year is 9 per cent., and the increase in the number injured is 17 per cent., while the increase in the number of men taken into employment is less than 5 per cent. The corresponding comparison for casualties to passengers shows that, while there has been a relative decrease in the number of passen gers killed, the number of passengers injured shows a much greater increase than the increase in the number of passengers carried.

### Snow, Snow, Beautiful Snow.

The day of real snow bucking when a string of engines drove, or tried to drive, a wedge-plow through drifts and filled-up cuts, are, we hope, about over.

Machine plows now cut out and remove snow without danger to the engine and crews behind them, and do lots more of it and do it better than the old "strong and ignorant" plan of working

There is a certain amount of fascination in running a snow-plow engine. There is enough excitement and enough danger to make it interesting, and the writer of this owns to having always delighted to get "the plow engine" to run

While most of the big roads have rotary plows, many of them still buck snow by main force.

The pictures shown herewith were made from photographs of wrecks caused by snow—most of them happened last winter The last wreck shown happened some years ago in Western New York

IN THE CUT—SNOW TOO HARD

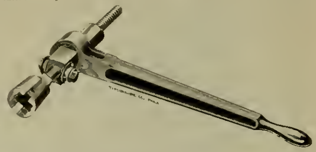
The banks of snow that our locomotive engineers will attack—nine times out of ten with success—without any kind of plow, simply the engine pilot, is appalling to European enginemen A few winters ago eight inches of snow tied up half the roads in Great Britian, and twelve inches is counted a blizzard

Four feet of the beautiful don't scare enginemen of the Northwest, unless you mix trees, sand or rocks in it, and if they think it's clear snow they will get back far enough and "take a run for it" at anything lower than the stack—and go through it with a hurrah, with something of the same feeling, we imagine, that a soldier feels when he goes over the breastworks and sees the coat-tails of the enemy as they take to the woods.

FIRST ENGINE STUCK—SECOND ONE [illegible] DOWN

### O'Brien's Flue Beader.

This machine is designed to make the bead on the end of the boiler tube without the labor ... of cracking the end
The machi ... steel, the rollers are
tool steel, ... t and sliding head of
mild mach ... l case-hardened, and
the ratche ... of cast-steel. Each
machine u ... l to take two sizes of
tubes, tha ... ll expand a 2-inch or a
2¼-inch tube. To operate machine have the tube ends well annealed and have the ends project $\frac{3}{16}$-inches, then expand them with a Dudgeon tube expander, have the sliding end run back, insert the ends having the expander pieces into the tube just back of the tube sheet, give it a quick pull when the taper end is drawn into the expanding parts, then push up the rolls against the end of tube, tighten with the nut on the screw of shank and slip the ratchet handle on, and proceed, following up and keeping a pressure with the nut. The ratchet and pawls are made to work



either way, allowing work to be done in cramped places over to the outside rows of tubes on either side of the boiler. The rolls are made the right shape to commence to flange outward and gradually expand and form the bead quickly and without injury to the tube; should by any means a tube project too far, a cutter is furnished to trim the end off the desired length of $\frac{3}{16}$ inches.

This tool was designed by G. W. O'Brien, master mechanic of the Central R. R. of Ga., at Atlanta, Ga., and is being built by Pedrick & Ayer, Philadelphia, Pa.

### A Puzzle on a Trestle.

Locomotive engineers, as is well-known, are subject to many and various experiences of every nature during their trips This was fully realized on a passenger engine on the Southwestern railroad a few days ago The evening train from Montgomery, due at Macon at 4 30 o'clock P. M., while on its way along the road from Montgomery, approached a trestle and had almost reached it when a mule and a horse were seen just ahead. The mule, frightened at the rumble of the train, ran on to the trestle, followed by the horse, but soon fell through between the cross-ties, catching by the body, and was hardly down, when the horse was in the same predicament, down between the ties. The engineer applied his brakes and stopped at a safe distance. He could have run the stock down, but it would be at a great risk, even if his engine was not derailed it would have been badly damaged. So the next consideration was to find some plan to get them off the trestle. The passengers, by this time, were all on the scene, and many were the plans proposed and discussed for clearing the road. But all were unavailable, until a passenger asked if there was a rope about the train. A bell-cord was procured from the engine, and the gentleman proceeded to carry out his plan. The horse's feet were tied fast together, after considerable resistance, and they were then pulled from between the cross-ties and his body laid broadside on the track. A rope was tied several times around his body and a dozen stout hands soon pulled him to the embankment at the head of the trestle. With the mule a more difficult experience was had, owing to the stubborn nature of the brute, but finally he was secured in the same manner, and the track was cleared with only a slight delay to the train—*Savannah News*

SNOW BUCKING ON THE LEHIGH VALLEY.

The mechanical department of the Erie have been very much interested in the process of whitewashing shops by an air pressure arrangement as described in the December issue of LOCOMOTIVE ENGINEERING The practice originated on the Central Pacific and is very successfully followed all over the road. We understand that the Erie people intend not only to adopt it for shop whitewashing but that they intend using a modification of the plan in the painting of freight cars.

In the Ditch—New York Snow.

Forsaken—Track Built Around Wreck.

A Bad Mess—View from Track.

The Pennsylvania Railroad shops, at Altoona, finished last month a car which is reputed to be of the largest capacity ever built. This car will be used to transport from Sparrow's Point, Md., to Chicago the 124-ton cannon now being made at the works of the Krupp Gun Company, in Prussia, for exhibition at the World's Fair. The car practically consists of two cars with eight pairs of wheels each, joined by an iron bridge, thus presenting the appearance of one long car with 16 pairs of wheels.

---

Not long ago a couple of engines on the D. & H. "got together" and into the ditch. One was on its side, twelve feet from the track, the other simply off the track. H. C. Smith, master mechanic, and J. R. Skinner, master car builder, arrived on the scene and cleared the wreck up in just one hour. The engine the farthest away was back on the rails in just forty minutes. This is lively work.

---

We have received a number of letters from "the boys" asking if we were not "off" in the answer to Question 1 in the January number. The valve would *move*, but would come back to the same place on the seat.

---

A somewhat novel form of spark arrester for locomotives, has been patented by John E. Zimmerman, Trinidad, Col. An open stack is used and an iron rod is secured in the middle, extending from the base to the top of the stack. Around this rod and extending to the walls of the stack, is fastened a spiral of perforated wire netting. The gases from the smokebox are required to make five rounds of the smokestack in their way to the atmosphere—they will get tired.

A Bad Mess—One Side of the Wreck.

A Bad Mess—The Other Side.

"Didn't git back fur 'Supe'"—Don't Happen every Day.

## Moon-Struck Writing.

When we find an article in a paper that is otherwise in apparently sane management telling of locomotives that are bewitched or get balky, we conclude that the writer is some moon-struck blockhead. The idiots who write the nonsense of this kind have lately been excelled in their own line by a writer in the *Plumber and Decorator*, under the caption, "Effect of Sun and Moonlight on Steel." We are told "It is not generally known that the light of the sun and moon exercise a deleterious effect on edge tools. Knives, drills, scythes and sickles assume a blue color if they are exposed for some time to the light and heat of the sun; the sharp edge disappears, and the tool is rendered absolutely useless until it is retempered. Purchasers should therefore be on their guard against buying tools from retail dealers and peddlers which, for show purposes, have probably been exposed for days together to the glare of the sun. The unserviceableness of tools acquired under these conditions is generally wrongly attributed to bad material or to inferior workmanship. A similar prejudicial effect has been exercised by moonlight. An ordinary cross-cut saw is asserted to have been put out of shape in a single night by exposure to the moon."

---

There are in the United States, for each 100 miles of road, 20 locomotives, 17 passenger cars and 714 freight cars.

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER AND ROLLING STOCK

Address all communications and make all orders payable to

LOCOMOTIVE ENGINEERING,
5 Beekman Street, New York.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } *Editors and Props.*
JOHN A. HILL, }
J W CURRAN, *Mgr Advertising Dept.*
FRED S HILL, *Mgr Subscription Dept*

### Subscription Price.

$[illegible] per year, $[illegible] for six months, postage paid to any part of the world. Single copies, [illegible] cents.

### Special Notice.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary; always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as Second-class mail matter.

For Sale by Newsdealers Everywhere.

PUBLISHERS' AGENTS.
American News Company, New York.
International News Co., London, England.
W. W. Hume, 21 Fink's Bldg., Melbourne, Australia.

20,000 COPIES OF THIS ISSUE ARE PRINTED.

### Notice.

Fred S. Hill will hereafter act as general subscription agent of this paper. He will form agencies and appoint agents where there are none, help club raisers wherever found, advertise the paper, and in every legitimate way extend its circulation. Mr. Hill will pay particular attention to placing valve motion models in lodge rooms, and will personally aid in forming clubs for lodges that want a model without cost. In all matters concerning subscriptions he is authorized to act for SINCLAIR & HILL.

## Responsibility for Acts of Fellow-Servants.

A member of the Illinois Legislature has prepared a bill which abolishes that part of the old English law which prevents employes of railroads from collecting damages for injuries due to accidents which have been caused by the fault of a fellow-servant. This ancient law is a direct inheritance of barbarism and ought to be repealed in every State not given up wholly to agricultural pursuits. Like many other laws inherited from ancient codes, this act never was based on justice or equity. It was one of a species of laws which the strong made for the legal plunder of the weak. When society was in a more elementary form than it has been for the last century, the law did not inflict much injustice because men were nearly all well acquainted with the habits of fellow-servants. If one servant was reckless and dangerous in his methods of doing work, his fellow-servants easily became aware of the fact and could protect themselves by refusing to be subjected to the danger, or they could call for his removal. At the time this law became operative, it was evidently understood that every servant was familiar with the habits of every fellow-servant and could act to protect himself. This state of affairs has long been changed. Persons in the same employment are so numerous in the present condition of industrial operations that it is impossible for a man to know when dangerous persons are his fellow-servants. The employers or their authorized agents are in the best position to judge of the habits and efficiency of the complex human elements forming the working force of a railroad or large manufacturing concern, and these employers alone ought to be held responsible for damage done by reckless or incompetent members of the force. That they should be held responsible is only asking what is reasonable and just.

The absurdity of the present law may be graphically demonstrated by an illustration given from an actual occurrence. Engineer Burns and Fireman Hoffman were employed by the A. B. & C. Railroad. They were reputed to be careful and competent men, and they were engaged operating locomotive No. 27, pulling freight trains. In following their business, it was necessary for these men to receive train orders at Springfield from a telegraph operator named Breem. This Breem was a fellow-servant of this engineer and fireman and the law presumed that they were aware that Breem was a no-account plug discharged by another railroad company for carelessness and hired by the A. B. & C. company on a salary of $30 a month. The law presumed that the engineer and fireman, knowing the careless habits of Breem, would protest to their employer, and until there was time to remove the source of danger, exercise care that he should not jeopardise their lives. These were the presumptions of a law established in the infancy of civilization. The facts of the case were that Burns and Hoffman had no means of knowing anything about the habits of Breem or of his history. It happened that this Breem received an order to hold train No. 39, conductor Nixon and engineer Burns, for an east-bound extra, which he carelessly failed to deliver. Burns did not know about this order and it was not required that he should stop at Springfield. But the law presumed that knowing the careless habits of Breem he should stop at Springfield and find out for himself if a holding order had been given. Instead of doing this he ran past Springfield as usual, and two miles farther on came in collision with a train and was killed, together with his fireman, Hoffman. As he had not done anything to obtain the discharge of Breem for carelessness and incompetency, he was deemed by this barbarous law to be guilty of a contributory negligence, and his heirs were debarred from collecting damages, since the man's death was caused by the carelessness of a fellow-servant and his own combined. The retention of this law on the statute books of States having railroads or manufacturing enterprises is an outrage on common sense.

## Changed Time of M. C. B. Convention.

A curious thing was done toward the closing hours of last Master Car Builders' Convention, which has evidently attracted little attention, owing to the parties most interested having been ignorant of what was done. For several years members of both the Master Car Builders' and Master Mechanics' Associations had been advocating that some arrangement should be made which would shorten the time required to attend the two conventions. When the meetings took place in 1890 a motion was made in the Master Car Builders' Association which resulted in the appointing of committees from the two associations, which were instructed to meet in joint conference and arrange some means of bringing the two conventions closer together. This joint committee duly met and had a very cordial and harmonious session. The deputies representing the two associations decided to recommend that an agreement be entered into for the Master Car Builders' Convention to meet on the second Wednesday in June, and the Master Mechanics' on the Monday following. They also recommended that the selecting of a place of meeting be delegated to a joint committee of the two associations.

The whole of these recommendations were agreed to when submitted to the conventions in 1891, and last year the Master Car Builders met on Wednesday and the Master Mechanics on the following Monday. The arrangement appeared to give satisfaction, and enabled some of the members to attend both conventions with little loss of time. Yet when the Master Car Builders' Convention wes in the closing hours, the report of a committee was adopted recommending that the day of meeting be changed back to Tuesday. In accordance with this decision the Master Car Builders' Convention meets this year on Tuesday.

As the arrangement for meeting on Wednesday was made on the recommendation of the joint committee, we think that it ought not to have been abrogated without the consent of both associations. It would at least have been nothing more than courtesy to give notice of the proposed change for one year, since it was understood that the Master Mechanics could not change their constitution that regulated the time of meeting without a year's notice. The Master Mechanics had the worst of the arrangement originally, in agreeing to meet on Monday, for that required that most of the members should travel on Sunday. We cannot possibly see any good reason for the Master Car Builders going back to Tuesday, as Wednesday was a convenient day to meet, and there was plenty of time for all the sessions necessary during the remainder of the week.

## Want of Co-operation Between Purchaser and User.

Railroad companies are large users of tin plates for car roofing, the roofing of buildings and the numerous tin utensils employed for office and train service, using up an immense number of such plates annually. Dealers in tin plates say that railroad companies are noted for using the worst qualities of this kind of material, the question of price almost always leading to the choice of an inferior article. This is attributed to the vicious system of purchasing by parties who have no knowledge of the quality of tin plate, and care for nothing but cheapness in first cost. This no doubt accounts for the short life of many tin car roofs and for the disrepute of tin plates as covering for car roofs. This is another illustration of the dear cheapness indulged in so much by railroad companies. There is said to be extraordinary ignorance among railroad men as to the different qualities of tin plates, an inferior article being accepted as readily as a good one.

The real difficulty, we suspect, is due to the idiotic system of purchasing followed by railroad companies. The men who do the purchasing are not in close enough communion with the men responsible for the use of supplies. A master car builder, a master mechanic or an engineer puts in a requisition for a supply of tin plate for roofing purposes. He wishes to have the best quality and may say so, but he has no assurance that the cheapest kind has not been ordered. When the delivery takes place the user has no resource but to accept the plates, no matter what the quality may be. Railroad companies doing business in this way are entirely dependent upon the honesty of dealers, for the user has no means of telling whether or not the quality paid for has been furnished. There is no doubt that in this and other lines of goods, dealers have delivered an inferior article after being paid for the best quality, and the user had no means of detecting the fraud. Private firms that attempt to do business in this fashion soon reach bankruptcy.

## Wooden Brake-Beams for Passenger Cars.

We have been much surprised to learn that the common wooden brake-beam has been specified for some twenty new passenger cars under construction for the Central Railroad of New Jersey. This is a very stupid piece of business, to say the least of it. Placing wooden brake-beams on cars that have the quick-action brake is a reckless proceeding, and magnifies the danger of travel in a fashion that no railroad company has a right to indulge in.

The dangers arising from this weak brake-beam are two-fold. When the brake is applied the beam yields so much that very little wear of the shoe lets the piston strike the cylinder-head without putting any braking power upon the shoes. This accounts for the long distance often required to make stops. The officials of the Central Railroad of New Jersey have been boasting that their trains have reached the highest speed ever attained on a railroad, and several of their trains are run at exceptionally great velocity. It might be supposed that under these circumstances the very best known appliances would be employed to give the engineer complete control of the train. But, no. To put on a weak brake-beam is to vitiate in a great measure the action of the power available for stopping the train properly.

The second source of danger from a weak brake-beam is its liability to break when the emergency brake is applied and to fall down before the wheels. These are no imaginary dangers. Repeated tests have demonstrated that the wooden beam is too weak for emergency stops, and numerous breakages of the beam in service have proved the figures of testing experts to be reliable.

An iron beam costs a little more at first, but it is cheaper than wood in the end. To specify a wooden brake-beam for any kind of car that is to use air-brakes is a conspicuous case of dear cheapness for which railroad companies are so notorious.

## Hard Usage to Business Men.

Suppose a large shipper of railroad freight, such as Armour, of Chicago, were to invite all the railroad managers in the country to meet at his office for the purpose of settling rates and routes. Suppose they gathered there from the East and the West, from the North and the South, and were kept hanging round the offices of the shipping magnate for three or four days, and then told that Mr. Armour was not ready to settle on rates and routes, and that it would be as well for all of them to return home. Would there not be rage and indignation among the crowd? Would they not heap curses and profane sayings upon the head of Armour and protest that they had been scornfully used?

Now, suppose that one of these railroad managers sent word to all the points of the compass that he intended contracting for the construction of two thousand cars on a date mentioned, and that he wanted to have all the car-builders who were prepared to build the cars come to his office on the day specified. That he also wanted to see at the same time and place all the men who were prepared to sell attachments for the cars. Suppose the day duly came round, and from all directions came car-builders, and wheelmakers, and car-coupler patentees, and grain-door agents, and roof artificers, and a great many other men ready to supply some useful member of the car corporate. Suppose, when all this host was gathered with the expectation of seeing the business promptly settled, the general manager intimated through the mouth of a messenger that he could not do anything about the cars that day.

Suppose that he sent out the same information on the morning or noon of three or four successive days, and on the following day intimated that he had changed his mind and that no cars would be ordered for the present. Are we to be surprised if the business men who went to meet the manager by invitation came away mighty wroth? Have they not as much right to courteous treatment as if they had been general managers?

This is not exactly a parable. Men have been repeatedly invited of late to bid on cars or locomotives and after days of waiting received intimation that the bids were not wanted. Next time we hear of a case of this kind we will roast the parties at fault by name in a fashion that will let them understand the popular estimate of their action.

### Compounds Improving the Simple Locomotive.

At the last Master Mechanics' Convention, when the subjects suitable for investigation during the current year were under discussion, a suggestion was made that a committee be appointed to inquire into the best means of improving the simple locomotive. The suggestion did not receive much attention, evidently because it understood that the labors of the Association have been principally devoted to the finding out of means of improving the locomotive as a whole by improving its details. The experience of the last year, however, demonstrates that the simple locomotive is capable of very decided improvement, and that influences are at work which are carrying into practical effect all the possibilities. For years the builders, designers and operators of locomotives have been contented to follow the beaten path with little change. Boilers were made a little larger, the proportions of working parts were improved and minor details of design were altered for the better, but there was little reason for believing that the locomotive of 1892 was decidedly a more efficient motor than the locomotive of 1882. The new factor which has come upon the scene with great accelerating influences is the compound locomotive.

There are now a great many compound locomotives at work on our railroads, and there is so much diversity of opinion about their utility that it appears still to be an open question whether or not the compound is destined to have a prominent place in railroad motive power. But there is no question that this form of engine is exerting great influence in improving the simple locomotive. When one or more compound locomotives are placed upon a railroad where none of that type of engine had been previously used, the reception extended to the stranger is not generally cordial. If it becomes a favorite, pure force of merit is the sole cause, for nearly every one concerned in its care, maintenance and operation is more inclined to search for faults than to accord good qualities. The usual course appears to be the comparing of the compound with some of the best engines on the road, and the striving to make the simple engines excel the compounds in all the qualities most desirable in a good locomotive. The race for merit between compound and simple locomotives is notable for the efforts made to favor the simple engine. This spirit is stimulating our mechanical men to study every point where the simple engine can be made more economical, and the compound is having a more difficult race to run than it had at first. The movement in favor of compound locomotives is likely to pay railroad companies directly and indirectly.

### Unjust Punishment.

There are two articles in the agreement which the engineers and firemen of the Southern California have with the company (extracts from which are printed in another column) which deserve to be inserted in every agreement of this kind. One affirms that no man will be suspended or discharged without a fair hearing, and the other says that verbal complaints made by engineers against firemen will not be noticed. These are both very sensible and very reasonable provisions against injustice, and their general enforcement would do no wrong to anyone. Those who are not prepared to accept an agreement with articles of these terms are not willing to have plain justice done.

An agreement that would prevent officers from punishing or discharging men, according to the dictates of their own will, would change the prevailing practice on not a few railroads, but it would be much better for the companies, better for the men and better for those in charge. On many roads the methods of investigating the cause of accidents are lamentably defective and one-sided. When an accident happens it is presumed that some one must be punished and very little discrimination is displayed in locating the blame upon the right shoulders. Every month there are hundreds of men punished for things they were not guilty of and the effect is the demoralization of the service. Men get to believe that justice cannot be obtained in case of anything blameworthy happening to them, and they naturally turn to the combinations that have the power to demand justice. To the practice of blind indiscriminate punishment is due the rise and triumph of the Grievance Committee.

There is a sort of wolfish man who frequently reaches a place of authority on railroads, and his leading sentiment is a desire to punish. He is never happy unless he is torturing some unfortunate. We all know this type of man. He is found in some place on nearly every railroad, and he is the worst kind of a curse to his employers. The higher he rises the more pernicious is his influence. When a trainman makes a mistake that calls for punishment it is good policy to treat him as lightly as the circumstances will warrant, for wisdom is often built on the foundation of mistakes. The company that habitually discharges men for every blunder lose the benefit of the prudence and caution taught by hard experience.

In regard to the rule which requires engineers to put in writing every complaint against firemen, we feel that it is calculated to prevent much injustice. There are some engineers who are always in hot water with their firemen, and the common practice is to make secret complaints to foremen or others to the effect that the firemen are no good. Some men who will not say a word openly against a fireman habitually make requests for changes, and try to put on foremen the onus of punishing when no punishment is deserved. A complaint that will not bear the light of writing is not worthy of consideration.

### Good Locomotives are Scarce.

There was an unusually long list of serious railroad accidents reported during the month of January, many of them due to the severe weather which prevailed all over this continent. Snow blockades have caused delays and much suffering on some roads and the increased resistance due to cold made trains unusually late. In connection with the severe weather the scarcity of locomotives suitable for pulling heavy passenger trains was made very apparent. The writer went into Chicago on a train six hours late, and the engine was so badly adapted for the work that slack had to be taken several times at every stopping point before a start could be made. On returning by another line similar experience was gone through.

Putting small locomotives on heavy trains in severe weather is trifling with the passenger business of a road, but suitable locomotives are so scarce that the master mechanics have no other recourse. The policy which brings about this condition of affairs appears to be very short-sighted, but it appears to be general at present.

A compound locomotive was built by the Old Colony Railroad people two years ago, and it is working so satisfactorily that they intend building another for passenger service. Mr. Lauder, the superintendent of motive power, is working on the design of the new eight-wheel of this type. She will be equal to a simple engine of 19 x 24 inch cylinders with boiler carrying steam of 180 pounds pressure. The driving wheels will be about seven feet in diameter. The intention is to put the firebox between the frames, and the driving wheels will be spread so that the side rods will be 9½ feet long. It is calculated that this length of rod will be safe with the slow rotation due to the large driving-wheels.

There have been two serious collisions on the Pennsylvania Railroad during the past month due to clear signals being given before trains were off the protected section. In one case the signalman presumably to blame alleged that he received notice that the train was off the block and that the man at the next tower had been playing with signal notices all day. This is a species of play that kills. The indications are that the signalmen's habits when on duty need investigation.

### BOOK REVIEW.

BUILDINGS AND STRUCTURES OF AMERICAN RAILROADS. By Walter G. Berg, C. E., Principal Assistant Engineer Lehigh Valley Railroad. John Wiley & Sons, New York. Price $7.50.

This work is one that has been much needed by railroad officials and those whose duties it is to design and construct suitable buildings of all kinds for railroad purposes. The book contains upward of 500 large pages with numerous cuts of every description of railroad building from a switch shanty to a union depot. We are of the opinion that with this work at hand there will be less of the slow, tedious and aggravating system of writing to neighboring roads for blue prints and account of the way they framed the last roundhouse. Not only perspectives are shown, but details and plans given. The book will become a standard authority.

POORS' HANDBOOK OF INVESTMENT SECURITIES. H. V. & W. H. Poor, Publishers, 70 Wall street, New York.

This work of 1,000 pages is now issued as a supplement to Poors' Manual of Railroads. It contains a statement of the debt of the United States and each State and county in the nation, besides giving the population, area, history, assessed valuation of property, rates of taxes, etc., etc. Besides this it contains a list of the stocks and bonds of all the railroads in the country, giving their price, earning power, etc. The book is just what it pretends to be—a classified list of all the securities that are on the market. It must be of great value to investors.

ATMOSPHERIC RESISTANCE AND ITS RELATION TO THE SPEED OF RAILWAY TRAINS. By Frederick U. Adams, M. E., Tribune Building, Chicago, Ill. Published by the author. No price given.

This book, a model of typographical art, by the way, seems to have been published to explain the author's inventions for reducing the atmospheric resistance to railroad trains. The author makes a most interesting and readable defence of his case, and cites all the authorities there are. Very little is really known about this important subject. No man who has pulled a train, rode a bicycle, or lived on the deck of a box car, needs convincing that atmospheric resistance is a most important factor in train-pulling, yet there is not the slightest attempt made in American car construction to even reduce this load put upon our locomotives. Any one interested in the subject should write the author. One of the most interesting things he says is the final sentence in the book: "The actual operation of trains about to be constructed will furnish results more eloquent than any predictions."

We can heartily sympathize with the numerous subscribers who have written complaining about LOCOMOTIVE ENGINEERING being late in reaching them. The last of the papers of the January issue were mailed the day before the first of the month. The writer lives in East Orange, N. J., less than one hour's journey from the New York post-office, and the January number was not delivered there till the 7th of the month. The trouble is that the facilities for handling mails in the New York post-office are away behind the requirements.

This is the last call for those calendars of ours. Free.

### EQUIPMENT NOTES.

The Chicago & Northwestern have given Schenectady a contract for fifty-five engines.

The Canada Cattle Co. have ordered one thousand cattle cars from the Ensign Mfg. Co.

The Lehigh & Hudson, for the Central Railroad of New Jersey, have ordered 100 box cars.

The Brooklyn Elevated have placed with Bradley & Co., of Worcester, an order for sixty coaches.

The Pullman Company have taken contract from New Jersey Central for their twenty-five coaches.

The B. & O. Southwestern and B. & O. jointly are still considering the matter of ordering 1,000 cars.

The Rhode Island Locomotive Works have orders for twenty-seven engines from the Brooklyn Elevated.

The Chicago & Northwestern people are considering the propriety of ordering about thirty more new locomotives.

The Pennsylvania lines west of Pittsburgh are letting 2,000 coal cars. No contracts yet closed, however.

The Pittsburgh Locomotive Works are building seven consolidation engines for the Cincinnati, Hamilton & Dayton.

The B. & O. have given the Baldwins an order for 107 engines. This is claimed to be the largest order ever placed with one concern at one time.

The Metropolitan West Side Elevated Railroad of Chicago has ordered one hundred passenger cars from the Gilbert Car Co., Troy, N. Y.

The 1,500 coal cars for the Pittsburgh, Shenango & Lake Erie have not yet been ordered, but are expected to be closed by the 4th of February.

It is reported that the West Side Elevated of Chicago will order, in all, 300 coaches and 100 engines for their line, to be ready by the completion of the road.

The Juniata shops of the Pennsylvania are said to have received orders for the construction of thirty-two Class P locomotives and fifty-eight of miscellaneous types.

The W. & S. Hydraulic Works, this city, have issued their catalogue of hydraulic jacks of all kinds and for all purposes. It includes everything from a little piston remover to a 100-ton machine.

The Richmond Locomotive Works have lately put in one of the Pratt & Whitney heavy milling machines that flute a side rod in one cut. They speak enthusiastically about the fine work done by this tool.

Specifications for the 1,200 coal hopper cars and 100 box cars, to be built by the Wilkesbarre & Hudson River Construction Co. for the New York, Susquehanna & Western R. R., are out and bids are being asked for material.

The Brooks Locomotive Works are building thirteen locomotives for the Wisconsin Central. They have also an order from the Chicago & Northern Pacific for six ten-wheelers, four six-wheel switchers and one passenger engine.

The Chicago, Milwaukee & St. Paul have six trains in service equipped with the Mason Air-Signal System, and the management speak [illegible] highly about its working. The signal is said to be particularly well adapted for use on long trains.

Paul S. Reeves, of Philadelphia, has been obliged to enlarge his plant; this increase the capacity from [illegible] pounds of brass and bronze casting per year to [illegible]. The new works are especially designed for locomotive and car work.

The National Hollow Brake-Beam Company, of Chicago, has leased its entire [illegible], plant and patents to the Chicago Railway Equipment Company. Mr. [illegible] B. Leigh becomes general manager of [illegible] company and Messrs. A. J. Farley and E. C. Burge will be in charge of [illegible] in the West. Mr. F. G. Ely will [illegible] of the Eastern business at 29 [illegible], New York.

[illegible] coaches ordered by the West [illegible] Co., of Chicago, from the [illegible] are to be duplicates of the [illegible] built by Gilbert and Jackson [illegible]. They are to be leased to [illegible] for use during the World's [illegible]. Engines ordered twenty-five [illegible] from Baldwin for this same company [illegible] to be leased to the South Side, [illegible] of South Side engines.

The Rhode Island Locomotive Works [illegible] received an order from the Brooklyn [illegible] for twenty locomotives, three of [illegible] cylinder compounds. They are [illegible] twelve passenger engines for the [illegible] & Albany and three two-cylinder compounds for the Chicago, Milwaukee & [illegible]. Among the order of thirty engines [illegible] the N. Y., N. H. & H. there will be [illegible] with wheels [illegible] feet diameter.

The Lake Shore & Michigan Southern [illegible] are badly in need of about fifty [illegible] motives with cylinders 19 x 24, wheels [illegible] feet in diameter, and with boilers capable of maintaining a good supply of steam [illegible] pounds pressure. We have no in[illegible] that engines of this character [illegible] ordered, but we are certain that [illegible] train service would be in a much better condition if such engines were in [illegible].

Among orders recently placed with the Baldwin Locomotive Works are twenty Vauclain consolidation compounds for the Norfolk & Western. These engines will have cylinders 14 inches and 26 x 24 inches, drivers 56 inches, and will weigh about [illegible] pounds. The Monterey & Mexican Gulf has ordered ten 10-wheelers for freight service and the Metropolitan West Side Elevated Railroad of Chicago has ordered twenty compounds.

The Westinghouse Air Brake Co. announce that they can at an hour's notice fill orders for 1,000 sets of freight car brakes. Their annual capacity is sufficient to equip 250,000 freight cars, 6,000 passenger cars and 10,000 locomotives. There are now 20,000 locomotives and 350,000 cars of all kinds equipped with this brake. Supplying material for keeping all these brakes in order makes an important part of the business done by the Westinghouse Air Brake Co.

A circular has been issued by the Walker Automatic Smoke Consumer Co. of Chicago, saying that they will guarantee to save ten per cent. of the fuel by using the smoke-consumer. The circular says that "a practical mechanic can easily understand how a bright, clear fire will produce more steam in a locomotive than a dull, smoky one; but the higher officials of railroads who have no mechanical training generally require more positive proof." It is a good thing to consume smoke, and the firing necessary to prevent smoke will generally save fuel, but the statements of the circular referred to are rather misleading. The experience of most engineers with smoke-preventing devices is that they increase the consumption of fuel.

The Ways and Means Committee of the House of Representatives had a somewhat extraordinary bill under investigation last month. It was a bill introduced in the interest of what is called the Chicago & St. Louis Electric Railroad and was to permit the importation of material for the road free of duty. The claim is made that trains on this road will be run at a speed of 100 miles an hour, but nothing has been done to show that such a speed is practicable for regular business. In fact, the whole scheme has all the appearance of a stock-selling business with cranks as promoters. The bill to enable material to be imported duty free for this company is a piece of impudent advertising.

Our Texas correspondents inform us that there is much excitement in Southeastern Texas over the rosy prospects of a new railroad being built from Portland, Texas, to Monterey, Mexico. Portland is situated upon the famous Corpus Christi bay, the head of navigation of the Aransas Pass country, and is the gateway of a vast rich agricultural region which remains dormant for want of good means of transportation. The proposed road will make a link in the most direct coast line into Mexico.

A bill has been prepared by the New York Railroad Commission, and is about to be submitted to the Legislature, which enacts that all freight cars moved on railroads in New York State after November, 1898, shall be equipped with automatic car couplers of the master car builders' type. Power will be given to the Board to extend the time one or two years on good cause being shown for the concession. The measure ought to become a law. It is fair toward railroad interests and is short of what humanity dictates.

The *Railway Times* says that the new railroad to the summit of Brienzer-Rothhorn, in the Alps, is the highest in the world, giving its altitude at 2,252 feet, and giving a long list of other mountain lines less than that. What is the matter with Fremont Pass, D. & R. G. Ry., 10,540, and a half-dozen other Rocky Mountain passes more than three times as high as the one they call the highest.

We have received a long letter from A. F. Keffle explaining what he considers the cause of the peculiar indicator diagram shown on page 17 of our January number. Our correspondent attributes the defect to valve being badly set and proceeds to explain the details of how the steam comes to make such a peculiar diagram. As this is not the real cause of the trouble we do not think it necessary to publish the letter.

A patent has been granted to Henry C. Buhoup, Chicago, for a combined car coupler and buffing mechanism for passenger cars. It is a strong, simple arrangement and has every appearance of being a real improvement. The interest in the invention has been assigned to William McConway, Pittsburgh, which means the Janney Car Coupler Company.

We can supply a few more bound volumes of 1892, and a few complete copies for the year unbound. We cannot supply single copies of January, February or March, however. If you want a set order now, as the supply will soon be gone and no more can be had for love or money.

A year ago a change was made reducing the number of meetings of the New England Railroad Club to five a year. The change does not give satisfaction. There is a movement on foot to return to monthly meetings.

A new slack adjusting device for car brakes has been patented by Howard Hinckley, Trenton, N. J. He formerly invented a device of this kind which has been used by several roads.

## PERSONAL.

Mr. M. C. Kennedy has been chosen president of the Cumberland Valley Railroad.

M. M. Dodd has been appointed traveling engineer and air-brake instructor of the Seaboard Air Line.

Mr. L. E. Smith has been appointed superintendent of the Columbia & Puget Sound, with headquarters at Seattle, Wash.

Mr. Clerk Haire has been appointed assistant superintendent of the Saginaw & Mackinaw division of the Michigan Central.

Mr. C. H. Ketcham has been appointed superintendent of the Western division of the West Shore, with headquarters at Buffalo.

Mr. A. N. Molesworth has been appointed superintendent of the Charleston, Cincinnati & Chicago, in place of Mr. H. E. Englesing.

Mr. H. S. Newkirk has been appointed assistant general superintendent of the Long Island Railroad, with headquarters at Jamaica, N. Y.

Mr. Charles Kennedy has assumed charge of the Ewald Iron Works' office at Chicago. He was formerly with the National Tube Works.

Mr. C. Millard, in addition to his duties as chief engineer of the Charleston, Sumter & Northern, has been appointed superintendent of that road.

Mr. J. V. Murray, traveling engineer of the Chicago, Burlington & Quincy, has accepted a position with the Grant Locomotive Works, of Chicago.

Mr. Eyes Randolph, for six months chief engineer of the Newport News & Mississippi Valley, has been appointed superintendent of the road.

Mr. I. E. McCracken has been appointed master mechanic of the Kansas City, Osceola & Southern, with headquarters at Coburg shops, Kansas City.

Henry Horton, formerly of the Florida Midland road, has been appointed general superintendent and master mechanic of the Tampa Street Railway Co.

Mr. J. L. Keegan, roundhouse foreman of the Newport News & Mississippi Valley at Paducah, Ky., has been promoted to be general foreman at Memphis, Tenn.

Mr. John Holland, foreman of the boiler-making shops of the Chicago & Alton, at Bloomington, Ill., has resigned, after a service of thirty-four years with that road.

Mr. R. B. Starbuck has been appointed superintendent of the Peoria, Decatur & Evansville and Chicago & Ohio River roads, with headquarters at Mattoon, Ill.

Mr. J. P. O'Brien, heretofore assistant superintendent of the Iowa Central, has been appointed superintendent of that road, with headquarters at Marshalltown, Iowa.

Messrs. Robert Spencer and Carter H. Fitz-Hugh have been appointed representatives of the Baldwin Locomotive Works for the Northwest, with headquarters at Chicago.

Mr. J. F. Bradfield has resigned as superintendent of the western division of the West Shore road to accept the general superintendency of the New York, Ontario & Western.

Mr. W. W. Smith has been appointed general foreman of the Newport News & Mississippi Valley shops at Paducah, Ky. He was previously general foreman at Memphis, Tenn.

Mr. T. H. Sears, train master of the New Mexico division of the Atchison, Topeka & Santa Fé, has been promoted to be superintendent of the Rio Grande division of that road.

Mr. H. M. Steele, recently assistant engineer of the New York, Lake Erie & Western, has accepted the position of southern agent of the Hall Signal Company, with office at Baltimore, Md.

Mr. J. W. Luttrell, for some time master mechanic in charge of the Illinois Central shops at Water Valley, Miss., has been transferred to take charge of the company's shops at Chicago.

Mr. V. Blackburn, formerly master mechanic of the New York, Lake Erie & Western shops at Susquehanna, has been appointed master mechanic for the Philadelphia & Reading at Buffalo.

Mr. J. R. Sample, who has been superintendent of terminals at Evansville, Ind., has been appointed superintendent of the Louisville, Evansville & St. Louis, with headquarters at Huntingburg, Ind.

After fourteen months' absence J. T. Edwards has again taken charge of the mechanical department of the Birmingham, Sheffield & Tennessee River Railroad with headquarters at Sheffield, Ala.

Mr. George C. Smith, assistant general manager of the Missouri Pacific-Iron Mountain lines, has been appointed general manager of the Kansas City, Wyandotte & Northwestern Railroad and its operated lines.

Mr. P. J. Milan, who has been assistant superintendent of the Matamoras branch of the Mexican National, has been appointed general manager of the Rio Grande & Eagle Pass, with headquarters at Laredo, Tex.

Mr. A. T. Dice, supervisor of signals of the New York Central & Hudson River, has been appointed assistant superintendent of the Hudson division of that road, and will also continue in charge of the signal department.

Mr. J. R. Kingan has been appointed traveling engineer of the Chicago, Burlington & Quincy on the Galesburg division. Mr. Kingan is a machinist as well as engineer and is considered a highly capable man for the new position.

Mr. W. M. Corbett has been appointed superintendent of the Evansville & Terre Haute and associate roads, in charge of the operating, mechanical and maintenance of way departments, with headquarters at Evansville, Ind.

Mr. Rollin H. Wilbur, assistant to the second vice-president of the Lehigh Valley, has been appointed general eastern superintendent of the eastern division of the Philadelphia & Reading, with headquarters at South Bethlehem, Pa.

Mr. George Dickey has been appointed master mechanic of the Illinois Central at Water Valley, Miss. Mr. Dickey was formerly general foreman of the Newport News & Mississippi Valley shops at Paducah, Ky., and had been in the employ of that company for twenty years.

Mr. J. H. Burns, traveling engineer of the Burlington, Cedar Rapids & Northern has been promoted to be assistant master mechanic. Mr. Burns has been on the road about fifteen years, having commenced railroading there as fireman. He has been traveling engineer about five years.

Mr P. A. Murphy, for several years train master of the Burlington, Cedar Rapids & Northern, has been promoted to be assistant superintendent of the same road. Mr. Murphy is an old Erie man and was yard master of one of the roads running into Buffalo before going West.

A Collection of Specimen Car Bodies.

Mr James Macbeth has resigned the position of superintendent of motive power of the Adirondack & St. Lawrence, and been appointed master car builder of the New York Central at Buffalo. Mr. Macbeth was formerly master mechanic of the West Shore at Buffalo and his home has always been in that city.

Mr. H C. Ives, superintendent of the lines of the Atchison, Topeka & Santa Fé east of the Missouri river, has been appointed general purchasing agent of all the company's lines. Mr. Ives was secretary to President Manvel for several years, and is well informed on the supply business, as Mr. Manvel has always been practically his own purchasing agent

Mr C F Lape, for the last ten years master mechanic of the Wabash at Springfield, Ill., has been appointed a railroad commissioner of Illinois. The appointing as railroad commissioners of men with good sense and some knowledge of railroading has been badly needed for years in Illinois The past incumbents have been noted for nothing except imbecility.

Mr. A. A Allen has been appointed general superintendent of the Missouri, Kansas & Texas, with headquarters in St. Louis. For the last three or four years Mr Allen has been superintendent of construction of the Everett & Monte Cristo road in Washington. He was previously on the Wisconsin Central and was for a time general manager of the Northern Pacific terminals at Chicago.

Mr. W K. Niver has been elected vice-president of the Boston & Maine, and he will take charge of the road as general manager. Mr. Niver is a graduate of the Delaware, Lackawanna & Western, and was for eight or nine years general superintendent of that road at Syracuse N. Y Since the Philadelphia & Reading got control of the Lehigh Valley Railroad, Mr. Niver has been in charge of the P. & R interests at Buffalo. He is a personal friend of Mr. McLeod's.

In the course of a discussion at the New England Railroad Club Mr. F. D. Adams mentioned a case which illustrated in a striking fashion the wear of tires caused by the action of brake shoes. His company purchased sets of English wheels for two passenger cars. One set was put under a car used on suburban service, and the other was applied to a car running on through trains. The tires of the wheels on the suburban car wore out with less than half the mileage obtained from the other tires

A Collection of Car Trucks

Mr. Theodore Voorhees, general superintendent of the New York Central for the last four years, has been elected vice-president of the Philadelphia & Reading. Mr. Voorhees is a civil engineer, a graduate of the Rensselaer Polytechnic Institute, of Troy, N. Y., and an accomplished writer on railroad subjects. He began railroading in the engineering department of the Delaware, Lackawanna & Western. He was afterward superintendent on the Delaware & Hudson Canal and went from there to be assistant general superintendent of the New York Central

Mr. A. Dolbeer, superintendent of motive power of the Buffalo. Rochester & Pittsburgh, has resigned. Mr. Dolbeer has been on the road for about five years, having gone there from the Erie division of the Pennsylvania. He is one of the best shop managers in the country, and has gone through a hard struggle on the Creator's problem of making things out of nothing. The Buffalo, Rochester & Pittsburgh Railroad Company is the tail of a coal company kite, and there is very little sustenance reaches to the tail We pity any officer who has to attempt making a record on that road.

A railroad accident that happened in Iowa some time ago has proved that the romance writer who turns the hair of a hero white through terrible excitement is not dealing entirely with the vagaries of the imagination. Ovid Musin, a famous violinist, was in the accident The shock of the collision of the two trains and the nervous strain resulting from fear of permanent injury produced a great effect on his high-strung temperament, the outward sign of which was the sudden transformation in the color of his hair. Before the accident happened the hair of his head and beard were black. Within a few weeks they became white.

Mr. John Ortton, for some years past superintendent of motive power of Toledo, St. Louis & Kansas City, died at Frankford, Ind., last month. Mr. Ortton came originally to this country from England to take charge of the mechanical department of the Canada Southern He received his training in one of the best-known English shops, and was associated with several of the men who have become prominent in railway management in the British Isles. Mr. Ortton's career in America was very much chequered The change of ownership of the Canada Southern, three or four years after he took charge, left him without a position. He was afterward in charge of the New York Central shops at West Albany, and subsequently engaged in mechanical engineering. He was exceptionally well educated, and was an able writer on mechanical subjects.

Mr. N E. Chapman, agent for the Latrobe Steel Company, died at Philadelphia last month. He was one of the best-known among the old railroad officers who have entered the supply business. Mr. Chapman was for years one of the best-known and most progressive master mechanics in the country He was one of the fifty master mechanics who met at Cleveland on June 24, 1868, to organize the American Railway Master Mechanics' Association, and he signed the call for the first regular meeting. At that time he was on the Cleveland & Pittsburgh, now a portion of the Pennsylvania Railroad. When the association was organized he was elected vice-president and held that office for nine years and then was elected president. This office he held for four years. In 1881 he was appointed superintendent of motive power of the Baltimore & Ohio and made a heroic effort to put the rolling stock of that road on a modern basis. He was in the habit of telling amusing anecdotes about the intensely conservative tastes of the managers of that road ten years ago. Two years of a struggle against forces that would not move ended Mr. Chapman's connection with the Baltimore & Ohio and he entered the steel tire business. Three years ago he became a partner in the Latrobe Steel Company.

## The Spiral Tunnels of the St. Gothard Railroad.

One of the most interesting pieces of engineering in the world is the spiral tunnels in the Alps The engineers of the St. Gothard Railroad could not find room in the snow-covered gorges and gulches of the mountains to get the line, with the proper grade, across the range

They got the needed distance and avoided the snow by building crooked tunnels Some of these make complete loops, one end being much higher than the other, thus forming a spiral

The large engraving herewith shows one of these tunnels, where both ends of the loop come out nearly together.

The smaller picture is much more interesting Here some real stair-climbing is done, and enough of it is left out-of-doors so as to be seen.

In the foreground the road can be seen running toward the left, crossing the little stream on an arched bridge, it makes a turn and comes back, crossing the same stream and gorge on a truss bridge, and disappears under the mountain, in the solid stone it makes a long detour and comes out again and once more crosses the stream on the third bridge and runs around a grade in front of the church, makes a big curve and comes into view again behind the church, where, a little to the right, can be seen the white dumps of a long fill, the road curves out of sight again up the gorge, crosses the stream once more and comes into view high up on the mountain side, directly above where it came up the valley A high wall supporting the track can be seen in the upper left-hand corner of the picture

SPIRAL TUNNELS OF THE ST. GOTHARD RAILROAD.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates. They are made by BRADLEY & POATES, 251 William Street, New York City.

## The New York Railroad Club.

The New York Railroad Club at their last meeting, January 19th, had the largest attendance in the memory of the oldest member, and the discussion of topical questions was interesting and carried on with spirit. Active railroad men are taking more interest than ever.

The question, "Which is the preferable plan for consolidation engines, to make the second or third pair of drivers the main wheels?" brought out the advantages and disadvantages encountered in practice with engines coupled up both ways.

The question, "How can we fasten solid bushings in main connections of side rods in moguls, 10-wheelers and consolidation engines, to prevent their getting loose and turning around?" brought several master mechanics to their feet who gave the question up.

Mr. Dixon, of the Rogers Locomotive Works, gave Punch's advice "Don't" and cited the Schenectady Locomotive Works as having abandoned the use of a bush on the main connection while retaining it for the other pins. The opinion prevailed that the loosening was caused by the heating of the bush and rod and by the want of area of bush for the work done.

"Why have variable exhaust nozzles never come into general use?" was an interesting topic. Mr. Baker of *Engineering News*, who proposed the question, asked that the discussion take the form of answers to the following questions:

1. Is it because little or no benefit would be gained by the use of such nozzles, supposing them to work perfectly and to be properly handled?

2. Is it because no variable exhaust nozzle has ever been invented which is sufficiently moderate in first cost, and durable and reliable, to enable it to be used successfully in regular service?

3. Is it because the engineers and firemen will not take pains to properly regulate the blast through such nozzles, so that the theoretical benefit from their use is not realized in practice?

Mr. Davie, an English engineer, was here introduced, and made an interesting talk on the subject, exhibiting model and photographs of the Macallan nozzle used on the South Eastern road in England. This pipe is a straight nozzle with a hinged ring that shuts down over it when it is desirable to reduce the area of the opening.

There was quite a difference of opinion as to whether such a device would be most successful if placed in the hands of the engineer or made automatic. Some of the members favored putting the manipulation of a variable nozzle in the hands of the fireman.

The general opinion seemed to be that variable nozzles were desirable if they would not stop up so easily and the men could be induced to use them.

Mr. Mitchell, of the Erie, and Mr. Mendenhall, of the Pennsylvania, reported recent petitions from the engineers for variable nozzles for hard coal engines.

Mr. Forney, remarking that he was raised on variable nozzles, told some interesting experiences of the days of Ross Winans, and said he had devoted considerable thought to the subject and as a result had recently taken out a patent on a variable grate bar—which he thought was attacking the subject at the right end of the boiler.

There was a good discussion on the question of driving-boxes, and a great diversity of experience. Mr. Mendenhall, of the P. R. R., reported the successful use of phosphor bronze, while Mr. Mitchell, of the Erie, said they had some engines built with solid bronze boxes that gave them more trouble than any they had.

Mr. Sinclair reported the use of solid Ajax metal boxes under the fast engines of the N. Y. Central, and Mr. Dixon, of the Rogers Locomotive Works, reported the use of malleable iron on some engines built for the Savannah, Florida & Western, had no report, but they had recently ordered engines with the same kind of box, which was taken as an indication that their use was satisfactory.

Mr. Fowler sketched a suggestion as a cure for broken flanges that came from Mr. Gibbs, of the R. & D., which consisted of making a round faced shoe and wedge and a box with a very heavy fillet for the flanges.

Mr. Hill mentioned the cure for broken driving-box flanges used on many roads, which consists of planing out the front and back of the box so that it will fit the wedge and shoe in the center only and be loose at the top and bottom, then when one wheel drops the box can retain its bearing on the axle and cramp in the frame without danger of putting the load on the flange of the box.

On the subject, "The care of foundation brakes," Mr. Jas. Howard read a most able paper which was applauded and voted to the point and all true. After a short discussion the Club adjourned to the basement and partook of a lunch.

---

The Thatcher Car and Manufacturing Co. are doing lively business for a new concern. They are having 22 Thatcher dump-cars built at New Decatur for J. W. Worthington & Co. of Birmingham, Ala., 30 are being built at its Bloomsburg car works for the Coney Island Construction Co., and they have an order for 35 for a Western road that the building contract is still open to bids.

---

W. T. Small, late superintendent of M. P. of the Northern Pacific, has been appointed superintendent of M. P. of the Buffalo, Rochester & Pittsburgh, in place of A. Dolbeer, resigned.

---

The Boies Steel Wheel Company, of Scranton, Pa., have removed their New York offices to the Taylor Building, 39 Cortlandt street. Mr. H. W. Boies, vice-president, and formerly Western representative of the company, will make his headquarters hereafter at the New York offices, in charge of the sales department, Messrs. Coolbaugh & Pomeroy having resigned. The Western office continues at 531 The Rookery, Chicago.

---

Coolbaugh & Pomeroy, the well known supply men, have resigned the sales agency of the Boies Steel Wheel Company, and taken the railroad agency for the Latrobe Steel Works, making a specialty of tires.

THE SPIRAL TUNNELS OF THE ST. GOTHARD RAILROAD.

### Metzger's Slide Valve.

A peculiar form of slide valve, shown in the annexed engraving, has been patented by Jules P. Metzger, Paterson, N. J. The valve is formed of two parts, that forming the cavity being separate from the outside and having a sliding movement of its own. The purpose of the invention is to protract the exhaust opening after the main portion

of the valve has commenced to move back. Referring to the engraving it will be seen that the valve is in the position to begin the admission of steam. When the outer part of the valve *A* reaches the end of the travel and begins to return, the inner portion, *B*, remains stationary until the edge *1* is struck by the part marked *2*.

Valves of this form have been tried a great deal, but have generally failed owing to rapid wear. The merits of this invention appear to be the peculiarity of design which cushions the blow when the two surfaces come together. This is done by the admission of steam through the upper casing.

An engine equipped with valves of this kind has been at work over a year on the Minneapolis & St. Louis, and is said to be doing remarkably good work.

### Southern California Enginemen.

There is a peculiar method of running engine crews in vogue on the Southern California. The oldest men are given the preference in the choice of runs, as is common on many roads, but here the choice is confined to the runs and not to the engines. In ordinary circumstances certain engines are kept on the regular runs, but if an engine belonging to a run fails or has to be put on an extra train, the crew do not follow the engine. They go to the station for their own train and take whatever engine has been provided. This gives the extra men much better treatment than the ordinary plan of men following certain engines, and it is reported to work well all round. The company get more service out of the engines than with the old plan, there is no dissatisfaction about men being taken off their runs or missing their engines, and all are agreed that the arrangement is fairer all round for the men and better for the engines.

They are a remarkably bright and intelligent class of men on the road, and a great many of them are orange-grove owners or proprietors of some other form of real estate. During a visit to California we were favored with a complimentary visit from a deputation of these men. When they were ushered into the room at the hotel our better half concluded that the principal citizens of Los Angeles were giving us a surprise party. She was not far off.

The men have a remarkably fair and equitable agreement with the company. The following are a few extracts:

No engineer or fireman shall be suspended or discharged upon any charge without first having an impartial hearing. * * * If charges are not proven, he shall receive full pay for all time off, with the exception of such cases as serious collision or intoxication.

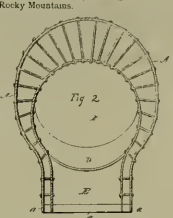
* * * *

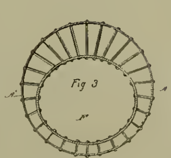
The rating as to the average load to be hauled (by engines) will be fixed from time to time as necessities may arise by the superintendent of motive power. * * *

Engineers and firemen shall be promoted by seniority; oldest men shall have preference of runs. * * *

No fines shall be imposed upon any engineer or fireman for damage caused by negligence, but suspension or discharge shall be inflicted as the case may require. * * * Where engines are required to double hills as regular service, engineers and firemen will be allowed extra mileage at the rate of ten miles an hour. * * * Engineers and firemen, when assigned to regular runs, will not be required to do work not included in their regular runs when it can be avoided. * * * Verbal complaints made by engineers against firemen will not be noticed. Engineers will be required to submit their complaints to superintendent of motive power in writing, a copy of which shall be immediately sent to the fireman against whom the complaint is made.

The schedule of pay is very liberal. On eight-wheel passenger engines the pay for engineers is $3.50 per day, of 100 miles or under; the fireman receiving $2 10. Extra running to be paid in proportion. When the engine has more than two pairs of drivers, the engineer gets 25 cents and the fireman 15 cents extra per day. Freight engineers receive from $4.00 to $4.25 per day, and firemen from $2.40 to $2.60, according to the type of engine and kind of service. The men on construction trains and switching service are all paid a little more than the rates prevailing east of the Rocky Mountains.





### In the Hancock Inspirator Works.

The Hancock Inspirator Works, of Boston, have the largest works we have ever seen devoted to the manufacture of injectors. Although comparatively little known on railroads their inspirator has for years enjoyed a large share of the boiler-feeding business, and a very elaborately worked-out plant is in use for the manufacture of the instruments. They have a special tool made by the Pratt & Whitney Company which looks like a drill press with ten heads set in line. The tools for the various operations are set in these heads and the instrument is moved successively from one to the other. This plan is considered quicker than doing the work on a turret lathe.

Mr. W. H. Park, the Superintendent of these works, has been for years working on an inspirator for locomotive work, and the company are now putting it upon the market. A great many railroad companies have got one or more inspirators and are watching their performance carefully.

The leading merits claimed for the inspirator are, reliability in starting, no adjustment of water required on account of change in steam pressure, and a range of 50 per cent. between maximum and minimum delivery.

Besides inspirators, this company makes about 500 globe valves daily

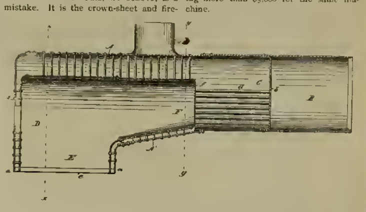
Mr. Park has a most interesting laboratory where he spends a great deal of time experimenting with appliances for raising and forcing water. In connection with it he has a museum of injectors of all kinds. Some of them are fearfully and wonderfully made and more complex than a Jacquard loom.

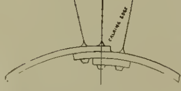
### Connelly's Boiler and Boiler Seam.

J. T. Connelly, of Milton, Pa., has recently obtained a patent on a boiler for locomotives, illustrated herewith. Fig. 1 is a longitudinal section, Fig. 2 a cross section through fire-box, and Fig. 3 a cross section through combustion chamber.

The inventor's idea is to produce a boiler without places for deposits of mud and scale, without flat surfaces, except at water leg, and with short, rigid flues.

We observe by the drawings that the stays for the fire-box are just what they are called, "radial." They all go through the shell straight, and start for the center of the boiler, going through the fire-box wherever found. This, we believe, is a mistake. It is the crown-sheet and fire-





box you are trying to stay, not the shell. The flue area in this boiler is greatly reduced, as will be seen.

Mr. Connelly has also patented a lap joint, with an inside welt strip, put in as shown, his main object being to support the calked seam. The two outside rows of rivets are spaced twice as far apart as the center row.

### A Long English Engine Without Bald Tires.

Anent the discussion in the N. Y. Railroad Club about the use or non-use of bald tires, a case may be cited in the best English practice. Mr. Webb, of the L. & N. W., has recently turned out the first of a heavy class of eight-wheel connected mineral engines, the heaviest in the country; they have no truck and a rigid wheel base of 17' 3", yet all the tires are flanged. This engine has 51-inch boiler with a total heating surface of 1,245.3 square feet. Cylinders 19½ x 24 inches with a 53½-inch wheel. The side-rods are in short sections and are interchangeable, the wheels being the same distance apart; this calls for double bearing on two pins, but gets rid of the objectionable knuckle joint.

In our last issue mention was made in a paragraph that a tire which broke on one of the Johnstone bogie engines was of the Midvale make. This was on another engine and of another make. The Rhode Island Locomotive Works people writing on the subject, pay a high compliment to the reliability of the Midvale tires.

### Fire Door Flanging.

This cut shows the most popular form of fire-door flange in Europe, and one that is used some in this country. It calls for the least bending of the sheet, takes the seam out of the fire, exposes the rivets and is easy to repair. The fire-door joint is often made directly against the edge of the flange.

A well-informed English correspondent tells us that a first-class freight engine of average size costs there £2,600, and a passenger engine £2,800, this is $12,662 and $13,636 respectively. A well-known locomotive superintendent over there showed the writer a severely plain goods engine, without trucks, cab, continuous brakes or other extras, and using cast-iron driving wheel centers, and seemed to feel a great deal of pride because he turned them out for £1,600, or $7,792. We don't believe any builder in the United States would think of asking more than $5,000 for the same machine.

On the North Eastern road, in England, they have a great many locomotives where a reverse lever is used instead of a screw, but the quadrant is a long oval screw about 2 inches in diameter at the ends and 5 or 6 at the center, this has a handle at one end and a man who can't get used to using a lever can screw the old mill over to his heart's content. It's about the clumsiest looking thing that the writer ever saw.

The machinery department of the World's Fair, at Chicago, will be an interesting one to mechanics. The Egan Company, of Cincinnati, the famous builders of wood-working machinery, claim that they will make the finest display ever made in that line. Some novel time and labor saving machines will be shown in actual operation.

The Engineering Literature Company, of East Orange, N. J., report that their business has greatly increased among railroad men during the past year. They have a catalogue of books specially prepared for railroad men who are studying engineering subjects. This is sent free to any one who applies for it.

The expert engineer of the Illinois Railroad Commission recently went over two divisions of the Peoria & St. Louis and condemned the line as unsafe, and proceedings were at once instituted to make the company put it in proper condition.

The train robbers who tackled a C. & O. train on December 14 and got left were all in State's prison for life inside of twenty days. That's business. The ticket collector who stood them off has received $100 from the company—cheap bravery.

Several wholesale slaughters took place last month by sleighing parties being struck by trains. Young men who drive crowds around the country at 2 and 3 o'clock in the morning ought to give bonds to keep off the railroads.

### Jim Wainright's Kid.

By John Alexander.

As I put down my name and the number of the crack engine of America—as well as the imprint of a greasy thumb—on the register at our roundhouse on last Saturday night, the foreman borrowed a chew of my fireman's fine-cut and said to me

"John, that old feller that's putting on the new injectors wants to see you."

"What does he want, Jack," says I, "I don't remember to have seen him, and I'll tell you right now that the old squirts on the '411' are good enough for me—I ain't got time to monkey with new-fangled injectors on *that* run."

"Why, he says he knowed you out West fifteen year ago."

"So! What kind o' looking chap is he?"

"Youngish face, John, but hair and whiskers white as snow, sorry-looking rooster, seems like he'd lost all his friends on earth and wan't jest sure where to find 'em in the next world!"

"I can't 'magine who it would be. Let's see—'Lige Clark, Dick Bellinger, Hank Baldwin, Jim Karr, Dave Keller, Bill Parr—can't be none of them; what's his name?"

"Winthrop—no, Wetherson—no, lemme see, why,—no,—no, Wainright, that's it; Wainright—J. E. Wainright."

"Jim Wainright," says I, "Jim Wainright; I haven't heard a word of him for years—thought he was dead; but he's a young fellow compared to me."

After supper I went up to the hotel and asked for J. E. Wainright.

Mebby you think Jim and I didn't go over the history of the "front." "Out at the front" is the pioneer's ideal of railroad life, the memory of it is to a man who has put in a few years there like the memory of the marches, skirmishes and battles in the mind of the volunteer.

I guess we started at the lowest numbered engine on the road and gossipped about each and every crew.

Ah, how many of those men who blazed the way for the good runs there now have laid down their work and folded their hands across their pulseless breasts!

It makes me shudder when I think of the many noble forms, mangled and bruised, and scalded and crushed! I shudder at the thought of their agonizing, heart-rending deaths, but my heart fills with horror and resentment as I go back over the files of my *Journal* and read the confessions of superstition and the hopeless bowing-down to idols and ideals of the dark ages, and the shifting of responsibility from mankind to a deity, in the stereotyped resolutions of us survivors:

"*Resolved*, That it has pleased Almighty God to remove from our midst our beloved brother," etc., etc.

That sentence is at once the only monument, the only eulogy, and, alas! often the only history of many and many a noble man.

It is no little satisfaction to me that there is no incriminating evidence in the files of the *Journal* that I have ever accused man, God or the devil of "being pleased" to scald my friend to death by slow, awful torture.

Jim and I went through the list of engineers, and had fairly started on the firemen, when a thought struck me, and I said

"Oh, I forgot him, Jim, the 'Kid,' your cheery little cricket of a firesy; thought Jim Wainright was the only man on the road that could run an engine right. I remember he wouldn't take a job running switcher—said a man that didn't know that firing for Jim was a better job than running was crazy. What's become of him? Running, I suppose."

Jim Wainright put his hand up to his eyes for a second and his voice was a little husky as he said.

"No, John, the Kid went away—"

"Went away?"

"Yes, across the great divide—dead."

"That's tough," said I, for I see Jim felt bad. "The Kid and you were like two brothers."

"John, I loved the—"

Then Jim broke down. He got his hat and coat and said

"John, let's get out into the air. I feel all choked up here, and I'll tell you a strange, true story—the Kid's story."

As we got out of the crowd and into Boston Common, Jim told his story, and here it is, just as I remember it—and I'm not bad at remembering.

"I'll commence at the beginning, John, so that you will understand. It's a strange story, but when I get through you will recall enough yourself to prove its truth.

"Before I went beyond the Mississippi and under the shadows of the Rocky Mountains, I fired, and was promoted on a prairie road in the great basin well known to the railroad world.

"I was much like the rest of the boys until I commenced to try and get up a substitute for the link motion.

"I read an article in a scientific paper from the pen of a jackass who showed a Corliss engine card, and then blackguarded the railroad mechanics of America for being satisfied with the link because it was handy.

"I started in to design a motion to make a *card*, but, well, you know how good-for-nothing those things are to pull loads with.

"After my first attempt I put in many nights making a wooden model for the Patent Office. I was subsequently informed that the child of my brain *interfered* with about ten other motions; then I commenced to think—what I ought to have done before. I went to studying *what had been done*, and soon come to the conclusion that I just knew a little,—about enough to get along running. I gave up hope of being an inventor and a benefactor of mankind, but study had awakened in me the desire for improvement, and after considerable thought I came to the conclusion that the best thing I could do was to try and be the best runner on the road, just as a starter. In reality in my inmost soul my highest ideal was the master mechanic's position.

"I was about twenty-five years old, and had been running between two and three years, with pretty good success, when one day the general master mechanic sent for me.

"In the office I was introduced to a gentleman, and the G. M. M. said to him in my presence.

"'This is the engineer I spoke to you of. We have none better. I think he would suit you exactly, and, when you are through with him, send him back, we are only lending him, mind' and he went out into the shop.

"The upshot of the matter was that the stranger represented a firm who had put up the money to build a locomotive with a patent boiler for burning a patent fuel, and she had an improved valve motion, too They had asked our G. M. M. for a good engineer to send East to break in and run the new machine and go with her around the country on ten-day trials on the different roads. He offered good pay, it was work I liked, and I went.

"John, I came right here to Boston and reported to the firm. They were a big concern in another line, and the head of the house was a relative of our general M. M.—that's why he had a chance to send me.

"After the usual introductions the president said to me.

"'Now, Mr. Wainright, this new engine of ours is hardly started yet; the drawings are done and the builders' contract ready to sign, but we want you to look over the drawings to see if there are any practical suggestions you can make. Then stay in the shops and see that the work is done right. The inventor is not a practical man, help him if you can, for experience tells me that ten things fail because of bad *design* where one does because of bad manipulation. Come up into the drawing room and I will introduce you to the inventor.'

"Up under the skylight I met the designer of the new engine, a mild little fellow—but he don't figure in this story.

"In five minutes I was deep in the study of the drawings. Everything seemed to be worked out all right except that they had the fire door opening the wrong way and the brake-valve couldn't be reached—but many a good builder did that twenty years ago.

"I was impressed with the beauty of the drawings—they were like lithographs, and one, a perspective, was shaded and colored handsomely—I complimented him on them.

"'They are beautiful, sir,' said he; 'they were made by a lady. I'll introduce you to her.'

"A bright, plain-faced little woman, with a shingled head, looked up from her drawing-board as we approached, shook hands cordially when introduced, and at once entered into an intelligent discussion of the plans for the new record-beater.

"Well, it was some months before the engine was ready for the road and in that time I got very well acquainted with Miss Reynolds.

"She was mighty plain, but sharp as a buzz-saw. I don't think she was really homely, but she'd never be arrested for her beauty; and, while there was nothing fetching about her appearance, you couldn't help liking her; she was intelligent, and it was such a novelty to find a woman that knew the smokestack from the steam-chest.

"I didn't fall in love with her at all, but I liked to chin her over the work. She told me her story, not all at once, but here and there a piece, until I knew her history pretty well.

"It seems that her father had been chief draughtsman of those works for years, but had lately died. She had a strong taste for mechanics, and her father, who believed in women learning trades, had taught her mechanical drawing, first at home, then in the shop. She had helped in busy times as an extra, but never went to work for regular wages until the death of her father made it necessary.

"She seemed to like to hear stories of the road, and often asked me to tell her some thrilling experience the second time; her eyes sparkled and her face kindled when I touched on snow-bucking experience, and she often said if she was a man she'd go on the railroad; but after such a remark she would usually sigh and smile at the same time and say

"'Think of being anchored for life to a petticoat, and have to always say "Oh, dearie me," when your spirit longs to say "dammit" as hard as ever you can.'

"One day, when the engine was pretty near ready, she said to me

"'Mr. Wainwright, who is going to fire the "Experiment?"'

"'I don't know. I had forgot about that. I'll have to see about it.'

"'It wouldn't be of much use to get an experienced man, would it—the engine will burn a new fuel in a new way?'

"'No,' said I, 'not much.'

"'Now,' said she, coloring a little, 'let me ask you a favor. I have a brother that is just crazy to go out firing I don't want him to go without it's with a man I can trust; he is young and inexperienced, you know; won't you take him? Please do'

"'Why, I'll be glad to,' says I; 'I'll speak to the old man about it.'

"'Don't tell him it's my brother.'

"'Well, all right.'

"The old man told me to hire whoever I liked, and I told Miss Reynolds to bring the boy in in the morning.

"'Won't you wait till Monday? it will be an accommodation to me.'

"Of course I waited.

"The next day Miss Reynolds did not come to the office and I was busy at the shop. Monday came and no Miss Reynolds, but about 9 o'clock the foreman came down to the 'Experiment' with a boy apparently about 18 years old, and said here was a lad with a note for me.

"Before reading the note I shook hands with the boy and told him I knew who he was, for he looked like his sister.

"The boy was small but looked wiry, and had evidently come prepared for business, as he had some overclothes under his arm and a pair of buckskin gloves. He was bashful and quiet, as boys usually are on their first experience away from home.

"The note read

"'Dear Mr. Wainright—This will be handed you by brother George. I hope you will be satisfied with him. I know he will try to please you and do his duty; don't forget how green he is I am obliged to go into the country to settle up some of my father's affairs and may not see you again before you go. I sincerely hope the "Experiment," George and his engineer will be successful. I shall watch you all. Miss G. E. Reynolds.'

"I felt kind of cut up somehow about going away without bidding 'old business,' as the other draughtsmen called Miss Reynolds, good-bye, but I was busy with the engine.

"The foreman came along half an hour after the arrival of young Reynolds, and seeing him at work cleaning the window glass, asked who he was.

"'The fireman,' said I.

"'What! that "*kid!*"'

"And from that day out I don't think I ever called young Reynolds by any other name half a dozen times That was the 'Kid' you knew. When it came quitting time that night I asked the Kid where they lived, and he said Charlestown.

"I remarked that his voice was like his sister's, but he laughed and said I'd see difference enough if they were together, and bidding me good-night caught a passing car.

"We broke the 'Experiment' in for a few days and then tackled half a train for Providence. She would keep her water just about hot enough to wash in with the pump on It was a tough day; I was in the front end half the time at every stop. The Kid did exactly what I told him, and was in good spirits all the time, I was cross. Nothing will make a man crosser than a poor steamer.

"We got to Providence in the evening, tired, but after supper the Kid said he had an aunt and her family living there and if I didn't mind he'd try and find them. I left the door unlocked and slept on one side of the bed, but the Kid didn't come back; he was at the engine when I got there the next morning.

"The Kid was such a nice little fellow I liked to have him with me, and somehow or other (I hardly noticed it at the time) he had a good influence on me.

"In them days I took a drink if I felt like it, but the Kid got me into the habit of taking lemonade, and wouldn't go into drinking places, and I soon quit it. He gave me many an example for controlling my temper, and soon got me into the habit of thinking before I spoke.

"We played horse with that engine for four or five weeks, mostly around town, but I could see it was no go. The patent fuel was no good, and the patent firebox little better, and I advised the firm to put a standard boiler on her and a pair of links and sell her while the paint was fresh.

"They took my advice The Kid and I took the engine to Hinckley's and left it there; we packed up our overclothes, and as we walked away the Kid asked, 'What will you do now, Jim?' 'Oh, I've had a nice play, and I'll go back to the road. I wish you'd go along'

"'I wouldn't like anything better, will you take me?'

"'Yes, but I ain't just sure I can get you a job right away.'

"'Well, I could fire for you, couldn't I?'

"'I'd like to have you, Kid, but you know I have a regular engine and a regular fireman. I'll ask for you, though.'

"'I won't fire for anybody else!'

"'The devil you won't! Why? What would you do if I should die?'

"'Quit.'

"'Get out!'

"'Honest; if I can't fire for you I won't fire at all.'

"I put in a few days around the 'Hub,' and as I had nothing to do my mind somehow kept turning to Miss Reynolds. I met the Kid daily, and on one of our rambles I asked him where his sister was.

"'Out in the country.'

"'Send word to her that I am going away and want to see her, will you, Kid?'

"'Well, yes; but Sis is funny; she's too odd for any use. I don't think she'll come.'

"Well, I'll go and see her.'

"No; Sis would think you were crazy.'

"'Why? Now look here, Kid, I like that sister of yours and want to see her.'

"But the Kid just stopped, leaned against the nearest building and laughed, laughed till the tears ran down his cheeks.

"The next day the Kid brought me word that his sister had gone to Chicago to make some sketches for the firm and hoped to come and see us after she was through.

"I started for Chicago the next day, the Kid with me.

"I had little trouble in getting the Kid on with me as my old fireman had been promoted. I had a nice room with another plug-puller, and in a few days I was in the old jog—except for the Kid. He refused to room with my partner's fireman, and when I talked to him about saving money that way he said he wouldn't room with anyone—not even me. Then he laughed and said he kicked so no one could room with him.

"The Kid was the butt of all the firemen on account of his size, but he kept the cleanest engine, was never left nor late, and seemed more and more attached to me—and I to him.

"Things were going along slick enough when Daddy Daniels had a row with his fireman and our general master mechanic took the matter up. Daniels' fireman claimed the run with me, as he was the oldest man, and, as they had an 'oldest man' agreement the master mechanic ordered Smutty Kelly and the Kid changed.

"I was not in the roundhouse when the Kid was ordered to change, but he went direct to the office and kicked, but to no purpose, then he came to me.

"'Jim,' said he, with tears in his eyes, 'are you satisfied with me on the 12?'

"'Why, yes, Kid. Who says I'm not?'

"'They've ordered me to change to the 17, with that horrible old ruffian Daniels, and Smutty Kelly to go with you.'

"'The h—l they have,' says I; 'that slouch can't go out with me the first time; I'll see the old man.'

"But the old man was mad by the time I got to him.

"'That baby-faced boy says he won't fire for anybody but you; what have you been putting into his head?'

"'Nothing; I've treated him kindly and he likes me and the 12—that's the cleanest engine on the—'

"'Tut, tut, I don't care about that; I've ordered the firemen on the 12 and 17 changed—and they are going to be changed.'

"The Kid had followed me to the office, and at this point said very respectfully:

"'Excuse me, sir; but Mr. Wainright and I get along so nicely together; Daniels is a mean man, so is Kelly; neither will get along with decent men. Why can't you—'

"'There! Stop right there, young man. Now, will you go on the 17 *as ordered?*'

"'Yes; if Jim Wainright runs her.'

"'No *ifs* about it, will you go?'

"'No, sir, I won't!'

"'You are discharged, then.'

"'That fires me too,' said I.

"'Not at all, not at all; this is a fireman row, Jim.'

"I don't know what struck me then, but I said

"'No one but this boy shall put a scoop of coal in the 12 or any other engine for me; I'll take the poorest run you have, but the Kid goes with me.'

"Talk was useless, and in the end the Kid and I quit and got our time.

"That evening the Kid come to my room and begged me to take my job back and he would go home, but I wouldn't, and asked him if he was sick of me.

"'No, Jim,' said he, 'I live in fear something will happen to separate us, but I don't want to be a drag on you—I think more of you than anybody.'

"They were buying engines by the hundred on the Rio Grande, the Santa Fé, and the A. & P. in those days, and the Kid and I struck out for the West, and inside of thirty days were at work again.

"We had been there three months, I guess, when I got orders to take a new engine out to the front and leave her, bringing back an old one. The last station on the road was in a box-car thrown out beside the track on a couple of rails; there was one large, rough-board house, where they served rough-and-ready grub and let rooms, the latter were stalls, the partition only being about seven feet high. It was cold and bleak, and right glad we were to get there, turn the big 'hog' over to the watchman and get a warm supper, everything was rough, but the Kid seemed to enjoy the novelty.

"After supper I asked the landlord if he could fix us for the night.

"'I can jest fix ye, and no more,' said he; 'I have just one room left. Ye's'll have to double up, but this is the kind o' weather for that; it'll be warmer.'

"The Kid objected, but the landlord bluffed him—didn't have any other room—and he added 'If I was your pardner there I'd kick ye's down to the foot, such a cold strip of bacon as ye must be.'

"About nine o'clock the Kid slipped out, and not coming in for an hour I went to look for him. As I went toward the engine I met the watchman:

"'Phy don't that fireman o' yourn sleep in the house or on the caboose floor a night like this? He'll freeze up there in that cab with no blankets at all; but whin I tould him that he politely informed meself that he knowed men to get rich mindin' their own biz. He's a sassy slip of a Yankee.'

"I climbed up on the big consolidation and lighting my torch looked over the boiler-head at the Kid. He was laying on a board on his seat with his overcoat for a covering and an arm rest for a pillow.

"'What's the matter with you, Kid?' I asked. 'What are you doing freezing here when we can both be warm and comfortable in the house? Are you ashamed or afraid to sleep with me? I don't like this for a cent.'

"'Hope you won't be mad with me, Jim, but I won't sleep with anyone, there now.'

"'You're either a fool or crazy,' says I, 'and I want some explanation of such a trick as this. Why, you will half freeze here.'

"The Kid sat up, looked at me soberly for a few seconds, reached up and unhooked his door and said.

"'Come over and sit down, Jim, and I'll tell you something.'

"I blew out the torch and went over, half mad. As I hooked the door to keep out the sharp wind, I thought I heard a sob, and I took the Kid's head in my hands and turned the face up to the moonlight. There were big tears in the corners of each tightly closed eye.

"'Don't feel bad, Kid, I am sure some reason keeps you at such tricks as this; but tell me all about your trouble—it's imaginary, I know.'

"There was a tremor in the Kid's voice as he took my hand and said: 'We are friends, ain't we, Jim?'

"'Why, of course,' said I.

"'I have depended on your friendship and kindness and manhood, Jim. It never failed me yet, and it won't now, I know. I have a secret, Jim, and it gnaws to be out one day and hides itself the next. Many and many a time have I been on the point of confessing to you, but something held me back. I was afraid you would not let me stay with you if you knew—'

"'Why, you ain't killed anyone, Kid?' I said, for I thought he was exaggerating the trouble.

"'No—Yes, I did, too,—I killed my sister.'

"I recoiled, hurt, shocked. 'You—'

"'Yes, Jim, there is no such a person to be found as my sister, Georgiana—*for I am she!*'

"'You! Why, Kid, you're crazy!'

"'No, I'm not; listen, Jim, and I will explain.'

"'My father was always sorry I was not a boy. Taught me boyish tricks and made me learn drawing. I longed for the life on a locomotive—I loved it, read about it, thought of it, and prayed to be transformed into *something* that could go out on the road. My heart went out to you early in our acquaintance, and one day the thought to get started as a fireman with you shot into my brain and was acted upon at once. After the first move there was no going backward, and I have acted my part well; I have even been a good fireman. I am strong, healthy and happy when on the road with you. I love the life, hard as it is, and can't think of giving it up, and—and you, Jim.'

"And then she broke down and cried as only a woman can.

"I took both her hands in mine and kissed her—think of kissing your fireman on the engine—and told her that we could be happy yet. Then I told her how I had tried to get a letter to the lost sister, and how they never came back and were never answered—that I loved the sister and I loved her. She reminded me that she herself got all the letters I had sent and was pretty sure of her ground when she threw herself on my protection.

"It was a strange courting, John, there on that engine at the front, the boundless plains on one side, the mountains on the other, the winds of the desert whirling sand and snow against our little house and the moon looking coldly down at the spectacle of an engineer making love to his fireman.

"That night the Kid slept in the bed in the house and *I* stayed on the engine.

"When we got back to headquarters the Kid laid off to go home and I made a trip or two alone, and then I had to go to Illinois 'to fix up some family business'—Kid and I arranged that.

"We met in St. Louis, the Kid hired a ball dress, and we were married as quietly as possible. I had promised the Kid that, for the present at least, she could stay on the road with me, and you know that the year you were there I done most of the heavy firing while the Kid did the running.

"We remained in the service for something like two years, a strange couple, yet happy in each other's company and our work.

"I often talked to my wife about leaving the road and starting in new where we were not known, as man and wife, she to remain at home, but she wouldn't hear to it, always asking me if I wanted an Irishman for a side partner. This came to be a joke with us—'When I get my Irishman I will do so-and-so.'

"One day, as our hog was drifting down the long hill, the Kid said to me, 'Jim, you can get your Irishman; I'm going to quit this trip.'

"'Kind o' sudden, hey, Kid?'

"'No; been hating to give up, but—' and then the Kid come over and whispered something to me

"John, we both quit and went South. I got a good job in Texas, and the Kid was lost sight of and Mrs. J. E. Wainright appeared on the scene in tea gown, train and flounces.

"We furnished a neat little den, and I was happy. I missed my Kid fireman, and did indeed have an Irishman. Kid had a struggle to wear petticoats again, and did not take kindly to dish-washing, but we were happy just the same.

"Our little fellow arrived one spring day, and then our skies were all sunshiny for three long, happy years, until one day Kid and I followed a little white hearse out beyond the cypress grove and saw the earth covered over our darling, over our hopes, over our sunshine, and over our hearts.

"After that the house was like a tomb, so still, so solemn, and at every turn were reminders of the little one that had faded away like the morning mist, gone from everything but our memories—there her sweet little image was graven by the hand of love and seared by the branding-iron of sorrow.

"Men and women of intelligence do not parade their sorrows in the market-place, they bear them as best they can, and try to appear as others, but once the spectre of the grim destroyer has crossed the threshold his shadow forever remains, a dark reminder, like a prison bar across the daylight of a cell.

This shadow is seen and recognized in the heart of a father, but it is larger and darker and more dreadful to the mother-heart.

"At every turn poor Kid was mutely told of her loss, and her heart was at the breaking-point day by day, and she begged for her old life to seek forgetfulness in toil and to keep away from herself.

"So we went back to the old road, as we went away—Jim Wainright and Kid Reynolds—and glad enough they were to get us again for the winter work.

"Three years of indoor life had softened the wiry muscles of the Kid, and our engine was a hard steamer, so I done most of the work on the road, but the work, excitement and outdoor life brought back the color to pale cheeks and now and then a smile to sad lips—and I was glad.

"One day the Kid was running while I broke up some big lumps of coal, and while busy in the tank I felt the air go on full and the reverse lever come back, while the wheels ground sand. I stepped quickly toward the cab to see what was the matter, when the Kid sprang into the gangway and cried 'Jump!'

"I was in the left gangway in a second, but quick as a flash the Kid had my arm.

"'The other side! Quick! The river!'

"We were almost side and side as she swung me toward the other side of the engine, and I jumped just as we crashed into a landslide. I felt Kid's hand on my shoulder as I left the deck—just in time to save my life, but not the Kid's.

"She was crushed between the tank and the boiler in the very act of keeping me from jumping to certain death on the rocks in the river below.

"When the crew came over they found me with the crushed clay of my poor, loved Kid in my arms, kissing her.

"They never knew who she was. I took her back to our Texas home and laid her beside the little one that had gone before.

"The Firemen's Brotherhood paid Kid's insurance to me and passed resolutions saying that:

"'It has pleased Almighty God to remove from our midst our beloved brother, George Reynolds,' etc., etc.,

"George Reynolds' grave cannot be found; but over a mound of forget-me-nots away in a southern land there stands a stone on which is cut

"'Georgiana, wife of J. E. Wainright, aged thirty-two years.'

"But in my heart there is a golden pyramid of love to the memory of a fireman and a sweetheart known to you and all the world but me as 'Jim Wainright's Kid.'"

---

Nearly three pages of the United States *Patent Office Gazette* were lately occupied with the description of an elevated railroad invented by Arthur E. Hotchkiss, Cheshire, Conn., and Arthur himself is shown riding on it on a bicycle. It is a one-rail bicycle railroad and looks like a board fence.

## A Roundhouse Cat with Brains.

BY SOLOMON WHITE.

We have all of us read more or less about cats, and their peculiar traits of body or mind. Who has not seen the high-bred tortoise-shell tabby that was the pride and delight of her mistress, or the cat with the long white hair that comes from some foreign land, and that looks for all the world like a poodle dog; and we all remember reading in our youth of the pretty gray cats that gave a regular circus performance to the gentle word of command from their loving masters, and what numbers of common, every-day cats there are all about us that one never sees except as they skip under the woodpile or up a tree; and never hear but in the night when one wants nothing so much as to sleep—unless it be the chance of annihilating the cat. Some of these every-day cats are not so common after all, for we often read of the lawyer's office cat, who, in spite of his half-starved condition, stoutly maintains his master's superiority against the jibes of the sleek and well-fed banker's cat. And even the editor has his pet feline, that is a sort of walking encyclopædia to furnish him reliable data, and sometimes secrets not otherwise obtainable. To all these we wish to add the story of another of these ordinary cats—ordinary only in pedigree. Did any of you ever hear of a roundhouse cat? Perhaps so, but it was doubtless a poor, dirty, half-starved creature that ran and hid every time one of the workmen came near it and lived only in the fear of a bunch of dirty waste shied at it. But this is a different sort of a story I have to tell.

It was a cold, dark night in early November that our roundhouse cat came to us. The caller had just gone out, leaving the door slightly ajar, and soon there peered in two bright eyes, slowly followed by a long, lean body covered with yellow-gray fur. The boys were quietly at work, and after making a careful survey from where he stood, Mr. Cat slowly walked about the house, peering into corners and keeping pretty well away from everybody till he came to the sand stove. Here he found a place to suit him and lay down as if he was at home. A close look at him revealed the fact that he had had trouble; his ears were torn and bleeding and there was a long scratch across his nose. Undoubtedly he had had a disagreement—was it with a neighbor, or was it with a brother in a too full house? Perhaps the latter, and he had vowed to go out into the cold world and seek himself another home. Anyhow, he seemed pleased with his new surroundings, and after carefully dressing his wounds curled himself up for a nap. The boys went about their work, their torches throwing uncertain light on their greasy suits and grimy faces and on the shining sides of the great engines they were wiping, and none of them saw their new companion comfortably dozing by the warm sand stove. One of the wipers, whose merry whistle was always heard as he polished up the great drivers, passed near by the stove with his arms full of waste, and his whistle roused the cat, who jumped up in alarm, ready to run if danger threatened, but the whistle was already gone, and he lay down again. When midnight came the cat retired under the nearest engine, for the boys gathered around the sand stove to eat their lunch, and as each hunted his particular coffee can out of the hot sand they called to him in their most coaxing terms, and though they threw bits of their lunch toward him he would not come out. After the lunches were finished, there happened what often does happen—the boys all took a nap, "just to settle their lunch!" And while they were stretched out around the stove, oblivious of all surroundings, the cat came out of the pit and ate up all the scraps of lunch thrown on the floor, and seeming to realize that there was nothing to fear, he lay down near them to settle *his* lunch.

From this time on he never showed any disposition to leave us or be afraid of any one about, and it was not long before he was a regular luncher and showed his good living in his fat sides and sleek and shining fur. In the days that followed he began to show interest in the work going on about him, and might be seen sitting on the edge of the pit intently watching the boiler-washer splashing about in his big boots, or on the steam-chest watching the machinist lining up guides; or on the running-board with his bright eyes on the waste in the hands of the fireman, and if a long string dangled out behind you would be sure to see Tom jump at it. There was one set of workmen that he soon lost all interest in, and that was the boiler-makers. In his walks about, he one day came upon one of these men just emerging from a front end, and his sooty face with its stary eyes seemed to fill Tom with disgust, or perhaps fright, for he never afterward stopped to watch them at their work. It was soon apparent that Tom's special delight was the engineers and firemen; and before very long his peculiar bent made itself known and became one of the most interesting topics of conversation in the roundhouse. And this is how it all became clear to us.

Engines 93 and 126 always stood in the same stalls, side by side, and their engineers were two very different sorts of men. Sam McGuire, who ran the 93, was one of those young fellows who knew pretty well how to run an engine—in his own mind—and thought a good many of the instructions about oiling, looking over and the general care of an engine were old-fogy notions not at all necessary to follow. He used to say, "That great iron mill 'aint going to knock to pieces just because she 'aint tended like a baby." And so he used to saunter into the house any time of day, ask his fireman if she was all right, walk along beside her with his hands in his pants' pockets, perhaps stretch his neck enough to get a bird's-eye view of the links and eccentrics, and then spend the rest of his time swapping lies on the machinist's bench.

But the engineer of 126, John Bright, wasn't that kind of a fellow, he was one of your big, quiet chaps who always seemed to be thinking of something pleasant; he'd come down as regular as clock-work, and you could see him climbing under and about his engine, and you'd feel sure he'd never go out with a loose nut or a lost cellar bolt. He was always whistling softly to himself, and he never failed to see everybody that came by, and his cheery nod and smile didn't interfere with his work—or his whistling either. It was to him that Tom soon became strongly attached. He'd follow him everywhere, and when "Old Fogy," as Sam McGuire used to call him, was down in the pit tapping each nut to be sure it was tight, Tom was close by seemingly taking careful instructions. And when he filled his rod and guide cups—and he always examined the feeders carefully, so you knew pretty well that he wouldn't be laid out by a hot pin—Tom would follow, walking along the rods, and he'd peer into each oil cup just as interested as if he was watching a fresh mouse-hole. So their friendship grew, till you'd always be sure to find Tom where John was—that is, till John got ready to pull out of the house; then Tom would retire, for it seemed he never could get used to the steam coming from the open cylinder cocks, and the boys used to laugh to see him skip for the other end of the house at the first blast. But it wasn't very long till John had him so attached to him that he could take him up on the right side with him, and ride him out over the turntable, and sometimes to the coal chute, till finally Tom would contentedly stay till John put him off. One evening, when they were ordered out on a stock extra, John told his fireman he was going to take the cat with him for a trip over the road. So Tom, like all visitors, was put up on the fireman's seat, where he looked as dignified and knowing as a director of the road. They pulled out in due time, and, as they went whizzing over the road Tom seemed as interested as a woman in watching the grass and trees fly by, and occasionally looked over at John as if to be sure he hadn't deserted him. They were to meet No. 1 at Rufton, where they were also to take coal and water; and they drew into the passing track with five minutes to spare, just after dark.

While the fireman was up taking coal and water and the engineer hurriedly dropping on a little oil, the conductor appeared and handed the latter a piece of yellow manifold, saying, "Here is an order. No. 1 is running thirty minutes late, that will give us eighteen minutes to make Komo and clear them five. Can you make it?"

As John held the manifold in the glare of the fire-door he said to himself, "Twelve miles", at the same instant there flashed through his mind the condition of his engine and he saw no reason why he should not make Komo easily, and turning to the conductor said

"Are you ready?"

"Yes; let her go! The coal-man will shut the switch for us"—and before you could tell it they were well into the country. So they sped through the black night, past farm houses whose presence could only be told by the flash of light from their windows, over bridges whose rumble revealed them, and through snow-sheds that made the darkness more close by shutting out the stars, everything in the cab showed the intensity of the strain on brain and nerve. John leaned out of the window with his eyes strained to the farthest point of the lighted track, occasionally glancing at his watch in the glare from the fire-door; while the fireman divided his time between the steam-gauge and the scoop. They were in to clear at Komo and had three of their five minutes.

All during this quick run Tom had calmly laid upon his cushion with his bright eyes intently watching everything going on about him, but certainly not in the least excited or uncertain of the result. But when No. 1 whistled, and he saw the headlight, which seemed to be coming straight at them, he sprang up and looked quickly about as if to leave the cab, but seeing John sitting quietly in his seat, he too settled down; and during the rest of the trip lay curled upon the seat, sometimes sleeping, and sometimes watching the fireman. When they reached the end of their run, the hostler told them they were to go right back, and while he turned the engine John and his fireman went over to a neighboring high-stool-and-ham-sandwich hotel for something to eat. Tom staid on the engine, but sat up very straight and alertly watched the hostler; he was plainly disturbed at John's disappearance, but evidently intended sticking by the engine, and when John returned bringing one of those aforementioned sandwiches for him Tom showed his delight in unmistokable purrs.

The trip home was uneventful, and Tom slept most of the time, and when they ran into their regular stall he jumped down from the engine as if it was a usual thing for him to go over the road. The boys were all amused at the fireman's description of Tom's journey, and Sam McGuire thought it would be a fine thing to some day take him along on the 93, but Tom's brains just showed up right there. Do you think Sam could get him onto the 93? Not a bit of it! No amount of coaxing would induce him to set foot on that engine, and while it tickled the rest of the boys, Sam was mad and felt like killing the cat. And one day Jimmy Black, who has a way of telling the truth no matter how hard it hits, said "Sam, the cat's onto you, he knows you haven't been under that old scrap of yours for a month." And though Sam walked away, muttering something to himself about "d—— chumps," he didn't deny Jimmy's accusation, and the boys always laid Tom's refusal to ride on the 93 to his brains.

## A Heroic Conductor.

BY ANGUS SINCLAIR.

There are deeds of heroism performed every day in a matter-of-course fashion by our railroad men that would entitle them to honorable decorations were their actions done in spheres where gallantry, and daring, and endurance were rewarded. In the battlefield of industry, bravery and conspicuous courage are supposed to earn no special reward. They are the matter-of-course attributes of many occupations. Hundreds of heroes who have displayed these attributes in the saving of human life, or in the performance of daily duties, go in the course of nature to their graves without knowing that they have performed deeds worthy to be commemorated beside the acts of glory which have made other names immortal.

Such thoughts passed through my mind one evening in a quiet house in Kansas as I listened to H. R. Nickerson, general superintendent of the Atchison, Topeka & Santa Fé, tell for the amusement of his guests some reminiscences of railroading on the frontier of civilization. In relating his personal performances Mr. Nickerson was like Bill Smedley's frog after its phenomenal leaps, perfectly modest and unconscious of having done anything out of the common.

We had been talking about the hardships endured by trainmen in fighting snow.

"We have not been much troubled with snow on the Santa Fé of late years," remarked Mr. Nickerson, "but in the early days of the road's history we got enough to last us to the end of the chapter. When we first stretched out toward the mountains, the prairies and plains were perfectly bare and the snow was swept for miles to the nearest lee spot. Away about '76 I was conductor of a passenger train, and we got stuck in the snow about twenty miles west of Dodge City. We toiled and struggled to get out of a cut where we were stalled, but a fierce blizzard was raging and the snow drifting over the plains unchecked by bush or brake, filled up the cut quicker than we could work it out. We had been out for a day and night, and the situation was getting serious. The train was full of passengers, many women and children among them, and there was not a morsel of food to eat. Dodge City, over twenty miles away, was the nearest habitation.

"Being a telegraph operator, I carried an instrument with me. Thinking that a relief party might be sent out, I climbed a telegraph post and made connection with the wire, intending to ask Dodge City to send provisions. I called and called but no Dodge City or other haunt of civilization could be raised. The wires were down, but I did not know that then, and wasted much valuable time trying to establish communication that was hopelessly cut off.

"When at last I realized that the calling for help over that wire was useless, and that there was no hope of the storm soon abating, I made up my mind to walk to Dodge City. The other trainmen and even the passengers declared it was too risky, but I could not sit still for another night and look at those women and children crying with hunger.

"I wrapped myself up well, tied some bagging over my shoes and started out on the twenty-two miles tramp. The cold wind was blowing with cutting force, and the snow kept falling, falling as if the upper air was a reservoir with a never-ending supply. It did not fall fast, but kept up a steady downpour as if it had set out to keep up the operation for a month.

"There is a peculiarity about the kinds of snowfall. If it comes down in great flakes that nearly monopolize space in the air, the snow is likely soon to turn to rain. If a finer snow falls in blinding density it soon exhausts the supply and stops. But

when it keeps falling steadily, gently, as it trying to husband its strength, you may depend on having a liberal supply for days.

"This was the kind of snow which I had to encounter. It kept falling with painful monotony, but it never rested. Before reaching the ground it joined a moving tide of snow that was wafted before the wind in search of a resting place. The vast plains seemed to be a sea of moving snow. Silently and quietly it moved along in its white purity, too light evidently to harm the twittering birds, but woe to man or beast that sought shelter in a spot where protection from the wind permitted the snow to rest.

"With the thought only of my passengers in my mind and Dodge City for a magnet at the end of my vision, I kept trudging onward. The telegraph poles were the finger-posts that pointed to safety. Sometimes I walked on the track and sometimes on the prairie, but I never failed to keep within sight of the telegraph poles. When the snow or drift was so thick that I could not see from one pole to another, I counted the seconds, and if the next pole did not appear at the right time, I turned toward the track and by that regained my bearing. The wind kept steadily on my left, so that it helped as a guide, for the track was straight. The tramp was toilsome. Now I would be walking through soft snow that broke through at every step, then I would suddenly stumble into a covered slough or buffalo wallow and be half smothered before I could again reach firm footing. A great part of the way the track was raised slightly above the plain and the wind kept it fairly clear of snow, so that the walking was good. At other places there were small cuttings which were drifted level, and these parts sent me away from the track.

"The mileage numbers on the telegraph poles told me that Dodge City was yet far away when the shadow of a lurid gleam in the west intimated that the sun was going down. Toward nightfall certain forms had flitted past within my line of vision that gave me some uneasiness. They were prairie wolves, cowardly, harmless animals as a general thing, but I did not know how they might act in the case of a lonely tramp, encountered when they were stimulated to courage and fierceness by hunger.

"I carried my signal lamp, and thinking that it might be some obstacle to any of the wolves that might be inclined to eat my hams for supper, I proceeded to light it. That was no easy job. The oil was frozen, and the lamp would not burn. As dusk was falling, I began to feel certain that the lighted lamp was a beacon that would frighten my enemies, and I determined to make it burn. To accomplish this I groped under the snow for some bunches of dry grass, got down with them in a sheltered spot and started a small fire. On this I held the fountain of the lamp long enough to melt the oil, then lighted it without difficulty.

"When I started up to go after lighting the lamp, several wolves were snarling within sight. As the shades of night waxed deeper the animals became bolder and more numerous. They kept pressing toward me, yelling and snarling at each other and then staring at their intended victim with blazing eyes, but a wave of the lamp would send them scampering away. At first they would run far enough for most of them to be out of sight, but they gradually grew bolder. They kept pressing closer upon me and I continued to swing the lamp at them without making much impression. I was beginning to imagine how the first bite of their teeth would feel and how long it would take them to eat me up. I had no intention of permitting this performance to go on without resistance, and I had my revolver ready for the emergency which seemed impending. I noticed that one gaunt-looking fellow was more enterprising than his companions. He went the shortest distance at the swing of the lantern and returned first to the charge. After making half-hearted attempts he made a spring at my leg, and received a bullet from my revolver.

"There was a great hurrying to the front and rear, and I kept moving ahead while the wolves lingered to pick the bones of their comrade. The feast did not satisfy their longings for the good things of this life, for I had not passed many telegraph poles when the pack was within sight again.

"But they appeared to reason that there was some dangerous relation between the swinging of the lantern and the shot that gave one of their number as supper for his friends. They had no taste for figuring as the principal at that kind of a feast. For a time they kept without reach of an easy shot, but their memory of the disaster that happened to their gaunt member was short lived, or the necessities of their appetite were pressing. By degrees they crowded closer around me. A swing of the lantern would frighten them beyond bounds at first, but gradually its terrors waned.

"I kept plodding forward doing my very best to keep the hungry brutes at bay, but watching an easy opportunity for another victim. I had not to wait very long. The first of the pack to display conspicuous enterprise receive my next shot, and he was near enough to get it straight. The hosts scattered again, and again they united to pay the last tribute of affection for their relatives. Their obsequy ceremonies were not protracted. I had not time to grow lonely in my solitary journey, when they were beside me again singing their eerie requiem which I feared would soon apply to myself. Between rubbing my ears, swinging my lantern and keeping a watchful eye on my escort, I was kept busy. The drama that became a tragedy to two of the wolves was enacted twice again, but no sign of the hospitable dwellings of Dodge City greeted my longing eyes.

"The cold and the fatigue and the hunger (for I had not eaten anything since the previous day) must have begun to affect my senses, for during the last part of the journey it appeared to me that a wave of wolves was moving over the country as the waves of snow had been seen moving in daylight. But I continued to swing my lantern and hold out my revolver. The impression came that the whole thing was immensely funny, and I must have laughed loudly at the absurdity of the scene. This was the feeling pervading me when I stumbled into Tom Dowd's saloon at two o'clock in the morning.

"This was the only house in the town that had a light burning, and there I went, followed to the door by the wolves.

"I remember vaguely a crowd of men getting around me and of their dragging me outside and beginning to rub my face and ears with snow. I was rather badly frozen but soon was myself sufficient to explain what was wanted. A relief party was organized within an hour. A large sleigh was loaded with provisions, and before daylight broke we were far on our way to the spot where many hungry people were waiting to be fed."

---

Our various articles on "Railroading During the War Time" has excited in those who took part in the stirring events referred to a desire to come together in a convention and fight the battles over again. An old engineer who has read the articles with much interest and remembers many of the personages mentioned, wishes us to propose that a convention of men who were railroading in the South during the war time be held in Chicago this summer. We gladly put the suggestion before our readers and will be pleased to do all in our power to aid in organizing such a meeting. If any one will take the initiative we feel certain that the project will meet with a cordial response from hundreds of old railroaders who are anxious to meet associates of those trying times.

### The Invention of Cast Steel.

There are few subjects connected with mechanical engineering that have more romantic associations than the development of steel making. The first progress in the art was incited by the desire to make trusty weapons of warfare, but the scientific development of modern times has been accomplished in the interest of peaceful arts.

Steel has supplied a favorite simile to the poets. Milton says

"Arm the obdured breast
With stubborn patience as with triple steel."

Shakespeare speaks of the "flinty and steel couch of war"; "hearts as true as steel"; "hearts with strings of steel." Byron frequently uses this obdurate metal for illustration, and Scott speaks of

"The stern joy which warriors feel
In foemen worthy of their steel."

Since the important inventions and discoveries of Bessemer, Siemens, and others were made, which have so wonderfully reduced the cost of producing steel, it has been common to hear the present time spoken of as the age of steel. With all the good the cheapened metal has done for mankind, we hardly think that the metal is now regarded with the admiration and romance of early times when the article was scarce and when its production was an art of mystery. Stone and bronze were used as weapons of war and implements of peace in times preceding the working of iron, but it seems likely that steel was the first form in which iron came into use. Steel is mentioned by Homer, and the famous Wootz steel of India was described by Aristotle, who lived about 400 B.C.

The ancient metallurgists appear to have attained wonderful skill in steel making. The business was carried on by secret crafts, and there is reason to believe that certain parts of the art were lost in the cataclysms to civilization in the first seven centuries of the Christian era caused by superstition and barbarism. What little knowledge was perpetuated about metals in Europe found root in Germany and the Netherlands. Up to the seventeenth century these countries produced nearly all the steel used in the Western World.

Steel at this time, was not of the admirable brands from which the swords famous in history had been made. It was nearly all made by the blister process. That is, bars of iron were placed in a box among granulated charcoal and kept there at a red heat for many hours, thus causing the carbonization that converts iron into steel. The process of making cast-steel was not discovered until about 1750, and the art of making this kind of steel was not generally known till this century began.

Early in the seventeenth century the art of making cutlery began to extend in Sheffield, England, and the artizans who made the best articles were naturally those who were most skillful in manipulating the steel used. At first all the steel was imported from Germany, but after a time the more enterprising makers of cutlery began making their own steel, or it was made by parties in the district who went into the business. As the fame of Sheffield cutlery spread and business increased, a rivalry arose in the art of steel making. The improvements effected were not remarkably great and were achieved principally by skillful selection of good iron, but a steel was produced which satisfied the requirements of ordinary cutlery.

There was, however, in the district a clock-maker named Benjamin Huntsman who was very much dissatisfied with the clock springs made from the best kind of steel to be procured, and he began to experiment with the view of producing a better article. He was very intelligent, ingenious, something of a chemist and persistent beyond measure. His efforts to improve the quality of steel were carried on for many years before they were rewarded with success. Whether by reasoning or by accident it is not known, but he conceived the idea of cutting up pieces of the very best blistered steel into small pieces and melting them in a crucible. No crucibles had ever then been made that would stand the intense heat necessary to melt steel, but by patient effort Huntsman succeeded in making sufficiently satisfactory crucibles and melting the steel. The success was achieved on the altar of many failures, but the results obtained entitle Huntsman to an elevated niche among the heroes of industry. The invention of cast-steel was second in importance to no previous event in the world's history, unless it may have been the invention of printing.

Huntsman used his marvelous steel for a time exclusively for purposes connected with his own business. After a time he became convinced that cast steel would be valuable for the cutlery trade of Sheffield. He offered it for sale to the manufacturers of cutlery, but they refused to use it because it was more difficult to forge than the softer steel in use. Failing to find a market in his native country, he sent specimens of the cast steel to France. There it was patronized with avidity and used for the manufacture of all kinds of cutting tools. Its merits were so quickly recognized that French hardware makers bought all the cast steel which Huntsman could make, and pushed him to extension of his manufacturing facilities.

The fame of the French cutlery made from Huntsman's steel spread rapidly, and it soon came to pass that the Sheffield cutlers found out that they were being beaten by steel made in their own town. Their action in this emergency was characteristic of the unscrupulous grasping so frequently observed in trade competition. They did not propose buying Huntsman's steel and trying to beat the French in a fair way, but they appealed to the government to prohibit the exportation of Huntsman steel. They failed in this contemptible scheme, and then they proceeded to try and steal the invention.

Huntsman kept his process of steel making a secret. The work in his foundry was done by reliable, trustworthy men, who were true to the interests of their employer. He was a Quaker and kept in his employ only men of that persuasion and they proved incorruptible although large bribes were offered for the secret of making the new steel. A number of unnecessary operations were performed in the mixing of the material for the crucibles and useless fluxes were employed which lent an air of complexity to the work done. This no doubt aided in preventing the process from being divulged.

The process was kept secret for about twenty years and then it was stolen by a rival steel maker who, dressed as a vagrant, obtained the shelter of the foundry on a fierce winter night. But this made little difference to Huntsman. The secret had been kept long enough to enable him to establish a lucrative business, and he could afford to let the world have the full benefit of his invention.

---

Our weekly readings in that fascinating publication, the *Patent Office Gazette*, leads us to believe that the inventive genius of the world is wrestling laboriously over the production of an electrical locomotive. There must be a great many machines of this character protected by letters patent but the right one does not seem to be booming very high above the others. We are not much in the electric business but we have a very decided impression that the persons toiling over designs of electric locomotives are on the wrong track. It appears to us that the advantages of electrical traction are that the dead weight of the paying vehicles may be used and that the heavy addition of weight caused by a locomotive may be saved. If operating electric cars calls for the weight of a locomotive there is no advantage over operating the same train by a steam locomotive and many disadvantages.

### Corralling a Bucker.

Out at Pittsburgh one of the roads has a Swede named Murphy, who is night hostler. Murphy's assistant is of the same nationality and sails under the name of O'Rafferty.

One night, not long ago, Murphy had to bring in a big consolidation that had a very leaky throttle and no brake. As he brought her back from the table she didn't seem to want to stop, and Murphy promptly reversed her, then she dove for the turn-table pit.

In the excitement Murphy had neglected to shut her throttle entirely.

Murphy got excited and so did O'Rafferty, who was hopping around on the ground. The engine was diving back and forth from the inside to the outside of the house

"Moike!" yelled Murphy.

"Phwat?" answered O'Rafferty.

"Moike, phwen oi git her insoide agin do yes *shut the doure on her*!"

### Forewarned is Forearmed.

Joe Meadows was one of the hardest drinkers on one of our Western lines once, and the management were "onto him."

Joe could run an engine all right, pulled passenger, and all that, but when he got drunk he took an especial delight in "showing off" by wild and reckless running.

Joe got away one day full of rye, and down the road he pulled half the spikes on the line (so the section men said), he ran over it so fast.

He went into one town eighteen minutes ahead of time—that was the dispatcher's signal that Joe was on a tear.

He telegraphed an order for John Slitam to take the engine at the next station. John was there with a freight train.

Joe sailed into town ahead of time, one leg hanging out of the cab window and his hat in his hand. The conductor stopped him with the air.

John presented his order, and as Joe was too full to read, read it to him "John Slitam, Engineer No. 13. You will relieve Engineer Joseph Meadows and take charge of engine 164 at Davis Crossing, and pull train No. 1 to destination.—W T. B."

"Why the old man's at home, scheen him thish mornin', he never wrote that, when'sh it dated?"

"To-day, an hour ago."

"How'd it get here?"

"Telegraf."

"Tela—oh, yes, forgot about the tel'graf, but sahy, John, if I'd a knowed they was'a tryin' to catch me by telegraf, they'd a never done it—I'd a beat the fastest tel'graf they got, I would. See."

### Just to Accommodate the Conductor.

Jerry Simpson went up onto the hilly division for a few trips last month, and the men up there have a great deal of respect for Jerry's nerve

It's always been the by-word of the men on the hilly division that the men from the river division couldn't get along up with them—hadn't the nerve to run for the hills, etc

Up on the "hilly" the top is at Salem siding—it's down hill for ten miles each way from there.

The first day out, as the old ten-wheeler crawled up Salem grade, the conductor sent a brakeman over to tell "that new feller" when they got to Salem—"put him onto Salem," as the conductor expressed it. All the way up the crew had expressed disgust because Jerry had lost time.

The brakeman was one of that breed who were born languid; he slouched over the cars and got up on the fireman's side for a few minutes, looked at his watch as they passed the first switch, and said to Jerry, who was busy

"Salem!"

"All right," said Jerry

The brakeman dropped off to catch the train further back, and Jerry never shut off; he hooked her back a notch and let her go.

Pretty soon the coal commenced to shovel itself off the tank; some empty flats back in the train were dancing a jig and the conductor and crew were hanging on to the running boards.

They were making express-train time when Jerry said to the fireman

"Wonder where that next hill is?"

Just here the conductor crawled over to the engine.

"Say, man, let up; didn't the gufter tell you about this hill?"

Jerry shut off and dropped the lever into the corner, as he remarked.

"He told me to sail'm, and if this isn't sailing 'em fast enough I miss my guess. What do ye expect—want me to fly?"

### A Professional.

The contrary and argumentative spirit of the average Englishman is very well illustrated by Dr. Williams, of the Baldwin Locomotive Works. The doctor was in Australia with a lot of new engines at one time, and had a little difficulty in getting the men, who were used to English machines, reconciled to the new power.

One old fellow who got a new Baldwin, delighted to kick against the innovation. He didn't like a cab over him; couldn't do as much work with outside cylinders as with inside; plate frames were the only safe things when you got off the track; headlights were no good, etc., etc.

One day the doctor rode with this runner, and asked him how he liked the engine; he at once began to tell the virtues of his old engine.

"Now," said Mr. Williams, "this engine is equalized; don't she ride easier?"

"Well, maybe, but that makes no difference."

"Don't you like to sit down?"

"No; I like to see a man stand up to his work."

"Well, David," said the doctor, "I'll go and speak to Mr. Blank and ask him to put you on the old engine; it is wrong to make a man run an engine he dislikes; besides, there are some young men who think they can pull more cars and take more comfort on the Baldwins."

"Oh, I wouldn't do that, I can stand 'em well enough, but give me an old Bobby Stephenson an' I'll——"

"You shall have her back, Davie. I didn't think how a man gets attached to an engine."

"No, don't go on my account; it's too much trouble; maybe I'll get used to this one, but——"

"I'll go; fact of the matter is I don't think, feeling as you do, you can do our engine justice. You can't, or won't, pull as many cars as a young man."

"I'd like to see the young fellow who can best me, now."

"It's no trouble to me at all, Davie."

"Say, Mr. Williams, now you know I'm an old kicker. I don't mean half I say; this engine is better than the old one; more comfortable and all. Don't you ask to have me taken off, and I'll bet you nothing on the line will do more or better work than the Baldwin."

### A Problem in Arithmetic.

"One day last fall," said Traveling Engineer Poole of the Nickel Plate, socking in his breath with that of a perfecto, "our pay car dropped anchor in the yard and an anxious crew boarded her. One of the first men at the window was a green French fireman we had, and as it came his turn he smiled on the paymaster and said.

"Good avenin' till ye, sorr, have ye a bit ave a check for me?"

"Whose roll are you on?"

"Divel a roll is there on me, de'ye moind, 'oim assistont to the engineer."

"What's your name?"

The fireman took a look at the questioner, and then said, without catching his breath

"Pat Maa-haney, 'oim firing for Jimmie Killduff on the forty-foure, made noine days on construction, wan day on pile driver, siventeen hunder miles on way-freight, owe foive dollars and twinty cents for board, and going out on nineteen—ye's can figger it up yoursel'."

### An Independent Boarding House.

When the Prairie Midland was first run out into Dakota, the trainmen found very thin feeding between terminals, and provident providers invested in big lunch buckets. It was lunch on cold victuals for days at a time, and we were all very glad of any chance to get a mess of hot coffee and a warm potato.

A few rods from the water tank, at Muddy Creek, Tim Maloney, the section boss, had put up a very decent shanty where his wife lodged and boarded the section hands. This was provisioning station for many a hungry wayfarer, and it came to be a regular thing for the crews of certain trains to take their meals there. But the accommodation was given under protest. Mrs. Maloney had no taste for keeping a restaurant. She was noted for her freedom of speech, and the men who wanted to get their meals there regularly had to be on their good behavior. Mrs. Maloney gave lessons in self-repression to some of the men who never had learned to restrain their tongues before

People who knew Conductor Phil Nevans were not surprised that he was the first to get fired out of this boarding house run on the independent plan. Phil was a natural grumbler. He was never happy unless he was abusing some one or finding fault with things generally. The boys called Phil the shadow kicker.

The name originated in this way Phil was always in hot water with his brakemen There was a brakeman on the road called Sam Ramson, a good man but a little wild, strong as a Rogers pony and as free in his talk as Mrs. Maloney.

Well, Trainmaster Mission put Ramson on as hind brakeman with Nevans. They made one round trip together without overt acts of disagreement, but the next trip Nevans came out of the caboose at Greenville with a black eye and an unusually fat nose. How the difficulty had arisen and been settled no one was informed, but Phil was ever after particularly choice in the language he used toward his hind brakeman. When Sam was questioned about the marks of conflict on Phil's face, he answered that Phil got mad and tried to kick his shadow, and knocked down a coupling-pin on his nose.

Phil was not improved in his conversation toward others. One day he sat down at Mrs Maloney's table, and on the viands being brought in remarked "Hash! hash! Hash is good for hogs."

Mary Ann, who helped her mother and acted as waitress, said nothing, but departed for the kitchen, and presently Mrs Maloney walked into the dining room. "Phil Nevans," she exclaimed, trembling with suppressed excitement, "ye was sayin' that hash was good enough for hogs. Indade, Phil, in that case, hash will suit you very well. It will be the kind of vittals you will like. Take yer fill, but never come into this house again."

### Examinations.

The practice of examining firemen and brakemen before promoting them is greatly on the increase, remarked a traveling engineer at the last meeting of the Club. There are now few well managed railroads where it is not the rule to find out what men know about the business before putting them into the responsible position of locomotive engineer or of conductor. There was much opposition to examinations for a time. Ridicule and abuse were heaped upon book-learned men, but the men who had obtained book information in their business, in addition to the teaching of experience, were so much superior to the man who had the experience alone that there was no going back to the old plan.

We have examined the men for years with the very best results. Sometimes there are funny answers given to questions. In answer to the question "What is the dome for?" a would-be engineer answered "to keep the smokestack from being knocked off by the bridges." Another was asked, "What is a brace?" and answered "a full drink." One fireman told that the purpose of parallel rods was to keep the driving-wheel from flying apart, and another believed that the stand-pipe was put in to keep the engine from roaring.

Brakemen are not behind firemen in curious answers. One said that the purpose of a triple-valve was to trip the couplings when the train parted, while another demonstrated "train rights" to be the right to stop and eat any time the conductor was hungry. The brakeman probably spoke from experience who answered that the principal duty of the hind brakeman was to waken the conductor. He was not much further out than the candidate for a higher position who was asked the question, "What would you do if your train was running away on a grade?" answered, "signal the engineer to put on the steam-brake."

When people are under examination they are naturally nervous and often answer at random. School examination papers are full of funny blunders like that of the boy who was asked the meaning of a Papal Bull and answered, a sort of big cow, that does not give milk

### Have You Any Interesting Old Tickets or Time Cards?

It will be remembered that the Department of Transportation Exhibits of the World's Columbian Exposition some months ago appointed Mr George De Haven (General Passenger Agent of the C. & W M. and D L. & N roads), to make a representative collection of railway and steamship tickets and passes. It is desired especially to secure, by gift or loan, such tickets, time-tables, maps, etc., as have a special historical value. Large numbers of these are doubtless in existence, in the hands of collectors, or of those men or their descendants who were identified with the railway or steamship business during the first half of the present century It is hoped that this paragraph may reach the attention of many such, and that they will at once communicate with Mr De Haven on the subject. Suitable acknowledgement will be made and the best of care given to such loans.

Information as to the existence of such relics and whom to apply to for them will also be gratefully received Mr De Haven's address is Grand Rapids, Mich.

We are in receipt of a letter from Drifton, Pa., saying that the men behind the many-wheeled locomotive mentioned by Mr. Marks in the last issue, had sold some stock to a grocer there Our correspondent advised the stockholder to buy stock in the wheel foundry that got the contract for making the extra legs.

### Improved Pump Governor.

Two sizes of the improved pump governor are supplied, which differ only in the lower portions to which the steam-pipe connections are made. The 1-inch governor is intended to accompany the 9½-inch pump, which has 1-inch steam pipe, and the ¾-inch governor is intended to be used with the 8-inch pump, which has ¾-inch steam pipe. A description of one, therefore, applies to the other.

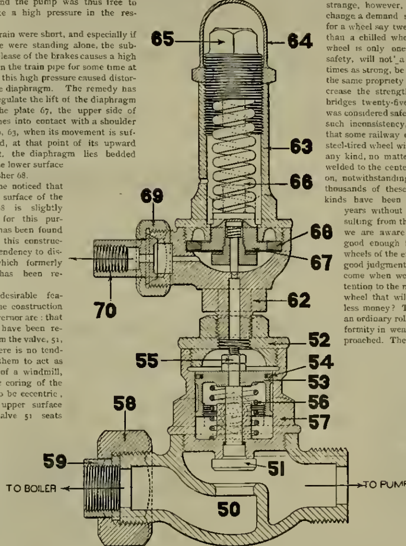
The chief difficulty which has existed hitherto has been the distortion of the diaphragm beneath the plate 67, which occurred when the brakes were a long time applied and the pump was thus free to accumulate a high pressure in the reservoir.

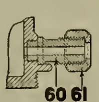
If the train were short, and especially if the engine were standing alone, the subsequent release of the brakes causes a high pressure in the train pipe for some time at least, and this high pressure caused distortion of the diaphragm. The remedy has been to regulate the lift of the diaphragm through the plate 67, the upper side of which comes into contact with a shoulder of the cap, 63, when its movement is sufficient, and, at that point of its upward movement, the diaphragm lies bedded against the lower surface of the washer 68.

It will be noticed that the lower surface of the washer 68 is slightly rounding for this purpose. It has been found that, with this construction, the tendency to distortion, which formerly existed, has been removed.

Other desirable features of the construction of this governor are: that the wings have been removed from the valve, 51, so that there is no tendency for them to act as the arms of a windmill, should the coring of the passage 50 be eccentric, also the upper surface of the valve 51 seats against the case 57 when the valve is in its upward position, so that no steam or oil can be forced up into the chamber and blow out of the exhaust port 60. This permits a reduction in the length of the stem of the valve 51 and the tube through which it extends, as was formerly necessary where the length of such tube and stem was depended upon to prevent the entrance of steam into the chamber above. Also, that the piston 53 is much longer and is kept tight with much more certainty than in the former construction.

Another feature which is perhaps worthy of attention is the fact that this governor has a cap, 64, as a part of the check-nut which screws on to the adjusting screw 65, and so avoids the conspicuous attention which the unprotected adjusting nut of the old governor called to the fact that that was the place to adjust the governor. One principal trouble in the past has been, that engineers have been in the habit of adjusting their governors to suit their own ideas. The air connection to this governor must be made to the train-pipe with the engineer's valve having an excess pressure-valve, and to the main drum with the new valve, shown last month.





### On Car Wheels.

By Steel.

It is somewhat remarkable that the railway systems of the world were developed on such different lines in the matter of wheels, those of this country being of the solid cast-iron type, while those of England and the Continent were composite or tired wheels. It might be said that this was owing to the fine quality and abundance of our charcoal iron, but this does not fully account for it, for there was plenty of just as good charcoal iron made on the Continent of Europe during the past fifty years. Hence, it must be due more to the matter of cheapness and the lack of any governmental supervision, allowing all railroad officials to follow their own bent in matters of construction and equipment. Certain it is, however, that the cheap chilled wheel assisted greatly in the rapid development of our railroads, and it is an important factor to-day in the problem of cheap freight rates. It can also be said with confidence that the chilled wheel, when properly and carefully made, is only one remove from entire safety for passenger and locomotive service, particularly that of a few years ago. Even now at least one of our great railways is still using chilled wheels largely under passenger equipment. Hence, it cannot be said they are unsafe. The record of the chilled wheel, as far as accidents are concerned, considering the enormous number that have been put in use, practically without inspection or test till within a very few years, is, to say the least, extraordinary, and the public certainly have no quarrel with them. And, for freight service wheels, it is doubtful if any other metal will ever supersede chilled iron, as it is difficult to imagine how we could get a cheaper material for the service rendered. Eight years is now considered the average life of a chilled wheel under even heavy freight cars.

The value of a 33-inch wheel being, say, $8, and when worn out, as scrap, $4—we have $32 as the cost of the wheel service for a freight car for eight years, or $4 per year.

But this is the age of steel, and it is natural with the increasing weight of equipment and higher speeds that steel wheels in some form or other are gradually displacing chilled iron wheels for locomotive and passenger service, both on account of safety and economy. It seems strange, however, that in making this change a demand should have been made for a wheel say twenty-five times stronger than a chilled wheel. Now, if a chilled wheel is only one remove from entire safety, will not a steel wheel, say five times as strong, be absolutely safe? With the same propriety we might as well increase the strength of all iron railway bridges twenty-five times beyond what was considered safe. As an illustration of such inconsistency, it may be mentioned that some railway officials will not use a steel-tired wheel with a cast-iron center of any kind, no matter whether the tire is welded to the center or shrunk or bolted on, notwithstanding the fact that many thousands of these wheels of different kinds have been used for years and years without a single accident resulting from the cast-iron center that we are aware of. Yet cast-iron is good enough for the large driving-wheels of the engine. Does this show good judgment, and has not the time come when we should direct our attention to the making of a high-grade wheel that will give more wear for less money? The chief trouble with an ordinary rolled tire is lack of uniformity in wear as the center is approached. The first, say, ¼-inch gives good service, the next ¼ gives less, and the next still less than the second, and so on till the center of, say, a 3-inch tire gives comparatively few miles per unit of reduction as compared with the outside. This is inherent in a rolled tire. Hence, it would seem that we must look to a solid cast steel wheel to get better wearing material, *i. e.*, material in the unforged state, which will not only give better wear than a tire in the beginning, but will continue to give the same service per unit of reduction till the rim is worn out. It might be said that improvement does not lay in the direction of a harder material, as a rolled tire, which is much softer than the chill of a cast-iron wheel, will outwear in the same service and before the first turning from two to three chilled wheels, but it must be remembered that chilled iron will not stand both heat and abrasion, and that the moment chilled iron is heated by the action of the brakes the surface structure is broken up and disintegration follows rapidly. While the comparatively softer material in the rolled tire will give much more service than chilled iron, it is very certain that a harder and more dense steel will give still greater service.

As is well known, great progress has been made in casting steel in the past few years, particularly in Europe, and unforged projectiles have been made to stand the shock of piercing through armor plate that seems almost incredible; a 9.2-inch projectile having penetrated 16½ inches of wrought iron and passed 8½ inches into another plate behind, without breaking, and a 6-inch shell has been fired through 8 inches of wrought iron without breaking—both unforged, or just as they came from the mold, except for annealing and treating. If unforged steel can be made to stand such shocks as these, surely we should be able to cast a solid steel wheel free from strain and blowholes, possessing better wearing qualities than any tires made to-day, and of course cheaper at the same time. Hadfield's manganese steel, for instance, while it has not so far been used for regular railway wheels, has shown extraordinary wear in mine car wheels, where they have been spragged (slid) for miles down heavy grades. It cannot be said that we do not need a harder material for better wear in car wheels, and in all probability this can be obtained better and more cheaply in the unforged state, *i.e.*, in a solid cast wheel, than with a rolled tire and a center.

At least 25% of the railway wheels used on the German railways are solid cast steel, and have been for more than twenty years, and some of the solid wheels that have been made and used in this country strongly indicate what should be done in this direction when undertaken by skilled and experienced steel founders.

That considerable prejudice exists against cast-steel wheels is undoubtedly true, and it has been caused by faulty material due to lack of experience; but this feeling will promptly give way when it can be shown that no ground for it remains, and, judging from what is now being done, this may be at no far-distant day.

---

The Sheffield newspapers say that there is little doubt that the Admiralty will use the Harvey armor plate in new war ships. The final decision will be considerably influenced by the latest experiments, but as the Sheffield *Telegraph* frankly admits, it is clear that so far the American invention has achieved the greatest success in armor resistance to projectiles ever known. There is to be another trial in England for the purpose of confirming the first impressions as to the value of the process. The Pennsylvania Railroad Company are investigating the suitability of Harvey treated steel for various railroad machinery articles, including tires.

---

We have been surprised to find by conversation with a man generally well informed, that he was under the impression that copies of patent papers were to be obtained only by the patentees. As others interested may be laboring under the same belief, we would inform them that a copy of any American patent may be obtained from the Commissioner of Patents, Washington, D. C.

---

The Lake Shore & Michigan Southern Railway people have decided to equip one of their largest roundhouses with the Smith fire kindling apparatus. This device is making its way steadily into favor. We do not remember of any improvement that is more urgently needed. The prevailing method of raising the steam in locomotive boilers by means of wood, is expensive, dirty, slow and dangerous, on account of the piles of firewood that must constantly be stored beside the engine houses. The cost of kindling a good coal fire by the Smith invention is small and the work is done in a sensible fashion.

---

The railways of this country are valued at $60,942 per mile of line—almost ten billion dollars' worth.

Best Yorkshire Bar Iron and Forgings.

Write on one side of the paper, state your point plainly and briefly, and then quit. We supply the generalities. No letters noticed unless name and address accompany.

### Who Knows the Best Way to Lay Out Eccentric Keyways and Properly Locate Them Before Wheels Are Put Under Engine?

*Editors :*

Have you ever come across a shop on this continent where the eccentric sheaves of locomotives are keyed on in their correct positions in the wheel shop prior to their coming in the erecting shop to be placed under the engines? We used to do it on the M S. & L. Railway Works at Gorton, (Lancashire, England). If you have, I should like a description of the method adopted. F. L. WANKLYN,

G. T. Works Manager.

*Montreal, Can.*

### One Run in Ireland, Where They "Biled the Wather" While Running.

*Editors .*

I am much obliged for the copy of your paper containing description of our works and those at Crewe, by Mr. Hill. I served my time at Crewe and was on the L. & N for two or three years after.

The inclosed cutting from a Cork paper will show that we do manage to "bile the wather" a little, while running, sometimes

"An occurrence which caused much excitement took place here to-day. An American gentlemen, who had booked a saloon passage in the White Star liner, Teutonic, for New York, named Mr J. S. Piza, of the firm of Messrs. Piza, Nephews & Co., dry goods merchants, New York, left London last evening by the limited mail, so as to catch the Teutonic here to-day. On arrival in Kingstown this morning, his luggage, through some cause or another, got astray, the result being that he missed the mail train at Dublin. This was a most serious matter for Mr. Piza, inasmuch as he had most important business matters to transact in New York on the 21st inst, on which day the Teutonic will be due there. Without much thought the enterprising Yankee arranged with the Great Southern & Western Railway Company to run a special engine with a carriage attached, to Queenstown for the sum of £50, and at 9.25 A.M. a powerful engine with its one passenger sped away from the Kingsbridge station on its long journey of 180 miles, at the rate of 55 miles an hour, which speed it maintained throughout The traveler left nothing undone to secure his chance of catching the White Star liner. He offered the engine driver an unlimited sum if he reached Queenstown within a certain time, and wired before he left Dublin to have a steamer ready to chase the Teutonic. Never before did a train travel as rapidly in Ireland; it broke the record between Dublin and Queenstown and accomplished the distance in the rapid time of three hours and twenty minutes. At 12.55 Mr. Piza alighted, and his luggage was rushed across to the Deep Water quay to the powerful Clyde steamer, Flying Fox, lying in readiness. All being on board the hawsers were cast off, and five minutes later the Flying Fox was chasing the big ocean liner out the harbor. Amidst much excitement, crowds on shore, as well as on the Teutonic, watched the result of the chase. The go-ahead American desired to catch his ship, for which he made such a bold race. His efforts were rewarded by boarding the Teutonic before she had reached Roche s Point, amidst much jubilation amongst his fellow travelers, and soon afterward was out on the Atlantic on his way to Sandy Hook."

The actual distance is 177¼, and the time was 3 hours 31 minutes, running speed, excluding signal stops and two stops for water, 54 Engine, 6-foot 6-inch, four coupled, 17-inch by 22-inch cylinders, small express type, same engine went through. There is nothing very remarkable about the speed as the load was light, (one carriage and one van, about 25 tons) but we had to find an engine at a moment's notice, and as there were already three engines with express trains on their way to Queenstown, we had to take the first we could get, and this was one due to work a slow train and not used to fast and long runs, so I think engine and men did very well.

Best part of the run was 62¼ miles in 65 minutes, start and stop. The offer of unlimited gold to the driver existed only in the fertile brain of the reporter.

### Faith Cure for Engine that Slips Shut Off.

*Editors :*

I see inquiry made again about engines slipping after being shut off. In my experience of over twenty-one years on an engine, I never had it occur until within the last six months. I had run the engine three months before she made the first attempt to get ahead of herself, and she did it for several trips when I shut off running fast.

I have been asked to account for it, but won't be positive that I have. About that time the engine had settled so that she was not properly equalized; had the engine raised some on engine trucks and also on different driving springs. I did not have this done to stop the slipping, but she has not slipped any since I don't know whether this has solved it or not; am waiting to see. The enigma is U P. build, 18 x 26, 5-foot 10-inch wheel.

### Dangerous Axles—What Causes Their Weakness.

*Editors .*

I have a word to say about your article on "Dangerous Axles," and your comment thus "And is a good illustration of the ultimate result of the race for cheapness, etc." Now, I'll venture the assertion that those axles, every last one of them, were made by piece-work. Yet your "senior philosopher," at least, is an advocate of that system, and every mechanical publication in the land teems with plans, schemes and ideas to produce cheap results. It seems to me that justice to all concerned would call for a little more liberality in this respect, good work cannot be insured where a ridiculously low limit of cost is established, and nothing tends to bring about this result more than the piece-work plan. I furnished your office some time ago, with an instance of cheap, quick work that came under my observation, where a new engine just from the builders, was completely overhauled before she ever made a trip; but to return to the axles; $8,000 (the cost of the accident) would have bought a good many first-class axles.

There is no doubt but that many of our most frightful disasters and sacrifices of life have been caused by defective and cheap workmanship. The laborer is worthy of his hire (if he is not, fire him and get one who is), and the patron of a railroad has a right to expect that the car he rides in has good wheels and axles under it, and that its weight will not crush down some fine-appearing bridge whose timbers or irons were so cheaply procured as to preclude the possibility of their being good. I was glad to see you take the position you did in the above case.

W. H. WESLEY.

*Nashville, Tenn.*

### Railroad Shop Kinks.

*Editors*

One can scarcely enter a railroad repair shop and look about without finding useful, and to him at least, new "kinks" and ways of doing work, and my experience in the E. T., V. & G shops at this place has been no exception to the rule, and I would like to tell the machinists who read LOCOMOTIVE ENGINEERING about one or two "kinks" which to me were new, and which I know will be found very useful by those who put them into practice. Possibly these kinks may be familiar to many, but I hope that they may be new to some, and as they can be made at very small cost, I think it will pay those who have not used them to do so. One of the first things which attracted my attention was a simple contrivance for holding work to a planer bed, and was made as follows The small wrought-iron or steel pieces which are commonly driven into the square holes through the bed, and used as

End View

Fig 1

snubs, are drilled through near the top ends at an angle of about 30 degrees, and tapped ⅝-inch, into these holes steel bolts having large centers in their thread ends are fitted loosely enough to be turned easily with the fingers. The only other things necessary are several pieces of ½-inch round steel of various lengths pointed at each end.

Lay the piece to be planed flat on the bed with one end resting against a snub in the usual way. Then, where the work to be planed is not too long, place two of the iron blocks containing the steel screws into holes in the bed at each side of the piece to be planed with the screws pointing toward the work. (See Fig. 1.) Then opposite each screw make a small center-punch mark in the work near the lower surface and insert one point of the round steel pieces in each, placing the other points in the large centers in the screws. By tightening the screws the work is forced solidly to the planer-bed, and against the snub. The work cannot move when held in this manner, and I have seen a ¼-inch cut taken from a piece of wrought-iron thus held, and the work not budge from

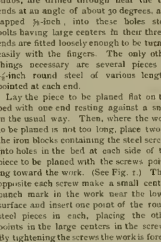

Fig.2

its position on the bed. When it is desirable to finish all sides of a piece of work, the center-punch marks in the sides already planed need not be made deep enough to prevent hammering them over after the planing is done, so that when the work is finished they cannot be seen. This manner of holding work to a planer-bed was introduced here by a former master mechanic, and to my mind is a useful kink

Another neat thing noticed here is an arrangement for pressing in driving brasses, bushings, etc., to make which the best plan is to have a cast-iron base made, about 18x24 inches and 3 inches thick, with two holes, each 2 inches square, bored through it. These holes should be about 18 inches apart Into these holes fit the lower ends of a 2-inch-square bar of steel, bent into the form of *A*, Fig 2, fasten the ends under the casting by putting through ¾-inch steel pins. The height of the top of bar *A* from the base must be determined from the thickness of the driving box, length of driving brass and length of the jack to be used. Place the driving-box with brass entered in it on the base with the brass directly below the center of the loop in bar *A*. Then place the base of a common 20-ton hydraulic jack on the upper end of the brass, with the jack-head in the loop in bar *A*, and you are ready for business. It is a good scheme to connect a hydraulic pressure gauge to the lower chamber of the jack, or, in case you have no gauge, connect to it a common small pop valve set to the pressure at which you wish the brass to go in. This simple, cheap tool can be put to a great variety of uses and very soon pays for itself

### A Neat Way to Fit Up a Room for Educational Purposes.

*Editors*

I have been a reader of your valuable paper since May, 1888, and have watched it grow from a small 16-page paper to its present size, and predict for it a future not equaled by any mechanical paper published. The hints dropped by it have been of great value to myself and I presume many other readers.

The Enginemen's Mechanical Association of North Platte, Neb., was suggested to me by reading your paper, and as I have not heard of any other association exactly like it, perhaps you might like to give your readers an idea of what we are.

The Union Pacific, through Master Mechanic J. H. Manning and Division Foreman M. K Barnum, furnished us a coach and fitted it up with tables and shelves In it we have one of your valve models, also models of different injectors, lubricators, metallic packings, Westinghouse and New York brake and triple valves, pump governor, Leach sanding apparatus and other engine appliances We subscribe for several mechanical papers, among them LOCOMOTIVE ENGINEERING. We meet as often as we can and exchange ideas, and I believe it has been of great benefit to most of its members

W J. STUART

*North Platte, Neb.*

### Some Improvised Milling Methods.

*Editors .*

Having a small gear to cut with V-shaped teeth, the teeth being on an angle to act as a worm gear, and having no milling cutter with the angle of 30 deg. on each side of the center of the cutter, had to use one having the right angle but having the front face straight, as shown in the cut, Fig 1.

So, turning the milling table on the proper angle to bring the teeth right for the worm, the table was brought forward until a line drawn through the center of the angle of the cutter was in line with the center of the work, this is shown by the dotted line in the cut.

Now it will be seen that all necessary feeding into the cut can be done by simply raising and lowering the table (with the work on it between centers) and that this will bring the teeth with their angles correct in relation to the center line of the gear wheel.

This method often proves useful where the variety of cutters is limited or where special work requires some maneuvering to accomplish the desired end.

The other cut, Fig 2, shows a method adopted to cut into a piece of finished brass work in order to show the internal arrangement, and the work was first attempted with a cutter of about the required angle but this was slow work and also cut

much more brass into chips than was necessary, so a saw with coarse teeth, for metal work, was put on the milling machine spindle and the work turned to the right position for the first cut. Then, after this was cut through from end to end, the work was turned to the right position for the other cut and the work was done in a very short time, besides saving the brass cut away in a solid piece, or rather pieces. I do not think the metal saw is used enough for

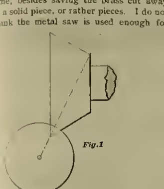

*Fig.1*

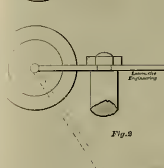

*Fig.2*

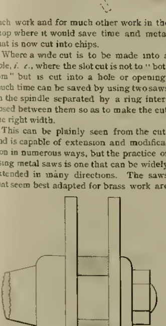
such work and for much other work in the shop where it would save time and metal that is now cut into chips.

Where a wide cut is to be made into a hole, *i. e.*, where the slot cut is not to "bottom" but is cut into a hole or opening, much time can be saved by using two saws on the spindle separated by a ring interposed between them so as to make the cut the right width.

This can be plainly seen from the cut, and is capable of extension and modification in numerous ways, but the practice of using metal saws is one that can be widely extended in many directions. The saws that seem best adapted for brass work are



those of coarse or few teeth and whose sides are concave from the very point of the teeth to the center, which prevents any binding on the sides if cared for in a half decent manner. The coarse teeth can be readily sharpened on any ordinary emery wheel or even grindstone if it is respectable shape, and there is more room for chips between the teeth. These are not expensive and will prove more useful than those who have never made use of them will imagine, while their saving in metal and time when they can be successfully used will be appreciated as their usefulness becomes known.

There is room for improvement in the ordinary milling machine vise both as to capacity and adjustment after the work is fixed in the jaws. Of course you can get anything you want in a milling machine vise, but most of the improved ones are special.

I do not want anything fancy in the vise, none of the ball and socket arrangements for milling around corners or anything of that kind, but one capable of being turned in a horizontal plane as well as having considerable adjustment in a vertical direction for use in milling surfaces with angular faces. These can be made without much additional expense and would, I am sure, be appreciated in the job shop where angles of all kinds, to say nothing of corners, slots, etc., have to be done and often with improvised cutters and rigs for holding the work as well. There are many who still persist in using the planer for all kinds of surfacing work but the milling machine is bound to hold its own on certain classes of work and the sooner this is realized the better for those who have work for them.

But above all things, remember the ever prevalent warning of a well known firm and "keep the cutters sharp."

For brass work the saws of about 5-inches diameter will be found about right for most work, although special work requires special tools. FRED H. COLVIN.

*Worcester, Mass.*

## Something for Our Air-brake School.

*Editors:*

Some time ago we had occasion to explain to an air-brake man something of the calculation of leverage, and the first difficulty that was encountered was a complete lack of knowledge of proportion; so we began by inculcating the first principles of this important branch of mathematics, after which we made an adaptation of an old rule for proportion which will apply to almost any problem.

It was as follows:

Let the letter $x$ represent the fourth term, or unknown quantity.

Put down for the third term the quantity that expresses the same thing as the answer required (for example, if $x$ or the result we are seeking is to be in inches, the third term must also be inches, and if $x$ is pounds the third term must then be pounds).

After this arrange the two remaining quantities in the problem as the first and second term respectively, putting the greater one down as the second term if $x$ is to be greater than the third term, and putting the lesser one down as the second term if $x$ is to be smaller than the third term.

If in the problem to be solved all that we have for the third term (that is, if the only given quantity that is of the same kind as the answer required) is the *total* length of the lever, then the pull or strain on the *center* hole must come as the first term. If the strain on the *center* hole of the lever is the third term, then the *total* length must be used as the first term.

To solve the proportion, multiply the second by the third and divide by the first, and the result will be the fourth or $x$, which is the answer required.

It will be immediately seen by those familiar with mathematics that this rule is based on Euclid's test of a proportion, and when understood can be applied to any kind of a lever.

To illustrate, let us take an example.

We have a six-wheel truck car weighing 60,000 pounds, the middle wheel of each truck having no brake attached. Hodge system used; see sketch.

Truck levers are 8 x 24 inches; equalizing levers, 18 x 18 inches.

Total length of the cylinder-lever, 24 inches.

Let us find the proper position of the center hole in the cylinder-lever, or in other words the length of its two arms.

As the middle wheel on each truck does not have any brake at all, we must subtract the weight carried by those wheels, which being one-third of 60,000, leaves only 40,000 pounds weight carried by the wheels against which the brake is to act. Now, to avoid danger of sliding wheels we must subtract 10 per cent. from this, which will leave us 36,000 pounds as the total braking power of the car. To find the pressure on each beam we divide this by 4 as there are four beams, and this gives us 9,000 pounds as the pressure on each beam. Now we come to the application of the rule. Put down $x$ as the fourth term. For the third term we must have some quantity that expresses the same thing as the answer required, and as the answer in this case is to be pounds, or the strain at the top end of the brake-beam lever, 9,000 will be our third term.

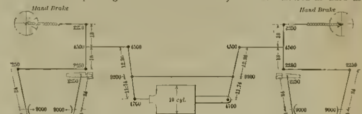
According to our rule, if the strain on the *center* hole of the lever is the third term, then the *total* length must be used as the first term. In this case 9,000, which is our third term, is the strain on the center hole, so we must place the total length of the lever, 32 inches, as the first term. For the second term we must use the shortest end or arm of the lever, as the strain at the top will be smaller than the strain at the lower end, as the upper end is of course the longer.

Our proportion then reads as follows

$32 : 8 :: 9,000 : x.$

Multiplying the 9,000 by 8 and dividing by 32, we have as $x$, or the strain at the top end of the lever, 2,250 lbs.

Since the equalizing lever arms are equal, each being 18-inches, the strain at the center hole of the equalizing lever will be



twice the strain at one of the ends, or 4,500 lbs., and this is transferred to the cylinder lever at the outer end. We have now 4,500, the strain on the outer end of the cylinder lever; 4,700, the strain at the inner end or next to the cylinder (in other words, the total braking force of the cylinder, a ten-inch passenger), and the total length of the cylinder-lever, 24 inches. Now we begin again, according to the rule.

Put $x$ for the fourth term. Since $x$ is to be inches, the third term must also be inches, so 24, which is the only known quantity in inches, we place as the third term. Now, as 24, or the *total* length of the lever, comes as the third term, the strain at the *center* hole, which is the sum of the two strains at the respective ends, must come as the first term. We find this to be 9,200 lbs. For the second term we can use either the pull on the cylinder end or the other end of the lever, but we must remember always, in applying the result, that the *heavier* strain always comes at the end of the *shorter* arm. Our proportion now reads as follows

$9,200 : 4,500 :: 24 : x.$

Multiplying the 4,500 by 24 and dividing the product by 9,200 we get 11.74 inches, which is $x$, or the shorter arm of the lever. The other arm will, of course, be the difference between 24 and 11.74 or 12.26 inches.

And the shorter arm will come next to the cylinder because the strain at the cylinder end is the greater.

Some might say, "What is the need of all this work, when a formula could be used?" That is all very well, but it must not be forgotten that if the slightest departure from the standard arrangement is made in making the design, then the formula is useless, and besides this, unmeaning formulas are hard to remember and if a mistake is made in substitution it is very hard to detect. PAUL SYNNESTVEDT.

*Chicago, Ill.*

## Vibration and Crystallization.

*Editors.*

In your January issue Mr. Lottes puts the question. "Now, when you a get a broken side-rod to weld, do you weld it where it was broken, or do you cut a piece out and put in a new one so as to keep your weld from the terminus of vibration?" Assuredly, by all means put in a new center.

He also wishes to know how I would go to work to crystallize a piece of good nail rod or a piece of Norway iron. Repeated hammering will make iron brittle; as an evidence in hammering a head on a Norway iron rivet, if the hammering is continued after the rivet becomes cold, the head will separate or fall off.

As I have stated, repeated hammering will make iron brittle, and brittleness is indicative of crystallization. This is one process of crystallization. Another is, put a Norway iron bolt to hold the riders in a drop-hammer and note the process of crystallization. I have known 2¼-inch bolts to break under the head and in the thread in this manner. Still another case; harden a piece of Norway iron, subject it to a certain process and it will crystallize to a great extent. All minerals, I believe, and the great majority of substances, are capable of undergoing the process of crystallization.

Now, Mr. Editor, with your permission, I beg to quote authority on the subject of soft iron *versus* hard iron. Samuel M. Vauclain, of the Baldwin Locomotive Works, says. "So it is with stay-bolts. The inclination of a good many people is to get stay-bolts as soft as possible. I do not believe in that at all. What I believe in for stay-bolt iron is an iron as hard as you can get it. You want a good, clean iron of good fiber. But you want it as hard as that iron can be made, to allow you to head them up nicely. Iron of this kind will stand a great deal more vibratory action on the boiler than when it is so very soft that you can hammer it up and squeeze it up like putty." Now I hold the same views and the conditions can be applied to side rods, on account of the vibratory action.

I might quote still further to bear me out, but it is needless.

*Gladstone, Minn.*

## Taking Centers—Quick Valve-Setting.

*Editors:*

I saw in your last issue some "Wants to know" why centers are taken from the main or parallel rods. I always do this, and my reason is on account of uneven track, as the wheel and rod rise and fall together; as for the lateral, that cuts no figure, but you can only use those centers once, and every time you set your valves you must take the centers over or prove the old ones correct, as main or parallel rod either shortens or lengthens, which would make some difference.

Well, if you stop to think, you will see the stationary mark for the wheel center is the same if you have a shoe forward and wedge back, every time you set up the wedge you carry the wheel forward. Now I claim this, that before setting the valves on any locomotive you should see that the wedges are set up properly and that parallel or main rods are lined up, then take your center and see that your valve stems are the proper length, then proceed with your valve-setting. Get your rocker arms to vibrate equal from center of arm forward and back, then I will guarantee your valves square in full stroke; now cut her back, say to 4 or 6 inches, try your center again, and you will find perhaps a little variation, make the change needed for an equal travel of rocker arm at this point, and I will guarantee your valves as square as any ear can detect.

I always gauge on a valve with the thickness of tin or iron, just the thickness I want lead, then I set my valves so my tram will drop in all center punch marks on the valve-stem on the four wheel centers. Now, I have explained the proper way of setting a valve, but I use the improper way—as all my acquaintances claim. Well, I am a kind of an improper fellow, but I get there all the same.

I set my valves in this way (but it may be hard for any of you to understand), but as I remarked some time ago in this paper, I do not want a foreman who will keep the laborers more than ten minutes pinching an engine around; I want him to be able to instruct the machinists what to do, and then attend to his duties as foreman. It takes a little practice to do this.

Now, do not all get up on your ears and say I am a "nigger driver," but just try and catch on and you will readily see I have not hurried anybody.

In the first place, the foreman sends a machinist to see that the wedges and rods are properly adjusted; if so, then the foreman takes the center on one side, uses the quarter on the other side. Now, you see, he only gets one turn for his wheels. In working in forward motion he puts the reverse lever in forward notch and pinches her back of dead center until the rocker arm moves, then come ahead, catch the dead center, then mark your valve stem on both sides of your engine, then throw the reverse lever back and pinch her ahead until the rocker arm moves, then pinch her back to catch the dead center, then mark both stems as you did in forward motion, then come ahead half turn and proceed as you did before.

I use a single-tram gauge for my valves, the same tram that I use for my wheel centers, so I only handle one tram and use my laborers just long enough to get one turn out of the driving-wheel.

I then divide the marks on valve-stem, this shows you just how much to lengthen or shorten the blades, then you call the machinist and tell him what to do. After he gets through then you go back and see that he has done it.

If you want to change the lead you just stay at the valve-stem with your tram and see that he does it.

If eccentrics are keyed on and you make any change in the lead, you have to take out the keys and offset them—you had better not stay at the stem then—just tell the machinist which way you want the eccentric, lead on or off.

You should always take off lead before you put it on.

Now, Mr. Editor, here is another nut for the boys to crack, and when cracked they will find lots of meat in it.

When an engine comes out new with eccentrics keyed on and are on properly they can be kept proper for a long time, and I will tell you why.

Most all engines of the present American type have a stationary shoe on front jaws, or "horn block" as you choose to call it, the driving-box fits up close against this with the wedge behind it.

As this shoe wears away and you push up the wedge, that carries the wheel ahead, takes lead off the front end of valve and adds to back end. Now if you will pull down the wedge a little below its original place to take up this wear and then line up the shoe, you will find your lead comes back to its proper place and also the blades if they have not been moved since coming out.

## Who Knows?

*Editors:*

Who knows and can tell the points wherein the standard Westinghouse freight triple valve differs from the standard passenger triple valve?

It has been noticed by many that special caution is given that one should not be used in place of the other under any circumstances.

This is for very good and sufficient reasons. The question is, What are the reasons?

An answer to this is requested from all men interested in air-brakes except those employed by the Westinghouse Company, as it is to be presumed that they could answer too easily, knowing all the fine points in their own construction.

PAUL SYNNESTVEDT.

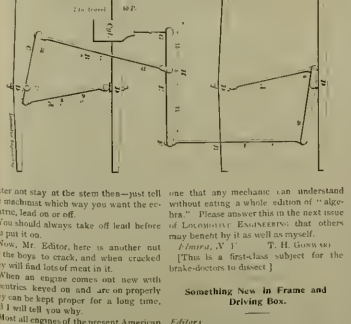
*Chicago, Ill.*

## Strange Brake-Rig for Tank.

*Editors:*

Here is a rough sketch of brake-rigging of locomotive tender that my attention was lately called to by one of the shop men. There are two Cooke engines equipped in this way. I have never seen a brake put up this way before, and do not think it properly designed. Please note the difference of power in the two trucks; you will notice in diagram that rod *B* or pull-rod is coupled at extreme end of lever *E* at *F*, 21 inches from center on front truck, and rod *B* on back truck is coupled to lever *E* at *H*, 6 inches from center, making a difference of 15 inches in the leverage of the two trucks; there is also a difference of 2½ inches in the long and short ends respectively of levers *C*, back and front trucks.

With 50-lbs. pressure and 7-inch piston travel, what will be the difference in brake-power of both trucks? Also give a simple rule for calculating the lengths of rods and levers for a properly designed brake—



one that any mechanic can understand without eating a whole edition of "algebra." Please answer this in the next issue of LOCOMOTIVE ENGINEERING that others may benefit by it as well as myself.

*Elmira, N. Y.* T. H. GONWSKI.

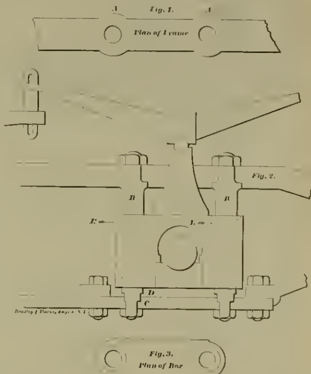
[This is a first-class subject for the brake-doctors to dissect.]

## Something New in Frame and Driving Box.

*Editors:*

The partial abolition of straps and keys being a step in the right direction to simplify locomotive construction, why should the wedges not go also? Some one says, how are we going to adjust the center and get the wheels in tram without the wedge? In reply to that question would say, on the same principle that we put on a solid end-rod. The wear on shoes, and wedges, and driving axle-journals, is no worse than the wear on crank-pins. Now, the question comes up, what shall we substitute in place of wedges?

Inclosed I send sketch of a new style of jaws for the frame. I propose to forge the frame with a swell, *A A*, Fig. 1, also make the frame somewhat heavier in its vertical section; drill accurately, and counter-bore the frame on the under side. Fit in the columns or studs, *B B*, making a good fit both in the hole and counter-bore. The idea of the counter-bore is to



have the shoulder on the stud take part of the thrust of the engine. The binder is drilled and counterbored also. You will notice two shoulders, *C D* on the lower end of the studs, the shoulder *D* is to allow for turning down in making repairs, without changing the fit in the binder. The studs can be 4 inches in diameter, which we will call the maximum. In fitting up new work 3¾ inches would be the best size to start on, as that would give us material in the box for reboring in repairs, when we could put in a set of 4-inch studs. The 4-inch studs can be reduced afterward to 3⅞ inches, and be used for new boxes. Fig. 3 shows top of box. The stud-holes in box should be bored after the brass is in and sides planed. The studs should be case-hardened, put in lathe centers and ground true with an emery wheel. You will notice the thrust is taken up at two points in this style of frame, ditto the wear, as shown by the arrows, *E E*, while in the frame in use at present the thrust is back and forth between the faces of the two jaws. I claim for this frame that it is cheaper to make and keep in repair, than the old style, and when fitted up with good malleable-iron boxes and case-hardened studs, and by a man who knows his business, it will give first-class results. Who speaks first, and what are your objections? Pull it to pieces, and look it over, you progressive men; strap-rod men may say it is no good. The solid end-rod has come to stay, and it wants company and here it is.

This frame is not patented; use it.

W. DE SANNO.

*Indianapolis, Ind.*

## Hardening Tools, Leaving a Soft Center.

The causes that regulate the efficacy of tool steel and the results depending thereon is a subject on which opinions differ.

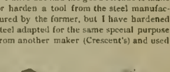
The conditions into which steel can be worked, and the hardness and elasticity it may be made to acquire, are qualities which have been turned to account, and upon these the tool-smith's art and skill depends.

But there is a great difference in steel, and it is only by knowing its nature and construction that any real advance can be attained.

The method pursued in making steel is the same in principle everywhere, yet distinguished variations are produced by different manufactures.

One maker of steel will furnish special grade as to carbon, designed for a distinctive tool, and instruct us to harden at a "high red," whereas the steel of another maker, designed for the same purpose, can be hardened with good results at a "low red."

I have not had the good fortune to make or harden a tool from the steel manufactured by the former, but I have hardened steel adapted for the same special purpose from another maker (Crescent's) and used



a low red heat. I reduced or hammered the steel to a certain degree, and that has a refining effect, at any rate it increased the carbon. Undoubtedly either brand will answer the purpose, but why this discrepancy—possibly a "trade secret."

We also made some bolt-thread cutting-dies out of some of the best English steel—steel adapted for that special [illegible] of work. We handled it in the same manner as we do Crescent's, but learned that we could not apply the same mode of treatment. We were obliged to use a higher heat in hardening and a different color temper.

The one great difficulty to overcome in hardening and tempering tools, particularly long taps, reamers and tools that are long, thin or narrow in proportion to circumference or thickness. Taps, reamers and like tools, above a certain size, can be straightened after they are hardened, providing you retain a soft center, but tools below a certain width or thickness will spring more or less. Heat that is perfectly

even, and water at a perfect temperature, or oil, will not prevent the trouble.

As to the cause I do not wish to presume to know. I only wish to indulge in what might be a probable cause. Is it not possible that the active power produced by sudden cooling affects the molecules or particles, causing them to contract and encroach upon each other? Sometimes it may be a single particle, or it may be a multiple of them, which gives cause to turn or twist the tool out of shape.

Of course, the larger the tool the less the tendency will be to get out of shape, on account of its having more support.

One of the most important and generally used tools is a chipping chisel, and I wish to direct attention to an evil effect (quite common) in dressing them, and that is, hammering them edgewise after the red heat is gone and the chisel has become black, which causes the cutting end of chisel to become foliated or lamellar, causing a shelly fracture which invariably causes the chisel to nip, nick or break off on the corners.

The better way is, before giving chisel the finishing blow and before the red heat leaves, to narrow it, giving proper estimate as to width, and let the final blows be applied to the face of chisel; harden at a low red, and as a result the particles are firmly and closely united with a tenacity that means business.

Not so long ago a special steel with soft centers was especially manufactured for a certain class of tools that required toughness and elasticity on account of the peculiar nature of the work, this is all obviated now, for the reason that steel can be hardened on the outside to almost any desired depth, leaving the center soft and in an annealed state.

The mode of operation is simple. Cool the tool in water, keeping it there long enough to obtain the desired depth of hardness, then quickly withdraw the tool out of the water and plunge in an oil tank for the purpose. It is not possible to say just how long to keep the tool in water before it should be taken out and dipped in oil, as much depends on the size of steel and the temperature of the water. A good way is to take a worn-out tap or reamer and use them as trial pieces, both as to heat and length of time for keeping in water; break a piece off and you will see on examination the consequence or effect; a few trials will put you in line.

GEO. T. HINKENS.

*Gladstone, Minn.*

[The photo illustrations here shown were made direct from broken taps hardened by Mr. Hinkens. As can be seen, the teeth of the tap are so hard that they were easily broken by a blow, while the center is so soft it was drilled. The structure of the metal is plainly shown.—EDS.]

### Brake Experience—A Tender Brake that Went On and Off All by its Own Self.

*Editors:*

While reading the air-brake problems as expounded by some of the readers of LOCOMOTIVE ENGINEERING, I was reminded of a little incident in "air-brake practice" which at the time seemed very mysterious.

Something less than two years ago the writer was firing one of those engines sometimes known as a "Pittsburgh Hog." We had pulled in on a siding, on a warm summer's night, with a train of stock, to await the passage of some "varnished cars," and seated on the ends of ties, alongside of the tank, cooling off, we were surprised to hear the brake rigging moving slowly, and finally the brakes were applied. My first impression was that we had "air-cars" next to engine and that some person was bleeding the train-pipe at some point, but an investigation showed that we had no air except on engine and tank. In a short time the brakes were released, only to set again in a few minutes, and so on, alternately setting and releasing. This set us to hunting with torches for a leak in the train-pipe, but after a careful search we were about to give it up for the time being, when we discovered a bad leak from the joint of the main air-pipe with the main reservoir at the point where it (the main reservoir) receives its supply from the pump. This had been overlooked on account of its being on the side next to boiler, and might easily be confounded with a blow from a mud-plug, stay-bolt, washout-cock or a seam.

Our solution was this. With handle of brake-valve in full release position the main drum forms part of the train pipe, only in greater area, consequently, when the governor shut the pump off, in a short time the pressure was reduced in main reservoir slightly below that in auxiliaries, thus causing the action referred to, and which was soon remedied by a few turns of a wrench.

Another case I think worthy of mention was where two engines were "double-heading," the leading engine handling the brakes, second or helping engine having brake-valve blanked, with service-stop exhaust closed, but no stop-cock in train-pipe below brake-valve. By some means the air-pump on second engine stopped working, pressure became reduced on top of rotary valve, which allowed the air in train-pipe from leading engine to raise the rotary valve sufficient to cause a bad blow at emergency port, thus setting the brakes. After some delay the pump was finally started, and after pumping up more air than was in train-pipe, the rotary valve was of course forced down to its seat. In a case of break-down, however, where the pump could not work, some way would have to be found, probably with a blind washer, to shut off the air from the brake-valve. Would this be considered good practice? If not, would like to know why.

JOHN BRUCE.

*Pittsburgh, Pa.*

### Oiling the Air Cylinder.

*Editors:*

I saw your item in regard to oiling air-pumps. You are quite right in saying that many engineers use too much and the wrong kind of oil in their air-cylinders.

An excellent lubricant for the air-cylinder is a very little lard oil. It don't gum, and keeps the brake-valve working free and easy. Soft soap makes a good lubricant for the air-cylinders, a tablespoonful or so each trip, letting the pump draw it through the bottom suction-valves. I have seen it used in air-pumps under hard service for twenty-four hours at a time, in shop work that would almost burn up otherwise.

Air pumps equipped with metallic packing get very little oil through gland into air-cylinder, but I think very few roads use metallic packing for air-pumps, but it is A No. 1, and saves lots of expense and trouble.

CORY S. CONCANNON.

*Hannibal, Mo.*

### How a Shop Boy Gained the Model.

*Editors:*

The valve motion model was safely delivered here last week and has been set up in my room. Every night since it arrived we have had a picnic in the house made up of shop boys and firemen who come in to see how the thing works, and they are all taken with the plain way it shows the working of the valve motion. We are going to have regular lessons in setting valves and Hiram Williams, who does the valve setting in the back shop, has promised to come and give us pointers.

We all think the model is a dandy and just the thing we want. After we were done working it the night before last, Phil. Moore, who is next in turn to be set up, said that he never understood before how the steam got in and out of the cylinder, but the model shows it clearly.

I have been thinking that it might amuse you to hear about how I contrived to get enough names for LOCOMOTIVE ENGINEERING to entitle me to the valve model. My father was killed when the flyer ran into the washout at Brandons four years ago, and I am only a helper in the shops, so I do not have any money to spare for buying models or anything else. But I have plenty of spare time of evenings and I made use of that to get what I wanted awful bad.

The way I came to know about the model was this. Walt Matthew, who runs the 29 rooms in our house takes LOCOMOTIVE ENGINEERING. He is a good fellow, Walt, everybody knows that, and he said that I might read the paper all I wanted and that I could get one for myself by raising a club. That was how I came to send for club rates. When I got the premium list I was stuck to decide what I should like best to have.

At first I thought of trying for a set of drawing instruments, but I have a set that belonged to my father and did not need them very bad. Then I thought of a clock but I do not expect to be running an engine very soon and there was no hurry for that. I am studying valve motion and the model took me, but I had no idea of getting enough names to get that. I went to work asking everybody to subscribe and showing them the paper. It was uphill work at first, for very few of the men had seen the paper. I began lending the specimen copies you sent to show what a good paper it was and on the first pay-day I got three shop men, seven firemen, two engineers and Mr. Brown, the master mechanic. I did not like at first to ask Mr. Brown. He was very pleasant and said he would like to see all the men taking the paper and would do anything in his power to help me to get subscribers. All through the work of getting the 85 names I have had Mr. Brown's encouragement, but he did nothing except speak a good word for the paper, and that was all I wanted. If he had tried to do any more the boys might not have liked it, and I did not want any form of compulsion to be tried.

All through, my motto has been moral persuasion. The paper itself helped me along, for the men who took it praised it to the others. It is funny to watch the motives that induce some of the men to join the club. Most of them took it because they were convinced that the paper would be worth the money to them, but others took it because they did not want to be considered of the class that take no interest in their business. Some took it because they had seen other men reading the paper and they wished to display equal enterprise. In three months I had got seventy-six names, and then the end seemed to be come. There were nine names more needed to complete the list that would entitle me to the valve model, but everybody had been repeatedly canvassed. Trying for more names seemed like trying to get milk out of a stone. I felt awful bad to be beaten with the prize in sight, but beaten I seemed to be. I made a final turn among the men without getting a single additional name, and then I made up my mind to write to you asking for the money commission on the names sent in. I had written the letter and was going to take it to the letter-box when Walt Matthew came in. I told him how disappointed I was and he offered to make up the shortage. This was very kind, but I would not take any help of that kind, for he had been my best friend in the canvassing.

"Have you tried the train men and the people in the general office?" he asked.

I had not thought of anybody out of the rolling stock department taking the paper and said so.

"Go right to the general manager," said Walt, "and take in the superintendents, train master, conductors and brakemen. You will get subscribers among them all."

I hated to go among these people, but after thinking it over I concluded that they could not eat me. I went to Mr. Brown and he gave me a line to the general manager, so I started out in fear and trembling. In one afternoon I got fourteen new names and since that have obtained eleven more, and there are others who will come in.

That is how I got the model and I am going to get a good gold watch next year and some pocket money besides. Getting subscribers to a club is a picnic when your heart is in the work.

*Chicago, Ill.* ROBBIE WILSON.

### Traveling Engineer's Puzzle(?)

*Editors:*

Traveling Engineer, in his "Lame Exhaust Puzzle," says that he examined valve motion thoroughly, then in his answer states that the lame exhaust was caused by "loose lifting-arm on tumbling-shaft." Is not the lifting-arm a part of valve-motion? This must be the same traveling engineer that gave the "Alex Cunningham Puzzle" some time ago.

*New Castle, Pa.* P. W.

[We have several letters similar to this.]

### Answer to "A Blow; Where Was It?"

*Editors:*

The engine had the long curved eccentric blades, and the right go-ahead one had elongated or stretched ⅜ of an inch. The valve had ¾-inch lap, and the steam-chest was long enough to permit the valve to open the exhaust port in traveling back. In springing there was not a crack nor flaw opened up in the rod.

C. G. BRITTINGHAM.

*Danville, Ill.*

### That Engine that Limped when at Work.

There is a liner riveted on the inside of the smokestack and has become loose at the bottom end. Now, so long as the exhaust does not go under this liner it gets out of the stack to the air, and engine sounds all right. But sometimes the exhaust goes under the liner, and the exhaust is not heard, so the engine sounds lame.

THE ANSWER.

*Editors:*

Engine has loose cylinders. This only affected her when she had a hard pull.

*Vandalia, Ill.* TOM.

### That Puzzle Diagram.

*Editors:*

I should say that puzzle diagram was caused by a case of bad valve-setting.

*St. Louis, Mo.* H. E. MATHEWS.

*Editors:*

I guess that puzzle card was caused by slack in the valve-gear, perhaps the yoke; evidently the valve had no lead.

*Atlanta, Ga.* J. GOKES.

THE ANSWER.

*Editors:*

The defect in card was caused by tapping the holes for indicator pipe into the cylinder in such a way that the piston, when at end of stroke, shut off the communication to the cylinder. F. S.

*South Kaukauna, Wis.*

The National Railway Spring Company has been formed by a consolidation of the National Car Spring Company, of New York, and the Oswego Railway Spring Company. The new company intend to build first-class shops at Depew, near Buffalo, and equip them with the best tools. The officers of the company are all well known to spring buyers. They are: President, Thos. Irwin, Oswego, N. Y.; vice-president, Thos. M. Bell, Philadelphia; secretary and treasurer, Geo. B. Sloan, Jr., Oswego, N. Y.; general superintendent, Edward Cliff, New York.

The Interstate Commerce Commission estimate that in 1891 each locomotive engineer in the United States hauled 369,077 passengers and 2,329,639 tons of freight one mile.

# Car Shops and Car Builders.

## Some "Americanisms" in English Passenger Cars.

The photographic reproduction at the top of this page shows a pair of dining cars recently put on the run between London and Glasgow, and known as West Coast Joint Stock, being owned and operated by the London & Northwestern and the Caledonian Railroads. These cars are called "American," but the true citizen of this country will see at a glance that they are very small compared with our diners.

They are "American" in that they have 12-wheeled trucks, are vestibuled, and can be traversed from end to end.

The car body of the one next the train is only 45 feet long; they are always run in pairs—it is 47 feet 9 inches over the platform, having but one; the other car is 50 feet 6 inches over the platform, they are only 8 feet wide over all. Real "Americans" would be 9 feet 8 inches, or 10 feet even.

One car contains the kitchen for both, and in it there is a dining-room for twelve persons and another for six, and a lavatory. The other car has a lavatory, a luggage compartment, a dining-room for twelve persons and another for four; it also contains a small stove chamber and a 6 ft. 6 in. room between the dining-rooms.

These dining-rooms are designed to accommodate the different classes of travel without mixing.

"AMERICAN" TWIN-DINING CARS IN ENGLAND.

The second picture is a view of the largest dining-room in the car containing the kitchen, showing single seats on one side and double on the other, although it is not intended to put four people at a table; the third picture shows the larger dining-room of the second car.

DINING-ROOM FOR TWELVE PERSONS.

These cars ought to be appreciated by the sandwich-eating British railroad travelers; but the other joint stock is composed of eight-wheeled cars 42 feet long, having room for seven first-class passengers, nine second-class and nineteen third-class, and (height of American perfection) a lavatory for each and every class. These cars are of the abominable compartment breed, and a hungry passenger can just wait till the train stops before he can get into the "eating-car."

These joint stock carriages are 7 feet 5 inches wide on the floor, but the body swells out to 8 feet. The entire train is lighted by Pintsch gas, but are not heated except by the ancient hot-water can. Only the platform between the two dining cars is vestibuled.

## A Magnificent Sleeping Car.

The most handsome sleeping cars that we have ever seen have lately been placed on the New York City & Northern to run over that line and the New York & New England between New York and Boston. If convenience and comfort can make a line of cars popular these are destined to liberal patronage. The express train for Boston leaves 155th street, New York, at 11 30 P. M., and an express train is run over the Manhattan elevated to make connection. As passengers coming over the elevated road have merely to cross a platform to reach the Boston train, the new service will be very convenient.

The sleeping cars were built at Pullman and are considered the finest ever turned out of these shops. They are finished in mahogany most elaborately carved on unique designs. They have arched roofs and are so high that unusually great head room is provided in the berths. The ceiling or head-lining is finished in a green ground that is nearly yellow with traceries of silver decorations. The effect of this combination resembles some of the fine Mosaic decorations that East Indian artists put upon beautiful boxes for holding jewels and other ornaments.

There are special ventilating appliances at the ends of the cars, but air can also be admitted through half-elliptical sashes which are set along the sides of the roof. As a marking between each berth there is a wide band of elaborately carved mahogany that stretches from the seat over the ceiling and down the other side. These bands have a most imposing effect. The doors at each end of the body of the car are loosely screened by curtains made of braided woolen rope. The upper part of the end partitions, beginning at the spring of the roof, are filled with half-circles of colored glass with fantastic brass scroll-work laid on. The seats are of a novel design that has "comfort" written on every thread of the yielding mass. The color looks like old gold and is not exactly that tint. Those who want this question settled to a nicety can apply to General Manager Vreeland, who is an expert on describing cars.

The drawing-room of the car appears to be a most *recherché* affair, in other words, all that taste, skill and labor could do to make it attractive have been liberally spread out. We can speak with more authority of detail regarding the smoking-room where no ladies were about to look upon minute inspection as an impertinence. It is finished in mahogany, like the body of the car, and has seats of embossed leather. The portion of the smoking car touching on the side aisle is formed of turreted panels profusely carved, which give an impression of castellated bordering.

Under the end-hood of each vestibule there is a half-spherical dome containing the Pintsch lighting globe. The cars are carried on six-wheeled trucks, and have all modern appliances for promoting safety and comfort.

## The Rodger Ballast Car.

The Great Northern has lately ordered over 400 new Rodger ballast cars in addition to about 200 that have been in use for some time. This car is rapidly becoming popular, especially in the West, and is a great time and labor saving help in the distribution of ballast. The Illinois Central people have used this car for upward of two years in carrying broken stone from the quarries, and those in charge speak in the highest terms of the advantage gained as compared with flat cars. Each car carries about twenty tons of ballast. It is dropped upon the track through two hoppers, one at each end of the car, and lies in a bed reaching up to the axles. On the last car of the train there is a distributing plow which scoops up the gravel wanted for the outside of the rails and lays the supply in ridges over the ends of the ties. The distributing train can be run as fast as ten miles an hour while dropping the ballast. The supply of ballast is left in such a shape that there is no danger in running trains. The Rodger Car Co., Monadnock Building, Chicago, control this useful car.

### Claiming Patent Rights on Car Side Stakes.

There appears to be considerable feeling among railroad men about what is known as the Congdon patent for side stakes of cars. It is a common practice in car building to extend the side stakes down so that the lower ends rest against the two center tie timbers. This is a method of construction as old as car building, yet in 1885 Isaac H Congdon obtained a combination patent for extending the cross-ties downward so that they should act as braces for the side stakes and for putting supplementary tie planks for bracing the stakes at the points where it is not customary to put tie planks. The parties controlling this patent now hold that the railroad companies extending their middle stakes to lean against the tie timbers or needle beams are infringing the Congdon patent. This is an impudent attempt to make a patent go far beyond its claims. If a railroad company puts in the supplementary cross ties to hold the stakes they will infringe the Congdon patent, but to put their stakes against the middle tie beams is merely following a common practice and is no part of the Congdon invention.

The head of the mechanical department of a prominent road which has been annoyed by the claims under the Congdon patent, writes us: "If we are to steer clear of patents on such simple and common devices as this we will next have to look into the Patent Office to see if we can mortise a car frame together without infringement."

A question that occurs to us in connection with the railroad companies which have been harassed over the claims made under this patent is, What is the use of the Eastern & Western Railroad Associations? These associations swallow a great deal of money from railroad companies ostensibly to defend them against patent litigation. Why don't they show up the real hollowness of the Congdon claims?

### Car Heating of the Season.

The exceptionally cold weather of January has provided a crucial test for the various systems of heating railroad cars by steam. There has been very little cause for complaint in the cars, the principal objection being that most of the trains were kept too hot. The writer was traveling almost constantly during the coldest weather and was struck with the influence of the personal equation in keeping cars comfortable. Some conductors are watching the temperature of the cars all the time and they see that the heat is maintained evenly Others seem to pay no attention to changes of temperature and adjustments are made only when passengers complain that the car is too hot or too cold. Wagner cars are not attended to so intelligently as the Pullman sleepers. This is merely a matter of supervision and means that the former company does not manage details as well as the latter.

The lessons of experience with car heating during this severe winter have been that the inventors of car-heating appliances have provided the means of heating cars safely under the most trying conditions but that the railroad companies and sleeping car companies have not got their men properly trained concerning the care and regulation of the appliances put under their charge. On more than one road the vicious practice has again been repeated of putting complex attachments upon cars and giving no instruction as to how they should be managed. When passengers are half roasted or partly frozen in the cars of any railroad company the experience is an impressive intimation that inferior management is in control.

We still have a few of our special calendars, which we will be glad to send free to anyone asking for them.

### How They Exchange Cars in Russia.

Mr. S. Michin, superintendent of motive power of the Russian Government Railways of Polesie, made this office a call recently.

Mr. Michin is studying American roads and American methods. He finds much to admire here and is going to take home several devices to test, among them the Janney coupler, air-brakes for freight cars, steel-tired wheels, etc.

He is at something of a loss to understand our car-interchange system, and don't see how we keep track of cars or how a road keeps its own proportion.

In his country the conditions are not unlike ours—a rigorous climate, long hauls and interchange of business. But in Russia the roads simply trade cars; if one road has a loaded flat to send over another line that other line has to deliver a car of the same class to the shipping road, and if it has no car of that class at the interchange point, the load waits until it is exchanged—like a prisoner of war—and the road that is "short" pays a per diem charge for the delay. By this plan a manager of a line that owns 1,871 box cars knows that there are 1,871 box cars on his own road, though they may not be all his.

This plan has some advantages, no doubt, but if adopted in this country would strip some roads as naked as a Digger Indian, and, we surmise would make something of a boom in the car building line.

### Substitution of Steel for Iron.

At the January meeting of the New England Railroad Club Mr. George Richards read a paper on the above subject. Iron, he admitted, had done much for the world, but the improved form of iron to be found under the various grades of steel is forcing this metal rapidly into use for nearly all purposes. The belief was expressed that steel castings will soon take the place of cast-iron and expensive forgings.

Mr. J. N. Lauder took a decided stand against steel except for boilers and tires. He held that where a part was subjected to reciprocating strains, steel was more likely to fail than iron His experience with steel in piston-rods and side rods had induced him to return to iron. The Eureka steel made at Chester, Pa., did very well for crossheads but it was cast-iron with the surface converted into steel. Steel is very likely to fail if nicked or if it has an abrupt change of section. He considered iron better for locomotive and car construction.

Mr. J. W. Marden favored the use of steel in car construction because it was stronger than iron and costs less. He had experience with steel that was not satisfactory, but he attributed the trouble to unsuitable quality of the steel. He thinks that steel axles are now likely to be perfectly reliable.

Mr. F. D. Adams favored steel except for axles. His experience convinced him that the journals of steel axles wore more rapidly than iron, and that the material was not reliable.

Mr. J. T. Chamberlain spoke of steel axles the journals of which wore with unparalleled rapidity. He had no use for steel.

Mr Angus Sinclair believed that most of the trouble experienced with steel axles arose from the use of inferior material. When steel axles were specified without particulars being given, Bessemer steel was generally supplied and that steel was not suitable for axles. He had devoted much attention to the subject, and found that steel axles did not wear any faster than iron if the proper quality was used. The impression he received was that the failure of parts made of steel was due to faulty design

### Air-Moving Machinery.

Travelers on the Boston & Providence Railroad in passing Jamaica Plain obtain a glance of a long brick building, close to the track, which is notable as being the largest fan-making factory in the world. The factory is the works of B. F Sturtevant Co., whose fans and blowers are known wherever fires have to be forced or buildings warmed.

During a visit to the works we found that, although fans and blowers were the principal articles of manufacture, the machinery that has to be built in connection with the operation of blowers would make a big business for firms that are large makers of special machinery. For instance, these works turned out over 1,000 steam engines last year, and they built more electric dynamos than important concerns that do nothing else.

This company manufacture an immense number of small portable forges with blast attachments, but their principal business is the making of fans, blowers and exhaust apparatus. A few years ago a demand arose for fans to be driven by electric dynamos acting directly on the fan shaft and this company proceeded to supply the demand. Owing to the inferior construction of the dynamos put on the market five or six years ago, this company proceeded to make their own dynamos, and they have now a good plant devoted to this work. The making of steam engines was an earlier enterprise, and they now make all kinds of engines adapted to the driving of their machinery

The system of heating shops made by this company is familiar to nearly all railroad men. It is undoubtedly the most efficient system in use Of late years they have been doing a good business in the making of apparatus for exhausting the smoke and gases from blacksmith shops and other places where smoke abounds. The arrangement is not costly and it is so effectual in keeping a pure atmosphere in shops that it deserves to be much more used. The company also make exhaust-blowers for planing mills, lumber dryers, and all kinds of appliances for forcing hot and cold air

English Dining Car Interior.

We are in receipt of letters from the Ferrocaril Interoceanico (Interoceanic Railway of Mexico) stating that the engineers and firemen are badly treated down there; they work by the month and get nothing for overtime, and overtime is constantly demanded of them. When hurt they receive no attention, often being left at wrecks all night, and when complaints are made they are told to quit if they don't like it The enginemen are Americans, and reported to be steady men. Our correspondent advises enginemen not to go there

## The B. & O.'s New Line.

### Preparing for the Immense Traffic Incident to the World's Fair.

The management of the Baltimore and Ohio Railroad is preparing for an immense business in 1893 while the World's Fair is open in Chicago. The terminals at Chicago are capable of accommodating a much heavier traffic than is now being done, and important changes are being arranged for the handling of very heavy freight and passenger business to the West from New York, Philadelphia and Baltimore. New equipment for largely increased passenger business and an extensive stock of freight cars have been ordered. The various roads of the system will be improved by straightened lines, reduced grades, extra side tracks, and interlocking switches. The new line between Chicago Junction and Akron has shortened the distance between Chicago and tide water twenty-five miles, and between Pittsburgh and Chicago fifty-eight miles.

The distance between Chicago and Pittsburgh and Chicago and Cleveland by the construction of the Akron line and the acquisition of the Pittsburgh and Western line and the Valley Railroad of Ohio, is about the same as via the Lake Shore from Cleveland to Chicago, and by the Pennsylvania from Pittsburgh to Chicago. The alignment is to be changed and grades reduced to a maximum of twenty-six feet. It is expected that within twelve months the old Baltimore & Ohio through line between Chicago and the Atlantic Ocean will have passed away and the new line via Pittsburgh be established, with no greater grades or curvature than on any of the trunk lines.

Work has already begun east of Pittsburgh to meet improvements making west of Pittsburgh. These improvements will consist of additional second and third tracks, a general correction of the alignment, and completion of the double track on the Metropolitan branch. It is expected that the new through line will be ready simultaneously with the completion of the Belt Line through the City of Baltimore, which is intended to unite the Washington Branch with the Philadelphia Division and do away with the present line via Locust Point. Forty new and powerful locomotive engines were added to the equipment during the last two months, and others are in process of construction. The permanent improvements now under way and in contemplation involve the expenditure of some five millions of dollars.

# ? A. What You Want to Know. ? A.

Don't ask questions that simply require a little figuring to determine; make each question separate. No notice taken of anonymous questions.

(16) J. D. B., Manastee, Mich., asks. What is the most popular packing for locomotives. *A.* We suppose you refer to cylinder packing; there is more plain snap ring packing than any other kind.

(17) J. S., Moncton, N. B., writes:

I would like to ask a question on the air-brake. On a train of twenty-six cars, the first five working air, when making a service application, and when the gauge pressure would be reduced five or six pounds, the train-pipe pressure would jump down ten pounds more, making an emergency application which, as you may judge would take the slack up on train rather sudden. What was wrong? *A.*—Something kept piston 17 from forcing its valve to a seat, probably gum or dirt.

(18) Ignorance, Mechanicsville, N. Y., writes:

One of our firemen, who was examined for promotion, said he failed to pass because he declared he would back an engine if necessary with both side-rods down, and he was told such a proceeding would be entirely wrong. This is something new to me What do you think of it? I have fixed up a mogul with the main driver broke off outside the box and she went in all right, and I thought she was good for 100 miles if run slowly, but according to the above I was wrong. *A.*—There is no reason why an engine should not be run either way with her side-rods down, unless it is an engine with her eccentrics on some other axle than the main one. We think perhaps the fireman didn't state his question just right to you.

(19) E. S. G., Havelock, Neb., writes:

Will you please explain what J A. H. means in his article, "The Best Shop I Saw in England," in No. 1, Vol. VI., where he speaks of their failure to make Richardson strips work. He says "Or the slots may have been milled instead of planed." Does he mean they cannot make a good job of them by milling? If so, why *A.*—We believe that these slots can be milled out properly by taking a fine finishing cut but where milled as they are ordinarily, we don't think they make a job; there are tool marks *across* the slot that form channels for the steam to go *around* the strip Planed slots have the tool marks in such a way as to pack against the steam. The late George Richardson, inventor of the packing, made some experiments with milled slots and pronounced against them. He said that *average* milling would not do.

(20) D. O. B., Mancelona, Mich., writes:

It seems I did not state plainly enough what I wished to know in regard to the vacuum in a cylinder, so was misunderstood. The question was, why will not steam of 150 pounds pressure, destroy a vacuum in a cylinder when it is cut off very early in the stroke, steam of that pressure having a volume 169 times that of the water from which it is derived; in other words, why will the expansion line on an indicator card go below the atmospheric line and thus form a loop? It is, of course, not found in locomotive practice. *A.* The steam having been expanded down, say to six pounds, when the exhaust valve opens the cylinder to the condenser, which contains a partial vacuum, say equal to 10 pounds below the atmosphere, the steam would go on expanding—and destroying vacuum in proportion—below the atmospheric line, it is exhausting into a condenser containing a vacuum instead of into the air which has a pressure of 14.7 pounds per square inch.

(21) Harry, Hartford, Ct., writes

Two locomotive engines, built exactly alike, are of the same dimensions every way, one of them is logy and liable to stall, and the other steams beautifully and pulls easily all the load that is intended for her size. Both engines are apparently handled precisely the same. What, in your opinion, is the reason? It is advocated by some that an explanation of the cause could not be given. Will you please give us your ideas, in words that all can understand. *A.*—It often happens that two engines of the same class *seem* very dissimilar, but we do not believe there is a difference without a cause. If one engine steams and the other does not there is some *reason* why she don't. Don't believe for one minute that there is any superstitious "because it is" excuse for condemning the poorer machine—*hunt for the cause.* Twice two is four the world over. If 140 pounds of steam won't push as hard on one 18-inch piston as another, find out what is the matter with the piston—the steam can't tell whether it's in the cylinder of the 11 or the 12.

(22) H M. T., Wheeling, W. Va., writes

Please answer the following through the columns of your valuable paper 1. What is outside lap? *A.*—Outside lap is the amount that the valve is wider than the distance between the outside edges of the steam ports. When the valve is in the center of the seat both ports are covered and the valve over-*laps*; if the valve is an inch and a half wider than the parts it is said to have three-fourths of an inch lap—$\frac{3}{4}$ on each end. 2. Can outside lap and lead be given to a valve at the same time? *A.*—Certainly; lap is given by making the valve longer, lead is given by so moving the eccentric that the valve opens the port a certain distance when the piston is at the end of the stroke—this distance is the *lead.* Lap or lead can be changed, increased or diminished independent of each other except as a matter of adjustment, for instance, if lap were added to a valve it would be necessary to move the eccentric ahead to recover the lead. 3. Will an engine slip as soon cut back as she will working full stroke? *A.*—It all depends upon circumstances, condition of rail, speed, etc. If an engine is slipping hooked up, she can often be stopped by full-stroking her *with a lighter throttle* This simply applies less power but during a longer part of the stroke.

---

During a visit paid last month to Berry & Orton's Works, at Philadelphia, we found them unusually busy. Quite a demand has arisen for their cold cutting-off saw for use in machine shops This is a remarkably useful tool and is certain to be appreciated in shops where there is much cutting of iron in lengths to be done. There was in the shop parts of a very large tool of this class for the Franklin Co. Among recent deliveries were two wood planers and a large band-saw to the East Tennessee, Virginia & Georgia, a large bench saw for the Pennsylvania, several heavy tools for the Elgin, Joliet & Eastern and for the Louisville & Nashville. Pullman's people had ordered a large planer, and a heavy special form of grinding machine is under construction for the Johns town Iron & Steel Co.

A correspondent says "A good gunsmith can make most anything in metal, for the work required of him is in most cases very exact and intricate. A gunsmith has to know how to weld, braze and solder, he has also to temper springs of all kinds, besides being able to do fine fitting to cover repairs of any guns, and above all things, he has to be a good file hand."

## Ten Years' Experience With One Class of Compound Locomotives.

John A. Hill, Editor Locomotive Engineering, New York:—

I send you herewith a statement showing the miles run, quantity of coal consumed and consumption per engine mile run, by each and every compound engine on the London & North-Western Railroad since the date of first turning out up to June 30, 1892. The statement shows the average performance of each class as well. We class by the size of the wheel.

| Size of Wheel | Engine No | Name of Engine. | Date first turned out. | Miles run. | Coal consumed. | Consumption per mile Lbs.* |
|---|---|---|---|---|---|---|

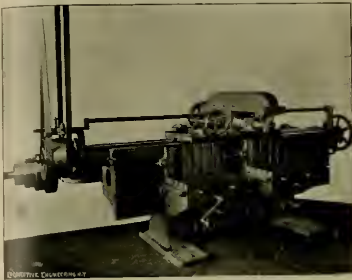
* Includes 1 2 lbs. for raising steam.

F. W. Webb,
Locomotive Superintendent L. & N. W. Ry.

*Crewe, England.*

## Heavy Open-side Miller, Slabbing and Sawing Machine.

This machine was made and designed for Messrs. R. D. Nuttall & Co., Allegheny, Pa., for facing large steel gears that are made in halves to bolt on the axles of electric cars; the wheels are of cast steel 27 inches in diameter, 7-inch face, one-half being milled with a groove, with a corresponding projection on the other half making a surface 27 inches long by 7 inches wide, and to be finished with one cut. The operation of the machine is designed to be cutting almost continuously, or start in any part of the travel, also at either end of the machine, the belts are shifted automatically, not allowing any chance for jambing or doing damage. The cutter-arbor has a shank 12 inches long, 3 inches at the large end and 2½ inches at small end, with a square lock-clutch to insure its being revolved by spindle, it is supported by a heavy, over-hanging arm bolted on top of the spindle carriage, carrying a bearing that is bushed with bronze 4 inches long, with a 1¼-inch hole arranged to take up wear or substituting any size that the operator desires. The saddle that slides on top of the



New Slab Milling Machine.

by using both tables for the work; while one half is being milled off the operator is adjusting another piece on the other table. The feeds of the machine are so arranged that should the tables be placed quite a distance apart a quick feed of twenty per minute is taken over the open space, the feeds are operated by two hand wheels, one on each side of the tool head; the one to the right controls the quick-feed while the left one throws in or out the milling-feed, and they are so arranged that they cannot interfere with each other; it is readily seen that with this arrangement of tables and feeds the machine is capable of doing the work of nearly twice one machine, and the operator is kept busy in placing work on and off the machine without retarding any of the work that is being done. The cut shows it to be built upon the bed of the well-known open-side planer, the driving-gear saddle feed-screw being modified to suit the new conditions. The arbor is geared with wide-face course-pitch gears of large diameter, and driven by a 4-inch belt that is back-geared 17 to 1; this gives the machine ample power to drive the milling cutter. The arbor is of forged crucible steel, has a diameter at the cutter end of 5 inches by 9¼ inches in length, 4½ inches in diameter at back end, and 8¾ inches in length. The feed-screw is of 3-inch diameter, single thread of 2 per inch engages bronze nuts, that are so arranged as to take up wear and prevent lost motion.

For feeding the cutter into the work, it is driven direct from gears from main driving-shaft on the back of the machine, it being necessary to compound these gears from a fast-running shaft, and the screw gives an endless change of feed, from the finest to the heaviest wanted, and insuring that when the cutter is running the feed is absolutely positive. For quick handling the open and cross belts on the left of the machine are used, there being three pulleys, one tight and two loose pulleys, with shippers that have a self-locking arrangement that insures them staying in their proper positions while the feed is running fast in either direction, and are controlled by the operator. To stop bed is held down on large and properly scraped bearing with bronze gibs and a square lock front; these gibs are of the wedge type and adjusted by studs and nuts, it being simply impossible for the cutter to be raised out of its cut. The length of bearing this slide has on the bed is 44 inches, and width of end on top is 24¾ inches, giving ample support in all directions with sufficient wearing surface. By taking off the outer arbor support, large saws or butt mills with inserted teeth up to 20 inches in diameter can be used.

This machine was set up in the works to run and to test its qualities, much to the satisfaction of the builders and those who saw it running. One of the tests was a 5½-in. cutter running 17 ft. per minute, peripheral speed, cutting 2¼ in wide by ⅜ deep, 2½-in. per minute, it not being belted up for more, as it was erected on the second floor of shop, where all light tools are run, and could not without loss of time spare more belt power. In another test with the same cutter, same material, 2¼ in. wide by ⅜-in. deep, 2½ per minute was made, when any more depth of cutter was taken the line shaft belt slipped, and no sign of tremor or stress was shown by the machine. All this cutting was with the work feeding against the cutter, this being a test to see the operation of the tool and not its capacity. The construction of this tool admits of the cutter being run in either direction, and feeding into or against the work, and of using any of the latest construction of mills with staggered teeth, etc. The mill used was an ordinary spiral mill, not of the latest or best design for heavy cutting.

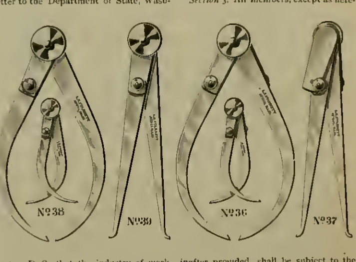
This firm are now designing a rod and slab miller, to mill 10-ft in length, 12 in. or 14 in. in width, with a platen suitable for the work to be raised and lowered by power, and have a very powerful hand-raising attachment for sinking the cutter into the work, embodying all the features of this machine. They claim with the tool traveling instead of the work, space in the shop can be saved and the machine more readily manipulated, and have the cutting tool always bearing the same relation to the bed, and consequently more rigid than the type that the head raises—the larger the work the weaker the machine—while with this system the bed of the machine forms the support for the work as well as the cutter, tying them together as one mass. This machine weighs 12,650 lbs., mill travels 5 ft. 10 in., tables lower 22 in. below cutter, and was built for a special purpose, and will admit of many changes for different heavy work. It was built by Pedrick & Ayer, of Philadelphia.

## Some Improved Calipers.

The well-known builder, L. S. Starrett, of Athol, Mass., has recently put on the market two kinds of calipers that have marked improvements over the ordinary tools and are almost as cheap.

The styles marked No. 38 and 39 have a firm lock-joint, and are still capable of fine adjustment. The improvement consists, first in a socket joint, made tapering, and locked or released by a partial turn of the knurled disc, drawing it together. A spring washer under the disc maintains an easy friction in the joint when unlocked. In the under side of short arm is a slot containing a stiff spring. Riveted into the middle leg and projecting through an opening in the arm, is a threaded stud on which is a knurled nut having a beveled hub—this bears against a cone in the arm —the action of the spring holding them together turning the nut, presses them apart and adjusts the leg while the joint is locked. The spring taking up all backlash the legs are firm. Hermaphrodite calipers and dividers are made in the same style.

The calipers shown in cuts 36 and 37 have all the features of the first tools described, but in addition to common use may be used inside of chambered cavities, over flanges, etc., removed and replaced without losing the size calipered. This is done by loosening the nut, binding one arm to the auxiliary leaf and swinging it out or in (while the joint is locked) to clear the obstruction, then moving it back against a stop, where it will show the exact size measured.



The Hon. T. H. Anderson, United States Minister to Bolivia, says in a recent letter to the Department of State, Washington, D. C., that the industry of working wood by machinery is a growing one in South America, and the trade for all classes of wood-working machinery is given to the United States. And he further says that the Egan Company, of Cincinnati, Ohio, controls over 50 per cent. of this trade in this class of goods, simply as the result of their enterprise in successfully placing their superior goods before the South American buyers.—*N. Y. Evening Post.*

The Chicago, Rock Island & Pacific people have lately erected a new roundhouse at Valley Junction, near DesMoines. It is a substantial brick building of about thirty stalls.

## Constitution and By-Laws of the Traveling Engineers' Association.

### CONSTITUTION.

Article 1.—The name of this association shall be "The Traveling Engineers' Association."

Article 2.—The objects of this association shall be to "Improve the Locomotive Engine Service of American Railroads," through the advancement of knowledge concerning the duty of traveling engineers or road foremen, by discussions in common, the exchange of information on subjects interesting to its members, thereby making the work in all branches more systematic and efficient for members and profitable for railroads and to provide an organization through which, by joint action, the best methods may be adopted.

Article 3.—*Section 1.* The following persons may become active members of the association on being recommended by three members of good standing and signing an application for membership and agreement to conform to the requirements of the Constitution and By-Laws or signing the Constitution and By-Laws.

*Section 2.* (*a*) Traveling engineers in active service, whether assigned to duty on the entire system of railroad or on a single division of any road, their assistants, when said assistants have charge of a division and are responsible for the condition of the engines and discipline of engineers and firemen to the same extent the traveling engineer is, provided that said assistants are not engaged in one line of duties only, such as instructions in firing coal properly, or inspector of engines when in roundhouses.

(*b*) Those who have been traveling engineers and are now employed in other positions of railroad service.

(*c*) Experts in air-brake practice employed by the railroads or air-brake companies.

(*d*) Those whose knowledge of locomotive running and management will be of service to the association can be admitted as associate members at any meeting by a majority vote.

The title Road Foreman of Engines is taken to mean the same as Traveling Engineer.

*Section 3.* All members, except as hereinafter provided, shall be subject to the payment of such annual dues as it may be necessary to assess for the purpose of defraying the expenses of the association, provided that no assessment shall exceed $5 a year. Such dues shall be payable when the amount thereof shall be announced by the president at each annual meeting. Any member who shall be one year in arrears for dues, and neglecting to pay the same within three months after notification by the secretary, will have his name taken from the roll. Members whose names have been dropped for non-payment of dues may be restored to membership by the unanimous consent of the executive committee on the payment of all back dues.

*Section 4.* Any member who, during

the meetings of the association shall conduct himself in an unbecoming manner, may be expelled by a two-thirds vote of the members present at any regular meeting within one year from the date of the offense.

ARTICLE 4.—The officers of the association shall be a president, a first vice-president, a second vice-president, a treasurer, a secretary and three members of the association, who shall be elected by ballot at the regular annual meeting, who shall, with the officers, constitute the executive committee.

ARTICLE 5.—The president, first vice-president, second vice-president, treasurer and secretary shall hold office for one year or until successors are chosen, the three members to serve on the executive committee will be first elected to serve for one, two and three years respectively, their utive committee shall constitute a quorum for the transaction of business.

ARTICLE 8.—*Section* 1. At the first session of each annual meeting an Auditing Committee consisting of three members, not officers of the association, shall be elected by ballot. It shall be their duty to examine at once the accounts and vouchers of the treasurer and the books of the secretary and certify whether they are correct or not. After the performance of this duty they shall be discharged by the acceptance of their report by the association.

*Section* 2. At each annual meeting the president shall appoint a committee of five whose duty it shall be to report at the next annual meeting subjects for investigation and discussion, and if the subjects are approved by the association, the president shall appoint special committees to report on them. It shall be the duty of the com-

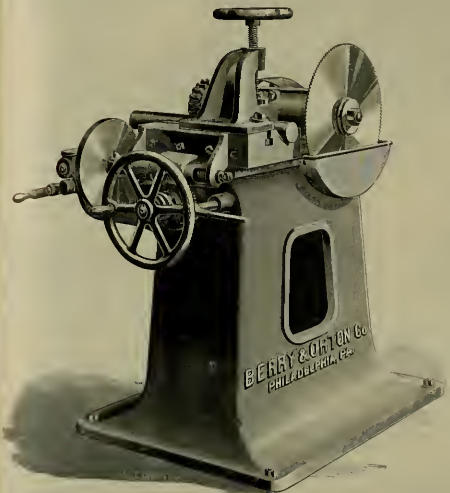
SECTION 5.—Order of Business: 1. Address by the President; 2. Calling the Roll; 3. Acting on the Minutes of the Last Meeting; 4. Reports of Secretary and Treasurer; 5. Election of Auditing Committee, 6. Unfinished Business; 7. New Business; 8. Reports of Committees; 9. Reading of Papers and Discussion of Questions Propounded by Members; 10. Election of Officers; 11. Adjournment.

SECTION 6.—Unless otherwise ordered, the discussion of questions proposed by members shall be the special order from 12 o'clock noon to 1 o'clock P. M. of each day of the annual meeting.

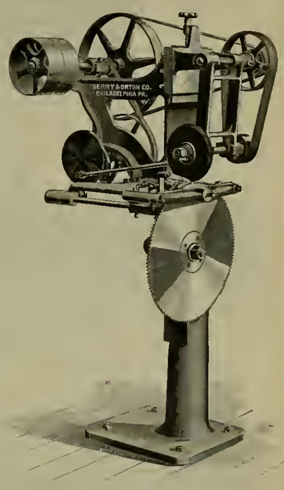
SECTION 7.—No patentees or their agents shall be admitted in the meeting of the association for the purpose of advocating the claims of any patent or patentee unless by unanimous consent.

### Artificial Limbs.

During a recent visit to the workshop of Mr. Edwin Osborne, in Philadelphia, we were much interested in the elaborate work performed in the making of artificial limbs. As the accidents common to railroad life require not a few of our readers to use artificial limbs, it is proper that the unfortunates should be informed of where perfect articles are made. Mr. Osborne has been in the business for forty years, and has worked with rare skill and intelligence to make the artificial article perform as near as possible the functions of nature's limbs. The casing of the legs is made of a light, strong wood, beautifully fitted, finished, the joints being wonderful specimens of special mechanism. Steel bushed pins hold the joints in place, and strong rubber springs give the re-



NO. 2 COLD CUTTING OFF SAW.



AUTOMATIC SAW SHARPENING MACHINE

successors shall be elected to serve for three years.

ARTICLE 6.—The duties of the president, vice-president, treasurer and secretary shall be such as usually pertain to their offices, or may be delegated to them by a unanimous vote of the executive committee.

ARTICLE 7.—The executive committee shall exercise a general supervision over the interests and affairs of the association, recommend the amount of the annual assessment, to call, to prepare for and to conduct the general conventions and to make all necessary purchases, expenditures and contracts required to conduct the current business of the association, but shall have no power to make the association liable for any debt to an amount beyond that which at the time of c ntracting the same shall be in the treasurer's hands in cash and not subject to prior liabilities. All expenditures for special purposes shall only be made by appropriations acted upon by the association at some regular meeting. Five members of the exec- mittee to receive from members questions for discussion, which, if the committee determine are suitable, shall be reported to the association at same meeting.

ARTICLE 9. This Constitution can be amended at any regular meeting by a two-thirds vote of the members present.

BY-LAWS.

SECTION 1.—The regular meetings of the association shall be held annually on the second Tuesday in September.

SECTION 2.—The regular hours of session shall be from nine (9) o'clock A. M. to two (2) o'clock P. M.

SECTION 3.—Places for holding the next annual convention may be proposed at any regular meeting of the association. Before the final adjournment the places proposed shall be voted for by the members, the place having the highest number of votes shall be declared the place for holding the next regular convention.

SECTION 4.—At any regular meeting fifteen or more members shall constitute a quorum.

### Cold Cutting-off Saw and Cold Saw-Sharpening Machine.

The accompanying engravings hardly need description. The makers of these tools have a reputation on this kind of work.

The saws are made in three sizes for cutting merchant bar, etc. One size cuts up to 3 inches of round bar, another cuts up to 5 inches, and a third up to 7 inches. The engraving is of the second size.

This machine has a hammered steel arbor 3 inches in diameter, driven by a bronze worm wheel and a hardened worm. The feed is automatic and can be instantly changed.

The success of cold sawing largely depends on the sharpening of the saws. The machine shown here will take in saws up to 36 inches in diameter and sharpen each tooth uniform at the rate of 56 teeth per minute, and leave the saw perfectly round. They are made by Berry & Orton, of Philadelphia, Pa.

quired elasticity and resistance to motion. There are tendons performing functions similar to the tendons of a natural leg, and other ingenious fastenings that tend to give the wearer ease and natural movement. The legs are so well made that the wearers walk as naturally as if they had never lost a limb.

A patent for a four-cylinder locomotive has been granted to Jackson Richards, who is a master mechanic on the Philadelphia & Reading. The patents are granted on the valve-gear being all actuated by two sets of links and eccentrics. We hardly believe that the invention was worth patenting as it calls for two inside cranks which no superintendent of motive power is likely to adopt to any alarming extent.

An improvement in car couplers has been patented by Joseph E. Forsyth and Erskine R. Merrill, of Chicago. It consists substantially of a chain attachment to prevent the coupler from falling on the track in case of breakage, a safety appliance which is badly needed.

# Cast Steel Works of FRIED. KRUPP, ESSEN, Germany.

**Represented by THOMAS PROSSER & SON, 15 GOLD ST., NEW YORK.**

These works cover an area of 1,200 acres, employ about 18,000 men, have the most improved plant, and stand unique, from the fact that they have their own Ore and Coal Mines, Blast Furnaces, etc., and that *every* stage of manufacture is under their own supervision, and are not (like others) dependent on the open market for a miscellaneous assortment of crude material; which, in connection with 75 years' experience, enables them to turn out a product of a very superior quality, second to none, and at the same time the different grades of Steel are always of the *same uniform* quality.

**Locomotive Tires, Crank Pins, Piston Rods, Spring Steel, Steel-Tired Wheels, Etc.**

After a test of over 25 years the "KRUPP TIRE" has proved itself the best in the market. If a reliable article is wanted, which will give satisfaction, get KRUPP'S.

### Home-made Small Tools.

The prevalence in railroad shops of the select machinists being found engaged in making taps and dies is a convincing proof of how slowly sound doctrines of production extend to the men in charge. Tool-making is naturally regarded as work requiring advanced skill, and we frequently find that the best workmen in a shop are engaged on taps, dies and other small tools that could be purchased cheaper and better from those making a specialty of the business. It is edifying to watch the deliberate movements of the man who works on tool-making in railroad shops. He comes to work in the morning prepared to add a new set of ¾-inch taps to the tools of the place. Pieces of steel are selected and subjected to ostentatious inspection. These blanks are then turned upon the lathe to the desired taper. Then they are threaded with no particular degree of accuracy. This makes them ready for the milling machine where the slots are cut and the head milled. The taps are then "relieved" and they are ready for hardening. The machinist has worked steadily and deliberately at this job for nearly three days, and he will show the set of taps and declare they are as good as anything ever made by a manufacturer. The fact that the taps have cost more than they could be bought for is not investigated, and everybody is gratified that the shop can turn out such creditable work. Little regret is expressed that the repairs on locomotives in the shop are dragging behind for want of good men to do the work.

If the history of the home-made taps is followed closely the cause for satisfaction with the work done is frequently modified. The blacksmith did not have his fire just right for tempering, and it is found that one of the taps is slightly burned. This spoils its appearance somewhat, but that is counted as nothing. When rough Rob. Johnson uses this tap some weeks later and gives the lever an unmerciful twist, as is his way, the tap breaks off and its usefulness is ended.

No machinist can relieve two taps exactly alike with the file, and one of our taps has too much taken off to relieve it and the other has not enough. The first one begins its own self-destruction at once. In backing out the tap the cuttings get between the thread and the metal around the hole and gradually grind up the threads. The tap that has not got enough relief works hard, and in the hands of the brute-strength and stupidity of workmen soon snaps off and no one can understand why it has broken.

The manufacturers of taps and dies have special machinery which enables them to reproduce articles of exactly the same size and formed precisely in the desired shape. They have the most approved furnaces for heating and tempering the steel, and the work is done by experts on whom practice makes perfect. These people make tools that are durable, and owing to the wholesale system of production they can be sold at a profit cheaper than inferior articles can be made in a common shop. The master mechanic or car builder who takes pride in making his own small tools is away at the tail of the procession, and is an expensive man for any railroad company to employ.

### Platform Gates.

We understand that among the measures about to be introduced to the New York Legislature at Albany is one compelling railroad companies handling suburban business to put gates upon the platforms of cars. This practice is generally followed by railroad companies handling suburban business about Boston and several other large cities. How it comes that scarcely any of the railroads about New York, except the elevated roads, provide this cheap, simple and efficient means of safety to their patrons, is difficult to understand. People have repeatedly fallen from trains in the neighborhood of New York, owing to want of protection on platforms. The danger of open platforms is well understood, and it is not surprising that the people to blame for neglecting this safeguard are about to receive the pressure of compulsion.

## Cutting Eccentric Keyways Before Wheels are Placed Under Engine.

BY [illegible]

I see there is considerable inquiry about proper methods and "sure" ways to lay out eccentric keyways when the axle and wheels are in the shop, and considerable experience in this line encourages me to write.

First of all, let me say that I am very much in doubt if there is any rule that can be called "sure"—bound to come out right every time. If all engines were alike there would be little or no trouble, and I venture to say that with new work and direct motion engines there would be little or no difficulty, but *lost motion* is the trouble, and every joint between the eccentric and the valve adds to the danger of a miscalculation.

For repair work—and all my experience has been in the "back shop" of a railroad—there are scarcely ever two engines worn alike, and extra care must be exercised if the pit foreman wants to save time and trouble, and at the same time keep up his reputation among the men for "knowing his business," by cutting the eccentric keyways on a new axle before they are run under the engine. Perhaps the best known plan is the "stick" rule, and in the hands of a careful man it works pretty well. This plan was described in this paper some five years ago by Hiram R. Jones, and with the pleasantest memories of this excellent mechanic (for I put in my first apprentice days under his general foremanship) I will let him describe the "stick" rule himself, for surely none understood it better than he.

The stick is constructed as follows: Take a piece of clear pine three or four feet long and 1½ in. square, Fig. 2. Lay off a line in the center at *A*, lay off another line at *B* as far from *A* as the sum of lap and lead multiplied by length of bottom rocker arm, and divided by length of bottom rocker arm. Set your dividers at ½ diameter of shaft, and with *A* as a center lay off lines *C* and *D*. Set dividers to ½ diameter of eccentric, and, with *B* as a center, lay off lines *E* and *F*. To use this rig set crank-pin on center as before. Place the stick—resting on a support of some kind—under the eccentric, with the face of stick projecting a little beyond side of eccentric, as shown in Fig. 3, which is a plan view. In this way it will allow the plumb lines shown in Fig. 4 (one of which is thrown over the axle and the other over the eccentric) to fall each side of the stick, and close to it at the points indicated by the dots in Fig. 3. Adjust the stick so that the lines *C* and *D*, Fig. 2, will coincide with the plumb lines *C* and *D* hanging over the axle. Then turn eccentric so that the plumb line hanging over it will correspond with the lines on stick at *E* and *F*.

There are one or two important points that should be noted. The crank-pin is not necessarily on its center line when its center is level with center of axle. The crosshead pin is usually an inch or two above center line of axles, which would bring the crank-pin above said line on forward center, and below it on back center. This may be more fully understood by reference to Fig. 5, in which *A B* represents a center line through centers of axles. *C*, the center of crosshead pin at mid stroke. *D*, the center of main driving axle. *E*, the forward center of crank-pin, and *F*, back center of crank-pin. The height of *E* above center line may be obtained by multiplying height of crosshead pin above center line by ½ the length of stroke of crosshead, and dividing by length of main rod, or, simpler still, draw the lines in Fig. 5 on a board and measure the distance at *E* or *F* with a rule. Set crank this distance above center line of axles.

Another thing: If the pin in bottom rocker arm is above center line of engine it will necessitate a new position for crank-pin in using this arrangement.

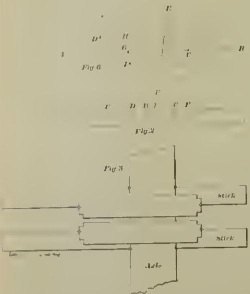

Fig. 6

Fig. 2

Fig. 3

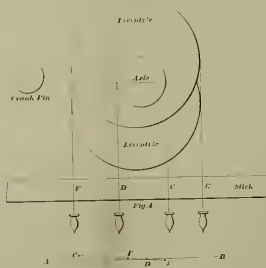

Fig. 4

Fig. 5

Referring to Fig. 6, let *A B* represent a line through center points of crank-pin (not center line of axles). *C*, center of main axle. *D*, bottom pins of rocker arm, and *G*, forward center of crank-pin.

Now for the sake of illustration, the elevation of the pin *D* above line *A B* is somewhat exaggerated. It will be seen that, in order to bring the eccentrics in their right positions, a line *E F* drawn across the front edge of eccentrics will be perpendicular to *C D*, and not *A B*. Now, as the line *E F* represents the direction taken by the plumb lines in Fig. 4, and the eccentrics must be set in that position, and the crank-pin *G* must be kept in the same relative position, we lower the point *G* to *I*, a point as much below *A B* as *H* on *C D* is above it. This distance may be obtained by drawing a diagram on a board, as before, and measuring with a rule.

It may seem as though this procedure was complicated and intricate, but when locomotives are all of one class, a stick once made and properly marked will do away with any further calculation. The proper elevation of the crank-pin should be noted in writing on the stick, and then the stick varnished, to keep dirty fingers from soiling it. It is then ready for use at any time, for any engine of the same class.

When eccentrics are only fastened with set-screws, there will be no particular advantage in adopting this plan; but if they are to be keyed on, especially for a narrow-gauge locomotive, where there is little room, it is a decided convenience.

To me the stick was not very satisfactory, and for a long time I have used a shorter plan, the measurements being found graphically and in such a way as to leave little room for mistakes.

I don't claim that this rule accomplishes results every time, but I have never yet got so far off with it as to call for offset keys all around, and I have had it come out exactly right. A better plan, where sectional eccentrics are used, is to put them up and mark them before cutting keyway.

When I put in a new axle I carefully caliper the journal bearing, and on a—shall I confess it?—piece of tin I draw a circle just the size of the axle. I assume that the pin has been plumbed exactly above the center of the axle, and I draw a perpendicular line, *A B* (Fig. 8), supposed to cut the centers of the pin and axle; at right angles to this and at the center of the axle I draw a horizontal center line. Then, inside the circle representing the axle, and from the same center, of course, I draw a circle the diameter of which is equal to the travel of the valve.

Now I take the sum of the lap and lead of the valve, say the lap is 1 inch and the lead $\frac{1}{16}$-in.; ¾" and $\frac{1}{16}$", or $\frac{13}{16}$", above the horizontal center line I draw another line, *E F*, parallel to it; this, for want of a better name, I call the lap-and-lead line.

Now, from the center of the axle I draw lines *GG* and *HH*, these lines intersect the lap-and-lead line where it crosses the travel circle, and extend out across the circle representing the axle. Where these lines cross the axle circle should be the center of the eccentric keyways—provided your keyways in eccentrics are where they should be—exactly opposite the largest part of eccentric under the stiffening rib.

I have seen men plumb their pin above the axle and go monkeying around trying to draw these circles and lay down these lines on the end of the axle itself. This is all foolishness, as the sole object of laying down these lines is to get a measurement, namely that from the center under the pin to the keyway.

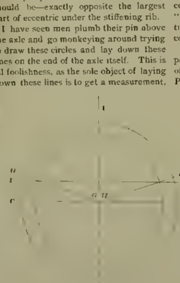

Fig. 8

After getting this measurement (on tin) I plumb my pin above the axle, put the centering piece on my "Starrett universal," and the level piece above it, level to the center and prick-punch. It's a good idea to turn your square around, and if there is a difference it is due to an error in the level; divide this error. From this center-punch mark I lay off, both ways, the measurements I have found, and cut my keyways with perfect confidence that they will come pretty close to right; so close that to slightly offset a key or two is far easier than to drill and chip keyways after the axle is under the engine. Right here let me call attention to the necessity of keeping your wits about you and lay off your keyways in the proper place, the go-ahead next the axle, etc. It will be seen that this plan throws out all figuring on the difference on the length of rockers; it simply deals with the size of axle and travel of valve.

The difference in length of rockers often troubles men who have to overhaul valve motion, and I have often seen them worrying at a row of figures to find the travel of a valve where the top rocker was, say, 7¾-inch long, the lower one 6¾-inch and the throw of eccentric 5-inch.

For such a case I use a graphic method that may be new to some and one that is plain, sure, simple and easily remembered.

From a given point *A*, Fig. 7, I erect a perpendicular, and with my dividers take the length of the lower rocker arm, say 6¾-inch, and scribe an arc of a circle across the top of my perpendicular; then I find the throw of my eccentric and divide it each side of the center line; say it is 5 inches, total movement of the eccentric blade, I lay off 2½ inches each side of the center on my line *B C*, as at *D E*—this is the travel of my lower arm—the one the eccentric actually moves.

Now, with my dividers, set the length of the upper arm, and from the point *A*, which represents the center of rocker shaft, I scribe circle *F G*. Then from the center *A* I draw lines 1 and 2 that intersect the lines *D* and *E* on arc *B C*, continuing the lines 1 and 2 across the arc *F G*. Between the points where 1 and 2 cut this arc will be the throw of the long arm (and the travel of the valve) actuated by the shorter arm and shorter throw. These are actual measurements that can be taken with rule and dividers and found without any figuring at all.

## The "Gowan & Marx."

In August, 1891, we published a description of the engine "Mercury," built in 1842, for the B. & O., by the firm of Eastwick & Harrison, of Philadelphia, and in that description told something of the success made by this firm with the engine "Gowan & Marx"; we did not know at time that there was a picture of her in the country.

Recently one of the philosophers of the paper stumbled across a drawing of her in the office of the Wellman Steel Company, in Philadelphia. The original drawing was

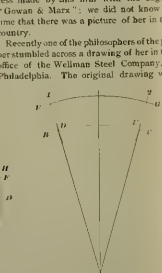

Fig. 7

made for Eastwick & Harrison by a young mechanic, Enoch Lewis, now purchasing agent of the Pennsylvania Railroad.

Some years ago Mr. Wootten, general manager of the Reading road (for whom the engine was built), found the drawing among some other old papers and sent it to Mr. Lewis. From this a photograph was made and framed by Mr. Lewis' son, who is in charge of the office of the Wellman Steel Company, and from it our engraving was made.

This engine was the first to have an axle under the fire-box, the first to have equalizers, and the first to use a blower.

We can't describe her better than to repeat what was said in this paper on the date given.

"Late in 1836, the firm of Garrett & Eastwick, of Philadelphia, built an eight-wheeler, called the "Hercules," for the Beaver Meadow road (now the Lehigh Valley), in which an attempt was made to make the engine more flexible. Mr. Eastwick devised a separate frame with pedestals, in which the two pairs of wheels were placed. This frame vibrated upon a center bearing, and could move as a truck does, except that it could not turn. This allowed it to adjust itself to uneven tracks, provided the unevenness was alike on both sides, otherwise it racked the framing; this frame was underneath and separated from the main frame by side bearing springs.

* * * * * * * *

"This engine was so flexible that she could accomplish more work than the others in use, and more like her were ordered. But in the meantime the firm took in as a partner a young mechanic, Joseph Harrison, Jr., who set about simplifying the flexible engine, and the result was the invention of the modern equalizer, now universally used in this country and most foreign countries.

"Harrison's first equalizers were made of cast-iron, very heavy and clumsy, and were hung above the frame just as they are now in 8-wheelers, the ends bearing on round pins that went down and rested on top of the box; this can be seen very plainly in our illustration. Mr. Harrison's patent covered all the combinations of equalizers now known, and also provided one for the truck. This device made it possible to use any number of driving-wheels on the roughest track, and was, up to that time, the most useful improvement made in the engines of Stephenson.

* * * * *

"In 1839, Eastwick & Harrison got an order from the Reading road for a then 'big engine'; she was to weigh all of *eleven* tons, not less than *nine* tons to be on four drivers, and must burn anthracite coal in a horizontal boiler. This engine, when built and in service, made the fortunes of her builders.

"In order to properly distribute the weight, the rear axle was placed *under* the firebox, just as they are now in mogul and consolidation engines; the boiler was a 'dome' or 'Bury' boiler with a 5-foot firebox.

* * * * * * *

"Two-inch tubes were used, placed close together, and nearly filling the cylindrical part of the boiler.

"The cylinders were 12½ x 18. There was no cut-off used. The wheels were 42 inches in diameter. The exhaust was a box filled with numerous small jets, known as the Gurney exhaust, and the common blower was here used for the first time. When finished, this engine was named the 'Gowan & Marx,' after a London firm of bankers.

"This engine interested the whole railroad world by her great tractive power. On her trial, February 20, 1840, she drew from Reading to Philadelphia one hundred and four 4-wheeled cars of coal at the rate of 9.82 miles per hour—the road had a falling gradient of nearly 4 feet per mile, 27 miles of dead level, 9 miles of it in one place, and only one ascending grade of 26.4 feet per mile for 2,100 feet. This train weighed 423 tons, and, including weight of the tender, equaled *forty times* the weight of the engine. That was the best ever done then, and is pretty hard to beat now.

"This remarkable work attracted no little attention at home and abroad, and among others who came to see and be convinced, were two colonels sent out by the Emperor of Russia to report on the best machinery and appliances for a road then projected between St. Petersburg and Moscow—the first in the empire. These officers reported in favor of engines built upon the general plan of the 'Gowan & Marx,' and in due course of time the Emperor Nicholas asked Eastwick & Harrison to visit St. Petersburg, with a view to contracting extensively for his government.

"In 1843 Mr. Harrison went to Russia, and formed the firm of Harrison, Winans & Eastwick, taking into the firm Mr. Thomas Winans, of Baltimore, and entered into a contract for building 162 locomotives and iron trucks for 2,500 freight cars.

"In 1844 they closed their place in Philadelphia, taking their tools and instruments to Russia, and established the Alexandroffsky Head Mechanical Works, where they completed their fat contracts.

"When the first engine was being built, Mr. Harrison designed and built a machine for accurately boring the holes for crank-pins exactly at right angles to each other—this is believed to have been the first quartering machine—a rude application of the principle had been used by him in Philadelphia in 1838. This contract was finished in 1851, but a new contract was entered into for repairing the rolling stock that kept the firm busy up to 1862, when they came home to America full of honors—and shekels."

The Famous Old-Timer "Gowan & Marx," the First to Haul Forty Times Her Own Weight

## Combustion Chambers for Shallow Fire-Boxes.

During the last ten years the practice has spread very rapidly of designing locomotives with long, shallow fire-boxes set on top of the frames. Increasing weight of trains and acceleration of speed are putting such demands upon the capacity of the boiler that every resort which ingenuity can suggest is employed to augment the steam-generating power of locomotive boilers. The boilers are raised more and more towards the sky to make room for a large shell and the necessity for increased grate area leads to the raising of the mud ring above the frames. By doing this valuable increase of grate area is obtained, but the change has developed a resulting drawback which seriously detracts from the efficiency of locomotives built in this way. A firebox placed entirely above the frames must necessarily be very shallow with limited space between the grates and the lower row of tubes. This puts the tubes almost close to the fire and from some cause or other the tubes are very much given to leaking. We cannot understand why the close proximity of the fire to the tubes should couse leakage, but it is certainly the case, for we do not know of a single road using shallow fireboxes where complaints are not made of trouble with the tubes.

In fireboxes of this form the flame has such a short distance to travel before entering the tubes that theory would say there must be loss of heat due to imperfect combustion, and the coal records appear to show this to be true.

The remedy for leakage of tubes due to the close proximity of the incandescent fuel and for the loss of fuel due to the short journey of the flame appears to be the use of a combustion chamber. When deep fireboxes where used combustion chambers appear to have been of no service, but with a shallow firebox the case is different and we expect to see this aid to combustion largely adopted. A chamber twelve or fifteen inches long ought to be sufficient. Boilers are made so long now that the tubes could easily bear being shortened the distance mentioned. Those who are using combustion chambers with shallow fireboxes speak highly of the influence they exert in preventing leakage and also credit the arrangement as being good for preventing the stopping up of the tubes with cinders. The success of the Wootten firebox appears to give testimony in favor of the combustion chamber.

A novelty in locomotive fire-boxes has been patented by Charles W. Hullings, Philadelphia. This inventor proposes putting in a baffle above the fire door, constructed in the form of a water leg. Pipes to create circulation in the baffle are led across the firebox to the front sheet. A baffle plate for projecting the air that enters the door down upon the surface of the fire is an excellent aid in the prevention of smoke, but we are afraid that using a water leg for this purpose is going beyond paying limits.

## Some Wrecks in India.

One of our readers, Mr. Philip A Hyde, at Saidpur, India, sends us some wreck photos, taken away in the land of the Bengal tiger, the Coolie, the crocodile and Rudyard Kipling's stories

One picture shows an English engine with a crimp in her Yankee pilot and a hole in her abdomen—don't know what else to call it The cork helmet on the "runner" and airy costume of the native galvanizer" give a faint idea of the difference in temperature between that country and our own Dakota "banana belt," the latest reports from there only claiming 57 below zero.

That iron "goods wagon" will need the services of a blacksmith and boiler-maker before she will ever be able to haul rice in bulk

If that Hindoo had only stayed behind the bush for a second more we might have shown up the wash-out picture as a bird's-eye view of gentle spring on some road out of New Orleans It looks very natural

If you look closely at the six-wheeled freight engine you can see the waves of heat rising off the boiler, the engine may be dead for all we know, but they have a sun in India that gets up before daylight and tends to business as long as he can see to work

Maybe you will think it is egotism, but we think it a good time right here to repeat what a railroad man recently wrote

"The showing up of engines and railroad scenery in LOCOMOTIVE ENGINEERING is doing a great fraternal work in making locomotive engine and shop men, the world over, better acquainted with one another" Here's a chance to fraternize with the Hindoo

The superintendent of motive power of one of our leading railroads lately talked in a very edifying manner about his experience with brake beams. He was a firm believer in the merits of the wooden brake beam and clung to its use for long years But the quick-action brake convinced him that an improvement had to be made He tried various ways of trussing the wooden beam, but it did not materially decrease the trouble from broken beams. Finally he tried a few iron beams, and they did so well that he made no more of wood. To his surprise he now finds that the metallic beam is much less costly than the wooden beam which he patronized so long on account of its being cheap

## Heat and Combustion.

BY ANGUS SINCLAIR.

### ELEMENTS.

The nature of fuel, the composition of the air that fans the fire, the character of the gases formed by the burning of fuel, and the proper proportion of air to fuel for producing the greatest amount of heat are the principal things to be learned in the study of the laws relating to combustion. If these things were properly and popularly understood many egregious blunders in the designing of furnaces and fireboxes would have been avoided, and millions of tons of fuel that have been wasted by bad firing would have been saved.

By the process of analysis the science of chemistry has discovered that all matter in the universe has been formed from about seventy simple substances or elements. There are celebrated scientists who believe that the time will come when it will be shown that all matter has originated from one fundamental element, but this is to a great extent speculation, for the most powerful analytical forces have yet been unable to separate elements into more than one substance. Elementary substances combine or mix together and form compound substances. The great bulk of the earth, including air and water, are composed of compounds formed from about twenty elements.

### THE ATOMIC THEORY OF MATTER

In experimenting on the divisibility of matter a celebrated chemist found that a coloring substance could be so subdivided that one billionth of a grain was visible to

AN INDIAN WASH-OUT

the naked eye. This is such an infinitely small particle that the mind cannot comprehend it. In figures it is a grain divided into 1,000,000,000,000 parts. Science has demonstrated that even these small entities are capable of still much greater division. The dividing may go on, however, until a limit is reached, when no further subdivision is possible. When this limit is attained the ultimate separation ends in excessively minute particles of matter which scientists have called atoms. Moved by the internal forces of nature, known as chemical affinity, the atoms group themselves or join with atoms of other substances and form larger particles, which are called molecules. A molecule is distinguished from an atom by being divisible, as it is composed of two or more parts.

GOT THE WORST OF IT

### COMBINING PROPORTIONS.

According to this atomic theory, all the atoms of each element are alike in size and weight, and they combine with atoms of other substances in fixed proportions by weight to form compounds. If one atom weighs 1 and the atom of another substance is double that weight, the two will always combine in the proportion $1 + 2 = 3$. They cannot combine $1 + 1 = 2$, because that would require the dividing into two of the heaviest atom, and division has already gone to the extreme to reach the atom.

The fixed proportions by weight in which elements unite are called the combining weights. The elements that have principally to be dealt with in the study of combustion are

| Element. | Symbol. | Combining Weight. |
|---|---|---|
| Oxygen | O | 16 |
| Hydrogen | H | 1 |
| Nitrogen | N | 14 |
| Carbon | C | 12 |
| Sulphur | S | 32 |
| Iron | Fe | 56 |

The symbol given after the name of the element is the chemist's short way of writing the name. These in connection with figures make up a sort of short-hand, which indicates the composition of a compound For instance, water is composed of two parts by weight of hydrogen, or two atoms as the combining weight of that element is 1, and 16 by weight of oxygen, or one atom. The compound water is therefore written by chemists, $H_2O$.

Some of the elements combine in different proportions and produce an altogether different compound This is illustrated very strikingly in the combinations which nitrogen make with oxygen. They are

| | | | | | |
|---|---|---|---|---|---|
| 1. Nitrogen monoxide, | containing 28 parts by weight of N, | to 16 of O, | written | $N_2O$ |
| 2. Nitrogen dioxide, | " 28 " | " " 32 " | " | $N_2O_2$ |
| 3. Nitrogen trioxide, | " 28 " | " " 48 " | " | $N_2O_3$ |
| 4. Nitrogen tetroxide, | " 28 " | " " 64 " | " | $N_2O_4$ |
| 5. Nitrogen pentoxide, | " 28 " | " " 80 " | " | $N_2O_5$ |

The first of these is laughing gas. It supports combustion. The others are nearly all poisonous and none of them support combustion.

We meet with a similar curiosity of combination in the combustion of fuel when in some instances carbon monoxide is formed with much loss of heat in comparison with what is obtained when the combination of oxygen and carbon produces carbon dioxide. Carbon monoxide is an active poison, and many persons have suffered from it when working about the rafters of blacksmith shops, and similar places where the gas accumulates; carbon dioxide does not support respiration, but is not poisonous.

### THINGS THAT BURN.

The only practicable way of obtaining heat for conversion into mechanical work, is by the combustion of cheap fuel. Combustion, as commonly understood, is the combining of oxygen with carbon. All elements except fluroine unite with oxygen and heat always results, but in many instances its generation is so slow that the heat evolved is imperceptible. The rotting of wood and the rusting of iron are instances of slow combustion, while the explosion of gunpowder, guncotton and fire damp are examples of violently rapid combustion.

There are other fuels beside carbon that evolve intense heat and light when uniting with oxygen. Sulphur and phosphorus will take oxygen from the air and burn hotly, while fine iron wire will act as fuel and burn violently in pure oxygen. If a piece of the pure metal potassium be thrown into a basin of water, its affinity for oxygen is so intense that it will separate the elements in the water and burn vividly, fed by the oxygen taken from the water. The metal sodium, when put into a jar containing chlorine gas, bursts into flame and burns rapidly. All these give good illustrations of curious acts of combustion, but the materials used are too expensive to be utilized in the generation of heat for commercial purposes.

### PRACTICAL FUELS.

The practical fuels that can be employed in steam-making are coal, wood and mineral oil, or gas, their principal constituents being carbon and hydrogen. The immense accumulation of coal found imbedded over a great area of this continent will be the main fuel supply for ages to come, but in special localities and for particular purposes wood, oil or gas may be used.

### FUEL IS STORED ENERGY.

The prodigious storage of potential energy reposing in our coal measures was laid latent by natural agencies during the formation of the earth. The theory is held, that when the globe first solidified the atmosphere was charged with a much greater quantity of carbonic acid gas than the air now contains. This supplied favorable conditions for the building up of trees, and the sun's rays decomposed the carbonic acid gas (or carbon dioxide, as chemists now call this gas), and water to assimilate the elementary carbon and hydrogen necessary for purposes of vegetable growth.

AFTER THE SCRAP.

By this process the sun was imparting to woody fibre the means of performing the work of driving steam engines, just in the way that the same rays by evaporating water and raising it into the clouds provide the power in streams to drive water wheels. It is estimated that the sun imparts 11,000,000 foot-pounds or units of energy for every pound of carbon formed in a tree. When the resulting wood or coal is burned the sun's energy, which has been lying latent, is brought back into activity.

### HOW COAL WAS FORMED.

The geology of the coal measures shows that there must have been an abnormal growth of vegetation when the coal was under formation, something different from what has been found in subsequent periods. There are still phenomena at work that are analogous to the original formation of the coal beds, such as the rank vegetable deposits settling from tropical forests and in the peat formations seen in various parts of the earth. But these deposits are small compared to those which formed the coal beds. As it required about ten feet of vegetable matter to form one foot of coal, the depth of the deposit that built up the thick seams of coal found in Pennsylvania, the Rocky Mountains and in Nova Scotia must have been enormous.

Those who are best entitled to speak with authority of how the earth rose out of chaos, say that uneasy times preceded and uneasy times followed the epoch when coal was formed. There was down-sinking and uprising of the earth's surface over great areas, and the deposits of vegetable matter were covered over with accumulations that afterward became layers of sandstone and beds of limestone. Under this covering the coal ripened or cooked into the forms now familiar to all civilized people.

The process by which the vegetable accumulations have been converted into coal is supposed to be thus When wood, peat and other vegetable matter was buried in the earth exposed to moisture and partially or entirely excluded from the air, they decomposed, slowly evolving carbon dioxide, thereby parting with a portion of their original oxygen. By this means the mass became gradually converted into lignite which contains more hydrogen than wood or peat. Continued decomposition changed the lignite into bituminous coal chiefly by the discharge of carburetted hydrogen.

There are two theories held respecting the changes which converted bituminous into anthracite coal. One set of geologists believe that its composition was changed gradually by the natural process that converted the vegetable matter to lignite, and the lignite to bituminous coal. Others believe that the change was metamorphic or caused by intense heat which vaporized the volatile matters and deposited them in fissures of the rock as bitumen, petroleum and natural gas.

### MOST COMMON KINDS OF COAL.

The forms of coal most popularly known are lignite, bituminous and anthracite. The principal element constituting all kinds of coal is carbon, which, with hydrogen, is the basis of all the inflammable gases evolved from coal. There are a variety of combustible liquids derivable from coal, such as tar, naphtha and coal oil, which are peculiar compounds of carbon and hydrogen Most of these volatile substances are derived from bituminous coal, while anthracite contains little besides fixed carbon.

The American continent has been supplied with Nature's largess in the form of coal in peculiar abundance. The most reliable geological surveys indicate that there are coal measures extending over 192,000 square miles in the United States. There is also said to be 50,000 square miles additional, where lignite and similar fuels not belonging to the carboniferous strata proper are to be found.

In Great Britain, which is recognized as the coal cellar of Europe, the coal measures extend over 12,000 square miles.

### LIGNITE.

Lignite is found over a wide area in the United States and in some of the Western States it is used almost exclusively as fuel. It is the youngest form of coal and belongs to the cretaceous period of geology, which is far above the carboniferous period in which true coal was formed, as any one may see by examining the chart of geological strata in Webster's Unabridged Dictionary or in any book on geology. Lignite varies very much in quality and appearance. Some specimens look like fossil wood and others closely resemble bituminous coal, but in all cases it is deficient in the amount of carbon necessary to make first-class fuel On most of the transcontinental railroads lignite is burned by the locomotives on certain divisions. There are serious objections to its use. It crumbles badly on exposure to the weather and absorbs a large percentage of moisture,

STANDARD FREIGHT ENGINE, INDIA.

seriously detracting from the steaming qualities of the fuel which gives nothing to spare at the best. Another serious objection to its use is spark-throwing, due to the light, friable nature of the material. Rocky Mountain lignite on analysis ranges about 40 per cent. of fixed carbon, 40 per cent. volatile combustible matter, 10 per cent. water and 10 per cent. ash. Lignite found in Montana and Washington ranges from 50 to 60 per cent. of fixed carbon and is fair fuel when newly mined.

BITUMINOUS COAL.

The true coals are classed as bituminous or anthracite. Coal that contains 18 or 20 per cent. of volatile matter is called bituminous, but there is no fixed line of division between lignite and bituminous coal, or between the latter and the more volatile forms of anthracite.

The ordinary run of bituminous coal contains from 50 to 80 per cent. of fixed carbon, which is the coke of the coal. There are exceptionally inferior coals found in some of the prairie States with fixed carbon below 40 per cent. As the fixed carbon is considered the principal element utilized in steam making, it ought to be better understood that some kinds of bituminous coal possess twice the heating properties of others. Yet to most buyers anything is coal that is black, and inferior coal is purchased almost as readily as that of the best quality.

Besides fixed carbon, bituminous coal contains from 12 to 48 per cent. of volatile combustible substances, which burn with a lurid flame and emit the ingredients of coal gas. These inflammable compounds are known as hydro-carbons, since they consist of different combinations of hydrogen and carbon. Great heat energy may be obtained from the combustion of the hydro-carbons if the furnace is properly constructed and the fireman is skillful, but in practice it is found that the volatile gases add little to the heat value of the coal.

Mixed with all kinds of coal there are earthy and mineral impurities consisting of silica, alumina, iron, sulphur and saline matter, most of which does not burn, but settles on the grates as ashes.

Experiments have shown that bituminous coal loses from 10 to 40 per cent. of its evaporating qualities by being exposed to the weather. This makes the building of storage houses a paying investment.

ANTHRACITE COAL.

Anthracite coal contains from 70 to 95 per cent. of fixed carbon, that with the smaller percentage being classed as semi-anthracite. The most conspicuous quality about this coal is that it burns without smoke. The true anthracite is principally found in Pennsylvania. It is slow to ignite and conducts heat slowly. When once properly ignited it burns with a very high temperature, radiates great heat and is difficult to quench. Anthracite burns with very little flame and deposits no solid carbon from its products of combustion.

If fires could be burned indefinitely without cleaning, anthracite would evaporate as much water, pound for pound, as good bituminous coal, but there is much more loss of fuel in cleaning anthracite-burning furnaces than there is in cleaning a soft coal fire. A report of the United States Navy department on this subject gives facts in relation to the burning of anthracite in marine boilers, which applies with equal truth to locomotive fire-boxes and stationary boilers. The report says:

"Anthracite fires need to be cleaned out thoroughly every twelve hours. This causes loss of evaporative power in the following ways, to which the free burning coals are subject in much less degree:

"1. By the direct abstraction of heat from the combustible portion of the fuel to bring the earthy matter and ash to the high furnace temperature. 2. By the direct loss of heat when the clinkers and ashes are withdrawn at that high temperature. 3. By the unavoidable loss of some unconsumed coal during the abstraction of the clinkers. 4. By the influx of cold air through the open furnace door during the operation of cleaning fires. 5. By the loss of heat in raising the temperature of air over and above the quantity needed for combustion. 6. By the loss of effect during the time the newly cleaned fire is recovering full action."

COKE.

There are certain qualities of bituminous coal that tend to adhere into a compact mass or "cake" when heated. When masses of this kind of coal are heated in closed ovens the volatile ingredients are driven off and a coherent mass of fixed carbon is left, which is called coke. Coke is greatly used for fuel in metallurgical operations and it was once the only fuel used in the locomotives running in European countries. The strict ordinances passed in many of our cities against the smoke nuisance is bringing coke into limited use for locomotives and stationary boilers. The steady rise in the price of anthracite may bring coke still more into use for steam making. Its steam-making qualities are about equal to good anthracite.

When considering the purchase of fuel of any character it is wise to ascertain how much heat-generating elements it contains. This can best be done by a skillful analytical chemist. It is important that it should be done systematically. Apart from the large percentage of volatile matter in some kinds of coal, and which gives little return for the weight represented, there is a certain amount of incombustible matter from which no heat whatever can be obtained.

The relative proportion of that may vary to any extent. There is coal with only 1 or 2 per cent. of ash, but there are other varieties which look as good and have from 15 to 20 per cent. of impurities that turn into ash or clinkers. The impure coal nearly always sells as high as that of the very finest quality.

## Exact Sizes.

Some time ago the secretary of the Master Mechanics' Association sent out a circular urging railroad officers to keep strictly to United States standard sizes of screws, threads and nuts, and also advocating the more general use of the standards adopted by the mechanical association. Referring to this circular, Butterfield & Co. write:

"While we are heartily in accord with everything there laid down, there is yet another phase of the question not touched upon by the circular which is causing us more trouble than the frequent calls made upon us to make United States standard taps $\frac{1}{32}$ or $\frac{1}{64}$ over-size. It has always been our practice to make United States standard taps exact size, and we use the word exact in its strictest sense possible to ordinary manufacture, but in our trade with bolt manufacturers and railway and car companies, we have, within the past year, had taps returned with the complaint that they were too small, when, by a rigid measurement with the best michrometer, they were, as a matter of fact .001 or .002 large (this difference occurring in the process of hardening). Now, if exact size, or to use the phraseology of the circular, standard size, means strictly exact size, why are bolt manufacturers and railway and car companies dissatisfied with taps so made, and why do they ask to have them made larger? Or, if by exact size is meant a certain number of 1,000ths large, what is the scale or rule?

"Our trouble has been so great in this regard, that we have been forced to adopt the following as a temporary makeshift pending the determination of this question, viz.

"Size, $\frac{5}{8}$, $\frac{3}{4}$, $\frac{7}{8}$, .004 large; $1\frac{1}{8}$, $1\frac{1}{4}$, $1\frac{3}{8}$, .005 large; $1\frac{1}{2}$, $1\frac{3}{4}$, .006 large.

"We have done this with some hesitation, and we would be glad of your views prior to confirming our temporary scale.

"We deprecate the proposition to put any definition whatever to the word exact, believing that to a manufacturer of tools certainly the word should define itself, yet we must recognize the fact that from the beginning, in the use of a tap and die, the tap grows smaller and the die larger, and the difference in size *may* become appreciable before they wear out, if they are of the best material and construction, and the question to be determined is whether they shall be a few thousandths large, or of the exact size and the oftener replaced with new ones."

## Boasting Without Knowledge.

"There has been a very great improvement of late in the way engineers handle the air-brake," remarked one of the traveling engineers, "but there are still some men too well posted about things about the brake that are not true. Pure ignorance is not so hard to fight as the jumping at conclusions that are wrong. Since it is considered the correct thing to appear well posted about air-brake matters, some engineers continue to make-believe that there is nothing about air-brakes they are not familiar with when as a matter of fact the extent of their knowledge is understanding how to handle the brake without cause for complaint.

Jim Blimson, one of our engineers, is a man who thinks he knows everything by inspiration. Jim is rats on books and has nothing but contempt for those who resort to books for information about their business. "Observation is how I find out about things," Jim used to remark, and he would puff himself out like the frog of the fable and talk vaguely about valve-gear and injectors and lubricators till the boys would gape with admiration.

And still they gazed, and still the wonder grew
That one small head could carry all he knew.

With many of the boys Jim Blimson was a living contradiction of the belief that men need to study books to learn about train mechanism.

The Handsomest Engine in the "Land o' Cakes." Eight-foot Wheel, Single, Caledonian Railway.

One day the 390 that Jim was running broke a side-rod, and he attempted to take the engine in with one rod. The thing was a failure, and to his mortification Jim was laid off for two weeks to impress upon his mind that it is not safe to attempt to run with one side-rod. It also disturbed the confidence of several of the boys in Jim's knowledge for they were ready to quote different books that described just what would happen if a man tried running with one side-rod, and with Jim the case came out just as the books said it would.

The suspicion aroused about this hero of the roundhouse stove was beginning to settle down, for Jim had many plausible explanations to offer, when another blunder due to sheer ignorance hurled him forever from his high pedestal. Something went wrong with the air-gauge of Jim's engine just as he started out with the fast local, and he made the trainmen use the hand-brakes over the remainder of the division. For this he got ten days.

But the suspension was not the worst of the case. When the trainmen who did the braking learned that there was nothing to prevent the engine doing the work except Blimson's ignorance, they were furious.

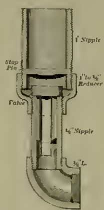
You may give offense to a master mechanic, or general manager, or president and he will get over it and cause you no harm But never give a brakeman a grievance against you, or lead him to believe that you do not understand your business. If you do you might as well quit. That was how Blimson fared. Within a week every man on the road heard the ridiculous story of Blimson stopping his air-pump because the gauge was out of order. All sorts of additions were made to the story, and many other instances were given of stupid things which Jim did when they were really done by others.

At the end of his suspension Jim took his engine again, but he soon found life a burden Instead of admiration for his voluble talk he now found ridicule. Even switchmen, when they passed his engine, would jeer as everybody knows in their way, and ask Jim if he knew the difference between a smokestack and a hay rake? He tried to live the thing down but it would not do. The brakemen would not forget if they did forgive. One day he took his time and went West. He is now running a saw mill engine in Oregon.

Some of the leading locomotive works are now employing men who have had long experience in handling different types of engines, whose duties are to assist in the location of boiler attachments and cab, when these matters are left to the discretion of the builders, so as to make cab as comfortable as possible and all the attachments as near get-at-able as possible for the convenience of the men who use them.

### A Cheap and Good Cylinder Cock.

The engraving shows a cheap cylinder cock used by Master Mechanic Wm. M Morse, of the Toledo and Ohio Central Extension Railroad, at Marietta, O. The cock has a loose, lift-up valve of the regulation pattern, but the rest of the device is made entirely of gas-pipe nipples, a reducer and an elbow, with one rivet ¼ inch by



2 inches long. No casting is required and the cock can be made without a machine shop. It looks to us as if it was just as good as the best and cost about half as much.

### Southern Pacific Metal Cab.

Our engraving gives two elevations and sections of several parts of a metal cab for locomotives, designed by Mr. H J. Small, superintendent of motive power of the Southern Pacific, and used on that system. The climate of the country through which a great part of the Southern Pacific lines pass, is so intensely dry that wooden cabs shrink quickly and then shake apart. This has made the use of a metal cab necessary. Complaints are frequently heard that iron cabs are uncomfortably hot and they must necessarily be worse in this respect than a wooden cab, but every effort has been made in the designing of the cab shown to make it as cool as possible. The roof, as will be seen, is double, with a hollow air space which is lined with asbestos cloth. The cabs are unusually high and wide, with ample windows for admitting air and light. The details of construction are so clearly shown in the engraving that no description is necessary.

### A Rail Joint That Saves Flagging.

When two railroads run side by side there is always some rivalry among the employés of the two companies. Engineers will race when they can do so without violating rules, and sometimes they will show the speed of their engines, rules to the contrary defying.

The Denver & Rio Grande and the Fort Worth roads run side by side, and there is *esprit de corps* feeling between the road departments of the two companies. Two road masters from the rival corporations lately met and were heard bragging about the possessions of the roads. They held their own fairly well till the Rio Grande man said: "There is one thing where your road is ahead of ours Yes has the Norris-Fisher joint on yer rails and it saves yer men from flaggin'. The joints make so much noise that yes can hear a train ten miles away!"

### Stopped Up.

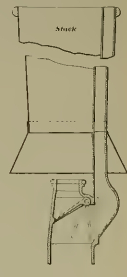
"During the 'Q' strike," said the master mechanic from out West, "I found myself in Denver and went to the Union depot one morning to go South over the Santa Fé. I found a crowd of men around one of the B. & M. engines and a green hand was trying to start her.

"He hossed her back and forth but the train didn't move—I guess some of the strikers had been monkeying with the brakes—the fellow would pull her over and take the slack, then throw her ahead, give her steam and look back out of the window to see what was holding him.

"After he had done this four or five times some one in the crowd yelled

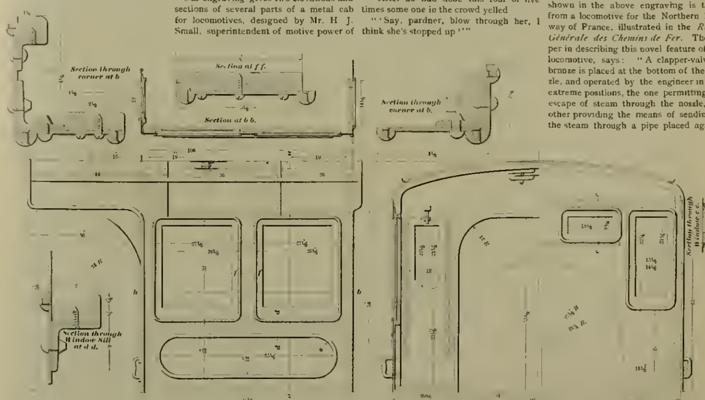
"'Say, pardner, blow through her, I think she's stopped up!'"

arrangement will look up "Clark's Railway Machinery" or Colburn's "Locomotive Engines," engravings will be found that are almost identical with the latest smoke-consuming inventions. The only novelty about the later forms of smoke preventers is in the providing of mechanism the purpose of which is to make the admission of air automatic and to dispense with the attention of the fireman.



### A French Idea.

The exhaust-pipe and arrangement shown in the above engraving is taken from a locomotive for the Northern Railway of France, illustrated in the *Revue Générale des Chemins de Fer*. The paper in describing this novel feature of the locomotive, says: "A clapper-valve of bronze is placed at the bottom of the nozzle, and operated by the engineer in two extreme positions, the one permitting the escape of steam through the nozzle, the other providing the means of sending all the steam through a pipe placed against



Southern Pacific Metal Cab.

This is something which will be appreciated by engineers and firemen; in fact, 'tis a long felt want supplied.

The Mack water-circulating device has been applied to several locomotives belonging to the Boston & Albany and the men in charge are so well pleased with the improved steaming qualities of the boilers that they intend putting the circulator upon other engines. This invention makes independent connection between the water leg and the front end of the boiler, and induces constant movement of the water from the cool to the hot parts. The saving of fuel attributed to the circulator is sufficient to direct attention to the invention as a means of materially reducing the fuel bills.

The agitation that has been carried on so vigorously in Western cities against the smoke nuisance is bringing out a bountiful crop of patented smoke-consuming fire-boxes for locomotives. Those who are familiar with what has been done in this line are frequently puzzled to find the parts of the devices that are patentable. Most of the inventors use some form of the Clark steam jet for injecting air upon the surface of the fire. Others use the baffle plate above the door, in combination with the brick arch, and have some means of conveying air inside. The invention of smoke-preventing firebox attachments was so exhaustively followed in Europe forty years ago that it is very difficult to produce anything new and practicable. If any railroad company anxious to find a good smoke-preventing

the interior of the smokestack to escape directly into the atmosphere.

"This arrangement has been adopted owing to a prolonged trial of a similar arrangement on a suburban locomotive which proved highly satisfactory."

We think we would prefer the Lutgens damper as a means of reducing the draft.

The Eastern Railroad Association gave an opinion some time ago that the Leach Sanding Device might be construed as an infringement of the Collins patent, 271,039, which was designed to use air for cleaning out the sand-pipes when they get stopped up. We now learn from the Leach Sanding Device owners that they have purchased all rights and interests in the Collins patent

LOCOMOTIVE ENGINEERING
A PRACTICAL JOURNAL of RAILWAY MOTIVE POWER and ROLLING STOCK

Address all communications and make all orders payable to

LOCOMOTIVE ENGINEERING,
5 Beekman Street, New York.

PUBLISHED MONTHLY BY

ANGUS SINCLAIR, } Editors and Props
JOHN A. HILL, }
J W CURRAN, Mgr. Advertising Dept.
FRED S HILL, Mgr Subscription Dept.

Subscription Price.

$2.00 per year, $1.00 for six months, postage paid to any part of the world. Single copies, 20 cents.

Special Notice.

*We invite correspondence on practical subjects from all men in the Motive Power and Rolling Stock departments of Railroads.*

*We will illustrate proprietary devices that are novel or interesting and that properly come within the scope of the paper. This will be done without charge, and without reference to advertising considerations.*

*The editors reserve the right to use or discard matter for the reading columns entirely on its merits. The reading columns will not be sold.*

*Correspondents must give their names and addresses, but not necessarily for publication.*

*Mailing address can be changed as often as necessary; always give old and new address, and if you subscribed in a club state who got it up.*

*Please give prompt notice when your paper fails to reach you properly.*

Entered at Post Office, New York, as second-class mail matter.

20,700 of this Issue Printed.

### Notice to Subscribers.

All subscribers will hereafter be notified that their subscription has expired by a patent return blank in the paper. This is ready to fill out, is itself an envelope and is at once the cheapest and best way for us to give the notice.

Should the subscriber neglect to fill out the blank before the next issue of the paper, we send it and notify him the second time by postal card of the expiration of his subscription.

This gives two chances to renew before a name is cut off, gives ample time to communicate with this office if the subscription has been sent and not acknowledged, or to see a club-raiser who has taken a name and neglected to send it in promptly.

With our immense list it is impossible to avoid sending notices to *some* who have renewed subscriptions received near the end of the month and between the time the wrappers are printed and papers mailed.

We assume that every reader wants to keep taking the paper, and we know that many of them are away from home a great deal, and that it is four weeks between pay days. This is why we send two notices and are as easy as possible.

With so large a list as ours no record can be kept other than the list itself, so we do not respond when a man writes "Put me on and I'll send you the money." We enter only paid subscribers, and the date on their wrapper shows how long their subscription is paid.

A receipt is sent for every single subscription and to club-raisers for all amounts received from them. If you have paid a club-raiser and then get a notice, nine to one it is all right and due to his delay in sending the list.

We have set our mark at 30,000 paid subscribers, and to this end propose to deal fairly, give full value and deserve renewal, keep all our old friends and capture many new ones. If there is any doubt the subscriber shall have the benefit.

SINCLAIR & HILL.

### Notice to Club Raisers.

There are more than 400 club raisers hustling for LOCOMOTIVE ENGINEERING and we have a favor to ask of each one of them. We find that many hold a list for a month or more trying to get it up to full size before they spring it on us. This is all right where all the names are of new subscribers, but where there are renewals it is not. We send notices to each subscriber, and a man who has paid a club raiser for his paper a month before dislikes to be notified that his subscription is out. Then he writes us a letter. This is the favor: *Please send in what names you have every month.* It will save lots of trouble in the mailing department. 4,522 names, counting renewals, were put on the list in January, and there were more in February. Every complaint calls for hunting for the name on the last list, and often the month previous.

It won't make a bit of difference to you to send in what you have—you can add to it during the whole year—and it will save us lots of annoyance. SINCLAIR & HILL.

### Profit and Loss of Chain-Ganging.

In the days when very few railroad companies had departed from the practice of regulating the work of a locomotive to the physical endurance of one crew, the president of one of our largest railroads went to Europe, and he traveled with his observing faculties active. He had watched with interest the ceaseless jar of the engines and found food for reflection in the fact that they never stopped from the time the pilot was put off until the boat was slowed to take on another pilot near Queenstown. When this railroad magnate returned he intimated that he did not see why a locomotive could not be run day and night without rest just as successfully as a marine engine. The difficulties in the way of making a locomotive run constantly were explained, but the president looked upon the objections as the excuses of conservative officials, and he insisted that the practice now known as chain-ganging should be adopted. His practice is now followed by many of our railroad companies.

The fact that the practice of keeping locomotives running constantly has extended so much within a few years that nearly all railroad companies follow it more or less is generally regarded as proof that chain-ganging is a decided success. From information that has come to us this winter about numerous delays that have happened on a trunk line from the failures of chain-ganged locomotives, and from our observation of similar causes of train irregularity on another line, leads us to doubt the saving of the long mileage plan. The practice of keeping locomotives running as much as possible enables a railroad company to perform the business with a comparatively small first-cost for motive-power, but curtailment of first-cost is very often extremely expensive in the end. There is some reason for believing that an increase of capital account necessary for the purchase of enough freight locomotives to permit them to be run by regular crews would be a highly judicious investment. In figuring up the expense of operating a railroad there is too much attention bestowed upon the means of making direct saving and too little thought devoted to estimating the causes of indirect expense. When two locomotives, each costing $10,000, are made to do the work of three engines by excessive running, the assumption is immediately made that the interest on $10,000 is yearly saved. This is about $500 annually, and it is easily wasted on increased consumption of fuel and additional expense for repairs. But the great source of waste with the overworked engine is in failures through breakages, which would not have happened had the engines been in charge of a man who followed the practice of thorough inspection, and through want of steam, which would have been kept up by a fireman familiar with the engine, or by an engineer who knew how to adjust the draft appliances. Delayed trains are a fruitful cause of collisions. When accidents happen or when derangement of traffic results from shortcomings which are directly attributable to the chain-ganging system, the loss or expense incurred ought to be charged to the method of engine operating. Were this done regularly, we are persuaded that the chain-ganging plan would be less popular than it is with those who figure up operating expenses.

There is, of course, great difference in the way that chain-ganging is carried out on different roads. On some lines the engines are run almost as economically and successfully as they are under the regular crew system. The secret of this success appears to be in the way inspection is carried out. Competent men are employed who thoroughly inspect every engine on its arrival at a terminus, and the necessary work is done. On other roads the inspection is a perfunctory affair, and failures are constantly happening on the road from defects that proper inspection would have remedied. But the most perfected system of caring for the engines does not overcome certain drawbacks inherent to the chain-ganging plan. It does not supply the live personal interest which working the same engine day after day supplies. The money value of this interest lies in the fact that deterioration of any part is noted and provided against. If a bearing inclines to run hot it receives timely nursing; if a valve has begun to cut, it receives extra lubrication. This kind of acquaintance prevents delays on the road. The engineer comes to know with certainty how the engine can be worked with the smallest drain on steam, and the fireman has learned how she can be fired with the least consumption of fuel. This line of information saves fuel. Theorists say that all locomotives of the same class can be worked in the same way and equal results obtained. It does not come out that way in practice. A very little difference in the alignment of the nozzles will make a decided difference in the steaming qualities of the engine, and variations in the position or condition of the other draft appliances will be strongly felt. Similar influences require peculiar treatment in the handling of an engine to secure the best results. Thus it comes that those who are thoroughly acquainted with one locomotive can work the engine more economically than strangers. When all the drawbacks to the practice which divorces the personal interest of enginemen in the locomotives are summed up, it will be found that the balance caused by chain-ganging is on the wrong side.

### Diverse Sizes of Taps and Dies.

In another part of this paper will be found the expression of views of Butterfield & Co., Derby Line, Vt., on the subject of sizes to be followed in the manufacture of taps and dies for United States standard screw threads. This firm are large makers of taps and dies, and like nearly all others in this line of business, experience annoyance through the diversity of practice that exists among railroad men in the ordering taps and dies. The railroad men who are satisfied with these things when they are made to exact sizes appear to be in the minority. A peculiar feature of the case is that there is very little disposition among all the other vast mechanical interests of this country to call for taps and dies that vary from the standard size. Why is it that those who are in charge of railroad rolling stock are the only class that object to following the standards that were established to secure uniformity and interchangeability? It was rightly expected, when the reform was accomplished establishing standard sizes of screw threads, that railroad companies would be the greatest gainers by the change, and this turned out to be the case. Before the reform was effected railroad companies experienced no end of trouble, expense and delay in repairing foreign cars owing to the diversity of screw threads in use. Now a bolt made and applied in Boston will take a nut threaded in San Francisco as readily as if it was fitted for that particular bolt.

In view of the great advantages that have accrued to railroad companies from the introduction of standard screw threads, we think it is very short-sighted policy on the part of their mechanical representatives to adopt practices that cause diversity of sizes. There is no doubt that a practice has grown up of ordering taps a little larger and dies a little smaller than the standard sizes, the purpose being to make the tool last beyond its natural wear. This is an objectionable practice at the best, even viewed from an economical standpoint. If a large tap is threading nuts larger than the standard, and dies are cutting the bolt smaller than the full diameter, a very poor fit is the result, and the loss of nuts falling off and breakage occurring in consequence is likely to cast up a bill of expense that will not be offset by the small gain secured by making taps and dies last a little longer. The practice, however, has become so prevalent that it ought to receive consideration from the mechanical associations. If it is advisable to depart from the standards it ought to be done systematically. The subject should be put into the hands of a committee that would inquire into the prevailing practice and make recommendations for the guidance of railroad companies and manufacturers. The committee having this subject under investigation last year reported very strongly in favor of maintaining exact standard sizes, but the question would not suffer any from renewed agitation.

### To Indicate Leakage of H. P. Piston.

A master mechanic who was at one time a marine engineer, and is now in charge where there are a number of compound locomotives in use, has urged us to advocate that gauges be placed on receivers so that the engineer may have the means of learning when anything happens to the high-pressure piston to cause excessive leakage of steam. This was, we consider, a good suggestion, and is well worthy of general adoption. Cases were mentioned where the piston rings of the high-pressure piston had broken all to pieces, yet there was no means of telling that anything was wrong, although the leakage of steam must have been very great. To be sure it passed into the low-pressure cylinder and was used there, but leakage of this kind must detract very much from the economical performance of a compound locomotive. An engineer who took an intelligent interest in the working of a compound locomotive would be likely to detect bad piston leakage by the cylinder cocks; but there are not many engineers who are studying the working of this class of engine very deeply, and the average runner does not understand how to detect leakage. A gauge on the receiver would make his diagnosis comparatively easy.

### We Are Pained to Observe, Etc.

The *Railway Age and Northwestern Railroader* comes out with a statement about circulation that shows how reckless some people can get with the truth. It says that it is "read by more railroad men than any other paper in America," and adds "all statements to the contrary are false." The biggest liar on the *Age* has never claimed above 5,000 circulation until the past year, and only a few days ago one of the officers of the company called upon us and stated that they printed 7,000 papers a week—this is doubtless somewhere near correct; say it is, they are *not in it*. LOCOMOTIVE ENGINEERING never prints less than 20,000, and has not printed less for nearly a year, and has printed as many as 30,000 in one month—and has no back numbers. The *Age* must have less than 7,000 readers—the same men don't count each time they look at a paper. We have almost three times as many. There is no doubt that the *Age* has more than any other weekly, but when it comes to saying *our railroad paper* they are off. We are willing to bet that the news-stand sales of LOCOMOTIVE ENGINEERING are more than the paid circulation of any other railroad paper, except the *Age*. Always glad to show our list to anybody—especially circulation liars—the *Age's* young man will please call and see it.

Later. Since the above was put in type the *R. R. & N. W. R.* has changed the wording of its challenge so that it knocks the chip off the shoulder of *weeklies* only. It may come back to us and all will be forgiven.

### Consolidation in New England.

If consolidation of railroads goes on as it has been progressing for the last few years there soon will be only a dozen separate companies in the country. New England appears to be rapidly drifting into two systems. The New York, New Haven & Hartford started a consolidation movement a year or two ago, and in that time it absorbed the New York, Providence & Boston and several smaller lines. Last month this small road, with the strong power of assimilation, opened its mouth very wide, and no less a morsel than the great Old Colony Railroad dropped in. The Old Colony did not have a long trackage as compared with some roads, but it did an enormous business on the 600 miles it reaches over. Its passenger business is exceptionally heavy and remunerative. The road was formed from the consolidation of a great many small roads, one of them having been a granite tramway near Quincy, which was said to have been the first railroad built in this country. The rolling stock owned by the Old Colony is exceptionally good.

Since the Philadelphia & Reading interests got control of the Boston & Maine the latter line has had its ideas of conquest sharpened, and they have been by no means dull for several years. The new deal was hardly accomplished when the Boston & Maine proceeded to swallow the Connecticut River road, and now it is said to be reaching out for other roads which have been considered within sacred keeping. There is likely to be more consolidation soon, but a conflict of giants would not be a surprising accompaniment of the next movement.

Since the above was written the battle predicted has been lost and won, and the Reading has been forced into the hands of a receiver. The intrusion of that corporation upon the preserves of New England roused the wrath of powerful keepers who proceeded to hammer the life out of all Reading securities.

### Send Information About Compound Locomotives.

A circular has been issued by Chairman George Gibbs, of the Master Mechanics Association Committee on Compound Locomotives, asking for information about this type of engine from all those who have notes of experience to offer. The questions asked are particularly comprehensive, and if answered will present valuable facts about compounds which railroad managers are anxious to obtain. The popular interest in compound locomotives has not subsided any within the last year. Nearly all intelligent men connected with the motive power department have been studying the subject, and the large number of compound locomotives in use are giving object lessons of much value. During the last few months we have heard several men who have the best of opportunities for observing the working of compound locomotives make the statement that this kind of engine is not well adapted for high speed. They think that the compound is destined to come largely into use, but that very large driving-wheels must be employed to make the engine do well on passenger service. Others say that the engine is not adapted for anything except freight service, and that of a fairly uniform character. When all the opinions and notes of experience are in, the able chairman of this committee will no doubt sift all the points worth being known and present them to the railroad fraternity in the most intelligible and attractive form.

We would suggest to all concerned that it is their duty toward railroad interests generally to send to Mr. Gibbs all the information in their possession concerning compound locomotives.

### Curious Advertising Methods.

There are some so-called railroad papers which exist merely for the purpose of getting advertisements and are seen by very few people except those who do the advertising that keeps them alive. They take advertisements for what they can get and can afford to do so because very little expense in brains, engravings, typographical matter and paper is expended on the publication. Only enough papers are published to go round the advertisers and a small free list. Yet papers of this character receive patronage from parties who manage the other lines of their business well enough to achieve success. There is a wild scramble for advertising among what might be termed bona fide railroad papers, but we can hardly believe that any of them are referred to in the annexed letter. One of our advertising agents had called upon the American Steam Gauge Company of Boston, and a few days afterwards we received from the company the following letter:

"We have been looking into the matter of advertising in different locomotive and railway papers and have inquired of some parties whom we thought much better posted than we are. We find that while your paper stands very well there are other papers which are considered ahead of it. We will make you the same proposition we have made some other parties with whom we are now advertising, they having accepted our proposition. If you will give us six months' advertising for nothing we will agree to continue for twelve months more and pay you for the twelve months. At the end of this time we can decide whether we are benefited by the advertisement or not, and if so we shall be pleased to continue with you, you to give us space at the top of the page next to reading matter and any little articles on our specialties which you would like to put in the reading matter from time to time."

Among recent railroad news of interest is the announcement that Henry S. Ives has obtained control of the Cleveland, Akron & Columbus road. This is the gentleman who came within an ace of obtaining control of the Baltimore & Ohio as a tail to the Cincinnati, Hamilton & Dayton. Had it not been that the president of the Pennsylvania Railroad and other moneyed magnates stepped in and blocked the movement, Ives would have carried out his plans, and instead of going to prison he would have been hailed as the greatest financier of the day. The railroad world has by no means seen the close of Ives's career. He is the irrepressible sort of a man who does not know when he is beaten and converts defeat into the beginning of victory. Shortly after the collapse of his C., H. & D. scheme, which was just as legitimate as many other railroad deals that met with general approval, Mr. Ives opened an office in Wall street and began making money. He quietly secured control of the Ohio Southern and is building up the property. Some day it will be an active competitor of his old line, the C., H. & D. We shall be greatly mistaken if Mr. Ives does not cut a wide swath in railroad circles before many years.

An order of court has been given to sell all the assets belonging to the Cyclone Snow Plow Co. The history of this company is a good illustration of the fact that it is never safe to count very much on the value of a mechanical appliance until it has been tried. It also shows that ordinary business men are not good designers of machinery.

### PERSONAL.

Mr. Alonzo Dolbeer has been appointed master mechanic of the Lehigh Valley, at Buffalo.

Mr. J. H. Graham has been appointed master mechanic of the Iowa Central at Marshalltown, Ia.

Mr. R. K. Mulcahy has been appointed superintendent of the Oregon Pacific, with headquarters at Corrallis, Ore.

Mr. D. H. Blair, an engineer on the Southern Pacific, has been promoted to acting road foreman of engines.

Mr. George F. Evans has been appointed superintendent of the Connecticut River Railroad. He was formerly on the Boston & Maine.

Mr. C. M. Lawler, assistant general manager of the Philadelphia & Reading, has been made general superintendent of the main line.

Mr. George P. Hodgman, one of the Railway Master Mechanics' Association scholars at Stevens' Institute of Technology, is president of the class of 1894.

Mr. J. A. Wagner has been appointed superintendent of the Des Moines Union Railway, vice Horace Seeley, who goes to the Des Moines Northern & Western.

Mr. Thomas Roope, for some time acting master mechanic of the Sioux City & Northern, at Sioux City, Ia., has been appointed to the position he held on trial.

Mr. Weston Lewis has been chosen president of the Sandy River Railroad, and Mr. Josiah Maxcy vice-president and general manager, with offices at Gardiner, Me.

It is reported that the Rogers Locomotive & Machine Co. has been reorganized, Mr. J. S. Rogers retiring from the firm. The style hereafter to be Rogers Locomotive Co.

Mr. E. Dickinson, for several years assistant general manager of the Union Pacific, has been promoted to the position of general manager, succeeding Mr. S. H. H. Clark.

Mr. I. H. Lyman has been promoted from roundhouse foreman on the New York, New Haven & Hartford at Bridgeport, Conn., to be general foreman at Falls Village, Conn.

Mr. H. W. Hammond has been appointed superintendent of the Western division of the New York & New England. He was formerly on the Rome, Watertown & Ogdensburg.

Mr. W. J. Murphy has been appointed superintendent of the Cincinnati division of the Cincinnati, New Orleans & Texas Pacific. He was formerly on the East Tennessee, Virginia & Georgia.

Mr. O. R. Whitney, for some time master mechanic of the Alabama Midland, has been appointed general superintendent of the New York & Yonkers Steamboat Co., with headquarters in New York.

Mr. W. H. Russell, road foreman of engines of the Southern Pacific, has been promoted to the position of acting master mechanic of the San Joaquin division, with headquarters at Bakersfield, Cal.

Mr. F. A. Harrington, superintendent of the Mohawk division of the New York Central, has been chosen managing director of the Troy Union Railroad, to succeed Mr. Theodore Voorhees, resigned.

The following promotions have been made on the Jacksonville & South Eastern line: J. P. Warner, from roundhouse foreman to be traveling engineer, W. W. Morrow, from engineer to be roundhouse foreman.

Mr. W. H. Voorhies has been promoted to be assistant superintendent of the Iowa Central. He began work on the road 20 years ago as brakeman, and has risen through the grades of conductor and trainmaster.

From an article in a Pacific coast paper regarding the women in California who have graduated as lawyers, we learn that one of our correspondents, Mrs. J. C. Baker, of Oakland, Cal., is one of seven female lawyers in that State.

Mr. G. R. Hardy has been appointed superintendent of the New York, New Haven & Hartford, with charge of engineering work on the New York division. Mr. Hardy has been for some time with the Westinghouse Electric Company.

Mr. E. C. Hieser has been appointed master mechanic of the Adirondack & St. Lawrence division of the New York Central at Herkimer, N. Y. Mr. Hieser has been an engineer on the western end of the New York Central, and was foreman at Lockport when promoted.

Mr. William Renshaw has been promoted to be superintendent of machinery of the Illinois Central, succeeding Mr. Henry Schlacks. Mr. Renshaw has risen on the Illinois Central from a machinist. He was successively foreman, master mechanic and assistant superintendent of machinery.

Mr. T. Hackworth Young, roundhouse foreman of the Chicago, Milwaukee & St. Paul, at Chicago, has been appointed superintendent of the Railway Division of the World's Fair. Mr. Young is a grandson of Timothy Hackworth, one of the pioneers in the development of the locomotive in England. His selection for the position is a graceful tribute to a great inventor.

Mr. E. G. Russell has been appointed superintendent of the Rome, Watertown & Ogdensburg with headquarters at Watertown, N. Y. Mr. Russell was for several years superintendent of the Illinois Central, and attracted considerable attention by the fight he carried on with the striking switchmen of that road at Chicago. He is a man of strong personality and does not tolerate any interference with his authority.

We have to acknowledge several pleasant visits from Mr. E. Tatlin, superintendent of the Moscow-Brest Railroad general works, at Moscow, Russia. Mr. Tatlin has been making a visit to our railroad system for the purpose of obtaining information of a useful character. He was very much pleased with what he saw and with the courtesies shown him. Mr. Tatlin has arranged to translate "Sinclair's Locomotive Engine Running and Management" into the Russian language.

We have received an announcement that the co-partnership between J. G. Hendrickson and F. J. Clamer has been dissolved and all interests acquired by the Ajax Metal Co., Incorporated. In the circular making this announcement there is a very interesting history of Ajax metal, which is an addition of lead to copper and tin in such a way that the lead is not only perfectly diffused through the mass but is fixed and stable in its distribution, so that the alloy can be repeatedly melted without any separation or deterioration of the lead from the other metals.

Mr. Henry Schlacks, who has been superintendent of machinery of the Illinois Central for ten years, has resigned. Mr.

Schlacks had been with the Illinois Central, with a few short breaks, for thirty-three years. He was for a short time foreman of the Rock Island shops at Chicago at the time Mr. Allan Manvel was shop clerk there. A friendship sprung up between the two men then that has been unbroken since, although they have followed different roads. Mr. Schlacks rose on the Illinois Central from machinist to the head of the mechanical department.

After being away from the road about two years, Mr. Allan Cooke has returned to the Chicago & Eastern Illinois as superintendent of machinery. We took occasion to tell some wholesome truths to the management that crowded Mr. Cooke out of the position he had held with so much credit to himself and profit to the road, and we are very glad to learn that he is back in his old place. Without being brilliant Mr. Cooke is essentially a safe man to be in charge of railroad rolling stock. No one understands the practical part of the business better. He will spend the money available to the very best advantage and keep officers and men in good humor. There is no fear of any trouble in the motive power department of the Chicago & Eastern Illinois while Allan Cooke remains at the helm.

Of the many well-known men who were directors of the New York Central from the time it was organized in 1853 until it came under the Vanderbilt control in 1867, only four are alive. The best known of these is Russell Sage, who was State Senator from Troy when he was elected director. Mr. Sage rose into prominence and riches through the political highway. He was originally a saloon keeper in Troy and attended his own bar. His place was noted for its good whisky, and Russell by this means and other methods obtained so much influence with the boys that he became their political representative. He has always been known as a hard man, who will never yield a cent that is not forced from his grasp. He is the kind of railroad owner who has made combination of railroad employes imperative as a means of self-protection.

Professor Arthur T. Woods died at Chicago of typhoid fever, last month. He was a graduate of Annapolis Engineering School, and afterwards spent several years in the navy. Seven or eight years ago he was appointed professor of mechanical engineering at the Illinois State University, where he became a highly popular teacher. While here he devoted a great deal of attention to railroad machinery questions, particularly to compound locomotives. At the writer's suggestion he wrote a series of articles on compound locomotives, which were put in book form, and is the only reliable work on the subject. About two years ago he was appointed professor of dynamic engineering at Washington University, St. Louis. This work he left to accept an editorial position with the *Railroad Gazette* at Chicago. Professor Woods was a pleasant, genial gentleman, and had many friends among the master mechanics, having been an associate member of the association.

The Central Railroad of New Jersey have ordered from Baldwin's fifteen consolidation engines for freight service and twenty eight-wheelers for fast passenger trains. The latter engines, designed by Superintendent of Motive Power Thompson, are well deserving of special mention. They have cylinders 20x24 inches and driving wheels 6½ feet in diameter. The main bearings are 8x12 inches and all the other bearings are unusually large. The boiler is 58 inches diameter at the front ring, made of ⅝-inch steel and arranged for 250 2-inch flues, with ¾-inch space between each. The firebox is 11 feet 1½ inches long, the large grate area being needed for burning hard coal. The boiler provides about 1,700 square feet of heating surface.

## Poughkeepsie Bridge.

The handsome supplement which accompanies this issue of LOCOMOTIVE ENGINEERING gives a striking view of the Poughkeepsie bridge over the Hudson River. Those familiar with the physical topography of the Eastern States understand that the elevated ridge extending southeast from the Catskill Mountains, with the Hudson River at its side, makes a natural barrier between Pennsylvania and the New England States. The spanning of this obstruction was long projected, but it was not till 1871 that the scheme of bridging the great river at Poughkeepsie took practical shape. A company was formed in that year to do the work, and a charter was obtained in 1873. Work was commenced two years later, but the financial panic took life out of the enterprise, and work was entirely suspended three years later. For eleven years nothing was done, but in 1886 a new company was organized which purchased all interests belonging to the old company, and a contract was made with the Union Bridge Co. to push the work to completion. The work was pushed rapidly, and the bridge was opened for traffic two years ago.

This bridge and the connecting lines are now in control of the Philadelphia & Reading, and are used as a direct route for conveying the coal products of Pennsylvania to the New England States. This connection originated the ambition of the Reading management to control important railroads in New England.

The bridge, which is seventy-five miles from New York, spans a gorge about 200 feet deep and nearly 7,000 feet wide. The bridge proper consists of five spans, two cantilevers 548 feet each, one cantilever 546 feet, two connecting cantilevers 525 feet each, and two anchor spans 201 feet each. The western approach is by a viaduct 1,034 feet long, and the eastern approach viaduct is 2,640 feet long, the whole making a structure 6,768 feet in length. The water in the river at that point is sixty feet deep, and there is a depth of seventy feet of mud through which the foundations had to be sunk. The bridge rests on iron towers that stand on stone piers forty feet high. The rails on the bridge are 212 feet above high water mark.

The scene which our engraving presents is the view of the bridge as it appears from the tracks of the New York Central Railroad.

It is estimated that the engines in two new vessels lately launched for the Cunard Line will develop 30,000 indicated horse power.

Under a pressure of 5,000 pounds the deflection of a good oak brake beam is about ¾-inch. A good steel beam will endure the same pressure with a deflection of $\frac{1}{16}$-inch.

It must sometimes be a little exciting living in houses close to the elevated railroad structures. A news item in a Brooklyn paper recently mentioned that a woman was badly hurt by being struck by a cylinder-head while sitting at her window.

The bill before Congress requiring railroad companies to use automatic car-couplers and continuous brakes also makes it unlawful for any railroad company to use cars that are not provided with hand-holds for the convenience and safety of men in coupling. This is one of the Master Car Builders standards and is an inexpensive attachment that has saved many lives. The railroad companies that require legislation to compel them to adopt hand-holds are a disgrace to a civilized community.

The Bridgeport Machine Tool Works have opened a new office in room 86, Taylor building, 39 and 41 Cortlandt street, this city. Mr. N. B. Lyons is in charge.

## EQUIPMENT NOTES.

The "Soo" has placed an order with Schenectady for ten locomotives.

The Pennsylvania has contracted for the construction of 1,000 new freight cars.

The L. I. R. R. is also reported to be about placing orders for some freights.

Buffalo, Roch. & Pitts. are contemplating ordering additional freight equipment.

The twenty coaches for the Long Island have been let to Jackson & Sharpe, of Wilmington.

The Allison Mfg. Co. of Philadelphia are reported to be very busy with freight car building.

It is reported that the K. C., Ft. S. & M. are in the market for ten locomotives and 500 box cars.

The Schenectady Locomotive Works have taken an order from the Mich. Cen. for ten engines.

The Rogers Locomotive Works have taken an order from the Ill. Cent. for seven switchers.

The contracts for the 1,300 freights for the extension of the N. Y., Sus. & W. Line have not yet been let.

It is reported that the Illinois Central have ordered 30 passenger cars from Billmeyer & Small, York, Pa.

The Rhode Island Works have received an order for seven locomotives for the Toledo, St. Louis & Kansas City.

The Chesapeake & Ohio have contracted with the Basic City, Va., Car Works for the building of some freight cars.

The D., L. & W. have placed an order with the Jackson & Woodin Company, of Berwick, Pa., for 500 coal gondolas.

The Lehigh & Hudson have ordered 100 box cars of 60,000 pounds capacity, to be used in the Central Dispatch Freight Line.

The order from the Pitts., Shen. & Lake Erie Road for freight equipment was placed as follows: 500 to the Ohio Falls and 500 to the Pullman Company.

The Pittsburgh Locomotive Works are building three compounds of their two-cylinder type for the Union Elevated Line of Brooklyn.

The N. J. Central orders for twenty-five engines have been placed with Baldwin. They are said to be in the market for 500 freights.

The Boston & Maine have ordered thirty new engines. They consist of twelve eight-wheelers, twelve moguls and six four-wheel switchers.

The Schenectady Locomotive Works have received an order from the Union Stock Yards of Chicago, for thirty switching engines.

Brooks people have received orders from the Duluth, Missabe & Northern for two heavy locomotives. They are working on 45 engines for the Great Northern.

Vice-President Thomas, of the Erie, is said to be contemplating ordering some ten-wheel locomotives suitable for pulling heavy passenger or fast freight trains.

The triple drum sander, for polishing and sandpapering wood-work, made by The Egan Co., Cincinnati, has been awarded the medal of "Superiority" at the fair of the American Institute, New York City.

The St. Charles Car Works are delivering passenger cars to the Missouri Pacific, and they are said to be particularly well designed and equipped with all the most modern luxuries, including Pintsch gas.

The Great Northern, which hitherto has been noted for opposition to the use of safety appliances, has adopted the M. C. B. standard coupler. The vertical plane type will in future be applied to all new cars.

The boys have loaded us up with criticisms of Campbell's valve-setting article; we have not room for all of them, but they are much on the same line; they don't believe much in his plan of throwing wheels by a liner to get his valves square.

Cooke's people are building a large ten-wheel compound locomotive, which they expect will make a record that will attract attention. The first compound they built was used as an object of study, all the weak points being fortified in the new engine.

The Illinois Central have ordered from the Rogers Locomotive Works eight new suburban double-enders of the Hudson type. These will be a little heavier than the engines in use, the cylinders being 17 x 24 inches. The fireboxes will be made large enough to burn anthracite coal.

The Lake Street Elevated Railway of Chicago are about to order 125 passenger cars and a full equipment of locomotives. The engines will be similar to those used on the elevated roads of New York, but a little heavier. The cars will be the same as those used in New York, and will be heated with the Morton system.

In a great measure the prejudice against bushed rods is from a theoretical and not a practical point of view. In support of this we refer to the results of the West Shore Road. Quoting at random from their records we note two bushes, ordinary brass, making a mileage of 101,614 miles to ⅜ inches of wear, and another showing 174,322 miles to ⅓ inches of wear. Comment is unnecessary.

The Wellman Steel Co., Thurlow, Pa., have made a contract to supply all the steel plates for one of the new Inman liners about to be built in Philadelphia. The quantity of steel required will be about 10,000 tons. This increase of business will make the works busy, but no extra plant will be required, as the capacity of the works is now about 2[illegible] tons a day, and about a year is given for supplying the plates.

The piston-rods, crank-pins, side-rods and power transmitting levers of the great double-ended locomotives for the Mexican Central were made of Tennessee iron by the Ewald Iron Co. of St. Louis. The company reports a growing demand for their fine quality of iron for the parts of railroad rolling stock given to breakage. If more of this product were used there would be fewer failures from broken rods, axles and piston-rods.

There is a good deal of killing the goose that lays the golden egg in some of our cities. The latest case of this kind reported is that the Peninsular Car Works are about to leave Detroit on account of the heavy taxation. We wonder if ever our sovereign voters will ever come to realize that other forms of property escape without a fair share of taxation, while every industrial establishment has to bear the burden. If there was more taxation of vacant lots, there would be less of that form of property waiting for a rise.

The introduction of compound locomotives appears to be making rapid headway in France, most of the railroads having this type of engine at work. French lo-

motive designers appear to be celebrated for the complexity of their machinery. London *Engineering* lately had illustrations of a four-cylinder compound locomotive built for the Northern Railway of France, which is one of the most complex engines ever built. She is an eight-wheel engine, with two inside cylinders set under the smoke-box, and transmitting power to a cranked axle on the front pair of drivers, and an outside cylinder set on each side outside the frames, close to the front drivers. The latter cylinders have mechanism connecting with the back pair of drivers. The design calls for two sets of valve motion and a most objectionable arrangement of steam pipes.

The tendency on the part of railroad managers to curtail their equipment orders, that is, keep them behind the absolute wants of their road, is growing to quite an alarming extent. These constant car famines are working great injury to the business interests of the country generally. Nowhere perhaps is this tendency more noticeable than throughout New England. In a conversation with the general manager of a New England road, of a wide and long experience, he stated, that with an experience covering some twenty years, that scarcely a road in the New England States had owned sufficient equipment to do the business offered and that in his judgment it was very short-sighted policy on the part of the managements to do business in this way. They should provide enough cars for their own traffic at all times of the year, that the business was not of a fluctuating character and that the failure to provide these cars suppressed a great deal of traffic, and deprived the railroad company of a handsome revenue, that a careful study of the question had satisfied him that the cars more than paid for themselves in mileage earned on their own road or if engaged in service on other lines, that in his judgment the roads of New England owned less equipment per mile than any other roads throughout the country. Just what percentage less had not been carefully figured out, but that it was surprising to him and doubtless would be to others who would investigate the subject. It is a surprise to us that this matter is not receiving the attention it deserves. The niggardly policy on the part of these managements certainly ought to be stopped. Shippers complain very bitterly throughout the country and they certainly have reason to do so. Many of the sections of country are not provided with competitive lines and they are completely at the mercy of one corporation.

A party has brought suit against the Lake Shore Railway for $5,000 damages on account of his children having been put out of the waiting-room at Adrian on a cold night, where they went to await the arrival of their father on a late train.

There is a boiler-maker working under Mr. Fred Griffith, master mechanic of the Delaware Lackawanna at Buffalo, who has been a cause of much anxiety to Fred. The man's full name is Perterje Zmnchzizkomskekowlowski. Railroad men in Buffalo—Macbeth and others—say that Mr. Griffith's time-keeper has been claiming over-time for writing this boiler-maker's name. An official correspondence arose in consequence, and an extra typewriter had to be employed to help spell the man's name.

The Q & C Company have always been very liberal in the use of printer's ink, which has no doubt contributed largely to their great success. Not content with ordinary advertising, they have now established *Railway Specialties*, an illustrated journal with humorous tendencies. We welcome our new rival with a warm grasp of good fellowship. If it develops according to the implied promise of No. 1, Vol. 1, the *Railway Specialties* will soon be a formidable rival to *Puck*.

### A Traveling Blacksmith.

Superintendent of Motive Power John Hickey, of the Northern Pacific, has created a new office in appointing James J. Thornton traveling blacksmith of the system.

The idea of having a general foreman of a whole system, whose duty it is go from shop to shop and see that the practice is the best and nearest to standard, is a new one, and it looks like a good one.

So many new schemes are tried in all shops, so many little kinks, all their own, gotten up that others do not hear of, and, on the other hand, so many neglectful and wasteful practices become second nature that an "evener" in the shape of the traveling foreman has a chance to show pretty good results. He can introduce kinks from one shop to the other, stop wasteful practices, and his word will go a long way toward securing needed tools and stock, where a requisition or complaint from the local foreman would be overlooked, turned down or refused.

We understand tha Mr. Thornton has shown after a year of service a saving in the blacksmithing department and that the use of such an officer is shown to be a paying investment; we have been informed that the Santa Fé and the Southern Pacific have both put on traveling smiths.

Blacksmithing is one of the most important of the shop departments but less care is taken in it and less attention paid to it than almost any other.

The blacksmiths are waking up, they are beginning to study their business and will soon bring the importance of their work into notice by the improvement made in it. A great deal of interest has been taken in the railroad blacksmithing articles published in this paper.

The periodically expected visit of the traveling smith will help to keep many a shop cleaner, the stock in better order, the steam-hammer packed, and scrap in its place.

All hail, traveling smith, you are welcome.

We learn that the last year has been by far the most successful period in the business done by the Otley Manufacturing Company, Chicago. The principal products handled by this company are Otley's steam packing cement, asbestos pipe and boiler coverings, sectional hair felt, mineral wool, canvas and paper covering. The cement is the most popular of their goods. Nothing equal to it has ever been tried for making joints, stopping leaks, and for making all sorts of seams tight. It is particularly good for extension smoke-boxes, front ends, stack-saddles, exhaust-pipe joints and such work. The cement is used by a great many railroads and those who try it once always continue its use. A sample for trial will be sent on application.

An improvement in ash pans has been patented by Artemus Welsh, of Lawrence, Kan. Mr. Welsh proposes making an ash pan with oblong openings in the bottom, which are covered with stationary slats. When the pan has to be emptied the bottom is moved away from the slats, mechanism being provided for shaking the bottom to and fro.

### Using the Wells Light for Heating Tires.

The annexed engraving is the reproduction of a photograph taken at the Kingsland shops of the Delaware, Lackawanna & Western, when they were using the Wells light to take off tires. The light seems to be very well adapted for doing this work, as it heats the tire so quickly that the wheel center is not warmed. They took the tires off two sets of 58-inch driving wheels, and in each instance the heating was done in about 15 minutes. With an improved casing to go around the tires, the heating could be done in about 12 minutes. An ordinary sheet-iron casing was used, and a space was left open at each side where the burner was applied. One burner blew the flame round the upper half of the wheel while the other sent it round the under part.

Two tires were afterwards heated by the light and put on to wheels. In this case

WELLS LIGHT.

the tires were hung beside the wheel on brackets, heated in the same way as those that were taken off and then slipped on to the wheel centers.

For other heating purposes the Wells light meets requirements almost, if not quite as important, as tire expanding. Bent locomotive frames can, in a few minutes, be heated by the direct application of the flame sufficiently hot to straighten without burning the paint off, or heating adjacent parts, and the time required for such heating is less than the time required to build up an arch on a forge, as is done in most shops at the present time.

For boiler shop work in laying up laps and corners around water legs and openings, in boiler repairs for heating dropped crown sheets or shaping patches on fire-boxes, the Wells light supplies a long-felt want, as it is practically a large blow-pipe and will heat a considerable section of the plate red-hot in from ten to fifteen minutes.

As a combination shop tool for lighting shops, turntables, yards, tire expanding, heating bent frames and boiler making and repairing, it becomes invaluable and no shop can afford to be without it. It is sold by Wm. Halpin, of 46 Washington street, this city.

### Test of Simple and Compound Locomotives on the Cincinnati Southern.

Through the courtesy of Mr. James Meehan, superintendent of motive power of the Cincinnati Southern lines, we have received a copy of a report made to the general manager of a series of tests carried out to find out the relative efficiency of simple engine and a Vauclain compound. The tests were conducted in a very thorough and careful manner, no labor, expense or care having been spared to obtain accurate results.

The simple engine was a 10-wheeler, with cylinders 19 x 24 inches, driving-wheels 62 inches diameter, and a total weight of 111,000 pounds, 80,000 of which was on the drivers. The diameter of the boiler is 56 inches at the smallest ring, and had 1,566 square feet of heating surface and 18.81 square feet of grate area.

The compound has four cylinders 13 and 22 inches diameter by 24 inches, driving-wheels 68 inches diameter, and a total weight of 120,000 pounds, 84,800 being on the drivers. The diameter of the boiler is 58 inches, and has a total heating surface of 1,822 square feet and 18.4 square feet of grate area.

The report is based on 10 runs made with passenger trains, care having been exercised to make the weight of trains and speed uniform for the two engines under test.

Respecting the dimensions of the two engines the report says: "The saving of fuel approximates 35.5 per cent. in favor of the compound. . . You will observe that the compound has 16.3 per cent. more heating surface with the same grate area, or in detail, the compound has 99 of square feet of heating surface per square foot of grate area as against 83.26 square feet for the simple engine. This gives the compound engine's boiler more efficiency, primarily, on account of the above mentioned additional surface for expenditure of heat units, and shows that the total saving of 35.5 per cent. is not to be attributed wholly to the compounding principle. Just what per centage is assignable to this feature is a difficult matter to determine, and I regret our inability on account of the lack of necessary engines to furnish a comparison of engines that are identical in every respect except the cylinders."

The report concludes:

"In order to see if the actual record as kept by the comptroller, from which he compiles the performance sheet, corresponds with the record of the test, I obtained from him the result of the working of the three simple ten-wheel engines, Nos 530, 531 and 532, and compound engine 604, for the months of September and October. You will notice that the percentage in this case is calculated on the performance of the engines in respect to the miles run per ton of coal, consequently, the comparison in amount of per cent. would exceed that as shown on the blue prints if we take into consideration merely the pounds of coal consumed per mile. The result, however, is the same, and I find by working the matter out that the monthly showing, as obtained from the comptroller, is a little less in merit than that shown by the test, which is no doubt due to the changing of the coal used at Oakdale in banking the fire, etc. I think it would be well to make an estimate of the saving that would accrue were all our engines on the road compounds instead of simple engines. I therefore find that the total cost of the fuel for the year 1891 amounts to $219,552.26, and from this sum I wish to take the amount consumed by the regular switching engines, as I do not believe that it would be practicable to use compound engines for this service. The total amount of fuel of switching engines in 1891 was $17,622.94, leaving a balance for road engines of $201,929.32.

"Now, while our records of tests show a saving of 35½ per cent. in pounds of coal used per car mile, I consider that a portion of this is due, as mentioned above, to the larger heating surface, and would therefore consider that if we take 25 per cent. as the saving, it would be sure to be on the safe side, and figuring the amount in money that would have been saved in 1891, you will notice that it equals $50,000 in round numbers.

"In conclusion, I wish to say that, all things considered, I believe the period of experiment has passed and that the compound engine has come to stay, as the record of test made proves it to be far more efficient in the performance of its work, as compared with simple engines of the same class, and the same result is true in respect to the economy in operation."

We are requested to intimate for the benefit of clubrooms having models for educational purposes, that the Leach Sanding Device Co., 55 Oliver Street, Boston will supply working models of their device to any parties interested.

Our Line Engravings are made by the wax process, a plan securing accuracy and distinct lines on original copper plates. They are made by BRADLEY & POATES, 251 William Street, New York City.

## OUR ENGRAVINGS.

Of late we have had a great many inquiries as to who made the fine half-tone plates shown each month in LOCOMOTIVE ENGINEERING. Credit is due the expert anywhere and we are glad to recommend the engravers of our plates to those wanting good work at reasonable prices. All the half-tones and reproductions we use are made by the STAR ENGRAVING & PRINTING Co., 607 & 609 Sansom St., Philadelphia, Pa. SINCLAIR & HILL.

## Strong Brake Beams Needed.

The indications are that within a few years railroad companies will begin equipping their best passenger trains with re-enforced brakes for the purpose of stopping trains more quickly than they can be stopped with brakes that exert uniform pressure upon the wheels. It has been known for about thirty years that the coefficient of friction is not nearly so great at high velocities as it is when the speed is much reduced. Owing to this a much greater braking force can be applied when the train is running sixty miles an hour without danger of sliding the wheels, than can be applied at thirty miles an hour.

High speed trains are becoming so common that the necessity for more powerful braking force is becoming daily more apparent and the re-enforced brake has been designed to meet the demand. The Westinghouse Air Brake Co. and the New York Air Brake Co are both offering to railroad companies a re-enforced brake. Both of the brakes provide the means of putting a material increase of pressure on the brake-shoes at the higher train speeds and are so designed that the extra pressure can be released before it becomes powerful enough to slide the wheels.

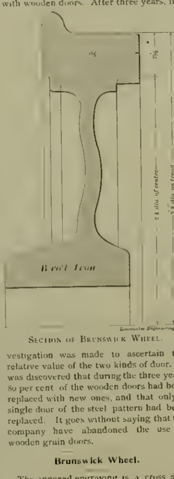
In connection with this important improvement railroad companies ought to realize the necessity for having thoroughly substantial brake rigging. The number of cars still running on fast passenger trains equipped with plain wooden brake-beams is not creditable to the owners. In fact there are few wicked practices due to the ignorance of men in charge of railroad rolling stock that are so dangerous to the traveling public as that of using for powerful air-brakes the same weak connections that were found sufficient to withstand the strains of hand braking. This is not a mere potential danger. We have no doubt whatever that the weak wooden brake-beam has been responsible for more than one of the serious collisions of this winter.

There are so many rods, levers and pins intervening between the brake piston and the brake shoe that the piston must necessarily exhaust a considerable portion of its travel in the taking up of slack. If the brake-beams are not fairly rigid there is imminent danger that the air-brake piston will move up against the head without transmitting but little pressure to the brake-shoes. This is just what is constantly happening. A good steel brake-beam will stand a pull of 5,000 pounds with a deflection of 1/16 inch. Under the same strain the best kind of oak beam will bend 3/8 inch. This amount of deflection is sufficient to make the brakes unreliable, for its yield added to small wear of shoes permits the piston to exhaust its travel without applying the brakes. This happens at a critical moment, the brakes fail to stop the train within a reasonable distance and a crash ensues. The men responsible for keeping in service a form of brake-beam that has long outgrown its usefulness are directly responsible for the destruction of life and property caused by collisions resulting from its weakness.

## The Convenient Wooden Grain Door.

One of the most troublesome parts about a box-car to maintain possession of has been the ordinary wooden grain door. The door, although an absolute necessity in cars loaded with grain, is easily removed, and is a convenient article for many purposes not connected with the keeping of grain inside a car. With cheap attachments it is frequently converted into a shanty table. A bed can be made out of it when the sleepers are not too nice about their resting place it has great capacity for the making of gates and a collection of grain doors has been found built up into a fairly comfortable shed for the protection of cattle. In the hands of a saw and axe carpenter grain doors make very decent hog pens and they make elegant floors for dwellings in the regions where lumber is scarce. When a locomotive happens to be short of fuel the grain doors will frequently do better service than fence rails in helping to the nearest coaling station and we all know that the dry boards make excellent kindling when split up.

With all these attractions to draw grain doors away from their proper destiny, it is not surprising that few of them become old and worn out in the service of grain trapping. There are complaints to be heard on nearly all railroads about the expense of renewing wooden grain doors, but few people realize just how costly this thing is. The Michigan Central Railroad people lately went systematically to find out the life of grain doors and the information obtained is instructive. This was done in connection with claims that it was cheaper to use the Michigan Supply Company's steel grain door, although the latter was more expensive than wood when first applied. The Michigan Central Railroad people had put in steel grain doors into 1,000 new cars about the time that the same number of cars had been equipped with wooden doors. After three years, investigation was made to ascertain the relative value of the two kinds of door. It was discovered that during the three years 80 per cent of the wooden doors had been replaced with new ones, and that only a single door of the steel pattern had been replaced. It goes without saying that the company have abandoned the use of wooden grain doors.



SECTION OF BRUNSWICK WHEEL.

## Brunswick Wheel.

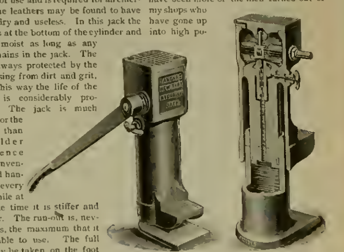
The annexed engraving is a cross section of the Brunswick wheel handled by Page, Newel & Co., Boston. This has a wrought-iron center put in a form to combine strength and elasticity. The steel tire is secured by the Brunswick fastening. The whole thing is seen very clearly in the cut. No bolts are employed about the wheel.

## Use of Dead Blocks.

In a discussion at the New York Railroad Club on "Should dead blocks be applied to freight cars with M. C. B. couplers?" there was considerable diversity of opinion among the car builders present. Mr. George West said that they were putting dead blocks on all cars passing through the shop, and found that they protected the couplers from breakage. But he said they had two lawsuits on their hands; one because the dead blocks caused injury, the other because their absence caused injury. President Blackall reported that they were following a similar practice. They put them on for two reasons—to protect the drawbar rigging and to protect life.

## Tangye's New Type Hydraulic Jack.

It has been objected to the older form that in hot climates, when a jack has been long out of use and is required for an emergency, the leathers may be found to have become dry and useless. In this jack the leather is at the bottom of the cylinder and is kept moist as long as any fluid remains in the jack. The ram is always protected by the outer casing from dirt and grit, and in this way the life of the leather is considerably prolonged. The jack is much shorter for the run-out than the older type, hence more convenient and handy in every way, while at the same time it is stiffer and stronger. The run-out is, nevertheless, the maximum that it is desirable to use. The full load may be taken on the foot as well as on the head, and in each size it can be raised by one man.



The cylinder and base are in one piece, and bored. The ram is fitted at the bottom end with a cup leather, held in place by a guard plate. The pump and plunger are of gun metal. The cistern, outer casing and the foot are cast together, of special hydraulic metal.

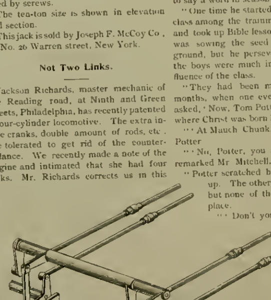
A desirable feature of this jack is the convenience of getting out the pump and valves for repairs, which is accomplished by removing the head-plate, which is fastened by screws.

The ten-ton size is shown in elevation and section.

This jack is sold by Joseph F. McCoy Co., of No. 26 Warren street, New York.

## Not Two Links.

Jackson Richards, master mechanic of the Reading road, at Ninth and Green streets, Philadelphia, has recently patented a four-cylinder locomotive. The extra inside cranks, double amount of rods, etc., are tolerated to get rid of the counter-balance. We recently made a note of the engine and intimated that she had four links. Mr. Richards corrects us in this and sends the sketch of link-gear shown herewith. Only two links are used, but there is an extra rocker of peculiar shape, and the old one has an extra horn on it, and they are not alike—one is left and the other right.



Taking the rig just as it stands, we would take two links in place of it every day in the month.

## On the Lehigh Valley Railroad.

"You all know Alexander Mitchell, superintendent of motive power of the Lehigh Valley," remarked the old member who is scheming to be elected president of the club.

"You all know," he continued, "that Mr. Mitchell invented and built the first consolidated locomotive, but I bet that none of you knew that he learned the machinist trade from me, and from me got the sound start in the business that has made him successful. Why, Miller, there have been more of the men turned out of my shops who have gone up into high positions than those from all the other shops in the country! Why, when I was on the Delaware, Lack—"

"Stop!" exclaimed Gannon, "no more of your Lackawanna chestnuts. What were you going to say about Mr. Mitchell?"

"Nothing much. Just a little anecdote that redounds to Mr. Mitchell's credit. You all know that besides being a good mechanic he is an earnest, pious sort of man, like many of the Scotch-Irish race he came from. Well, he was always trying to say a word in season—not many words.

"One time he started a Sunday evening class among the trainmen at Wilkesbarre and took up Bible lessons with them. He was sowing the seed on rather strong ground, but he persevered, and some of the boys were much improved by the influence of the class.

"They had been meeting for a few months, when one evening Mr. Mitchell asked, 'Now, Tom Potter, can you tell me where Christ was born?'

"'At Mauch Chunk,' readily answered Potter.

"'No, Potter, you are wrong,' mildly remarked Mr. Mitchell. 'Try again.'

"Potter scratched his head and gave it up. The others were appealed to, but none of them could name the place.

"'Don't you remember that in our last week's lesson mention was made that Christ was born in Bethlehem?'

"'Ah, yes,' exclaimed Potter, 'I was sure it was somewhere on the Lehigh Valley railroad.'"

It is reported that a peculiar form of flue tube, called the Mannesmann, is coming into use in Germany. It has the material made in taper form, the tube being thickest at the firebox end. The advantage claimed for this form of tube is that the thin part in the front end conveys the heat of the fire gases more quickly to the water than a thicker tube does. We fancy it would be difficult to estimate the amount of fuel saving due to this arrangement.

## Improvements at the Pittsburgh Locomotive Works.

### Building a New Shop on the Site of an Old One Without Stopping the Work.

[EDITORIAL CORRESPONDENCE.]

Last year the Pittsburgh Locomotive Works found themselves in the uncomfortable, yet not undesirable, condition of having too small a plant for their growing business, and had to face the problem of enlarging their works and at the same time fulfilling their contracts.

Unlike most locomotive works the cramping was not in the boiler shops, the pressure there having been relieved in an easier and better way—which will be mentioned farther on in this article. The need was more room in the machine shop.

To get anywhere near what was wanted a two-story shop 66 ft. longer and 5 wider must be erected on the site of the shop in use—and all the tools must be kept going at the same time.

Superintendent D. A. Wightman knew what he wanted and set about getting it, and to-day the new shop stands where the old one did, and the only shut-down was from Friday night to Monday morning a few weeks ago, and this only to lower the last length of old main shaft—the one carrying the engine belt—as this came directly on a line with the upper floor of the new shop.

The start was made by drawing a plan of the old shop, showing the exact position of every tool in it. Then, over this, the plan of the new shop was laid down. This plan was drawn to a scale of ½ of an inch to the foot, and when we try to reproduce it here very much smallar it does not give a very clear idea of the size of the job on hand, but it does show the general plan carried out. See page 121.

The old shop stood on the street line on one side and faced the yard on the other, so it was determined to bring the outer walls of the new shop inside the walls of the old one just far enough to get in the foundations without disturbing the old walls.

The posts of the other side were 8 feet outside the old wall. This is very plainly shown in the cross-section of the shop, where the M roof of the old shop is shown in dotted lines. Another difficulty was found in the desirability of lowering the floor 10 inches.

Concrete foundations were decided on, and concrete flooring covered with wood. These could be put in easily and quickly, and their use was not liable to stop the work by a building trades strike. A stoppage of the work would have been a calamity in the ripped up condition of things.

Upon the concrete pier foundations a steel frame was erected. This frame carries all the weight of the building, roof, gallery floors, shafting, etc.

On a separate concrete foundation, which is also carried by main piers, there is a brick wall built to inclose the sides, but the brick are very scarce, as their principal use seems to be to support window frames, about 60 per cent. of the sides being glass.

From the plan the location of internal posts can be seen, and from the cross-section it can be noted that there is a wide continuous skylight each side of the ridge of the roof for the entire length of the shop. While on a line with the second story gallery supports there are on each side a line of skylights occupying half the space.

The progress of the work is shown by our reproductions of photographs token when the frame of the new shop was up and the old one in full operation.

One of these shows the posts of the new shop sticking up through the roof of the old one, another shows the opposite side where the posts of the new are entirely outside the old; it also shows the stone foundation for the brick-work. The other view is taken at the end of the shop, showing old and new. The inclined girder at the end supports a stairway from the upper gallery to the drawing office.

These pictures, painted from nature by the sun, tell better than words possibly can just how the work looked as it progressed.

The other picture was taken inside the new shop at the time of my visit, when the work was yet incomplete, but after the last vestige of the old building had been removed.

In the foreground it will be seen that the floor is incomplete. This was the way the work was done: Commencing at the other end of the shop, a strip of concrete floor laid on the natural clay and 6 inches thick was laid; when this set there was a 3-inch oak floor laid on top of it and the tools that were intended to be permanently located there were placed; a section of line-shaft was coupled up and the tools put to work, no tool loosing more than a day's time. This plan was carried out right through the shop.

The line-shafting runs in self-oiling haogers only 6 inches deep, made in the shop, and are the simplest and neatest I ever saw. At the ends of the shop shafting is run at right angles to the main shaft by the use of bevel-gears, and very quiet and orderly gears they are, too.

The trusses for all longitudinal girders in this shop are flat steel bars, 9x1 inches; these interpose the least possible obstruction to belts between the line-shaft and the counter-shafts.

The center of the shop is traversed for 320 feet of its length by a 10-ton three-motor electric-crane of the Morgan Engineering Co.'s latest form, there is enough head-room to carry any part of a locomotive entirely over the bridge between the two galleries, shown in the engraving. There will be ten electric jib-cranes in the shop, eight on one side where the heavy work, such as driving-wheels and cylinders, are handled, only two swing-cranes are in yet.

On either side of the shop are hydraulic elevators of 6,000 pounds capacity, and around them open iron stairways lead to the second floor.

In each gable of the roof there is located a Sturtevant heating apparatus, small engines driving a fan that delivers hot air to the shop.

Throughout the shop and running to the other shops of the plant there is a 24-inch gauge-road, on which small locomotives will haul material.

One end of the upper floor is occupied by the laboratory and testing department, and at the same end of the shop there is a large cellar used for the storage of templates and such other devices as are seldom used. It also contains the wash room for the men.

There is one thing entirely new in this shop; the whole interior is painted white and Mr. Wightman proposes to paint the tools white; the large boring mill in the foreground was the only white tool in the place at the time of my visit, having the honor of being the "first white" born in the place; it had not been started yet. This color will make a great difference in the light in the shop, whether much virginity can be kept in sight, remains to be seen, but I can't see why white paint can't be kept as clean as green

As can be seen on the plan, the stationary engine stood in the machine shop, and for the present it will be left there, but they have made plans for locating a central power house independent of all the

Showing New Structure Outside of Old Shop.

shops, and carry shafts to each shop on trussed bridges.

The boilers used here are of the vertical submerged tubular pattern, about 66 inches in diameter and 25 feet high. They have a cone head at the top, the larger and lower end forming the flue-sheet and the small end the smokestack connection, thus keeping the flues entirely under water. These boilers are in two pieces, the joint being on a line with the crown-sheet; two very heavy cast-iron flanges are bolted together here, the castings having numerous hand-holes for cleaning the crown and lower flues.

When it is found necessary to change flues the whole boiler can be taken apart and cleaned, but the chief advantage to a big plant is that the upper part of the boiler, the shell, can be slung up and kept in its place in the nest, and a whole new firebox end be sent complete from the shop and bolted in.

Speaking about boilers, I think the plan of making boilers at this shop has a great deal to commend it; they come very much nearer to making boilers by machinery than any place I know of.

Back heads, flue sheets and throat sheets are formed at one heat and one operation on a great hydraulic press capable of taking in the largest head on a locomotive and exerting hundreds of tons pressure. This machine also forms steam-chest covers, cylinder-heads, smokebox doors, sand-boxes, dome rings, stack bases, etc.

All holes are laid out and punched or drilled while the sheet is flat, and a huge pair of 10-foot rolls make little work of bending up shell sheets.

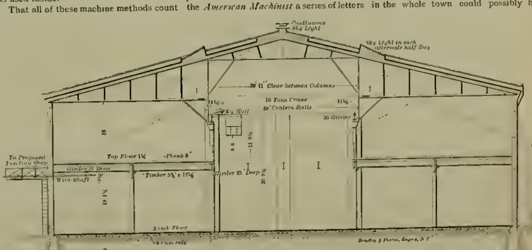
Mr. Wightman's patent stay is used; this is made by hydraulic forged fork-ends tapped to receive the stay-rod, a right and left forming a pair, these are pinned to feet, or double angle iron—also formed by machine—riveted to the shells or heads, and the stay-rod proper is screwed into these fork-ends. This insures the same tension on all stays and is a very great improvement on the old-fashioned, riveted, solid stay where the holes are marked in place and punched, leaving a certain amount for "draw."

Angles, stay-rods and fork-ends being practically uniform for any boiler they can be made and kept in stock, thus saving much time

Showing Old Shop with Frame of New Inside the Old Walls.

They make their domes in two pieces, the flange at the base being very heavy, requiring no stiffening ring and being riveted to the shell of the dome, and the boiler shell is flanged up into it; this makes another riveted seam but puts great strength where most needed and requires shorter rivets than where a forged ring is used inside.

That all of these machine methods count on time is shown by the fact that in these works you can always find completed boilers, they are ahead of their work all the time.



Cross Section of Old and New Shop.

The Pittsburgh Works already possess a model foundry and good boiler shop; they completed a new office building about two years ago, and now the new machine shop takes the pressure off in that direction. A new smith shop is also rapidly nearing completion. The next move will be the new erecting shop and the power house. When these are completed they will have a locomotive building plant second to none in this country for efficiency, and with a capacity of about 300 locomotives per year.

J. A. H.

## Improvident Workmen.

It is some twelve or thirteen years ago since James W. Lee, under the *nom de plume* of "Chordal," began writing for the *American Machinist* a series of letters on mechanical subjects, which formed the most interesting reading ever presented on technical subjects. In one of the early letters we find the following notes of a conversation which, we are sorry to say, applies to not a few shopmen and engine-men of this day and generation:
