Flambard's Church is extremely bold and simple in its parts, and well studied in its proportions. The clearstory and vaulting are of a later date; but Mr. Ferrey gives reasons for thinking the latter to have been from the first intended. The details are good and well considered; the capitals are of the cushioned form, and of that type noticed in the Tower of London and elsewhere. Some appear to have been subsequently carved with exquisite taste,

in a manner which reminds one of Greek foliage. The windows of the triforium gallery, with the oriel tabling over them, still remain, and are of excellent, though simple, design; while the beautifully arcaded stair-turret to the northern transept is one of the choicest relics of the Norman style.

The buildings I have thus imperfectly described I have selected as having been all commenced within the eleventh century. I trust I may be able during the next session to follow on the style through its subsequent and more ornate stages, and on again through the interesting period of its transition into the Pointed style; and, while doing this, I hope to illustrate my remarks by means of many of the smaller creations of the style, and by some which are other than ecclesiastical.

For the present,—after travelling over an eventful period of nearly seven centuries, and tracing out the rise of British architecture through many phases,—I must bring my course for this session to a close, apologising if I have, in the warmth of patriotism, been induced to lead you out of the beaten and accredited track of art; though at the same time convinced that the architecture we have been considering will be found on close examination to contain germs and principles which have been, and may again be made to germinate into styles of art of the highest and noblest character.

SCHOOLS OF ART.

THE BIRMINGHAM SCHOOL AND LOCAL SOCIETY OF ARTS.

THE annual meeting of the Birmingham Society of Arts and School of Design has been held in the Rooms of the Society of Artists, in New-street; the Right Hon. Lord Leigh in the chair.

Mr. C. R. Cope read the report of the committee, in which it was stated that the number of students receiving instruction had been 1,010, showing an increase of 3 since last year. The fees received amounted to 750l. 12s. 6d., showing a decrease of 25l. 17s. Of the 755 male students, 257 were school-boys (including 147 from the Grammar School). Recognising the fact that the present system of instruction required improvement, the committee had appointed a sub-committee to investigate the subject, to confer with manufacturers, and to obtain their views of what was required. They hoped that a scheme adequate to the requirements of the town would be the result. As the present accommodation was quite inefficient, and the Midland Institute classes were also cramped for room, it was most desirable that the whole of the rooms at the Institute should be given up to the Institute classes, and that large and commodious premises should be obtained for the School of Design.

Mr. Laundry read the statement of accounts, which showed that the income of the society for the year was 1,900l., and at the close there was a deficiency of 3l. 11s. 6d.

Mr. H. Cole, C.P., of the South Kensington Museum, who was present, addressed the meeting. He said he would venture to give them a piece of advice, and that was that the sooner they got better premises the better. But as to the Birmingham School of Design being in a bad way, it was a fact that on the whole they raised more money than any School of Design in the kingdom. They were at the top of the tree in respect to funds. Last year they took the greatest amount of public money by their results. In 1866 they had taken 148l., in 1867 that amount was increased to 297l. Having doubled their revenue was not a bad sign. And, again, he found that the students were more numerous than those of other schools. In Birmingham they had 2,537 children learning drawing; in fact, a larger number than in any of the other six great towns. And they had taken 146l. from the State, while the highest sum earned in any other town was 73l. He entirely agreed that South Kensington was for their benefit, and that they had the most perfect right to all the advantages from it that they possibly could get. They had been told that there was a horrid woman lived there, called Dalilah, and that no matter what Parliamentary Samson entered there, his locks were shaved by this Dalilah; and the mission particularly assigned to one gentleman was to get rid of this woman. He supposed the woman did exist; but he might remind them, in reference to South

Kensington, that if they did not have out of it what they wished to have, and what they desired to have, it was entirely their own affair. South Kensington had been perfectly willing—had been hawking out, indeed, all the time, and saying, "Do, in Heaven's name, come to Kensington and borrow what you want." How many things had they borrowed.

The exhibition of students' works has also taken place. The works exhibited were numerous in all the divisions and subdivisions prescribed by the Department of Practical Art. They occupied the walls of the Rotunda, and one of the small rooms was devoted to outline, mechanical, and architectural subjects. The drawings, which were very numerous, were chiefly from sculptured ornament, and executed in monochrome (sepia).

THE FOOD SUPPLY QUESTION.

An elaborate and valuable paper, "On the supply of animal food to Britain, and the means proposed for increasing it," has been read to the Society of Arts, by Mr. Wentworth Lascelles Scott, F.A.S.L., &c., whom many of our readers will remember as a correspondent of the *Builder*, chiefly on chemical subjects. The paper was illustrated by important statistical information, in a tabular form, collected, it would appear, with a view to the publication of "a somewhat ponderous volume, yet in embryo, on the 'Food Resources of the British Empire,'" and there was before the meeting a variety of samples of food prepared in different ways, according to patented and other processes, and amongst others a specimen of hainplitized beef, sent by Mr. Ede, of her Majesty's victualling yard, Deptford. The process by which this meat was preserved appears to be regarded by Mr. Scott as one of the most promising of all those various new processes of which one is every now and then hearing. On this subject, he said:—

"Of the chemical antiseptics, there is at the present time not one which appears to possess the necessary qualifications for preserving meat cheaply, easily, effectively, and without either injuring the nutritive qualities or imparting an unpleasant flavour; I allude to that great and wise process of Messrs. Medlock & Bailey (of which numerous illustrations are now before you) is founded—the bisulphite of calcium, or, as it is commonly rendered, the bisulphite of lime.

It is remarkable that sulphurous acid has frequently been employed alone for the preservation of meat, but has failed in all instances from its volatile nature, causing it to be dissipated too soon to be any real protection. The sulphites of sodium and potassium (combinations of sulphurous acid with soda and potash), in solution, have likewise been patented for the like purpose, but their unpleasant flavour, their action upon the meat itself, and the injury to the nutritive sulphates (or combinations of sulphuric acid with the bases) formed by their oxidation, have precluded their use in quantities calculated to induce the 'food of the people' in any great degree; moreover, their antiseptic action is not so certain as that of the preparation I would specially introduce to your notice.

The neutral sulphite of lime is only slightly soluble in water, and its antiseptic properties are by no means so marked as those of the bisulphite, which contains double the amount of sulphurous acid, is perfectly soluble, and, when oxidized, is merely converted into sulphate of lime—a substance perfectly harmless and inert.

In this preparation, I believe we have a means of converting to our use the enormous meat stores of Australia and South America, and I look forward with confidence to seeing beef and mutton imported for sale at 2s. to 3s. per pound, of a quality equal to any we can now procure.

I have prepared a number of specimens (now before you) which could be done in this department. Mr. Acres tells me that immense quantities of fish are frequently captured in the Bay of Youghal, but that, there being no adequate demand at the moment of the large surplus of the season—from 50 to 100 tons sometimes—has to be quickly destroyed, as is often the case elsewhere.

I sincerely hope that the bisulphite of lime may prevent some wholesale destruction of nutritive animal food, which, to my thinking, seems a reproach to our civilization, a stain upon our science, when we know that so many will spend hours in turning over dust-heaps—I have seen the poor wretches at the melting tanks for the purpose of extracting any tails or bones of fish to which some fleshy portions might adhere. These, an old woman in Whitechapel told me some years ago, "makes an old crust more filling, and her scanty meal certainly must have had a favour about it."

The obtaining of an indefinite supply of fish from the inexhaustible Irish coasts, we have often urged, and any process that would promote this immensely important object well merits the utmost attention. Even on our own coasts the waste of such food by hundreds of cart-loads used as manure while thousands and tens of thousands of the population of Britain and Ireland are either starving, or struggling on

the brink of starvation, from the dearthness of food, is truly awful. It really justifies what Continental say about the stupidity of the British islanders. On this subject Mr. Scott says,—

"I was speaking on the subject of deer food to a friend, not long ago, when he remarked, 'Why don't the people eat fish, if meat is so dear and so scarce? I have seen more fish thrown away, or allowed to decay for manure, within a few days, than would be required to keep Southampton in animal food for a month.' And this observation brings us to another subdivision of our subject,—the supply of fish. Here, again, the same melancholy story holds good,—The supply is but a fraction of the demand,—while, in addition we are forced to the humiliating confession that many thousands of tons of fish are being thrown away and absolutely wasted after they have been caught, in a country where 23,000 people die annually from insufficiency of food. Moreover, it is not only that fish, as a rule, is dear now, as compared with former times (when it was by no means uncommon for articles of industry to contain a clause stipulating that the apprentice was not to have salmon for dinner more than two or three times a week!), but we have the anomaly constantly occurring of a starving population in one part of the country, simultaneously with the absolute destruction of many tons of nutritious food in another.

Perhaps it is only some such process of preserving fish and other food as that, brought under special notice by Mr. Scott that is wanted to turn an abundant supply of capital to fishing and other food-providing purposes, and to bring about a wonderful change for the better in our food supplies.

MEMORIAL WORKMEN'S CLUB AND INSTITUTE, MADELEY, SALOP.

A MEETING of subscribers to the above memorial took place on February 3rd, in the Infants' School-room, Madeley, for the purpose of selecting from the collection of designs and plans sent in for competition the one most suitable for the purpose. It may be remembered that in the particulars issued to architects it was specified that the building should be of the red brick of the neighbourhood, with white stone dressings, and that it should contain the following accommodation, namely, workmen's common hall or club-room; youths' common hall or club-room; kitchen to supply refreshments; a smoking-room, a reading-room, committee and class rooms; a residence for hall-keeper; a large hall for concerts, lectures, &c.; retiring-rooms, lavatories, &c. These requirements appear to have been well kept in view by competitive architects, who, whilst adhering to them, have shown considerable care in the arrangement of the rooms and much artistic merit in the elevations which accompany the plans. The subscribers selected three designs from the collection of upwards of fifty sent in, which they agreed to submit to the decision of Mr. G. Maw, with a request that he would in the course of a fortnight make a selection and submit it to them at the next meeting.

The subscribers met on Wednesday, the 19th, to receive the report of Mr. Maw relative to the designs submitted to him. Mr. Maw's decision was in favour of the design bearing the motto "Well Considered," by Mr. John Johnson, architect, of Moorgate-street, London. The cost of the building will be about 1,400l.

MEDALS AND PREMIUMS OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At a special meeting of the members of this Institute held on Monday last, the recommendation of the council that the Royal Gold Medal of the current year, should, with her Majesty's gracious sanction, be awarded to Austen Henry Layard, D.C.L., M.P., was unanimously adopted.

The following medals and prizes were awarded:—

The Soane Medallion, to which, under certain conditions, the sum of 50l. is added by the Institute (subject of competition, "Design for a Town-hall"), to Mr. George Viall. A second prize of 20l. was given by Mr. W. Tite, M.P., president, to Mr. Henry L. Florence, whose drawings were considered next in order of excellence, and a Medal of Merit to Mr. Herbert M. Marshall.

The late Sir Francis E. Scott's prize of 10l. 10s. (subject of competition, "An Establishment for Baths and Wash-houses designed in accordance with modern requirements, and in the style of the thirteenth or fourteenth century") to Mr. Ernest Lee.

The Institute Silver Medal, with 5l. 5s. (subject of competition—"The restoration of the choir of Old St. Paul's Cathedral," founded on

the plates, illustrating Dugdale's work), first prize to Mr. Edmund B. Ferrey. Medal of merit to Mr. N. Renault Mangin.

In this competition Mr. E. B. Ferrey, complying with the conditions prescribed in last year's list of prizes, sent in drawings illustrating the restoration of the entire cathedral.

The Institute Silver Medal, with 5l. 5s. (subject of competition—"Measured drawings of any building erected before the year 1700," and hitherto unpublished), to Mr. William Henman. Medal of merit to Mr. Charles H. Heathcote.

In this competition the drawing of Mr. Morton M. Glover, were "honourably mentioned."

The Institute Medal for the best essay "On the origin and progress of window tracery," or other suitable subject, was awarded to Mr. W. Scott Champion.

The designs, drawings, &c., are now on view, from ten to five daily, at the Institute, where they may be inspected by any one taking a card of introduction from a member.

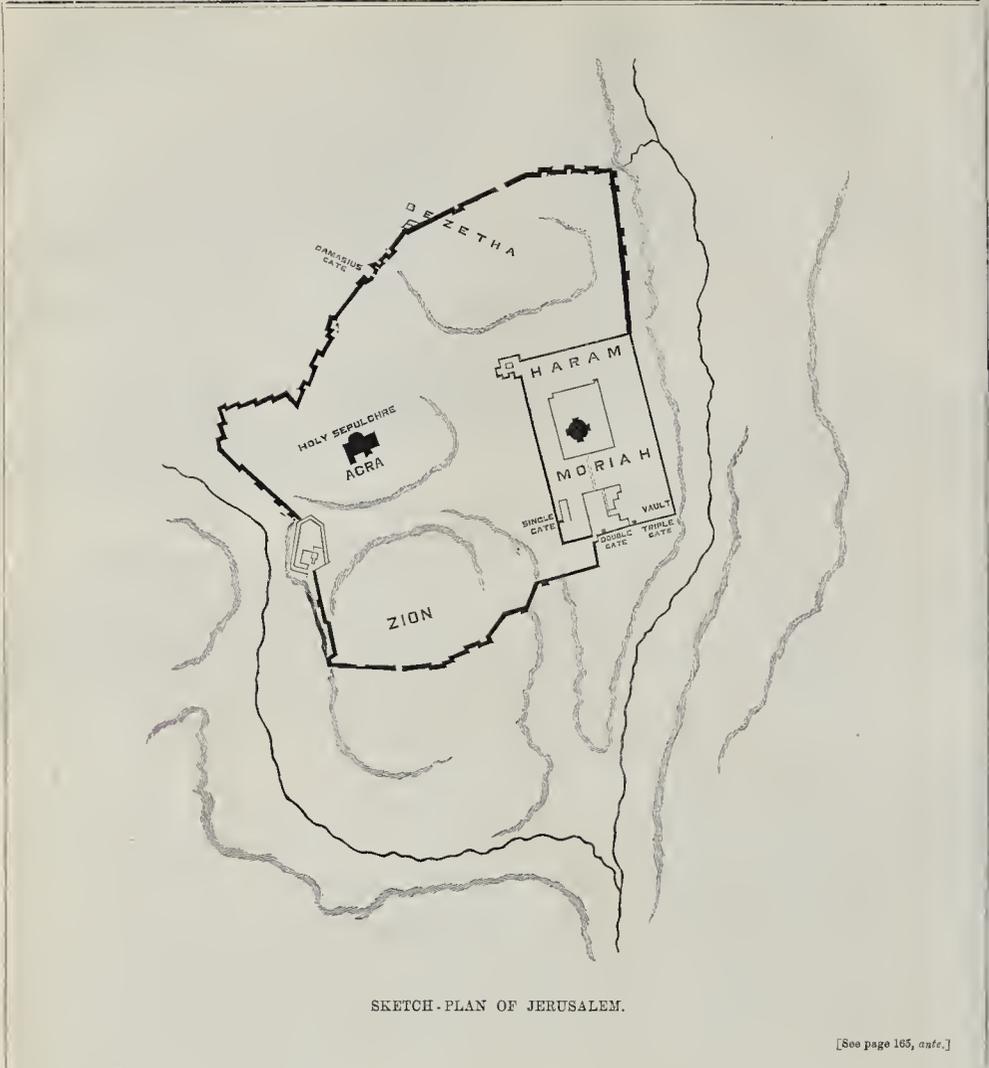

The following is a summary of the number of essays, designs, and drawings submitted in competition for the medals and prizes offered:—For the Institute medal (for essays), six essays; Soane medallion, five designs; Sir F. Scott's prize, three designs; Institute medal, with five guineas (restoration of the choir of Old St. Paul's), two sets of drawings; Institute medal, with five guineas (measured drawings), three sets of drawings; and Student's prize in books, one design.

THE LABOURERS' DWELLINGS FOR THE LIVERPOOL CORPORATION.

At the last meeting of the Health Committee, the tender of Mr. Hugh Yates, for the erection of a block of labourers' dwellings on the land purchased by the corporation, between Sylvester and Ashfield streets, at a cost of 12,321l., was accepted, being the lowest sent in. Mr. Newlands, the borough engineer, said the amount was below both his own estimate and that of the designer of the plans.

VITAL STATISTICS OF LONDON FOR 1867.

A SUMMARY of the weekly returns for the year 1867 has been issued in a printed form. Out of a population of 3,082,372 (containing 207,134 more females than males) the number of deaths was 70,588, of whom 36,276 were males, and only 34,312 females. The number of births was 112,264, of whom 57,502 were males and 54,862 females. If the rising and falling rate of mortality be taken as the criterion of health, the year 1867 was the healthiest that London has enjoyed since 1860. Through the four years that followed 1860 the annual mortality uninterruptedly rose, and reached 2,653 per cent. in 1864. It then began to decline, and probably the decrease would have continued in 1866 if cholera had not attacked London in that year. In 1867 it was 2,298 against an average of 2,436. In Birmingham the death-rate of 1867 was 2,427, in Sheffield 2,467, in Liverpool 2,957, in Newcastle-on-Tyne 3,079, in Manchester 3,140. In Dublin it was 2,706, in Edinburgh nearly the same, in Glasgow 2,854. Zymotic diseases, in which class the chief heads are typhus, small-pox, measles, scarlatina, whooping-cough, and diarrhoea, were fatal in 15,027 cases, which is more than a fifth part of the whole. This aggregate result was, however, considerably less than it had been in any previous year since 1860: and the only disease in this class which displayed increased activity was small-pox, the deaths from which were 1,332. Professor Frankland, in an appended report on Metropolitan water, says—"The New River Company stands alone in the perfection of its filtering apparatus. The seven companies who occasionally or habitually send out turbid water, subject the inhabitants of more than 300,000 houses to the unnecessary expense of private filtration. The distribution of water in the metropolis still continues, with but slight exceptions, upon the intermittent system, which has been abolished in almost every other town of importance in the United Kingdom. In addition to the well-known evils attending the storage of water in butts and cisterns under this system, there is the danger of the leakage of sewage into the pipes whilst the pressure is withdrawn. An instructive instance of this occurred in the West Middlesex Company's district in June last."

SKETCH-PLAN OF JERUSALEM.

[See page 165, ante.]

THE DUDLEY FOUNTAIN.

The people of Dudley (Worcestershire) are indebted to the Earl of Dudley for the fountain represented by our engraving. It is the work of Mr. James Forsyth, sculptor, who was selected in a limited competition, and it has cost about 3,000l. The fountain stands in the market-place, and consists of a quadrilateral, pierced by arches in one direction, and in the other supported by semicircular projections, each bearing a dolphin on the outside. Immediately above these latter are two large fronts of sea-horses, the whole surmounted by a pyramidal roof, culminating in an allegorical group, representing Industry in General and Industry in Particular. The former figure is a girl, with a spinning apparatus, and the latter is an engineer. The vaulted part is perforated by two windows, glazed with coloured glass, thus providing light to the central jet which starts from a series of three marble tazzas, one above another. In the two sides corresponding to the exterior semicircular projections are niches, occupied by figures representing an "agriculturist" and a "miner," in allusion to the characteristics of the county. The corners of the quadrilateral, forming piers, are ornamented with festoons of fruits; while the

keystones are decorated, one with the head of a river-god and the other with that of a water-nymph. The spandrels of the arches are enriched by genii, hearing scrolls, with mottoes. The legend, sub-divided into four parts, is one of the songs of the Children of Israel, under a providential supply of water as they were passing to the Promised Land. In our version (Numbers. xxi. 17) the whole song runs thus:—

"Spring up, O well;
Sing ye unto it.
The princes have digged the well,
The nobles of the people have digged it."

The words are applied in the first instance to the physical and material emblem; whilst the special historical circumstances of the living interest of the song at Beër find their correspondence in the work we are describing. The maidens of Israel, as they drew the water, claimed gratefully the bounties of God's providence, "Spring up, O well," and encouraged each other in glad recognitions of His goodness as manifested therein, "Sing ye unto it;" whilst the strongest feeling of sympathy and co-operation between the rulers and the people is conveyed by the way in which the latter made the labour of the former the burden of their song:

"The princes have digged the well: the nobles of the people have digged it." On the front of the fountain is the following inscription:—"Hunc Fontem in Usum Populi, D.D., Comes de Dudley, A.D. MDCCCLXVII." The base of the fountain is of red and gray granite, forming an agreeable contrast. There are two streams of water supplied to ladles from lions' heads; two large basins, for the use of cattle; and four smaller ones, near the ground, for the accommodation of dogs and other small animals. The cattle-troughs are supplied from the mouths of the dolphins previously mentioned. The height of the fountain is 28 ft.

A circular pavement in red and gray granite and black limestone has been recently added. This is arranged in geometrical patterns, in concentric circles. The outer circle is of gray Aberdeen granite, and the inner one red. These are connected by gray granite pitchers, which radiate in patterns like the points of a star, the ground being the black local limestones, which forms an appropriate ground-work to the whole erection.

Mr. Forsyth acknowledges his obligations to Mr. R. Monti, and to his own foreman, Mr. Dyke, for assistance in amplifying the design and carrying it into execution.

THE DUDLEY FOUNTAIN.—MR. JAMES FORSYTH, SCULPTOR.

LIGHT AND COLOUR.

The three phases of the theory of light and colour,—the physical, the physiological, and the aesthetic,—are too frequently separated as distinct specialities, and studied independently of each other. The aesthetic phase is of the three, perhaps, the most studied, cut off and isolated from its supports. This separation, either partial or complete, is, I venture to think, inimical to a comprehensive view of the entire theory of light and colour. I have therefore endeavoured to give symmetry to the materials I have gathered, in order that they may be grasped as a whole.

Though in some degree a student of science, I do not believe science has the power to be the all in all, to supplant feeling in art. The subtlety of taste, as of life, appears to elude close analysis. Its true importance to art is as the compass to the mariner when the heavens are clouded. But we might say the same of science in reference to many other professions.

A river has been accepted as an emblem of life; its continuity, smooth-flowingness, rolling roughness, and loud murmuring fall have analogues in human nature; but mention hydrodynamics, and unreasoning fancy receives a shock: still the thinker knows that there is not a ripple, eddy, nor wave, but moves in conformity with a few simple principles, and although science may be unable to follow and formulate all the complications of action and reaction, the currents and eddies of a cloud of dust, or a stream of water, it can point the way, and a correct compass is invaluable to the steadfast helmsman. This, I take it, is what true theory is to every earnest, practical man, he be artist or craftsman.

One very noticeable feature in the advance of science is, that it traces parallels and analogies between phenomena long believed to be divided and distinct, is the growing perception of their dependence on some common phenomenon of a more general and elementary nature than those which form the subject of either separately; thus the analogy subsisting between sound and light has been traced into a closeness of agreement, which can hardly leave any reasonable doubt of their ultimate coincidence in one common phenomenon, the vibratory motion of an elastic medium.

[The writer here gives a short history of the two great theories,—the Corpuscular and Undulatory,—which so long divided the scientific world and traced the growing conviction in the correspondence of the physical modes of light and sound; but this we need not print.]

More recently a very sweeping generalization has been suggested by Professor Grove, in the hypothesis known as the Correlation of the Physical Forces. It would ascribe all phenomena to a monophysical origin,—that is to say, it supposes light, heat, sound, electricity, &c., to be merely modifications of an active *substant*. That everything *objectively* varies only in configuration and in mode and degree of motion, but produces *phenomenally* or *subjectively* all that infinite variety in things which is commonly, but erroneously, believed to exist internally, and independently of sense; that we are sentient organisms amidst the great ocean of active matter, which now surging and vibrating against the optic nerve, produces light and colour; against the auditory nerve, and it breaks in sound or musical notes; against the olfactory and gustatory nerves, and its spray is scent and taste; or, heating against the broader quays of the nerves of common sensation, excites the sense of touch. That, independently of sentient beings, there is nothing but a colourless, silent, fluctuating universe. It is somewhat difficult to conceive this condition of material nature without some previous habit of abstract reasoning; nevertheless, it is one which both the Newtonian and Huyghenian theories support; for, if you recollect, Newton ascribes the production of different colours to the different velocities of the atoms emanating from the sun or other luminous source. The colours, mark, are not inherent in the atoms; for, if they were, colour would be independent of differences of velocity and refraction. In the undulatory theory, too, which makes the propagation of light analogous to that of sound, and which is the theory now generally accepted, light and colour are supposed to be produced in the eye by undulations of different velocities and magnitudes, just as sound is produced in the ear by the different velocities of the vibrations communicated by the

air. Muller says,—“That which, through the medium of our senses, is actually perceived by the sensorium, is indeed merely a property or change of condition of our nerves; but the imagination and reason are ready to interpret the modifications in the state of the nerves, produced by external influences as properties of the external bodies themselves. This mode of regarding sensations has become so habitual in the case of the senses, which are more rarely affected by internal causes, that it is only on reflection that we perceive it to be erroneous.” This is a most important consideration for all those who enter upon scientific or aesthetic studies; and no safe progress can be made in either till this position is thoroughly comprehended. But to return to what I was more immediately endeavouring to point out, viz., that in all three of the theories, recently glanced at, the supposed physical cause of light and colour is simply moving matter. This is the first great deduction we have to make from the purely physical inquiries concerning the nature of light and colour.

We now pass on to consider the facts on the physiological side of the theory of light. And if the physical hypothesis be correct, we might surmise, *à priori*, that the same simple physical cause which produces all those diverse effects on the retina from without might also cause similar effects from within; and such we find to be the case,—one of the first principles of physiology being that *external agencies can give rise to no kind of sensation which cannot also be produced by internal causes, exciting changes in the condition of our nerves*. The vibrations of a fluid existing in all space, when of a certain rapidity, produce in the retina the sensation of a certain colour; when of a different degree of rapidity, that of another colour, these colours or sensations being modes of reaction of the retina. The simultaneous impressions of undulations of different rapidity upon the same points of the retina excites the sensation of white light. These same sensations of colours and light may, however, be produced as we have just stated, without those external undulations.

One uniform internal cause acting on all the nerves of the senses in the same manner, is the accumulation of blood in the capillary vessels of the nerve, as in congestion and inflammation. This uniform cause excites in the retina, while the eyes are closed, the sensation of light and luminous flashes; in the auditory nerve humming and ringing sounds. The mechanical influence of a blow, concussion, or pressure also excites in the eye the sensation of light and colours. It is well known that by exerting pressure upon the eye when the lids are closed, we can give rise to the appearance of a luminous circle; by more gentle pressure the appearance of colours may be produced, and one colour may be made to change to another. A mechanical influence excites also peculiar sensations of the auditory nerve. It has become a common saying, “To give a person what will make his ears ring,” or “what will make his eyes flash fire,” or “what will make him feel,” so that the same cause, a blow, produces in the nerves of hearing, sight, and feeling the different sensations proper to these senses. Here, then, is another series of facts pointing to Force as the cause of light; and not only this, but to the correlation of light and sound, by it being possible to excite the senses of sight and bearing by the same means. Voltaic and frictional electricity, and chemical agents, such as narcotics, digitalis, &c., produce the different sensations proper to the two senses. From these phenomena we naturally turn to the consideration of the “ocular spectra,” consequent on impressions on the retina. The duration of the sensations of the retina is much longer than that of the impressions which produce them. According to Plateau, the sensation persists 0.32 to 0.35 of a second after the impression has ceased; and the duration of the “after sensation” or “spectrum” is greater in a direct ratio with the duration of the impression which caused it. Hence the image of a bright object, as of the panes of the window through which the light is shining, may be perceived in the retina for a considerable period, if we have previously kept our eyes fixed on the object for some time. The duration of these images in the closed eyes may also be very much prolonged by passing the hand up and down before them, so as to permit the light to fall upon them only at intervals. The after duration of sensations consequent on impressions of the retina explains the appearance of a circle of light produced by moving a luminous body in a

circle before the eyes, as well as that of the confusion of the images of the spokes of a rapidly revolving wheel, or of the prismatic colours painted upon a spinning top.

The ocular spectra may be divided into three classes. They are either colourless spectra left by colourless images, or coloured spectra after colourless images, or coloured spectra after coloured images.

Colourless Spectra left by colourless Images of real Objects.—The spectra left by the images of white or luminous objects are ordinarily white or luminous; those left by dark objects are dark. Thus, the spectrum of a luminous body rapidly moved before the eyes is also luminous. If the eye, after being subjected to a vivid impression, be closed and turned away from the light, or, what is better, quite covered, white or luminous spectra of the objects which were white or luminous are seen, and dark or black spectra of those which were dark or black. Thus, if while sitting in our room we look for some time at the light window with its dark framework, and then suddenly close the eyes, turn them from the window and cover them with the hand, so that no light, not even that which would pass through the eyelids, can reach the eye, bright spectra of the panes of the window, and a dark spectrum of the framework, are seen.

The relation of the light and dark parts in the images may, however, under certain circumstances, be reversed in the spectrum; what was bright may be dark, what was dark may appear light. This occurs whenever the eye, which is the seat of the spectrum of a luminous object is not closed, but fixed on another bright or white surface, as a white wall or a sheet of white paper. Hence the spectrum of the sun, which, while light is excluded from the eye, is luminous, appears black or grey when the eye is directed upon a white surface. In the same way the spectra of the window-panes appear dark, those of the dark framework light, if we look with closed eyes towards the light of the window, so that the light passing through the eyelids gently stimulates the retina. These phenomena are easily explained. The part of the retina which has received the luminous image remains for a certain period afterwards in an excited state, while that which has received a dark image is in an unexcited, and therefore much more excitable condition. If the eye in this condition be directed towards a white surface, the luminous rays from this surface produce upon the excited part of the retina a much more feeble impression than upon the other parts which are as yet unexcited, and therefore more susceptible of their action. Hence the parts of the retina upon which the dark portions of the previous image had fallen receive a much more intense impression from the white surface than those upon which the luminous portions of the image were directed; and hence the inversion of the light and dark parts of the image in the spectrum thus seen.

Similar phenomena are presented by the whole field of vision when a sudden change is made from light to darkness, and *vice versa*. On coming from darkness into a bright light, every object appears excessively bright, on account of the great susceptibility of the retina after its previous rest; and, on passing from light into moderate darkness, we at first see nothing, until the retina, exhausted by previous excitement, shall have recovered sufficient excitability to be acted on by the slight degree of light to which it is now submitted. A light object always appears brighter when viewed after a dark object, or even viewed side by side with it. Similar phenomena are observed with relation to the other senses. Cold is felt most intensely when it follows the impressions of heat or warmth; and, after exposure to a great heat, a slightly different temperature, which under ordinary circumstances would feel warm, will produce the sensation of cold. The distinctions between light and darkness, heat and cold, are therefore merely relative.

Ocular spectra seem to change their place with relation to our body with every movement of the eyes, and, for an evident reason, are still seen, in whatever direction we may turn the retina. If we look for a long time at a black square upon a white ground, and then divert our eyes slightly, so as not entirely to leave the square, but rather to look more directly at its border, a portion of the spectrum which it has produced, will appear free upon the white ground, as a bright margin to one part of the dark image; while, to a certain extent, the true image and the spectrum will lie upon the same part of the retina, corre-

ing each other; another portion of the true image of the object being left free. In such a case the free portion of the ocular spectrum appears very bright; the free portion of the true image very dark, while the parts of the image and the spectrum which are coincident appear of a dark grey colour, as if the two conditions of black and light were there balancing each other. The explanation of the phenomenon is this,—the sensation of white in the part of the retina which was before the seat of the image of the black object is more intense, because that part of the retina was previously unexcited; hence the bright margin. The part of the image where the true image and spectrum are coincident remains unchanged; while the portion of the true image which is left free appears blacker than before, because it now falls upon a part of the retina which had previously received rays from the white ground, and has consequently lost part of its excitability. If the impression of a luminous object on the retina be very intense, as when produced by the light of the sun's image, the spectrum consequent on it is not merely light when seen upon a dark ground, or dark when seen upon a white surface, but assumes different colours in succession, which are expressions of the states which the retina passes through in its transition from the condition of dazzling to its natural state. The dark spectrum of the sun, when the eye is fixed upon a white surface, assumes different colours, in passing from the dark to the light, in the following order:—Black, blue, green, yellow, white. The appearance of these colours commences at the borders of the spectrum. When the spectrum has become white, it is no longer distinguishable from the white surface on which it is viewed; that is, the white surface now produces the same sensation in this part of the retina as in all the other parts which had not been submitted to the dazzling action of the sun. If the eye, after viewing the sun, be exposed to perfect darkness, that is, if light be entirely excluded from it, the colours of the spectrum will succeed each other in the inverse order, namely, from white through the lightest, and then the darker colours, to black; thus white, yellow, orange, red, violet, blue, and black. When the spectrum has become black, it can no longer be distinguished from the surrounding darkness; the part of the retina which was its seat having regained the same unexcited condition as the other parts which were not acted upon by the image of the sun.

These phenomena, which cannot be explained by external conditions acting on the eye, are another proof that colours have their immediate cause in the condition of the retina itself.

The ocular spectra, which remain after the impression of coloured objects upon the retina, are always coloured; and their colour is not that of the object, or of the image produced directly by the object, but the opposite or complementary colour. The spectrum of a red object is, therefore, green; that of a green object, red, &c. If we fix our eye for any length of time upon a bright red spot upon a white ground, and then suddenly turn it from the red spot and let it rest upon the white surface, we see an ocular spectrum of the red spot of the same size and form, but of a green colour. If, on the contrary, we turn our eye only slightly to the side, so as to fix it on the border of the red spot, the spectrum is seen partly covering the object. A portion of the true image of the object appears free, and a portion also of the spectrum distinct from the true image; but this portion of the spectrum is green. At the part where the true image of the object still falls upon the same part of the retina,—that is the seat of the affection producing the phenomenon of the spectrum,—the colour of the object is seen, but it is faint and grey, whilst at that part of the true image of the object which now lies upon a part of the retina previously directed to the white surface, and which is therefore more susceptible to the normal sensation of the red. The physiological explanation of the phenomenon is the following. The perception of any one of the three simple colours consists merely in the retina being in one of those conditions to which it has a tendency when in a state of excitement. If this condition be artificially excited in an intense degree, the retina acquires a tendency to an opposite state, or that which is complementary, and which is consequently perceived as the ocular spectrum.

Physiological Colours produced by Contrast.—A very small, dull, grey strip of paper, lying upon an extensive surface of any bright colour, does not appear grey, but has a faint tint of the

colour which is the contrast of that of the surrounding surface. Thus, for example, a strip of grey upon a green field often appears to have a tint of red, and when upon a red surface a greenish tint, and so on. For the production of this phenomenon it is necessary that the colour of the extended surface should be very bright, containing abundant rays of white light. Every coloured paper is not adapted for it. It is shown most distinctly by holding a coloured glass covered with thin paper before a lamp, and covering any spot upon the glass and paper, with a strip of grey tint. The strip of grey is then readily seen to have the colour the contrast of that of the glass. The new colour is always that which, combined with the colour of the surrounding surface, would yield the sum of the three simple prismatic colours, red, yellow, and blue. The colour excited by the impression of yellow is, for example, violet, which contains blue and red. The colour excited thus, as a contrast to the exciting colour, being wholly independent of any rays of the corresponding colour acting from without upon the retina, must arise as an opposite or antagonistic condition of that membrane; and the opposite conditions of which the retina thus becomes the subject, would seem to balance each other by their reciprocal reaction. We have also in these phenomena a fresh proof that colours, physiologically considered, are merely certain states of the retina, which are capable of reciprocally exciting each other in different parts of that membrane. The coloured shadows sometimes observed are phenomena belonging to the same category. But all coloured shadows are not of this nature: some are owing solely to the shadow being illuminated by a coloured light. For if a coloured light fall upon a shadow produced by colourless light, or by light of a different colour, the shadow of course appears coloured. In the faint light of evening, the shadows of bodies appear by candle-light blue or yellow, according as the bluish light of the sky or the yellow light of the candle falls upon them. The two kinds of light may produce two shadows of different colours from one body. Of two shadows thus produced by a small rod upon a sheet of white paper, the one which cannot receive any of the bluish light of the sky, but receives light from the candle, will appear yellow; while the other shadow which receives no light from the candle, but is illuminated by the bluish light of the sky, appears blue. All other parts of the paper present no predominant colour, since they receive rays from both sources of light. The purely physical nature of these coloured shadows is obvious.

But there are coloured shadows, as we have observed, dependent on a physiological cause. If light transmitted through coloured glass, or reflected from a coloured body, fall upon a white surface, and a shadow be produced on this surface, which now appears coloured, by means of a narrow body raised upon it, this shadow, when illuminated by the white light of day, will appear of the complementary colour to the ground. The experiment succeeds also if illuminated by the light of a candle. The illumination of the shadow is a necessary condition for the production of the phenomenon. For if coloured light be thrown into a cavity otherwise perfectly dark, a shadow there produced does not appear coloured. The coloured shadows are usually ascribed to the physiological influence of contrast; the complementary colour presented by the shadows being regarded as the effect of internal causes acting upon that part of the retina, and not of the impression of coloured rays from without. A strong corroboration of this view is the fact observed by Count Rumford, that the colour of the shadow does not appear different from that of an ordinary colourless shadow, when it is viewed through a tube in such a manner that the coloured ground is not seen at the same time. Great probability is also conferred on this explanation of the phenomena by their analogy with the facts previously spoken of, viz., those in which a small grey strip upon the surface of a bright colour appears of the opposite complementary colour. In the instance of the coloured shadows, the case is complicated with many deceptive circumstances; but in that of the experiment just alluded to the phenomenon is reduced to its simplest conditions.

This brings us to the physiological basis of the harmony of colours. The phenomena we have just described clearly prove that the action of one colour upon the retina disturbs the equilibrium of its condition, exciting in it one pre-

dominant state, and that a tendency exists in it to the development of the opposite state complementary of the one thus excited: we cannot, therefore, be surprised at finding that the combinations of colours producing a pleasing and salutary impression both upon the eye and upon the mind are those which contain the colours thus opposed to, or complementary of, each other. All complementary colours have an agreeable effect, and all bright colours which are not complementary a disagreeable one, if they predominate. In this sense the complementary colours may also be styled harmonic; and those which are not complementary of each other, disharmonic. A combination of complementary colours is an harmonic combination; all other combinations of colours are disharmonic in proportion as they belong to one simple prismatic colour, and are at the same time very bright. A predominant flaming red is as unpleasant as a predominant glaring yellow, or a uniform predominant blue. Hence we are accustomed to mingle white or grey with these colours, when it is requisite to employ them alone over large surfaces, so as to soften and render them more supportable. Combinations of two of the simple colours,—the third, which would render them complementary, being deficient,—are the most offensive to the eye; for instance, combinations of yellow and red, blue and red, or yellow and blue. In these combinations there is complete disharmony; while, in the association of two colours, of which one forms the transition to the other, there is neither harmony nor disharmony. Such colours are indifferent to each other, as yellow to green, red to orange, or violet to blue. The disharmony between two colours may, however, be removed by the interposition of a third colour which is the harmonic of one of them, and is indifferent with relation to the other. We have examples of this in such combinations as red, green, and yellow; yellow, violet, and blue; blue, orange, and red; or red, green, and blue, &c.

I have only briefly adverted to the aesthetic branch of the theory, to draw your attention to the central principle of "balance" as the basis of the harmony of colour,—indeed, of all harmony; and to notice that the mode of neutralizing discord in music is another fact which links the two theories together, as it is similar to that by which two disharmonic colours are brought together by the intervention of a third, with one of which it harmonizes, while towards the other it is indifferent.

In the facts which I have collected and grouped together, it will be seen that both light and sound can be respectively produced in the eye and the ear by the same mechanical means, by a blow, by pressure, by the arterial pulse, by electricity, by narcotics; that the remarkable phenomenon of *interference*, by which two rays either of light or sound may be made to neutralise or extinguish each other, is common to both; and that the theory of light which has the widest acceptance is that which makes its propagation analogous to that of sound. The wonderful parallelism between the two phenomena "can hardly leave," as Sir John Herschel remarks, "any reasonable doubt of their ultimate coincidence in one common phenomenon, the vibratory movement of an elastic medium. Every colour, therefore, as every note, will be dependent upon the relativity of the vibrations which produce it, or of the states of the senses. This is very notably confirmed by the experiments in which the same grey spot successively assumes every hue, and by the phenomena of the complementary spectra and shadows. But the very principle of compensation which arrests our attention in studying the ocular spectra connects them with the larger physical phenomena of the solar system in which the law of compensation would appear to be eternally fixed. The law may be thus stated: every departure from a mean state on one side, must be compensated by an equal but opposite divergence on the other. And this would make good colour and good music to consist, as we feel they do, either in preserving an even temperament or in restoring a disturbed balance by means of compensation. But whether we consider colour in its physical aspect as the relativity of vibrations on or in the retina, as produced by mechanical pressure, or in the phenomena of compensation, it must be in the abstract just as music is, a science of relative proportion. And all proportional relation is comprehended in the movement of that instrument which I have called The Balance of Nature.

If the external cause of colour be merely

mechanical vibrations, how inconsistent it is with the received theory to dispute whether there be three or more primitive colours, and to talk about a substance absorbing certain colours whilst it reflects another, or of different coloured rays. For, according to the received theory, or any theory which has been entertained, there are no objective colours to absorb, but only various mechanical undulations or impulses. It is, therefore, more reasonable to suppose that substances respond the illuminating vibration with which their structure is in unison. And if an illuminating ray be constituted of mechanical undulations, it is also reasonable to suppose that it might be made to produce every colour on the retina by the raising or lowering of the velocities and magnitudes of its vibrations, and to establish the monogenesis of colour from force. I believe it will ultimately be discovered that colours are produced by modifications of the normal or mean undulation which produces the sensation of white light. That the illuminating vibrations are not conveyed by a continuous ether, but by transferred undulations, just as the pulses of a musical string are through various materials, and that transparency consists in their true and direct transference by certain substances.

There are still remaining, however, a few words to our summing up. Science very often speaks too confidently as if it had the power to penetrate causation, physical and physiological, but the truth is, in this respect, our knowledge is but inference at best. Science, all the time she fancies herself occupied with the study of the external is only contemplating the world in sensation, in its appearance to human nature, and the fundamental form of sensation is quantity. The science of proportion, therefore, is that which underlies all others; and when all our knowledge shall have assumed the form of correct quantitative statement, it will have attained its highest degree of certitude.

W. CAVE THOMAS.

PARIS.

The Palais de l'Industrie, at the Champs Elysees, has been conceded, for a term of five years, to the French Hippic Society. M. Dutron, architect of the building, is arranging the ground floor so that in one stable, or in two at most, the five hundred and odd horses can be lodged, to which the above Society purpose distributing training prizes to the value of about 2,400l. The contest is to take place from the 1st to the 15th of April.

At the New Opera-house the triangular building in which the stage will be installed has been roofed in. From the floor of the cellars to the roof of this portion of the Opera-house the height is 328 ft. Powerful machinery is to be used for working the scenery. The exterior sculptures of the ground floor are being terminated.

The immense ecclesiastical printing establishment of the Abbé Migne, at the Chaussée du Maine, Paris, has just been destroyed by fire. A portion of his library and furniture, also the paintings of the church, were preserved; but all the other valuable documents and MSS. are destroyed. The loss is irreparable. He had revived the works of the ancient churchmen in more than 500 volumes in 4to., and the fruits of his life's labour disappeared in a few hours. The establishment was the largest of its kind in the world; it was insured in thirty-five offices, but as they insured only for half the value the loss is immense. Upwards of 300 persons are thrown out of work, most of whom have families. The loss of the materials destroyed is over 120,000l. Several thousand volumes have also perished.

The mairie of the fourth arrondissement, that of the "Hôtel de Ville," is now finished, and is one of the new municipal establishments of Paris worthy of attention. It is from the designs of M. Bailly, architect of the Tribunal of Commerce, and covers an area of 24,748 square feet. Its principal entrance is on the Place Saint-Jean, and it is limited on its other façades by the Rues de Rivoli, Vieille-du-Temple, and Saint-Antoine. Access is given by three large bays; the centre one leads to a fine staircase, of triple revolution, preceded by a spacious vestibule. By the other two bays we enter into a court surrounded by closed galleries, serving as waiting-rooms, &c. On the *entresol* are placed the public library, engineers' offices, &c. Above are established the principal civil services, secretary's offices, &c., and the marriage saloon, which is well ornamented, and furnished

with a magnificent marble chimney. There is also another saloon, well decorated, for various purposes, distributions of prizes, exhibitions, concerts, charity halls, &c. It is 124 ft. 6 in. in long, by 33 ft. wide, and 24 ft. 6 in. high; it is lighted by seven large windows, with stone mullions and transoms, like those of the Middle Ages. Entrance is given to this saloon by five great doorways, the woodwork of which is of stained oak.

In the line of the Pont de Solferino, the clearance for the new street leading to the Rue de Grenelle St. Germain progresses rapidly. It will throw open the building called the Palace of the Legion of Honour.

At the ancient Louvre, under the gallery of Apollo, is the rich restoration of the ancient paintings of the apartments of Anne of Austria, which were given by the first Empire to the Museum of Antiquities. It is on the southern side of this portion of the Louvre that we see the balcony from which Charles IX., on the 24th August, 1572, fired at the unfortunate Huguenots who were swimming across the Seine, to escape the massacre of St. Bartholomew. They are occupied at present in arranging in these magnificent saloons, now restored to their primitive state, the busts and antique bas-reliefs they contained, adding to them those from the splendid collection of Compaña which the French Government purchased seven or eight years ago. When completely arranged, this museum will be unequalled in the world.

The iron framework of the roof of the new wing of the Tuileries is being put in place, and will be soon finished. Also the Emperor's entrance-gate has been finished and decorated with two life-sized lions of bronze placed upon the two pedestals which precede it. They are by the sculptor M. Barry.

We have already mentioned that the Hotel Carnavalet, in the Rue Culture-Sainte-Catherine is being restored and enlarged, so as to form a municipal museum containing an archaeological collection representing the six great eras of the town of Paris:—1. The primitive and obscure epoch of ancient Lutecia; 2. The Gallic and Gallo-Roman period; 3. Moyen Age; 4. The Renaissance; 5. The seventeenth and eighteenth centuries; 6. The present epoch. Each period will be represented by plans, instruments, tools, utensils, objects of art, design and geology, maps, human and monumental *debris*, fragments of architecture, &c., collected from excavations for foundations, past, present, and future. The present epoch will be represented also by specimens, copies, sketches, facsimiles of all that the monuments of Paris, churches, edifices, &c., contain most remarkable in artistic work, paintings, medals, decorative paintings, sculptures, statues, and curious works of all sorts.

THE PARIS EXHIBITION BUILDING.

On the 13th ult., the Exhibition Palace of the Champ de Mars was "knocked down," by adjudication, to M. Menot, since whose offer it was the highest. Viewed from the exterior, the building appears intact, but the interior has been completely cleared of its contents, and the galleries are attacked on all sides, so that they present the appearance of a scathed forest; the central garden is bare, but the central pavilion, in which the weights, measures, and coins were displayed, is still upright. The great machine gallery remains untouched, as far as its framework and roof are concerned, but the floor has been levelled, and all machinery has been removed.

Outside the building, the Champ de Mars presents a singular aspect; the red iron light-house is nearly taken down; each plate is carefully packed and placed upon a lighter, for its ultimate destination, Les Roches Douvres. Austria has removed all her own from the Park; Spain is at work dismantling the great pavilion; Switzerland, Sweden, and Russia have not as yet attacked their picturesque pavilions and chalets. Towards the north-west, or Asiatic part of the grounds, we observe many Turkish and Egyptian buildings yet standing, but the details of the latter, sphinxes, &c., are being demolished, and the pavilion of the Vicroy is attacked. The Chinese and Tunisian palaces, at this extremity of the park, seem to be the only buildings hitherto respected. The chimneys for the engine boilers are all down, and the reserved garden presents a piteous aspect.

The sale of all the materials forming the

ensemble of the Exhibition in the Palais and park was effected at the "Cercle International," on the grounds, and several days in the week were devoted by the Commission for this work. All this enormous mass of material passes away in large lots. In a very short time hence every lot will be sold, given up, and taken away, so that no trace will remain of the great Universal Exhibition of 1867, unless some spirited capitalists create a reminiscent building, like our Crystal Palace at Sydenham, of 1851, and that of Muswell-hill, of 1862.

TRADE UNION PERSECUTION.

SIR,—Can you give me the addresses of any respectable builders in or near London, who employ non-union men? I want to get work for a young man, a bricksetter, who has been positively persecuted by union men. He is remarkably steady, sober, honest, and a good workman. I had him employed on a parsonage which I am erecting, and all went on comfortably till one or two unionists, and some of them the worst hands on the work, threatened a strike, and the contractor was compelled to sacrifice the young man, whom he had from feelings of personal friendship and esteem engaged, and with whose work he expressed himself perfectly satisfied. I got him work in Lancashire, but the evil spirits followed him there also, and all because he did not begin to work until after he was fourteen years of age, while the contractor, who was employing him, had himself been a silk weaver, and did not learn his trade until after he was twenty-one.

In trade unions I see no objection so long as they are carried on with honesty and fair dealing, but I consider this an act of heartless, selfish robbery, to say to a young man, you shall not earn your bread by your trade, although you are a better hand, if may be, than many who can show their card. These brutes, for I can call them nothing else, are invariably the most ignorant, drunken muffs in the trade. By your helping me in this matter, you will do an act of charity.

A COUNTRY CLERGYMAN.

. One of our readers may, perhaps, need a bricklayer. We have the writer's address.

THE LEEDS WATERWORKS.

The first portion of the extensive corporation scheme by which the waters of the Wharfe are to be substituted by those of one of its tributaries,—the Washburn,—in the supply of Leeds, has been commenced, and there is a prospect, should the works proceed favorably, of the Wharfe being abandoned during the ensuing autumn, though several years will elapse ere the scheme in its entirety, with its extensive reservoirs in the upper reaches of the picturesque vale of the Washburn, will be completed.

The water-shed impounded by the new Waterworks Local Act it is estimated will yield about 23,000,000 gallons daily. The first part of the scheme is to pump from the Washburn at the point of its junction with the Wharfe, the 6,000,000 gallons now obtained from the larger river. This is to be accomplished by laying a 27-inch cast-iron conduit from a dam at the foot of the Washburn to the present pumping station at Arthington, a distance of about two miles. The conduit, after leaving the Arthington works, will be continued on till it meets the waters of the Washburn. For the purposes of this conduit, Mr. Filitter,—who has the exclusive supervision of the works from Arthington to the foot of the Washburn, in connexion with the pumping part of the scheme, while the reservoirs will be constructed under the joint management of Mr. Filitter & Mr. Hawksley,—has had the pipes cast specially in 12-ft. lengths, with the sockets downwards, after which they were coated, both inside and out, with a black glaze, this having the effect, to a considerable extent, of preventing corrosion, while the greater length,—pipes for similar purposes being usually 9 ft.—makes fewer joints requisite, and the leakage consequently smaller. Of the 1,000 pipes, which have been cast by Messrs. Hopkins, Gilkes, & Co. (Limited), of Middlesbrough, whose contract was for 5,630l., 900 have already been delivered. For this portion of the works, which Mr. Filitter is sanguine will be completed in about six months, the sum of 15,000l., in addition to the compensation,—

45,000l.—to be paid to Mr. F. H. Fawkes, bas already been granted by the Council.

The more important part of the scheme, however, is that comprising the reservoir works up the valley for providing the supply of the additional fourteen millions of gallons, which it is estimated will be required in Leeds for daily consumption by the end of the present century, and for sending down the compensation waters to the neighbouring landowners. The plan shows that four reservoirs are contemplated, one of these being situated at Lindley Wood, about two miles from the foot of the Washburn, two others about midway up the valley, at Fawston and Swinsty, and a fourth about three or four miles from the head of the valley. The following figures represent the approximate dimensions of the various reservoirs:—

	Lindley Reservoir. (Compensation and Supply.)	Swinsty Reservoir. (Compensation.)	Fawston Reservoir. (Supply.)	Thruscross Reservoir. (Supply and Compensation.)
Area of Watershed	21,700 acres	17,000 acres	13,000 acres	4,500 acres
Capacity of Reservoir	700,000,000 gals.	980,000,000 gals.	870,000,000 gals.	530,000,000 gals.
Area of Water Surface	117 acres	158 acres	158 acres	50 acres
Depth of Water	60 feet	65 feet	60 feet	85 feet
Height of Embankment	67 feet	67 feet	68 feet	102 feet
Height above Sea Level	300 feet	450 feet	600 feet	777 feet

SOUTH KENSINGTON PARK DRIVE.

GREAT excitement amongst the residents of this district has been caused by the temporary stoppage of the marginal Park road between the Queen's and Prince's gates. The grand quadrilateral of the Horticultural grounds being now completely surrounded by first-class mansions, has become the resort and abode of distinguished and wealthy families, who, having purchased or built their houses on account of the fine open roads, the vicinage of the Park and Gardens, and the direct access thereto by the Queen's gate, at the end of Albert-road, feel a dread lest these gates, which, by permission of the Commissioners, were erected by and at the expense of Mr. W. Jackson, should be summarily closed against carriages.

This carriage-way, in a direct line of about a mile and a half from Hyde-Park corner to Kensington, formed the most agreeable route of access to town, avoiding the not very pleasing defile opposite Knightsbridge Barracks, and offering the amenities of a seemingly rural park with wide waters and most effective floral ornamentation. The South Kensington Museum adds doubtless to the attractions of this quarter, and the new Hall of Arts and Sciences will, when completed, confer on it additional lustre; but its chief value is from proximity to the Park and the free intercourse by the marginal Park road, which will continue to be its first recommendation.

Some little deviation of the drive has become necessary at the base of the Albert Memorial, where probably another carriage-entrance may be opened, opposite to the Rotunda of Arts and Sciences; but on this side, within the distance of one mile, there are already four open carriage-gates, and one other, shut up, opposite Prince's Gardens.

For the public in general a great accommodation was conceded by the opening out of a road for cab traffic from Victoria-gate, Bayswater, to Kensington-road. This gave an improved route of communication between the important N.W. and S.W. districts; but the line which takes a southern direction to the Magazine turns off westward thence to the Albert-road, Kensington, diverging at least one-third of a mile out of the right line, which should have had issue at the gate facing the Exhibition-road. As an easy and direct intercourse between Bayswater, Brompton, and Chelsea, this line would be of general public utility; the only lines of access open to public conveyances previously having been by Park-lane,—a detour of over one mile and a half.

By adopting the suggested roadway, access to Kensington would be attained by a more level road across the plateau of the Park angle, at a distance increased by 100 yards only; whilst at all other points half a mile would be saved, and a great improvement made as regards the flower-walk of Kensington Gardens.

That an open communication should exist between the noble memorial to the regretted Prince and the Hall of Arts and Sciences suggested by him, is a proposition that meets universal concurrence; but that the beautiful drive extending from Hyde-Park corner to Queen's-gate, Kensington, should be curtailed, or that direct access from Albert-road should be

It is estimated that when the whole of the works have been carried out there will be provision made for a supply for 180 days.

As to the existing works of the corporation, the store reservoir at Ectup is about 40 acres in extent, and contains about 240,000,000 gallons, and the Woodhouse supply reservoir contains about 6,000,000 gallons, being only one-sixth more than one day's consumption. At Woodhouse are the filter-beds of sand, which cover about 2½ acres, and at Headingley the pumping-works for the high-level districts of Headingley-bill, Chapel-town, Bramley, and Wortley. Two engines send to the higher parts of the borough nearly 1,000,000 gallons per day. In addition to these works there is a small reservoir at Bramley which holds about 2,000,000 gallons, and another, very much smaller, at Beeston.

However, the works were resumed by the contractors, Messrs. Barry & Doyle, and have now been brought to completion. The building has not much pretension to architectural beauty, the intention evidently being to make it as substantial as possible, as well as comfortable for the congregation. Its length is 165 ft., and width 35 ft. The high altar has not yet been completed. It is intended to erect two side altars, to be dedicated to the Virgin Mary and St. Anthony. A sum of 4,000l. has already been subscribed towards defraying the expenses of the church, but it is believed that before it is completed an equal sum must be contributed.

BATH ABBEY RESTORATIONS.

At a vestry meeting recently held, the parishioners unanimously resolved,—

"That the churchwardens of St. Peter and St. Paul, Bath, be authorised to apply to the Consistory Court at Wells for a faculty to carry out the following alterations within the parish church, viz. to take down and remove the organ from the present gallery and re-erect the same on the north transept; to take down and remove the pulpit, reading-desk, clerk's desk, galleries, pews, and all other fittings now erected and being in the choir, and to remove the stone screen from the middle of the said church, and re-erect the same at the west end thereof, or some other convenient place, or otherwise; to take up the flooring of the nave, and re-lay the same with the stones taken up; to erect pews and sittings in the choir, nave, and transept; to use and employ any of the materials removed in the re-laying of the said choir and nave, or otherwise to sell the same, and apply the proceeds in and towards the expenses of such refittings; to remove all tombs, monuments, and tablets now erected, and being in and against the walls of the said church, and, without destroying or defacing any inscriptions thereon, to reduce to the same in size and re-erect and fix the said tombs, monuments, and tablets in some other appropriate and convenient place or places within the said church; and to remove, alter, and re-erect the rails of the chancel of the said church."

The groining of the nave is proceeding satisfactorily, but subscriptions to a considerable amount are still needed to complete this portion of the work. The roof and clearstory windows have been repaired; the transepts are nearly finished, and preparations may now be made for the removal of the organ to the north transept as suggested by Mr. Scott and approved by Mr. Hill. The stained-glass window which is intended to be placed in the south side of the nave in memory of the late Mr. J. H. Markland, D.C.L., has arrived; and the glass for another window is also in the church, leaving only one vacancy in that portion of the building.

THE PUGIN TRAVELLING STUDENTSHIP.

ELEVEN candidates sent to the Institute applications, drawings, and testimonials for the Pugin Travelling Studentship of the current year, and the studentship has been awarded by the council to Mr. C. Henman, jun., of 7, Bedford-place, Croydon.

WARMING AND VENTILATING.

DR. HAYWARD, of Liverpool, has recently made some arrangements in his own house with a view to warming and ventilating, which seem calculated to be efficacious, and recently invited several persons to examine them. The air is received in at the basement, through gratings from the street, into a chamber, where it is heated by means of hot-water pipes connected with a stove in another department. The warm air flows naturally upwards through other gratings into a lobby on the next floor, from which it is diffused into all the chambers on that floor, which are connected by gratings with the central lobby. A further draught of air is carried to a lobby on the next floor, and diffused in like manner, so on from lobbies into chambers, until we reach the top of the house, the temperature, of course, decreasing slightly as it rises. In each room, over the chandelier is another grating, into which the foul air flows, and is carried up from each room through a pipe until the entire foul air of the premises is concentrated in a small chamber at the top of the building. This chamber is connected by a shaft with the kitchen chimney, and the foul air is drawn down through this shaft, and escapes from the chimney shaft, through flues which

closed against carriages, would annoy and incommode the residents of the fine ranges of South Kensington, and damage their property.

As to the Park rides, equestrians have much to be grateful for towards the Commissioners, who, in addition to the mile-and-half course of Rotten-row, have opened out another course of equal length, completely encircling Hyde Park. Those also "who put their trust in chariots" have free circulation over well-kept drives, which command the best views of wood, water, and landscape; whilst all the borders within view are decorated with luxuriant blossom, tended with a skill and care, first introduced by official authority. With these experiences the residents of South Kensington may, we think, rest content, and feel assured that no change will be made in this angle of the Park which will not be as conducive to pictorial effect and popular enjoyment, as was the demolition of the old Cavalry Barrack and substitution of a Fairy Garden.

A COMPETITION ABROAD.

THE designs sent in for the competition opened for a public monument, commemorative of the victory obtained at Callao over the Spaniards by the republics of S. America, were examined on the 24th February last. The jury presided over by M. Gleyre, was composed of MM. Le Duc and Duhan, architects, Eng. Guillaume and Perraud, sculptors, both of the Institute. The design, selected to be classed in the first rank, emanated from M. Guillaume, architect, and M. Cugnot, sculptor. One of the designs sent by MM. Davioud, architect, and Cugnot, sculptor, obtained the place of second rank. Lastly, No. 11 of M. Simonet, architect, and Elias Robert, sculptor, held the third rank. Twenty-six designs were sent for competition.

FROM IRELAND.

Dublin.—The directors of the Industrial Tenements Company, and some personal friends (shareholders), have entertained Mr. Henry McClean, J.P., their chairman, at a banquet, in the Gresham Hotel, on the occasion of the new model dwellings, in Meat-street and Earl-street, being opened. Sir John Bagot occupied the chair, and Alderman Gregg the vice-chair. The new block of buildings contains 120 rooms, with every arrangement, it is said, for comfort, health, and decency. The Vartry water is laid on to every story up to the attics.

Killarney.—The Franciscan (R.C.) Church at Killarney has been consecrated. The church is named the Holy Trinity. On the 17th March, 1864, the foundation stone was laid. The designs for the building were furnished by Mr. J. G. McCarthy, of Dublin; and the style of architecture is as nearly similar as possible to that of Muckross Abbey, which was a monastery inhabited by the Franciscan Order in the year 1340. The new building was commenced through the exertions of the Rev. Mr. Patrick, prior of the order, and when the edifice was only seven feet above the ground that priest died. This caused a check to the progress of the building.

in parallel with the smoke flue of the kitchen. Mr. Hayward claims by his arrangement to always ensure an equable temperature either in summer or winter, and to obviate all the ordinary draughts of houses, so productive of cold and worse evils. If a heavy and cold wind blows the valves for admitting the air at the basement can be closed, and if it is warm they can be opened according to circumstances. The expenditure of fuel for heating the air, a thing accomplished by contact with hot-water pipes in its first stage of flow towards the upper chambers, is trifling, and is much more than saved by the diminution in the quantity of coal necessary for use in the grates. In summer, by the aid of iron what are in winter the heating chambers, the air can be brought to any temperature.

USE OF HOME-GROWN TIMBER.

BIRMINGHAM ARCHITECTURAL SOCIETY.

At a meeting of this Society, Mr. George B. Nichols, of West Bromwich, read a paper as an introduction to a more detailed discourse to be delivered on a future day before the same society, on "The adaptability of our own home-grown timber for internal purposes." Mr. Nichols said the subject had been forgotten by the profession for the last half century at least. The timbers of foreign countries having been brought rapidly into use on account of their adaptability and cheapness, the country had been led to depend entirely upon them, and home-grown timber had been allowed to degenerate, and become of no use except for inferior purposes. The beauty and adaptability for internal purposes of many of our home-grown timbers had been overlooked. He laid before the society samples of home-grown timber, "with a view to the introduction of a variety in order for an improvement upon the ever monotonous painting and graining." The samples he wished to bring under notice included "the vine prop alone," "the poplar never dry," "the bullock oak, solo king of forests all," "the willow, worse of foulness paramours," "the yew, obedient to the builder's will," "the birch for shafts," "the warlike beech," "the ash for nothing ill," the maple, the larch, the Scotch fir, the lime-tree, the wych elm, the sycamore, the cherry-tree, the alder, the hawthorn, the hornbeam, the apple-tree, the plumb-tree, the walnut, and the chestnut. He hoped the subject of internal decoration would be considered, with a view of bringing out in their natural state the material to be dealt with, relying on the beauty of nature for effect, wherever it could be obtained by judicious treatment of form and colour. He presented the samples to the society for the museum.

THE PROPOSED HOSPITAL FOR NEWCASTLE-UPON-TYNE.

SEVEN or eight years ago it was proposed to erect a hospital in connexion with the Union Workhouse, Newcastle-upon-Tyne; but, for wise economical reasons, that which was necessary then has not been erected yet. An opportunity, however, occurred—an opportunity in such excellent harmony with guardians' economy—that the hospital committee could not let it pass without making another effort to obtain the long-neglected requirement. According to the testimony of one gentleman, the plans had been drawn by an inmate! If this should turn out to be correct, surely the Newcastle guardians, who are about to expend from 10,000l. to 12,000l. over an erection to accommodate 250 patients, may justly be blamed for so recklessly risking the ratepayers' money, as they appear to have been accused of doing by some of their co-guardians. It is but fair, however, in explanation to say that another architect—not an inmate—has been requested, on the understanding that his commission should be reduced to 2½ per cent., in consideration of the work previously done, to revise and improve the designs of the hospital according to the matured instructions of the hospital committee. And it was on the occasion of the approving of these designs that what the local papers call a "scene" took place in the board-room of that august body. One gentleman, who advocated the pavilion plan, complained of the want of through-and-through ventilation,—of "outboots" in the shape of large day-rooms,

"which prevented the air from going all round the building,"—of the situation of the water-closets, which were "close to the wards, and under certain circumstances, which were of very frequent occurrence in all hospitals, impure air therefrom would readily get into both wards,"—and also of the position of the building upon the site, owing to which "some of the windows would face the north, and consequently be entirely deprived of sunshine." The chairman of the committee, in reply, said that "although several of them might have objections to certain portions of the plan, yet they considered it was a compromise of their various views; and that, having determined on the shape and position of the hospital, all they had to do was to give an architect instructions how to carry them out; and a better course for the interest of the ratepayers could not be pursued than the one they had adopted, either by having competition or any other mode of getting plans." After all that has been written and said upon the question of hospital construction, we fear the Newcastle guardians are behind what they ought to be as to the best mode of securing the best hospital for the least money.

THE PEABODY MEMORIAL CHURCH IN MASSACHUSETTS.

THIS church, in Georgetown, Mass., erected as a memorial of the mother of George Peabody, by her son and daughter, has been dedicated to divine service. Mr. Peabody, who was present when the corner-stone was laid, in September, 1866, was not able to attend the dedication. A letter from him was read, bearing date London, Oct. 18, 1867, and addressed to the members of the Orthodox Congregational Church in Georgetown. After stating that his sister, his "faithful coadjutor" in the enterprise, had informed him that the church had been satisfactorily completed, he adds:—

"In the building of the church we had a twofold object: first, its consecration to the memory of our beloved mother; and, second, its dedication to the worship of Almighty God, in its simple purity, according to the evangelical faith, as acknowledged and accepted by our dear mother, and as recognised by the Orthodox Congregational Churches of New England. On the completion of the building, its use will be legally conveyed to you and your successors, in trust, subject to the following conditions."

Then follow the conditions, which relate to the purposes of the edifice, its repair, and that of the memorial tablets, &c.

MR. PEABODY'S GIFT.

The following results are shown in buildings at Shadwell and Islington for the year 1867:—

	Cost.	Gross Rent.	Expenses.	Net Rent.	Interest Not Paid.	Expenses on Gross Rent.
	£	£	£	£	per cent.	per cent.
Spitalfields, for land & buildgs.	27,215	1,050	300	690	2.53	34.28
Islington	10,387	1,699	670	1,029	2.48	39.43
Totals.....	67,612	2,749	1,030	1,719	2.5	37.41

Spitalfields and Islington have been fully occupied. The annual expenses are taxes, rates, insurance, alterations, repairs, and collection. Fractions of 1l. are omitted. The net rents invested annually at 3 per cent. per annum would reproduce the whole original outlay in twenty-seven or twenty-eight years. (See *Builder* of 22nd. ult.) T. H.

A THOUGHTFUL ACT OF MASONS.

SIR,—I shall feel obliged if you will kindly insert the following lines in your valuable journal, which will set forth the manly character of the Cornish masons. When trade was prosperous, the masons of Penryn asked for an advance of wages, which they obtained. Now, when trade is dull, they have sent a memorial to the firm of Messrs. Freeman, beseeching them to deduct 6d. per day off their wages. These men appear to me to be free and use their own judgment. Such a case as the above, perhaps, was never known before. WILLIAM CROSS.

The Prince Consort Memorial, Hyde Park.

THE DESIGNER OF THE PENITENTIARY, MILLBANK.

"Dead sinners, as well as saints, should have an advocate, although not del diavolo."

SIR,—In the list of buildings designed by the late Sir Robert Smirke, R.A., published by the Institute, the fourth is the General Penitentiary, Millbank, London. This was designed, with the exception of the gateway, by a Mr. Williams, formerly teacher of military drawing in the Military College (see the style, and doubt it if you can). The writer assisted Mr. Williams in making the drawings in 1813. They were successful in the competition, and gained the first premium, and the building was carried out from them, *except the gateway*. This was designed and built by the late Mr. Thos. Hardwick; but it failed, and Mr. Smirke was called in, who put in a new foundation of concrete. The general building was not, that I am aware of, touched by him, and is not his, but Williams's design.

AVVOCATO DEL DIAVOLO.

** Making inquiries of those who know the circumstances, we are informed that when the foundation of the gateway and other parts failed, the work went into the hands of Sir E. Smirke, somewhere about 1816. The crippled pentagons were taken down, and the whole prison was rebuilt under Sir Robert's direction. Possibly the central part, round which the pentagons are arranged, may not have been rebuilt, but of this our informants are uncertain. Much constructive skill was shown, and it affords one of the earliest examples of the use of concrete in England (just fifty years ago). We have always understood that the radiating principle was devised by the late Sir S. Bentham. Lady Bentham, when alive, wrote several letters, in our pages, to assert it.

ENGRAVED LETTERS ON MARBLE.

YOUR correspondent "F. M." asks the best and most durable method of preparing engraved letters on marble or stone to receive gold-leaf.

The following will answer the purpose:—In half a pint of hot turpentine dissolve 2½ oz. of gum damar and 1½ oz. of best white wax; when cold, give the letters one or two coats of this, allowing a day between each coat to dry; then gild with double-thickness gold-leaf in the usual manner. It will not crack either indoors or exposed to the weather. TROS. KERSHAW.

HERNE BAY PIER.

ABOUT four-fifths of this pier are available as a promenade. Possibly an expenditure of 1,500l. to renew the cross planking of the platform and some longitudinal timbers would at once enable the pier to be opened.

Nothing can be more absurd than the barriers erected at the entrance to the pier, which is boarded in; and nothing would be easier than removing them at once two-thirds of the distance down the pier. Anything more creditable to the town than the closing of this pier, when a few slight repairs could at once obviate its being barred to the public, cannot readily be conceived. There may be defects in the piling, but to no considerable extent, and none which a little management could not overcome. The bays or spaces between piles are small, and might easily be trusted where defective. It may readily be imagined the money lost that has accrued to the enlightened inhabitants. PAULATIM.

ARCHITECTS' CHARGES.—RANDAL v. GRAY.

SIR,—Having seen a letter from Mr. W. Butterfield, published in the *Builder*, and on the subject of a trial concerning architects' charges between Randal and Gray, and having been present at the trial, I beg leave to state that the clerk of the works called as a witness on the trial, and who, Mr. Butterfield says, is in his employ, distinctly stated in court that he was employed by a lady, whose name he gave. What right, therefore, Mr. Butterfield has to interfere either with what he says or does after he has so openly and so publicly contradicted himself is not apparent.

If Mr. Butterfield would think for a moment, he would see that had he endeavoured to prevent the appearance of the clerk of the works on the trial a subpoena would have overcome all such "arbitrary interference." As to the clerk of the works having given "incorrect evidence" and speaking of "that of which he could have no accurate knowledge," I can only say he particularly stated himself to be only a clerk of the works. He said he never knew architects to charge more than a commission of 6 per cent., but he could not say they did not. Any one present could see that he was called for the purpose of proving neglect in the carrying out of certain works spoken of in the trial. Mr. Butterfield's name only came out by the attorney for the plaintiff asking (by the name of the plaintiff), if the church restoration, superintended by the clerk of the works, was not being carried out under Mr. Butterfield. The answer was, "I

do not wish to mention Mr. Butterfield." Plaintiff's attorney then said, "Oh, but we want to hear all about him;" but on the attorney for the defendant speaking to him, no further mention of Mr. Butterfield's name occurred.

Mr. Butterfield's giving an opinion as to the charge not being an unreasonable one, seems to me uncalled for, as he had no concern in it.

Mr. Butterfield seems very sore at the idea that a wrong impression as to his charges has been given to the public. I can only say, if the result of this trial be to induce either Mr. Butterfield, or any other architect, to state his charges before undertaking a work (which is not the universal custom), it will have done some good for the public. I enclose my card. ONE PRESENT AT THE TRIAL.

FLATS versus LODGINGS.

SIR.—Will you allow me, through your paper, to call the attention of builders and owners of house property, to what is considered by many a great want in our metropolis, and especially at the west-end? I allude to what are called flats, such as those in Victoria-street, Westminster, and of which many exist in Paris, to the great convenience of many persons who do not wish, or cannot afford, the trouble and expense of a large establishment. You are truly aware that many families have been obliged to reduce their establishments owing to the recent failures in railways and other securities. Now, people who have been long accustomed to the comforts of their own house, find lodgings a very poor substitute, whereas by taking a flat, they would have all the advantages of their own house, and would certainly not require more than two servants, thus saving very considerably in wages, &c. Victoria-street, Westminster, is not exactly the place one would choose for a dwelling in, but on the outside of the park, in Tyburnia, I believe, flats would be eagerly sought after. There are many rows of houses in that neighbourhood still unoccupied, and others in the course of erection, which might be converted into rooms such as I mention, and would thereby be conferring a great benefit upon many. I firmly believe, and amongst others yours.

PADDINGTON.

* * * A block of houses to be let in flats, and called "Belgrave Mansions," has been built on Lord Westminster's estate.

THE LOSSES OF IRONMONGERS.

SIR.—It is an every-day practice for tradesmen in the City who have what they call a country house—that is, a house situated about five miles from St. Paul's,—to give orders for a competent person to go and inspect premises, make estimates and drawings, say, for a kitchen range, a warm bath, &c. After calling several times at the City address the ironmonger finds that about half a dozen engineers and ironmongers have tendered for the job, which was not named in the first order.

I certainly think that every ironmonger should in these cases send in his account for estimates and loss of time. He should in all cases ask if it is to be a competition job? S. C.

CASES UNDER METROPOLITAN BUILDING ACT.

DISTRICT SURVEYOR'S FEES.—At the Clerkenwell Police Court, Mr. A. N. Brett, builder, St. James's-road, Holloway, was summoned, before Mr. Cooke, by Mr. John Turner, one of the district surveyors of Islington, to show cause why he refused to pay the sum of 15s. for surveying the erection of a cellar attached to a bakehouse, erected after the roof of the bakehouse had been covered in.

Mr. Cooke, the case having been heard at length on a previous occasion and adjourned, delivered a lengthened judgment, in which he pointed out that where an addition to a building was not contemplated and commenced before the main building was covered in, it could not come under the "additions" referred to in the Act, covered by the first notice and first survey; but was an addition for which an additional notice must be given, and an additional survey made, and an additional fee paid. He thought the builder had a right to say that the cellar now in dispute formed part and parcel of the bakehouse, and was intended to be included in the original notice. The wall of the cellar formed part of the bakehouse, and though there was an external and not an internal communication, he thought that that did not make it a separate building within the meaning of the Act. The cellar being, therefore, a part of the bakehouse, the surveyor was not entitled to another fee.

BUILDING WITHOUT ARCHITECTURAL SUPERVISION.

DR. LANKESBEE has had an inquest at the Torrington Arms, Finchley, on the body of George Moore, who was killed by the fall of a part of the building which he was working on. The evidence showed that the house in question was intended for a public-house, and an effort was being made to get it finished in time for the forthcoming licensing day. In order to obtain large cellars, room the stacks of chimneys were not carried down to the ground, but were built projecting from the party walls, which were 9 in. thick. As soon as the centering was removed, the wall and chimney fell, burying the deceased and suffocating him. Mr. Richard Wale, an architect, who was examined, said that no architect could have designed, and no competent builder could have carried out, a building on the plan of the one which fell. It could not possibly have stood. If it had been propped up for twelve months, and the supports then removed, it must have fallen. The dead weight upon the structure was altogether too great for its capacity. If the chimneys had been carried down to the ground the wall would have stood. He had heard of no other profession for thirty years, and had never seen a building attempted on such a plan before. The jury, after returning a verdict of accidental death, passed a resolution declaring their opinion to be that sufficient care had not been taken by the owner of the building to have it constructed properly, and that the said owner and his advisers and assistants were consequently culpable.

PARISH CHURCH BELLS.

In the *Builder* of the 13th inst., calling attention to a bell weighing fifty-five cwt., recent cast for a new church at Woburn, I said, "It is the heaviest parish church bell in Great Britain."

Your correspondent "Verus" observes, in reply, "It ventures to doubt this, by 'forgetting' that there may be several latent heavy bells of little more than local cognizance and fame. There was, forty years ago, a statement of a bell at some parish church in Gloucestershire weighing 8,000 lb."

I may remark, however, that whatever there was in Gloucestershire, or elsewhere, forty years ago, is altogether beside the point. But your correspondent goes on to say, "There is a village tenor of six in Oxfordshire, I am pretty certain, near Witney (chs Banbury), 'undoubtedly' weighing fifty-six cwt."

Now, I venture to affirm that the heaviest village bell in Oxfordshire is the tenor of a peal of five in the tower of St. Mary's Church, Bloxham, near Banbury. It is a noble bell, remarkable for dignity of tone; but its weight does not exceed 34 cwt., according to my estimate, while its reputed weight has never been above 36 cwt.

"Verus" states also that "there is a tenor at the fine church of Felverham, Beds, believed on good authority to weigh 50 cwt."

It is, therefore, evident that your respected correspondent has failed in his attempt to weaken my statement that the new bell for Woburn is the heaviest parish church bell in Great Britain.

THOMAS WALTERS.

LIGHT ON THE PREMISES.

SIR.—A lady, under the impression that gas would be laid through the pariah, has fitted up her house with stables with pipes and gas-taps, &c., throughout, at a great outlay; but now, certain difficulties have arisen, causing the entire abandonment of the introduction of gas into the pariah. Can you or any of your correspondents recommend any safe and serviceable plan of lighting her house, either with gas or anything else, and using the pipes, burners, and gasaliers already erected, without going to the expense of having the misadventure of a gasometer, &c. on the premises. Does the portable gas answer for such a purpose? I recollect, some ten or twelve years ago, receiving a prospectus of some kind of lighting company, having offices, I think, in Bishopsgate-street, recommending some new light or new mode of kind, discovered by a Frenchman, and then used at the Jockey Club, Paris, in many other public buildings. Can it be recommended? J. B.

A NEW "patent gas-generator" for private gasworks, &c., is thus described in the *American Gaslight Journal*.—In this apparatus kerosene or petroleum is distilled in combination with wood, and converted into a fixed gas of great purity, which gives a light superior in brilliancy and beauty to ordinary coal-gas. The apparatus consists of an elevated oil receptacle, communicating by a tube and syphon with a small retort in a common box-stove or furnace. Here the oil is decomposed by a temperature of 800° Fahr., in combination with wood, with which the retort is first charged, and the resultant gas is conducted into a condensing box, and thence to the gas-meter. The gas is free from the impurities and disagreeable odours of coal-gas, and is exceedingly simple to manufacture and prepare for use, because it requires no purification. For private residences, hotels, factories, and even small communities, this apparatus, it is added, is meeting with much success. Messrs. George H. Kitchen & Co. patentees, 591, Broadway, manufacture and put up the apparatus.

THE NEW CATTLE MARKET AT SOUTHAMPTON.

THIS market has been opened. It is bounded on the north side by Chantry-road, on the south by the Bridge-road, on the east by the South-Western Railway (close to the Dock Station), and on the west by Terminus-terrace. The area in use is about one acre, but there is sufficient land to extend it to four acres. About half of this space is devoted to cattle stalls, and the other half to sheep and pig pens. The main entrance is placed in the centre of the Terminus-terrace boundary fence, and the sheep and pig entrances in Bridge-road. There is also another entrance at the corner of Bridge-road, opposite Day's Hotel. The cattle stalls are estimated to accommodate 280 beasts, and the pens 1,180 sheep and 500 pigs. The pens for both these classes of stock being of the same size are available for either. The surface of the land has been raised to the level of the road of Terminus-terrace at one end, and 2 ft. above the old surface at the other end, thus securing thorough drainage into the main sewer. The cattle stalls are formed by means of two wrought-iron rails and cast-iron posts, 3 ft. 6 in. in height, bedded in concrete. The flooring is of concrete, coated with Portland cement, and drained into stone

channelling, running the whole length of the stalls, thus securing cleanliness. The sheep-pens are 6 ft. 6 in. square, and will accommodate ten sheep each. They, too, are formed of wrought iron, with concrete flooring, coated with Portland cement, and channelled with stone all round. The pig-pens are of the same size and construction as those for sheep, the bars of which are placed much closer together, so as to safely accommodate small pigs. The whole of the works have been designed by the borough surveyor, Mr. James Lemon, and executed under his superintendance. Mr. John Cox executed the drainage, and the raising and forming of the surface, and the concreting and channelling. Messrs. Hill & Smith, of Brierly-hill, Staffordshire, supplied the ironwork; and Mr. Fry, of Southampton, fixed it as a sub-contractor. The iron fencing and gates were supplied and fixed by Mr. Kent, of Southampton; and Mr. Davies and Mr. Doggrell were the contractors for the painting.

THE DRAMA.

A FEW days ago we had the satisfaction of hearing a play, "Waldeck, or the Siege of Leyden," read by the author of it, Mr. Angiolo Slons, well and widely known as the author of the first T. P. Cooke prize drama, "True to the Core," and several other successful pieces. The prize drama, by the way, added many hundreds of pounds to the funds of the Dramatic College. "Waldeck" is a very charming production, poetic and dramatic, written in a high tone that is well sustained throughout, and we cannot avoid expressing a hope that a manager may soon be found to place it properly upon the stage. It would need three actors and one actress of high class. The siege of Leyden, it will recur to our readers, which was sustained against the Spanish forces, more than 6,000 of the inhabitants dying of famine and pestilence during the investment, took place in the year 1574. The play it has given rise to is a worthy addition to the dramatic literature of the country.

STAINED GLASS.

Winslow Church.—A stained-glass memorial window has been fixed in the parish church of Winslow, Bucks, erected by Mrs. Miles, in memory of the Rev. J. Miles, B.D., late incumbent of Holy Trinity Church, Paddington. There are four lights, a subject in each, viz., The Agony in the Garden, the Crucifixion, the Resurrection, and The Ascension. The work was designed and carried out, by Mr. A. J. Mingay, of London. Lady Huntingdon's Church, *Cambridge Wells*. A memorial window, 22 ft. high by 11 ft. wide, in the Decorated style, containing five openings, with subjects in nearly life-size figures, has been put up in this church by Messrs. William Holland & Son, of Warwick, stained-glass artists. In the three centre openings the subject of "Our Saviour blessing little children," forms a picture, in nearly life-size figures. In side lights are—"Christ as the Tender Shepherd," "Our Saviour placing a Child in the midst of his Disciples," and under each of the above subjects, forming the pedestals, are the following:—"Jacob blessing Joseph's Children;" "The finding of Samuel;" "Eli brought to Samuel;" "The Israelitish Maid;" and "Timothy taught the Scriptures," under canopies. In the tracery are "Angels playing upon musical instruments," with smaller openings filled with Gothic ornament. The inscription states the window to be in memory of T. A. Gibb. A rose window has also been inserted by the same artists in this church as a memorial. The subject is,—"Eli and Samuel," surrounded by "Angels playing upon musical instruments," and ornamented with monograms. Two smaller rose windows have also been filled with Gothic floriated ornament and monograms by the same artists.

Durham Cathedral.—A stained-glass window, designed and executed by Mr. Wailles, of Newcastle-on-Tyne, has been fixed in the north aisle of this cathedral. The window has been provided at the cost of Mrs. Malby, as a memorial of her husband, the late Canon Malby. It is divided into three circular medallions, each one being filled with figures, and surrounded by conventional foliage; while round the whole runs a border composed of the Norman zigzag and leaves. The subjects in the medallions are as follows: in the upper one is represented Our

Lord in three characters,—in the centre as a Good Shepherd, bearing in his right hand a pastoral staff, and in his left a lamb; on the right he is leading a young child by the "still waters of comfort," and on the left guiding him through the "valley of the shadow of death," shown by a lion and serpent ready to devour him; in the centre circle Our Lord is represented holding a little child, "For of such is the kingdom of heaven;" the third and lowest medallion shows Our Lord giving His people into the charge of St. Peter. Across the bottom of the window is an inscription, "To the glory of God, and the memory of Henry Joseph Malthy, canon of this cathedral, and his sons, Charles Bradford and Ralph Howard. He departed Nov. 24th, 1863.

Horspath Church (Oxford).—The east window of this pretty little church has just been filled with stained glass at the cost of the Rev. H. R. Bramley, Fellow of Magdalen College. The style of the window is Perpendicular, and consists of three openings and tracery. The subject is the Crucifixion, in the centre our Lord on the Cross, with Mary Magdalen kneeling at the foot; and the side openings are filled with the Marys, St. John, and Salome. The group is surmounted by a canopy. In the tracery are depicted figures of St. Frideswide, St. Giles, St. Mary Magdalen, and St. John the Baptist. The window is the work of Mr. G. Baguley, of Newcastle-on-Tyne.

SCHOOL-BUILDING NEWS.

South Shields.—The newly-erected day-schools in connexion with St. Mary's Church, South Shields, have been opened. The building is constructed of red press bricks, with fire-brick facings. The school is situated at the head of Dock-street, Tyne Dock, and is within a few hundred yards from the church. The building is divided into three departments—girls', boys', and infant school-rooms. The entire length of the front of the school is 130 ft., by 60 ft. in depth. The height in the interior is 17 ft. from floor to ceiling. The roof is open timbered. There are three separate play-grounds, with laboratories, drinking-fountains, &c. The school-rooms are lighted with gas. The origin of the schools is due to the North-Eastern Railway Company, who contributed the sum of 1,213l. 6s. 1d. towards their erection. A large number of their workmen are located in the neighbourhood of Tyne Dock. The plot of ground on which the schools have been erected was presented by the dean and chapter of Durham and Mr. Ald. Williamson. The architect of the North-Eastern Railway, Mr. Prosser, designed the building, and gave his services gratuitously, Mr. Thomas Robson, South Shields, was the builder; Mr. J. Hall, the plumber; Mr. Edwards, the painter; and the ironwork was done by Mr. Hepple, of Gateshead. The estimated total outlay is 2,940l. 2s. 6d.

Newcastle.—The New British Schools, Tyne Dock, and also St. Mary's Church schools, have been formally opened. Both institutions are indebted to the North-Eastern Railway Company for assistance in the shape of money and of the gift of the ground. Of the 1,210l. collected, however, the workmen of the company themselves have contributed 230l. The Government have agreed to grant 588l., making a total of 1,798l. collected. The building and fittings will cost 2,250l. The schools are designed in the Medieval character, freely treated, without pretensions to ornamental details. An effect is obtained by the use of fire-bricks around the windows, doorways, and chimneys, in contrast with the red bricks of the walls. The plan of the building is nearly the form of the letter H, the boys at one end, the girls at the other, and the infants in the centre. Mr. T. Prosser, of Newcastle, was the architect; Mr. J. Scott, clerk of the works; Mr. R. Bates, the builder; Mr. J. G. Weir, the painter; Messrs. Walker & Emley, Newcastle, the plumbers; and Mr. Thomas Coulson the glazier.

Stockport.—The contract for the erection of a building in the Market-place, on the proposed site of the Bank of Stockport, has been let to Messrs. J. & J. Longson, of Stockport, from designs prepared by Mr. T. A. Allen, of Stockport, architect. It will command two fronts, one to the market and the other to the Underbank Bridge. The building, which is in what is called the Grecian-Italian style of architecture, will be four stories high, including the basement, having a stone front up to 25 ft., the remainder

being finished with stone dressings, enriched with stone pilasters and ornamental caps and moulded bases, cornice, and blocking stone, and decorated cantilevers underneath. There will be six windows looking into the Market-place, and sixteen to the bridge, the main entrance being from the bridge, each side of the door being supported by polished Aberdeen granite shafts, with carved Corinthian capitals, and a representation of the borough arms. The door opens into a vestibule, 8 ft. wide, the directors' room, 18 ft. by 16 ft., being on the left. The banking-room, which will be lofty and commodious, will measure 40 ft. by 25 ft. The ceiling will be arranged in panels.

Heckmondwike.—Alterations in the way of paving the market-place, laying new causeways, building a market-house and weigh-house, and several other conveniences in connexion with the market here, have taken place from time to time, but the new market is now complete, and a movement is on foot for the opening ceremony. Three triumphal arches are to be erected at the three entrances into the town, and the directors of the gas company have decided to supply gas gratis for the illumination of the market. Prizes are also to be given for the best show of butchers' meat, vegetables, &c.

Books Received.

Book of Designs for mural and other Monuments. JAS. FORSYTH, Sculptor. 3rd Edition.

IN this new issue of Mr. Forsyth's book the designs have been revised and drawn on stone by Mr. R. K. Thomas. In the preface to it the sculptor acknowledges the assistance of various architectural friends in the preparation of it. We should prefer to find the designer of each monument named. Mr. Norman Shaw, Mr. W. Smith, and Mr. R. H. Carpenter are amongst those, as we understand from Mr. Forsyth, who have contributed to the collection. It is the best work of the kind that we know of.

VARIORUM.

MESSRS. DEAN & SON have published "Debreit's Illustrated Peerage," and "Debrott's Illustrated Baronetage, with the Knightage," for the present year. The Peerage claims to be the oldest handbook extant relating to the upper classes. Containing, as is asserted, 200,000 facts, its general correctness must be deemed remarkable. Through these works, says the editor, with justice,—

"We learn of our public men, their seats, residences, and clubs, their marriages, their place of education (with University degrees), their children, their Church patronage, their services, their appointments in the army, navy, learned professions, and every particular of interest."

—Mr. Hardwicke sends forth his "Shilling Peerage," "Shilling Baronetage," and "Shilling Knightage," for the year, and also publishes the three together in a smart little volume, under the title of "Hardwicke's Crown Peerage for 1868." The fact that these are compiled by Mr. Edward Walford, M.A., is sufficient to assure us of their general correctness.

Miscellaneous.

LIVERPOOL WATER SUPPLY: THE BALA LAKE SCHEME.—The idea of obtaining a water supply for Liverpool from Bala Lake is still favourably entertained by many of the local council. At a recent meeting of the Water Committee of the Town Council several members expressed the opinion that instead of spending 100,000l. on additional works at Rivington and on works at Dudlow-lane, it would be much more advisable to obtain powers to spend from 2,000,000l. to 3,000,000l. upon a scheme to obtain water direct from Bala Lake, in order that the supply to Liverpool might be continuous both for present and future wants. After some bound to proceed chairman stated that they were bound to proceed with the works sanctioned by the council; and that if economy were exercised, and the present system of water-closets recommended by the council were not "pushed too far," there might be a sufficient supply from existing sources for the next twenty years. During the last two or three years the rain-fall at Rivington had been very slight in comparison with that in the districts of the Ribble and the Lane.

THE DISCOVERIES IN PALESTINE.—In a lecture on this subject at the Crystal Palace last week by the Rev. Chas. Boutell, the lecturer said a letter had just been received from Lieutenant Warren, in which he announces that he has discovered two new arches of 23 ft. span west of the west of the two arches of 14 ft. span to the west of Wilson's arch, and also a long vaulted passage leading towards the Yaffa gate. He has traced this for 120 ft., the masonry being carefully hewn. A flight of steps has been discovered at the Bir Eyhub, and a new tank north of Robinson's Arch.

THE IMPROVEMENTS AT LUDGATE-HILL.—On Tuesday the Commissioners of Sewers held a meeting at Guildhall. The clerk read a letter from the Metropolitan Board of Works, stating that they had voted in aid of the Mansion House improvement the sum of 7,354l., and in aid of widening the west end of Ludgate-hill the sum of 11,756l. A long discussion ensued as to the propriety of setting back several houses on the south side of Ludgate-hill, and it was eventually resolved that, having regard to the importance of the improvement contemplated, notice be immediately given, under the powers of the Act of Parliament, to take the whole of the premises and property connected therewith at such a sum as a jury may award, for the purpose of continuing the improvement on Ludgate-hill.

THE UNWHOLESOME STATE OF COURTS OF JUSTICE.—It is strange that the frequent complaints of Judges as to the state of the Courts in which they are called upon to sit are so little heeded. Mr. Justice Mellor, who presided over the civil side of the Northumberland assizes, has been complaining sorely of the state of the Court-room in the Moor-hall, Newcastle. About an hour after the opening of the assize, his Lordship said he should be obliged to adjourn the Court. He was nearly suffocated, and was badly seated. His desk was so far from his chair that he had to lean forward to take his notes, and the Court was overpoweringly hot from the steam, which rose directly under his feet! It was perplexing to have to attend to a case while suffering the abominable inconvenience of being half-baked. He had before made the same complaint, and unless the county magistrates made the place suitable for holding the business, he should have either to stop the business or to adjourn to another place. He should fine both the under-sheriff and the county surveyor if something were not done.

SALE OF THE BRIGHTON WORKHOUSE ESTATE.—The most valuable portion of the old workhouse site has been sold by auction. The ground being restricted to the erection of villas, the sale-rooms were well attended by both private and speculating purchasers, the latter predominating; and, with the exception of three lots out of twenty submitted, comprising thirty-eight plots, the whole was knocked down to the "trade." This was the only opportunity of obtaining land for villas in the centre of the town and away from the bustle of Brighton, commanding a view of the sea, the Downs, and the town; it is in close proximity to the railway and parish church; and abuts on to one of the principal pleasure-rides and drives in the borough, namely, the Dyke-road. The sales were all *bona fide*, the reserved price being exceeded in each case, and the aggregate amount realized was 1,000l. above the estimated value. The principal lot in the sale is situated at the corner of the Dyke-road, where the latter is intersected by Buckingham-road and Powis-grove. It has a frontage in the Dyke-road of 67 ft., and in Buckingham-road of 92 ft., being 79 ft. 3 in. in width at the east end, with an average depth of about 95 ft. The first offer was 650l., and, after some lively bidding in 10l. advances, Mr. George Attree, auctioneer, North-street, became the purchaser at 800l. With the exception of two single plots, two houses may be built on the several lots, of the value of 600l. each, but not more than two; but it is at the option of the purchaser to build one only, provided that it be of the value of 1,000l. The total amount realized was 12,125l., being nearly 3,000l. over the sum obtained in either of two previous sales. By the first sale, 8,755l. were obtained, and 9,465l. by the second; making an aggregate, with 1,179l. for the old buildings, of 31,524l., already realised for this land, verifying the calculations made by the guardians, that the parish would get its new workhouse for nothing: and the land is not yet all disposed of.

ARCHITECTS' BENEVOLENT SOCIETY.—We would direct attention to the circumstance that the annual meeting of this useful society will be held in the Rooms of the Institute, 9, Conduit-street, on Wednesday, the 11th instant, when it is hoped members and friends will attend numerously. The society is scarcely supported to the extent desirable.

THE HAMMER OF HAMMERS.—M. Krupp is about to construct at his works at Essen (Prussia) a single-acting steam hammer, far exceeding in size any now in existence. The design for this hammer—which will have a head weighing 129 tons—has already been prepared, and the patterns are now in hand. At present, the largest steam-hammer at M. Krupp's establishment is one with a 50-ton head, falling 9 ft. 6 in.

FATAL ACCIDENT AT A MANCHESTER BRICK-KILN.—The Manchester city coroner has held an inquest on the body of a young man who was engaged in getting bricks from a kiln, at the brickyard of Messrs. Johnson & Livesey, at Gorton, when a number of bricks fell upon him, and he sustained such severe injuries that a verdict of "Accidental death" was returned.

MORE FEVER AT THE MAURITIUS.—A regiment has just been thrown into a terrible fever at the Mauritius, because, as is asserted, the colonel was disinclined to undergo the inconvenience and discomfort of a return voyage to the Cape. The general and medical officers at the station remonstrated against the landing; but the colonel's convenience and comfort gained the day. The men were landed, and fever soon crept amongst them. The number of cases was increasing when the last mail left. The case has been mentioned in Parliament, and Sir J. Pakington, Secretary of War, held that the landing was reprehensible.

GAS.—The Belper Gas Company have declared their usual dividend at the rate of 10 per cent. per annum.—There is a strike at Malmesbury against the price of gas. The price charged is 6s. 6d. per 1,000 cubic feet: the consumers say it ought not to be more than 6s., and to bring the Company to terms they have reverted to the use of lamps and candles.—The Sudbury Paving and Lighting Commissioners have agreed to reduce the price of gas 3d. per 1,000 (from 6s. 3d. to 5s. 6d.), and make a further reduction of 6d. per 1,000, as soon as the consumption is increased from 6,000,000 to 7,500,000, without the public lamps. The great majority of the gas consumers have engaged, it seems, to take gas for five years of a new company at 4s. per 1,000 ft., and it is believed the reduction to 5s. 6d. will not satisfy them. A practical engineer had offered to produce gas at 4s. 6d. per 1,000 ft., and give the shareholders of either the old or new company six per cent. Mr. Burke, of the Anberley, who is chairman of the Imperial Gas Company, is about to erect new works for his house, and says the gas, after allowing interest of outlay and all other charges, will only cost him 4s. per 1,000 ft.

RESTORATION OF CHESTER CATHEDRAL.—Estimates have been obtained from Mr. Christian and Mr. Scott, of the cost of repairing and restoring this edifice, as follows:—Necessary repairs, 22,531l.; desirable repairs, 7,000l.; improvements, 20,000l.; total, 49,531l.; add architect's commission, 5l. per cent. (2,500l.), 52,031l. The "desirable repairs" include flying buttresses, restoration of cloisters, King's school, and bottom stage of west Norman tower, with lead instead of slate on the roof. The "improvements" include stone groining of the nave and aisles, restoration of the tower and spire, internal cleansing and repair, and complete restoration of the choir. No special fund is provided by the foundation or the Ecclesiastical Commissioners, for repairs or other contingencies. The Dean and Chapter have usually set apart from 300l. to 500l. annually for this object. By this means a sum of nearly 1,500l. had been accumulated in the course of ten years, which it had been intended to apply to the restoration of the fabric. It has, however, been applied to the purchase of the new bells, 500l.; to the warming of the cathedral, 500l.; to the fittings of the nave and other expenses connected with the special evening services. The entire cost of these has been 2,100l., so that there is a deficit on this head of 600l., to the met out of the annual revenue of the chapter. There is now no fund for the restoration or repair of the cathedral building.

NUISANCES.—A nuisance against which the Court of Chancery will grant an injunction must be a material injury to property, or to the comfort of the existence of those who dwell in the neighbourhood. This was the holding of the Court of Appeal (reversing a decision of Vice-Chancellor Stuary) in the case of Lucombe v. Stier, where it was remarked by one of the Lords Justices, that in such cases as these, the recovery of a verdict at law does not necessarily entitle the plaintiff to an injunction; but the fact that there is legally and technically a nuisance must be considered, together with the amount of damage, and the duration of the nuisance complained of.

LONDON LABOURERS' DWELLINGS SOCIETY.—At the thirteenth half-yearly meeting of this society, held last week, the directors presented their report for the six months ending December 31st, and the usual dividend at the rate of 5 per cent. per annum, free of income-tax, was declared. The capital of the society now amounts to 31,900l., the sinking fund (for the redemption of the leasehold property of the society) to 927l., and the reserve fund (for the equalization of dividends, or extraordinary expenses) to 9,887l., of which sum 1,500l. are deposited at interest in order to provide the means of purchasing temporarily at par any shares that a member may from unforeseen circumstances wish to realize.

THE AMALGAMATED SOCIETY OF CARPENTERS AND JOINERS.—Mr. Hughes, M.P., presided on Wednesday evening at a meeting held in the Arundel Hall, Arundel-street, convened by the Amalgamated Society of Carpenters and Joiners, "for the purpose of presenting the accident benefit of 100l. to each of two members of the society who, through affliction, have been rendered incapable of following their employment for life." The Chairman said, they were aware in the principles of trade societies were being inquired into by a royal commission, and if they had been called together to consider the question of trade unions, it would not have been proper for him to preside that evening. The questions involved in trade unions they would not go into that evening. They were present for the purpose of presenting 100l. to two of their members, that sum being the reward of George Burford was a resident in the hospital he had the honour to represent. Whatever the action of trade unions had been, societies like the Amalgamated Society of Carpenters and Joiners had done a great deal of good for the working classes in the hour of need.

TENDERS.

For villa residence to be erected upon the Albert Park, Abingdon, for Mr. E. Harries, Mr. Edwin Dobby, architect. Quantities not supplied.—

Table with 2 columns: Name and Amount. Includes Dover (21,300 0 0), Thomas (1,068 0 0), Selby (1,620 0 0).

For two villa residences, Wilmshor, Cheshire, for Mr. John Beaumont, Messrs. Eiston, Chambers, & Bradley, architects. Quantities supplied.—

Table with 2 columns: Name and Amount. Includes Bowden & Edwards (23,245 0 0), Neil & Sons (3,220 0 0), Gotthard (5,300 0 0), Thompson (3,275 0 0), Hughes (5,160 0 0), Royle & Mallor (2,950 0 0).

For erecting a dwelling-house and shop in Old-street, St. Luke's, for Mrs. Brain. Mr. Thomas J. Hill, architect.—

Table with 2 columns: Name and Amount. Includes Chessum (21,167 0 0), Rivet (1,023 0 0), Moreland & Burton (1,085 0 0), Perry (1,063 0 0), Henshaw (1,620 0 0), Ennor (871 0 0), Saley (931 0 0).

For alterations to White Horse Tavern, Fann-street, City. Mr. Thomas J. Hill, architect.—

Table with 2 columns: Name and Amount. Includes Fosse (4,340 0 0), Perry (335 0 0), Corbeldick (301 0 0), Tegg (237 0 0).

For new warehouses and offices, No. 61, Coleman-street, for Mr. Charles Tinserton, Mr. G. J. Lee, architect. Quantities supplied by Mr. T. R. Nixon.—

Table with 2 columns: Name and Amount. Includes Colls & Co. (22,180 0 0), Adamson & Son (2,137 0 0), Axford & Co. (2,100 0 0), Hart (2,060 0 0), Rider & Son (2,877 0 0), Winder (2,071 0 0), Gammon & Son (2,600 0 0), King & Son (2,471 0 0), Wells (2,460 0 0), Hill & Keddell (2,425 0 0), Conder (2,222 0 0), Wills (1,875 0 0), Crabb & Vaughan (accepted) (1,848 0 0).

For new 'stabling, Avenue, City-hill, Lower Newmarket, for Mr. J. W. Stelfox, Mr. G. J. Lee, architects.—

For alterations and additions to Fower Cottage, Kenton Town, to adapt the same as a Work Office for District No. 1, and a Labour-yard for the Parish of St. Pancras, Mr. E. C. Robins, architect.—

Table with 2 columns: Name and Amount. Includes Waters (22,400 0 0), Keeble (2,160 0 0), Palmer (2,167 0 0), Brass (2,419 0 0), Abbott (2,654 0 0), Till (2,026 0 0), Heming (2,000 0 0), Crockett (1,806 0 0), Newman & Mann (1,980 0 0), Crabb & Vaughan (1,888 0 0), Nightingale (1,873 0 0), Layley, Bros. (1,870 0 0), Kelly, Bros. (1,853 0 0), Mann (1,840 0 0), Nutt & Co. (1,790 0 0), Sorvener & White (1,789 0 0), Manley & Rogers (1,782 0 0), Sharpington & Coles (1,777 0 0), Thomas & Son (1,735 0 0).

For erecting a pair of semi-detached villas, at Hitchin, for Miss Hall. Mr. J. Chalcock, architect.—

Table with 2 columns: Name and Amount. Includes Butterfield (2,740 0 0), Jeeves (735 0 0), Stapleton (731 0 0), Ansell (719 0 0), Allen (accepted) (672 0 0), Allen (accepted) (670 0 0).

For alterations to 55, Old Broad-street, City, for Messrs. Somes, Bullock, & Co. Mr. Woodcock, architect.—

Table with 2 columns: Name and Amount. Includes Quantities supplied by Mr. G. Evans (1,935 10 8), Johnstone & Jeane (1,897 0 0), Gammon & Son (1,870 0 0), Carter & Sons (1,870 0 0), Piper & Wheeler (accepted) (1,824 0 0).

TO CORRESPONDENTS.

Agricultural Hall, Walsley.—The architect is Mr. O. B. Nichols. W. F. J. H. H. R. R. P. & Co.—I. O. R. J. W. P. & K.—L. M. H. C. P. J. P. P. H. W.—W. H. S. J. B. T. K. T. H.—Nestman M. G. B. A. M. R. (consult a proper person on the spot)—J. B. (next week).

NOTE.—Architects who are unwilling (as we are) that their names should not accompany lists of tenders with which they are concerned, may prevent the omission by sending a late themselves. We cannot repeat lists on the ground of such omission. We are compelled to decline pointing out books and giving addresses.

All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not to be casually for publication.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

TO SUBSCRIBERS.

NOW READY, THE TWENTY-FIFTH VOLUME OF "THE BUILDER" (bound), for the year 1867, price One Guinea.

CLOTH CASES for binding the Numbers, price Two Shillings and Ninety pence.

COLOURED TITLE-PAGE, Gratis.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of Three Shillings and Sixpence each.

Advertisements cannot be received for the current week's issue later than THREE o'clock p.m., on THURSDAY.

The Publisher cannot be responsible for ORIGINAL TESTIMONIALS left at the Office in reply to Advertisements, and strongly recommends that COPIES ONLY should be sent.

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent Garden. All other Communications should be addressed to the "Editor," and not to the "Publisher."

[ADVERTISEMENTS.]

CHURCH, TURRET, and STABLE CLOCKS. J. W. BENSON, having erected steam-power and improved machinery for clock-making, at the Manufactory, Ludgate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machines, especially cathedral and public clocks, chiming tapes on any number of bells. A descriptive pamphlet on Church Clocks post free for one stamp. Watch and Clock Maker by Warrant of Appointment to H.R.H. the Prince of Wales, and maker of the great clock for the Exhibition, 1862. 25, Old Bond-street, and 33 & 34, Ludgate-hill, E.C. Established 1749.

The Builder.

VOL. XXVI.—No. 1310.

Waste, Want, and Work.

ERTAINLY that intelligent foreigner who is always telling us that we are a difficult nation to understand, would be more puzzled than ever should he happen to be amongst us at this moment. London at this time offers a most singular philosophical study in what we will call the anomalies of civilization. Fourteen thousand people are living on the bread of charity at the East, whilst wealth and gaiety revel at the West. The "distress at the East-end" has become an annual crop, and, if some course "short, sharp, and decisive" be not taken, the state of affairs at that part of town will become one of the institutions of the country. Its influence is spreading and acting in an attractive manner; the tramping vagrancy of England is rolling towards the east, attracted by the very largeness of the charity that is hating with the native distress. Guardians are becoming helpless and paralysed, whilst the crew of *The Poor-law Board* are clearing the decks for action as against a second Lancashire famine. With respect to the staff that guardians are made of in general, and East-end guardians in particular, we must not be over-nice, nor expect too much. We dare say that Shadwell, Stepney, Poplar, and Bethnal-green acted as was their nature, and according to the light that was in them. Still, the wall of misery rose high, and the waves of destitution spread until a province in miniature was threatened to be engulfed. The question now is, what can be done for the permanent relief of the East-end? Let us look around us and see;—face the danger firmly.

A large army of the Will-nots, with a sprinkling of the Can-nots, is broken up into small detachments of fours and sixes, who parade the streets of the metropolis every day. We can hear them at this moment shouting their war-cry—"We've got no work to do!" From recently instituted inquiries, the proper rendering of the text in most instances should be—"We want no work to do." They generally disappear early in the afternoon, when, it is presumed, they have managed to scrape up enough to keep body and soul together until next day; and so they go on. This is a solution of the labour question that was never expected either by statesmen or philanthropists; a gradual gathering of all the able-bodied vagrancy of England into London every winter, to locate at the East-end, and extract a livelihood by the "got no work to do" plan, should everything else fail. Here we have the Lancashire abuses over again, and we must safely affirm that were work suddenly to become plentiful there would be an enormous percentage of this class of men who would not go near it as long as they could obtain a hand-to-mouth kind of existence by howling about the streets.

"How would you remedy it?" we fancy we should hear some one ask. Nothing could be easier if the public wished to be relieved from the double nuisance of the annoyance and scandal; and now is the time. If we are to have a "rate in aid"

for the special purpose of stemming East-end starvation, let us also have a "law in aid" for the purpose of stemming general able-bodied vagabondage.

London wants a new water supply that must come some time, either during the present generation or the next. London, too, is in process of rebuilding, and its highways and byways want increasing and widening and straightening. The water supply has been estimated at about seven millions, and the lines of communication for the metropolis would, for the next few years, absorb three millions more. Well, now, as posterity, which is on the road of the future, will find upon its arrival all these works for its benefit and enjoyment, minus the trouble and annoyance of making them, would there be any unfairness or unsound statesmanship in banding over to the said posterity a part of the cost along with the work? We think not. We have started this question as an argument amongst those whom the world recognises as "competent men," and have heard it warmly debated. We have heard Mr. Gladstone's widely-spread axiom quoted and—perverted. Reasoning by analogy is very pleasant cantering when you have a good level road, and the analogies run with their heads well together. It reminds one of the donkey-horsed, bare-back rider of the sawdust ring. As long as the wild steeds continue doing the stride nose to nose, so long will the rider perform you any number of amazing tricks; but let one steed only give a snort, shake his head, and throw back his ears, and you will soon see that the "hare-hacked phenomenon" has something more serious to attend to than dancing "Rob Roy" or "Tam O'Shanter" on the unsaddled one. So it is with people who take up the occasional Sibylline verses of ministers and ex-ministers, and imagine that such verses can be made by "analogy" to dovetail into anything that may be handy.

The story goes that Mr. Gladstone has laid it down as a State-finance axiom that every generation ought to pay its own expenses, and leave a clear ledger for the new-comers. No doubt but that, in the way which the ex-Chancellor of the Exchequer meant, the axiom is true enough; but to distort it and twist it into every possible shape and for every possible purpose, is both mischievous and absurd. As a great principle is involved in the proposition here laid down in reference to this very East-end labour question, it will be as well to be clear upon the point. The expenses of a nation, as of an individual, may be of many kinds, and may resolve themselves into the ephemeral and the permanent in the results obtained. For instance, the man who expends 500*l.* in a grand entertainment, is not in the same position as the man who buys a house with the money. When the money is expended and the feast eaten, the results are ephemeral; but with the man who has built the house the results are permanent, for the house has become property, and, when tenanted, will immediately begin the repayment of its cost. We are here assuming all other things to be equal; that is, that the first man could have done without the feast, and that the second man might have spent his money on some passing pleasure with a similar conclusion, and have been "no worse off."

Now, we will suppose that both these imaginary gentlemen have "posterity," and that they borrow 200*l.* each, shortly after spending which they die. But, the owner of the house has laid out his money in the enlargement and improvement of that "homestead," whilst he of the grand feast has merely supplied an unforeseen want, which some of the feast money would have provided had it not been all disposed of. Well, the "posterity" of each comes in for what is left. Surely the heir of the 700*l.* house can well afford, and would have no room to grumble to take up the 200*l.* mortgage to clear that

which he would not only enjoy himself, but would even pass on to his "posterity." The other party would not be in so good a position, because he would have to contribute towards the expenses of the spread of which he knew nothing, and could not possibly enjoy anything. It was ephemeral; it had passed away, and its pleasure with it; whilst the house on the opposite side of the question was in existence, paying rent, and would be permanent. And this brings us to the question of a rate in aid and public works in connexion with East-end, or any other chronic distress. There is no new political truth stated here; it is "as old as the hills," has often been used for other purposes, and elucidates the well-known principle of improving an hereditary estate, as the Marquis of Westminster is now doing in Pimlico, and many others are doing elsewhere. But there are many persons whose opinions on general subjects are entitled to much respect, who get on the back of some public man's dictum; they want every saying of their own to fit into the same harness, no matter what the difference may be, round or square, and, as they drive along at an immense rate, amid a perfect shower of flying sawdust, they exclaim,— "This is what we call 'reasoning by analogy!'"

We have at this moment a vast amount both of real and simulated destitution eastwards; an amount that has evoked a corresponding quantity of the charitable honny of the west. Such money is bringing no useful return; it simply feeds a large number of persons who are, perforce, idle; it is like that of the grand feast, will leave no permanent value behind it, beyond that of stemming starvation, which, we will admit, is something when taken by itself, but only then. Well, but employment for the same money would also stem starvation, and, like the outlay on the house already mentioned, would leave something permanently profitable behind it.

London wants re-arranging and re-whetting. Is it too much to ask that a rate-in-aid be established for the work,—to make a beginning,—and that it be so apportioned as to make "posterity" in due time pay a fair share of the cost of the regenerated and improved metropolis, which will be theirs as soon as they are ready for it? Why should we labour and smile not, nor rejoice, for the exclusive benefit of the ladies and gentlemen of the posterity train, and they to have nothing to pay? The principle is unsound and one-sided. We are aware of the argument on the other hand, that if ancestry had paid for all it had as it went along, we should not now be harassed in scraping up twenty-six millions a year as interest for the national debt. Our answer is, that ancestry should have attended to its own affairs, especially during the political dramatic era that was closed by the falling of the curtain of 1815. Ancestry sent its sons and its money to be wasted in war for people who despised it, who have long since repudiated being under any obligation whatever for such friendship, who have borrowed our gold and laughed in our face when payment was mentioned, and who have treated us very much like "the commonest dirt," whilst the posterity of the very people we tried to blow off the face of the earth are our fastest friends.

In 1826 we had to deal with a large area of distress, especially in the north-west, and public road-making was resorted to. The population of England and Wales at that time was about 13,000,000, more or less, whilst the total of the metropolis, suburbs included, was a little over 1,225,000. Profitable work had to be found then, and profitable work must be found now; the country is wealthy enough, and with some extra safeguards, the plan here sketched would be the most economical. A discussion has recently been going on about the income of the nation, and it has turned out that we have, as disposable money, every year, the enormous sum of 825,000,000*l.* Now it must

seem plain that if the nations of Europe would only agree to furl the flag of glory, and let the banner of peace permanently wave in the former's place, we could, all of us, do a great deal more in the way of preventing our several east-end distresses than we can now.

The first thing to be done is to ascertain from competent persons the more pressing improvements that are required in the metropolis, and obtain plans and estimates. Running on all fours with this, let a list of all the able-bodied men and boys applying for relief be made out; their age, where from, trade, how long in the present abode, when last at work, &c. In the meantime, Parliament must pass a *thorough, uncompromising Vagrancy Suppression Act*; one that can be unparaphrasedly applied to man, woman, and child, the hale, the lame, and the blind; one that could neither be evaded by the "We've got no work to do"ers, nor the "Fusses, a half-penny a-box" ontastors. All flimsy and colourable pretences for cadging, whether with a child in each arm, or three at the heels, should be relentlessly put down—down. The administration of our vagrancy law is not creditable to us. It is absolutely scandalous that the philanthropy of a private nobleman has to do the duty of the police in the conviction of barefaced street imposture. In no capital in Europe, and in no large towns, either in England or the Continent, does vagabondage and street ruffianism run the course of unchecked riot that they do in London. But, as the further consideration of this part of the subject at present would lead us out of our way, we will proceed in our proper direction.

Having got our organization of relief and repression complete, we might then begin to cope with the evil of distress and mendicancy, and to reduce it within reasonable limits. The infantile and the infirm aged should be cared for; but, with respect to the rest, work, unflinching work, or cruel, confinement, and hunger. When the "do-no-workers" begin to bawl their rounds, let them be immediately taken before the magistrate, and compelled to render an account of themselves. If they really had no work to do, send them where some could be had, if they were able to do it, and let very moderate wages be paid to them. With respect to the rising generation, who, half-naked and ignorant, infest our footways at every step, let them be all taken charge of, their parents, if any, "hunted up," and made answerable for their future good conduct, and those who have no friends put in the way of being trained. Can anything be more disgraceful than the fact of a whole army of vagabonds of all ages, amounting to many thousands, being permitted to render dangerous and almost impassable the principal thoroughfares of the metropolis of the world, and steadily recruit the ranks of the dangerous classes? It seems most belief; but it is so, and that, too, in the face of several Acts of Parliament, specially directed against such lawlessness.

When we have set up such an organization as this in motion, we shall have made a beginning towards the subversion of chronic East-end distress, and London vagabondage and street-rascality generally. Every able-bodied person, on applying for relief, whether to the parish or to private charity, should be able to read over the portals, "Work or Starve." But the work should be of a kind that would not uneducate the skilled, delicate hand, as it were, when the day of employment arrived. For instance, stone-breaking and oakum-picking would be almost permanent destruction to the highly-trained fingers of the scientific instrument maker, or in the more nicely-fitting parts of mechanical engineering. If a man has a wife and family, the public work wages resulting from a fair amount of industry should be sufficient to enable them to keep the Englishman's much-cherished home together until better work could be had. Another thing,—strict classification should be carried out, and decency enforced: the rough to the rough. The common language of a certain portion of the labouring classes, when they are conversing by themselves, is shocking in the extreme; oaths and abominable expressions nickerate every sentence. They are not entirely to blame for this. The want of an established system of national education for the children of the poor, the absence of a sound moral tone in the shop or the yard when the age of labour begins, the apparently utter indifference often shown towards them by those in whose interest they labour, and the wretched dens wherein they live, must be taken into account.

In consequence of the abundance of money that is finding its way from voluntary benevolent pockets to the scenes of suffering, the East-end is being literally flooded with the life-trained vagrancy of all England,—nay, to such an extent has this unexpected tide of cadgerly set in that single rooms in small tenements have risen in the market! Surely this ought to be put a stop to. Those who belong to the regular tramp-locust tribe may be refused relief of any kind beyond what will carry them out of the district. But then, in the absence of a common-sense vagrant law, see what a legion of rascaldom and imposture you turn loose all over the town! The seventy odd square miles of which London proper is composed would have gangs of "got no work to do" in every decent thoroughfare, whilst the "starving mother," with the twin babies that never grow bigger nor older, would bristle at every street corner. On the other hand, if the professional tramp and impostors knew that work of some kind must be done, that the streets were closed to their imposture, they would soon take some other course.

Whatever aspect this periodical East-end distress may ultimately assume, it will never do to feed twelve or fourteen thousand people every "now and then" winter without any productive result. If it be done, and some system of public labour be not organised with the heavy-handed repression of pure vagrancy, the East-end of London will be turned into the regular winter quarters of unmitigated imposture. The time to begin is now; sketch out the works that will be most useful, and have a commencement made as soon as practicable; let every able-bodied "distressed" know that—
"HE THAT WILL NOT WORK NEITHER SHALL HE EAT."

RAILWAY BOARDS, CONTRACTORS, AND SHAREHOLDERS.

It is a happy peculiarity of the English character that enables us to turn to good account a force which, in other countries, is for the most part merely disturbing or morious. We mean the force of public dismay. We have acquired the habit, first fully established during the Crimean war, of turning on any questionable points the full light of complete investigation. This method may be branded as commercial; it may be decried as forming no part either of the admitted government of the country, or of the organisation of the people in relation to their government. Still it exists, and not only so, but it answers its end. No doubt it was for the commercial purpose of increasing the sale, and augmenting the advertising power of the daily journals, that their proprietors went to the cost of sending educated men to procure reliable information wherever subjects of public interest were to be described. But the result has been far more than private utility. Exposures have become a terror to evil-doers in all directions. Very much, indeed, has yet to be done in the way of systematic searching for abuses; but let the abuse be of a certain magnitude, unconnected with political party or with great interests, and once brought to light, the investigation is likely to be probing and final.

For more than twelve months past the full force of public dismay has been brought to bear upon our English railway system. Not the full force of investigation, for as we write evidence is slowly collecting by Mr. Commissioner Winslow of a more reckless and unsparing mode of dealing with the property of deluded shareholders than has yet entered into the imagination of the most active Bear. A contractor quietly states that in September, 1866, he took certain works at the high prices which are likely to be imposed on those lines which pay for their construction not in cash, but in stock. In October of the same year these prices seem to have been augmented by some 20 per cent. Then he was allowed a commission of 25 per cent. for "placing" these shares. "He knew that in August, 1862, the A and B shares were treated as paid. That was subject to the deduction of 25 per cent. commission. In July, 1862, he proposed that he should receive a rebate of 50 per cent. upon the A shares in consequence of an agreement to postpone them. The directors replied stating that, however much they might regret the loss, they had no other course than to recommend the board to accept the offer. The rebate of 50 per cent. was in addition to the commission of 25 per cent., but under

existing circumstances the witness considered the arrangements fair and equitable."

The fairness and equity to the unfortunate purchaser of the A share would probably be to this effect. He paid 100l. in cash; of this 10l. went to the brokers and "rebates," amount to Balance of commission and "rebates," amount to 65l. This leaves 25l. for works; but, as it was "having regard to the fact that the firm was to receive payment in shares, which were to be taken at par," that Sir M. Peto "considered that the prices stipulated for were fair prices," we can hardly estimate the contractor's risk and profit at having been put at less than 40 per cent. on the schedule, especially after its increase in October 1860. Most likely 50 per cent. would be nearer the mark. The actual value, then, in land and works, which the unfortunate A shareholder has received for his 100l., will be from 15l. to 12l. 10s., a very satisfactory "b'porth of bread for the intolerable amount of "sack," properly so called, secured by the enterprising and adroit contractor,—from 697,000l. to 717,500l. out of the 825,000l. of the A capital. Shareholder and broker divide one-fourth of the United States' railroads, executing the work and making the market, and three-fourths go somewhere else. In this case it certainly would appear to an honest man not behind the scenes, that the gentlemen called directors are as much more blameable than the persons called contractors, as is the governor who betrays a fortress entrusted to his care more inexcusable than the captain of brigands or of free lancers who seizes the neglected stronghold. That, however, is not our present concern.

The attention of our readers will, no doubt, be curiously directed towards the further proceedings "in re Peto, Betts, & Crampton." We have referred to the case, not so much for its own importance, great as that is, as for the sake of giving some explanation of one or two round facts which are worthy of attentive study.

At the close of the year 1867, according to the report of the United States' Statistical Bureau, there were in those states 54,325 miles of railway, of which 38,605 miles were completed. The aggregate cost of the roads and their equipments was 1,654,050 dollars. Omitting the consideration of the unfinished lines, the average cost per mile of the United States' railways may be taken at about 42,000 dollars. In Pennsylvania, the leading railway state, the cost of 4,192 miles is given as about 222 millions of dollars, or 53,000 dollars per mile. The railways of the United States are, no doubt, of a rough and ready description; but when we come to remark on the sums expended on renewals and reconstructions in our own country, we shall find that we have not outstripped by any means built for eternity.

In Ireland, to June 30th, 1867, 39 railway companies have expended 26,652,433l., on 1,693 miles of line. The gross receipts for the year on this expenditure were 1,552,417l. The cost per mile was thus, in round numbers, 14,000l., each mile earning a gross amount, however, of a little under 1,000l. (975l.).

In Scotland, to June 30th, 1867 forty-nine railway companies have expended 55,921,649l. on 2,466 miles of line. The gross receipts for the year on this expenditure were 4,081,904l. The approximate cost per mile was 22,700l., each mile earning a gross annual revenue of 1,650l.

Up to the date of the last returns before us from France, the whole expended capital represented by shares and debentures was 233,000,000l., and the length of the lines of railway constructed was 8,134. The cost of these lines is thus about 28,500l. per mile. The net income is stated at 12,500,000l., or about 1,536l. per mile.

In England, to June 30th, 1867, 170 companies have expended 405,331,055l. on 9,634 miles of railway. The gross receipts on these lines for the year ending at the same date were 33,954,793l. The cost per mile was 42,000l., the gross earning per mile was 3,551l.

We thus find that the difference of cost between a railway in England and one in America is no less than the difference of value between a pound and a dollar. English railways have cost as many pounds per mile as American railways have cost dollars. The natural features of the countries are by no means such as to account for this enormous disproportion; in fact, the rule would appear rather to have been to ascertain how much the proprietary would in each case bear, and to spend accordingly. Thus, while English railways have cost almost exactly three times

the price per mile of Irish railways, and not far from twice as much as Scotch railways, their expenditure has been hitherto so far controlled as to allow (on the supposition that working expenses equal half the gross revenue) nearly one-half per cent. more return to the shareholders on the gross capital than that of the poorer sister countries. But in France the expenditure has been kept down so as to allow a return of one per cent. above that earned in England. It is clear to those who have practical knowledge of the railways under comparison that it is rather to investigations such as those which are now being conducted by Mr. Winslow, than to such as are carried on by Parliamentary Committees, that we must look for the explanation of the enormous additional cost of our English lines. Had they been kept down to the French cost they would now have paid all round 6½ per cent. Of course the consideration of the additional locomotive and carrying stock required for a larger traffic must not be lost sight of. But the revenue of the English lines, that is to say the measure of their need for working plant, only exceeds the revenue of the French lines in the proportion of 1767 to 1536, and this excess only regards the portion of the capital invested in working stock. The proportion of cost between the two systems is as 42 to 28½.

Now, it is on such a state of things as this that of late,—criminally late, but we trust not too late,—the force of public dismay has been brought to bear with a vengeance. The first result has been disastrous to an educated profession, to a great number of men who had risen to a mushroom wealth which has disappeared like those fungi themselves, and to a large and important body of English workmen; but it has been necessary, nevertheless. The railway system of this country is very far from having attained a development equal to the requirements of the day. It leaves room for a large and remunerative development of the requirements of the future. But it had been developed in the wrong direction,—for private, not for public ends,—for the benefit of lawyers and contractors, not for that of railway proprietors. Until this iniquitous development was checked, the constant swell in the tide of revenue was only made use of for encouraging expenditure and for facilitating the borrowing of capital. The better the return the wilder the extension. For this system to be put a stop to, for the capital accounts to be closed, for the actual state of things to be looked honestly in the face, and for the incessant pilferage of the railway proprietors to be stopped by the process of making them aware of what was going on, has been the function of the panic of 1867.

Already we are seeing results. The Great Eastern, with a diminished outlay, has earned some 30,000*l.* more for the second half-year of 1867 than for that of 1866. The Great Western, also, with a diminished outlay, 50,000*l.* more. With the steady increase of net revenue these companies are learning to struggle with that floating debt, in the permission or encouragement of the growth of which they were learning, at their proportionate distance, to emulate the borrowing states of Europe and of America.

It has been by the facility of borrowing money that the great vice of our own system has chiefly found opportunity to run riot. So long as the shareholder had to be asked for calls, so long was a certain check put upon expenditure. Most men have an instinctive dislike to be asked for money. Even those who part with it for the purpose of investment, are apt to ask for particulars in a manner that would be disagreeable to directors who had felt compelled to allow a rebate of 50 per cent. on A shares. Thus, in the early days of most lines, the constitutional forms of representative assemblies were kept up. The engineer of the line was invariably present at the half-yearly meetings, to throw the agency of his responsibility over the Board, and to take his proper share of badgering as to the progress of the works. But with the completion of the original lines, and with the expenditure of the original capital, crept in another mode of doing business. Men who were not asked at the moment to put their hands into their own pockets gladly compounded for immunity at the price of giving a tacit sanction to the borrowing, on the part of the executors who administered their joint property, of sums that were to be expended for the general welfare and prosperity. Few asked themselves the question of how far the half-year's dividend might have come out of the exercise of the half-year's borrowing powers. The dividend was a pleasant, tangible fact. The

increase of the capital was a matter of account. All men are not clever at accounts. Most men dislike them. So it came to pass that, without speaking of the floating debt, which, after all, is the main cause of the present cessation of dividends, the acknowledged debt which, under the forms of temporary loans, debenture loans, debenture stock, and preference capital, presses upon the original shareholders, is appreciably larger than their whole original venture. Of the total capital which, up to June, 1867, had been raised by 389 railway companies, amounting to 489,060,699*l.*, only the sum of 229,197,867*l.* was ordinary capital. The remainder was money borrowed or raised under one or another of the four above-named heads. On a property costing nearly five-eighths of the National Debt, more than half the value had been borrowed. This is the most favourable way of putting the facts. The proportion is that of 260,000,000*l.* of borrowed or preference capital to 230,000,000*l.* of original paid-up capital. Can we wonder that railway making became so lucrative a trade while the capital was so readily forthcoming from a confiding public? Can we wonder that, between landowners, lawyers, contractors, brokers, and others, the existing network of English railways has cost the respectable sum of 42,000*l.* per mile?

It is fair to mention that some, though not all, of our figures are taken from an analysis of the capital and revenue of the railways of the United Kingdom, drawn up by Mr. H. E. Bird, of Basinghall-street. Mr. Bird has continued the Parliamentary return of 1865 down to the close of 1867. The figures, so far as they go, appear to be reliable, and would have been a still more valuable contribution to our knowledge, if they had contained some information as to the distribution of capital, the cost of land, of works, of stock, and of legal and Parliamentary expenses. The natural result of Mr. Bird's figures (we will not say their object, but it looks like it), is to increase the feeling of dismay with which railway property is regarded. With an unsparring, but probably not with an unjust hand, the expenditure charged to capital is compared with the amount of ordinary dividend. "If the outlay commences at the same rate as heretofore, a great reduction, and in some cases an entire cessation of dividends on ordinary stock must be the result." In one sense this is a favourable mode of putting the case. The outlay has to be stopped, or has been stopped, and the dividends too. We have gone too far to be set right by a mere halt. We have, if it be impossible to retrace our steps, to wait till our friends come to our relief. Those friends are the travelling and freight-paying public. They are rapidly rolling up to the rescue.

The difficulties which oppose any attempt to speak with tolerable certitude as to the future of the railways of Great Britain arise chiefly from our ignorance of their exact condition at present. The floating debt is large, estimated at 20,000,000*l.*, although the cash in hand, outstanding accounts, and stores may go far to balance such a debit. Then, the question of the actual cost of working is one on which no definite judgment can be formed until the capital accounts are actually closed. Still, there is little reason to doubt the possibility of keeping the expenditure, exclusive of interest, beneath 50 per cent. of the gross intake. That income amounted, in 1866, to 38,164,354*l.*, being an increase of 2,274,241*l.* on the income of 1865. The net receipts are stated in the Board of Trade returns to be 4.04 per cent. on the paid-up capital. But notwithstanding the fact that the working expenses are only averaged at 49 per cent., the large increase in the traffic of 1866 is only allowed to have augmented the net revenue by the sum of 750,099*l.*, or from 15,602,582*l.* to 19,352,681*l.* As the latter sum gives a dividend only at the average rate of 4.04 per cent., it would seem, on the most unfavourable view, that an increased gross income of 10,000,000*l.* per annum would be requisite before railway capital, on the mean average, would pay 5 per cent., a state of things which, at the rate of the last year's increase, would not be attained before 1881. On the other hand, the several series, if acting in harmony may be expected largely to increase their receipts without any corresponding increase of expenditure; and if this expectation be fulfilled, the addition of four millions and a half to the nineteen millions of the present net revenue, which would be necessary to allow of the addition of one per cent., may be attained in the year 1870. With proper management, we hold that this date should be nearer the period of the resto-

ration of railway capital, taken in the gross, to the par value, than the more deferred period; but we place the limits and the dates before our readers, to enable them to form their own conclusions. In any event it can only go by a return to the former state of easy-going public indifference that the great railway revenue of Great Britain can be for the future diverted from the pocket of the shareholder to the hands of the schemer. In the check of profligate expenditure, in the exposure of the mode of "placing" and "rehabing" A shares, in the cessation of hostilities, and in the general attempt to look facts in the face, instead of striving to make them pleasant, we recognise the probability that a restoration of railway prosperity may yet be the result of the function of public dismay.*

ON THE ARCHITECTURESQUE.†

PART II.

If I have succeeded in conveying to you the precise meaning which I attach to the term *architecturesque*, it becomes my further task to pursue this idea from its direct application to architecture into its bearing upon other matters,—that is, upon certain other arts and kindred subjects which are more or less connected with architecture.

First, I will direct your attention to painting; and the question, of course, will be, What is the architecturesque in painting? My answer is this: The idea implies subordination to architectural forms and purposes in respect of painting applied to architecture. An architectural decoration produced by the painter may be, speaking in general terms, either suitable or unsuitable to the architecture; and, therefore, it will be so far either successful or unsuccessful in respect of the character of being architecturesque. A good illustration happens to offer itself at once. Two or three months ago an interesting communication was presented to the Royal Institute of Architects, by a painter, Mr. Scott,—of Edinburgh, I think. He had executed certain very noticeable decorative works on a considerable scale, in two mansion-houses in the northern part of the country, consisting of figure subjects, which were in themselves exceedingly well devised, well drawn, and well painted. He was able to show us in one case the actual pictures (they being on canvas, for being affixed to the walls), and in the other case he produced the full-size coloured cartoons; so that we were able to understand thoroughly what he professed to do.† One of these works was designed for the adornment of a central hall in a Classic or Italian mansion, the four walls being occupied by arched galleries, and the pictures being made to fill in the space between the arches and the entablature above, including the sprandrels formed by the meeting of the arches. The subject was found in the incidents of a Border ballad—one of the Percy ballads, I think; the series of paintings assuming a sort of panoramic form; and a very charming composition, as a whole, was the result of Mr. Scott's labour and skill. But some of us objected that, owing to the lower limit of the canvas being formed by a series of arches, the picture now and then appeared to be passing behind the arcade, the arches, in fact, constituting a succession of semi-circular gaps, cut out of the panorama. Others of us maintained that this was quite right, on the precedents of Giotto and other great masters. At all events, this was obviously a question of the very principle of which I am speaking; the real point was simply this,—whether the picture was treated architecturesquely or not; whether the figures were adapted to the forms of the architecture, so as to be in harmony with the architectural purpose. Although everybody was satisfied with the pictures as pictures, this was not all. We thought they had not been treated in an architectural spirit,—that is, in the manner which I venture to call the architecturesque manner. The same gentleman further exhibited, as I have said, another work. This consisted of figure subjects ascending an interior circular stair. The paintings were here in panels; the mode of designs was more or less Medieval; and they were, as in the former case,

* A slight modification was made by Sir M. Peto in his second examination. The first statement was that above cited; but on consultation with his painter, Mr. Betts, the hon. baronet corrected it to the effect that his firm ultimately took the A shares, not at 25*l.*, but at 37*l.* 10*s.* for the 1*st* share.

† See p. 169, ante. ‡ See pp. 31 and 73, ante.

exceedingly well done. But here another very curious principle came into view, quite as embarrassing as the line of arches.

Seeing that the subject was, so to speak, going up-stairs, and that the absolute horizontality and perpendicularity of nature are conditions that will not go up-stairs except by some artificial contrivance, the question was how should the designer treat his subject so as to make natural landscape accord with a circular stair. In a word, we occasionally found that he was treating his subject very satisfactorily, and occasionally it was not so: when it was architecturally treated it pleased; when not so, it did not please.

The landscape, for example, sometimes seemed to slope, in spite of itself, unnaturally, in accordance with the form of the panels. In other cases, it seemed to maintain its level and perpendicular in a sort of discord with the situation; and so there was a deficiency in respect of artificial adaptation to the forms and conditions of the architecture by which the composition, however admirable as works of painting, was placed at disadvantage,—picturesque work, but not architecturally.

Passing next from painting to sculpture, the idea in question is to a certain extent precisely similar. That is to say, when sculptural decorations are in panels, for instance, or spandrels, probably as *relievi*, we may say that, as in the case of paintings—indeed, even more decidedly so than in any case of paintings—it is necessary that the figures should be adapted conventionally, if you please to call it so, but beyond doubt artificially, to the forms of the architecture. Again, and this is the case of statuary used in what may be called a structural capacity; as, for instance, when a statue occupies one of a series of pedestals surmounting a colonnade or arcade, it is obviously essential that it should be posed in a particular way; for it takes the place of what, in another school of architecture, would be a pinnacle; and it is necessary that it should be treated architecturally,—or, I would rather say, architecturally. If designed with a great display of motion, or with fluttering drapery like the figures on Temple Bar, it is not suitably treated. It is, no doubt, treated sculpturally; but, as a portion of an architectural composition, not architecturally. As another example, it is even still more plain that when figures are used as brackets (as in the French roof-windows, &c.), it is absolutely necessary that they should be subordinated strictly and scrupulously to architectural forms and purposes; and this, once more, is the question of the architecturally in sculpture. Again, it sometimes happens that independent statues should be treated in the same spirit when placed in connexion with architectural work. To mention a second time the statues on Temple Bar, they are, as objects of art of the period, perhaps fine works; but, as statues encaased in architecture, they are wanting in architecturally repose. To turn to a modern example, you have perhaps seen the statue of Sir Robert Peel in Parliament-square, not yet unveiled, and you may have observed that it occupies a somewhat peculiar position. It is set down in front of a piece of railing. Seen from behind it will look—forgive me if I appear to fall into the diphany of British criticism,—but it will look very much like something in a cage, or perhaps in a pound; whereas, looked at from the front, the architectural critic, and even the sculptural critic, may be excused if he wonders how it is that a mere railing should be carried past the back of the figure without the slightest attempt to do what would be so easy, namely, to divert the pattern into some form calculated to harmonize with and enhance the sculptural effect. The railing in itself may be architectural enough; but why should it not serve to afford also to the statue the legitimate architecturally support due to the site?

Now, let us pass to a subject peculiarly well calculated to give us a clear idea of what I am aiming at,—namely, the architectural carving of natural objects, such as foliage. A more charming description of art, whether viewed by itself, for its own purpose, or for its architectural purpose, it is impossible to conceive; and I think we shall all agree that whatever may be sometimes said of the inferiority of various kinds of English art-workmanship, the high character of English foliage carving is unquestioned. Now, we all know that before natural foliage can be well or pleasingly adapted to architectural work it has to be in some degree conventionalized, in order to satisfy the critical

mind that it is not a mere portrait of a vegetable product, but a product of stone-working, hased only upon the nature-work which is copied. This, then, is architecturally conventionalized; and we are naturally led to remember how elaborately foliage was thus conventionalized by the ancient Greeks and Romans. With them, indeed, such foliage ceased altogether to be natural, and became architectural alone; and I think nothing can be a stronger illustration of the persevering resolution with which the Greeks, and, following them, the Romans, developed the architecturally principle. Here again, also, we have suggested to our minds the essential difference between the Classic and the Medieval schools of design; the Classic carving is more architecturally, Medieval more picturesquely.

Coming, in the next place, to decorative art, I need scarcely say that if the decorator, as a separate artist, is admitted into a building, to supplement the architect's work, he ought not to confine himself strictly within the limits of architectural motive. Observe in passing that the decorator's work is not architectural—it is not even architecturally, or even architectonic. But I certainly think that the term *architecturally* expresses with perfect fitness the adaptation of the decorator's work to the architectural and architectonic features. The other day, I stepped into the studio of my friend Mr. Owen Jones, whose felicity of design in decorative art has a world-wide reputation and I had a great treat, for he showed me a series of marvellous drawings whereby a whole house was to be decorated in his most elaborate manner—ceilings, walls, carpets, hangings, all harmonising in colour and form, and constituting one of the most exquisite sets of designs I ever had the good fortune to inspect. Now, what was the spirit which was actuating the artist in his design of all this? It was evidently this very principle of which I have been so long speaking,—the adaptation of all those various decorative efforts to one vital architectural purpose.

When we go again a little further, and look at the question of Furniture, we perceive the point quite as forcibly as ever. All the world knows that the cabinet-maker systematically objects to the architect's designs for furniture; and younger men may perhaps be persuaded by me when I tell them that whenever it is found that an objection of this kind is systematically and universally made by any class of tradespeople or others against the incidental demands of the architect in respect of what is their subject and not his own, it is a sure sign that the architect is going too far. Now, when cabinet-makers object to the architect's design for furniture the reason is this,—the architect in designing furniture is attending, no doubt loyally enough, to the architect's principles; but he fails to recognise the demands of the structural and other elements, and he treats his work *architecturally* when he ought to treat it only *architecturally*. Now, it certainly may be admitted that if furniture is to be adapted artistically to the features of the house it ought to be best done by the architect. In the abstract, the cabinet-maker himself will be ready to agree to that; but the architect must never attempt to treat the furniture as if it were architecture, for it is not architecture in any degree, but furniture altogether, and to adapt it to the architecture,—that is to say, to throw over it a mantle of what I call the architecturally,—is a more artistic task than any imitation of architectural forms can ever be.

The question of interior plan is one in which, the principle of which I am speaking comes very frequently into view. When one is designing interior effect,—an effective interior, as we are accustomed to say,—he is apt to think that it is a question of architecture and architecture only; but I think that, as a matter of experience, I have generally found that it was a matter of architecture directly to the features of the domestic arrangements to architectural purposes. Speaking not of great public buildings, nor of churches, where the interior is treated in a grand manner for its own sake, but rather of domestic and other more modest works, I think the first consideration in plan is obviously convenience; and therefore I say the motive is not architectural so much as architecturally which seeks to adapt this convenience to the purposes of architectural effect.

Let me allude for a moment to landscape gardening. This is acknowledged to be of two styles. One is called the Italian, the other the English. Italian landscape gardening is that which sprang up in the fifteenth and sixteenth centuries, the art having had no existence before

that time artistically; and the English that which has in this country and partly on the Continent supplemented and very much supplanted the Italian style within a comparatively recent period. In the English style, which is otherwise called the natural style, and which is in reality the picturesque style, formality is avoided, and little else than graceful irregularity is attempted to be produced, the ordinary effects of natural landscape being refined upon as the sole elements of effect. On the other hand, in the Italian style the principles are based upon regularity, symmetry, and system, in every form, of severe and often purely architectural strictness. The effect produced in either case may be very fine, but the two systems are essentially and entirely different; and, indeed, in connexion with the large mansions of wealthy owners, it is the rule for both styles to be introduced in separate portions of the grounds, for the express sake of their equal value,—the garden attached to one of the drawing-room façades of the house being perhaps laid out with perfect regularity in what is called an "architectural garden"; whereas, the land on the other side of the house,—that is, the park, shrubbery, and other ornamental grounds generally,—are treated in the English style, with everything irregular and picturesque natural. Here, then, we see contrasted the architecturally of the Italian garden and the picturesque of the English garden.

The Houses of Parliament, in respect of site, afford us, I think, a very fair instance of the application of the principle in hand. That building is one about which there will be probably much controversy in the future—more than there has yet been—not in respect of its authorship (which is comparatively immaterial), but in respect of its artistic value; but I think there is one thing we may all agree to declare,—that it is a building of exquisitely graceful design, and, if not academically sound as Gothic work (a proposition which, I think, may generally be accepted now),—a composition, nevertheless, in which the artistic sentiment of Sir Charles Barry took that particular course which was always characteristic of his genius—the architecturally rather than the picturesque. The great grievance of Gothicists in this case is, that the Gothic work does not follow properly picturesque models; hence the symmetry which severe Gothicism objects to; hence the uniformity which many others not Gothicists complain of. However, as regards its site, opposing the river shore from the building to the water had been irregular,—a mere sand-beach or something of the kind, or a bank tufted with shrubs, the effect of the building would have been very much inferior to what it is. But when the site is treated, as it is, architecturally by the formation of the long and unbroken terrace wall, with the unbroken line of lamps which in the evening forms so pleasing a feature with Westminster Bridge, also designed in adaptation to the building (not so much in respect of style, for that we need not look at, but in its treatment as an approach), you have only to turn to the picturesque sites of squalid buildings which extend westwards beyond the building, and there you see the effect of what is decidedly at the least a non-architecturally treatment of site. Again, the Thames Embankment in itself is interesting to us as architects in this precise way. As far as regards the formation of a new road along the river, that is only a matter of convenience; as far as regards the sanitary question of the contraction of the river current, that also is of course not a question in which we as artists take any special interest; but, looking upon the Thames Embankment in connexion with the buildings which will be erected along the line, then we perceive an instance of architecturally design, contrasting the new artificial elegance with the very natural and perhaps picturesque, but inelegant and unpleasing aspect of the former shore. We have another and a most admirable class of illustrations of architecturally sites throughout the Parisian streets. Whatever may be said on the monotony and sometimes feebleness displayed in the design of the Boulevards, there can be no doubt that, for classical artistic treatment of thoroughfares, Paris is perfection. Compare this with that academical system of Medievalism of which some of our friends appear at times to advocate a revival, saying, "Let us give up straight lines and squares; let us have piquant winding thoroughfares where we shall be constantly turning corners and coming upon fine things unexpectedly." That is no doubt good Medieval doctrine, sound picturesque; and I do not deny

that a town treated on that principle might be made extremely charming in its way; but all I have to do with it here is to offer it as a contrast to the Parisian system, which is the architectesque. Lastly, I may remark, that if the principle of the architectesque be what I have described it, how is it neglected in London? There is scarcely a public building which is even creditably disposed as regards the arrangement of site. As for the picturesque in site there is, of course, no attempt at such a thing—and even nature does not give us the picturesque by accident, except it be in Whitechapel. Compared with Paris everything in the London streets is almost sordid, certainly most remarkably devoid of the charm which attaches to liberal artistic effort. There is no attempt to support architectesquely even our most costly buildings. The Palace of Parliament itself, as regards the outlook upon the west, is in no less deplorable circumstances than if it were a gin palace: indeed, the magnificent Victoria Tower, the portal of sovereign majesty, actually looks down upon a petty tavern and a coal wharf! Surely, to surround such a building with some of those simple contrivances of site which I identify with the term architectesque would not be money wasted. On the contrary, a very slight homage to this principle would, in the case of most of our costly buildings, simply double their value. Therefore, if I am right in what I have been endeavouring to develop, it is, I think, extremely important that this principle of the architectesque should be thoughtfully studied by English architects. Pray consider that I have not myself been able to devote any very considerable study to the subject. I may be more or less wrong in much that I have proposed; I have had no authorities to consult upon the matter; moreover, I am speaking extemporaneously: what I have said is meant to be suggestive only, certainly not dogmatic. I am not in a position to offer instruction on such a subject, but only to submit reflections of my own upon a new theme, which I am sure will well reward careful study, and prove in every way worthy of intelligent development. ROBERT KERR.

LIFE AND DEATH IN OUR LARGE TOWNS IN 1867.

So great is becoming the aggregation of human life in our large towns that the death-rate of the nation may now be said to be governed by the mortality, and consequently by the sanitary condition, of our urban population. The Registrar-General's detailed Annual Report of Births and Deaths for 1866 has not yet appeared; a considerable time must, therefore, elapse ere we may expect that for 1867. However, the quarterly return for the last quarter of 1867, and the annual summary of the weekly returns for London and twelve other large towns of the United Kingdom, furnish facts sufficient for a general view of the vital and sanitary statistics for last year. The satisfactory conclusions to be derived from such a retrospect cannot but be gratifying to the inhabitants of those towns where recent sanitary activity has in a measure already reaped its reward, while it should stimulate the dawning energy in others whose past apathy is still reflected in excessive death-rates.

During the three years 1860-2, the annual death-rate per 1,000 in the population of England and Wales ranged so low as 21.2, 21.6, and 21.5; in each of the four following years it exceeded 23 per 1,000, in 1864, and, influenced by the cholera epidemic, 29.6, in 1865. Last year it fell again to 22.0,—a lower rate than in any year since 1862. The meteorological conditions of the year presented no unusual features, but were, on the whole, favourable to public health, more especially in large towns where the density of population and the combined effects of indifferent water-supply and imperfect sewerage render the inhabitants more susceptible of such influences. The mean temperature of the year at the Royal Observatory, Greenwich, was 48°6', which, although considerably lower than that of the two previous years, differed but slightly from the average of ninety-six years. In each of the first three quarters of the year there was a slight excess of temperature; while the last quarter of the year, although unusually cold, was not unfavourable to the public health, as there were no continued frosts. Rain was abundant, measuring 28.4 in. for the year, and nearly 4½ in. above the average of the twenty-

eight years 1840-67. There was during the year an unusual amount of wind, the average daily amount of horizontal movement of the air being 283 miles, against 248, the average in the twenty years 1848-67, and higher than in any year since 1848, when it was 318 miles per day. The year 1867 had a winter without continued, although severe, frosts; a summer unmarked by excessive heat; a fully abundant fall of rain; and a more than average amount of movement in the air. These conditions in great measure account for the low death-rate of the year, which cannot be entirely attributed to the recent rapid increase of sanitary knowledge and activity.

The Registrar-General's annual summary for 1867, just published, gives instructive details of the births and deaths in London and twelve other large towns of the United Kingdom, estimated to contain in the middle of that year the large population of over six millions of persons. Of these, half inhabit the metropolis, a million are shared between Dublin, Edinburgh, and Glasgow, and the remaining two millions are divided among nine large cities and boroughs of England. The total urban population of England and Wales, including all the large town districts, must last year have numbered at least twelve millions, even at the same rate of increase that prevailed between 1851-61, whereas there is every reason to believe that the aggregation to purely rural districts, has proceeded still more rapidly since 1861 than in the previous decennial period. For the purposes of comparison, however, the figures published concerning the six million persons inhabiting these thirteen large towns, including London, are fraught with considerable interest.

These thirteen large cities and boroughs were estimated to contain 6,187,764 persons at the middle of the year 1867. During that year 230,199 births and 155,943 deaths were registered, giving an annual birth-rate of 37.3 per 1,000. In the whole of England and Wales for that year, including alike the town and country districts, the birth-rate for the year was 35.8. Setting aside Dublin, where registration, more particularly of births, is yet in a most defective condition (showing as it does, a birth-rate for the year of only 25.9 per thousand, and an excess of deaths over births), the death-rate for the year in the other large towns varied from 36.4 and 36.6 in Bristol and London, to 41.3, and 44.3 in Sheffield and Leeds. These excessive rates in Leeds and Sheffield suggest the probability, strengthened by local evidence that the estimated population of these two towns is below the actual population; the effect of this would be to exaggerate both the birth and death rates, calculated by means of the estimate. These estimates are framed upon the assumption that the rate of increase in the population of each of the towns since 1861 has been the same as prevailed between the census of 1851 and that of 1861. Many of these towns are the centres of some one or other of the manufacturing districts, and their populations are subject to excessive fluctuations dependent upon the flourishing or depressed condition of their particular manufactures. The American war, for instance, producing the cotton famine, at the same time infused most unusual activity and prosperity into our woollen districts. Thus a considerable portion of the unemployed population of the Lancashire cotton towns were attracted by the increased demand for labour in the Yorkshire woollen towns. Thus are the estimates for particular towns and another rendered inaccurate, and the accuracy of calculated birth and death rates disturbed. Nothing short of a quinquennial census for, at least, all the large towns will give a sufficiently trustworthy basis for sanitary statistics, which are now studied so carefully throughout the country. France, with a population comparatively stationary, has long had a quinquennial census. Why should England, where the increase is so much more rapid and variable, only have its people numbered once in ten years?

In the thirteen towns above mentioned the 155,943 deaths registered during last year showed an annual death-rate among these six millions of inhabitants equal to 25.3 per 1,000. This was 1.4 per 1,000 above the rate in the twelve millions inhabiting all the town districts, and 3.3 above that for the whole of England and Wales for the same period. The following table showing the death-rates in each of the thirteen towns for the three past years, considered with reference to the known amount of sanitary work done in recent years in the different towns, is highly

instructive. The towns are arranged in the order of their death-rates for 1867, from the lowest.

Annual Death-rate to 1,000 Persons living in the Years 1865, 1866, and 1867.

	1865.	1866.	1867.
London	24.4	28.5	23.0
Bristol	29.5	24.9	23.1
Birmingham	24.6	24.0	24.3
Sheffield	27.0	29.1	24.7
Hull	27.3	24.6	25.0
Leeds	31.0	32.5	27.0
Dublin	25.8	28.5	27.1
Edinburgh	28.1	27.4	27.1
Salford	29.3	29.0	25.6
Glasgow	32.9	29.6	28.5
Liverpool	36.4	41.9	29.8
Newcastle-on-Tyne	29.2	32.1	30.8
Manchester	33.0	32.0	31.4

Before proceeding to consider some of the details of the summary bearing especially upon London, let us glance at a few conclusions to be derived from the foregoing table. Setting aside the mortality from cholera in 1866, which was purely exceptional, and made an addition of 1.8 per 1,000 to the mortality for that year, the death-rates from ordinary causes will remain for that year but little in excess of that for 1865, and still shows an important reduction in the rate for 1867. The rates in Bristol for the three years were almost stationary, and place that city very nearly at the top of the list for each year: summer diarrhoea and a few cholera cases somewhat raised the mortality in 1866. In Birmingham the rate scarcely varied at all in the three years: the low death-rate enjoyed by this town, notwithstanding a considerable mortality each summer from infantile diarrhoea, and a recently increasing fatality from scarlatina, whooping cough, and other infantile zymotics, is strong evidence of the natural sanitary advantages possessed by this town. Sheffield, during 1867, showed a marked improvement upon the two previous years, while in Hull the decrease of the death-rate commenced with 1866. It is to Leeds, however, that the advocates of sanitary reform can most confidently point, in proof of what may be done by well-directed and continued efforts in that cause. The death-rate in Leeds in 1865 was 31.0 per 1,000; in 1866, through a somewhat more severe epidemic of summer diarrhoea, although there was no cholera, the rate increased to 32.5, but fell to 27.0 under the régime of a new medical officer in 1867. Since the beginning of this year the continued decline in the death-rate of Leeds is still more remarkable. Edinburgh, Glasgow, and Salford each show a small but continuous decline in the death-rate in each of the three years. The success of recent earnest co-operation on the part of the municipal authorities in Liverpool with their zealous health officer appears to have borne fruit. The death-rate in that town, which in 1865 was 36.4, and influenced by the cholera epidemic, rose to 41.9 in 1866, fell last year to 29.6. The continuous decline of the proportion of deaths from zymotic diseases, and especially of still more considerable reductions in the present and succeeding years. Of the last two towns on the list, with their steadily maintained excessive death-rates throughout the three years, what can be said? Their example is perhaps useful, but at too terrible a cost of human life, to show the result of apathy in dealing with these important sanitary problems. The cases of these two towns are very similar. In Newcastle, a continued mortality from typhus and typhoid fevers, with a more than usually severe epidemic of scarlatina, helped to make up the high rate for the three years: it was not till nearly the end of 1866 that the town appeared to awake from its lethargy, and if the death returns for the past ten weeks of this year may be taken as evidence of its improved health, we may hope for a more favourable return for 1868: no officer of health has, however, yet been appointed. In Manchester the same class of diseases has produced the same results as in Newcastle. We are glad to hear that an Officer of Health has been appointed, and we shall hope to see the sanitary horizon clearer before long. Since the beginning of this year the mortality in Manchester has continually exceeded that in any of the other large towns furnishing weekly returns, and fever in various forms, besides scarlatina and whooping-cough, have been continuously and fatally prevalent.

London was healthier in 1867 than in any year since 1860, which was exceptional, inasmuch as the summer of that year was remarkably cold and wet, and there was in consequence an almost entire immunity from the usual mor-

tally from summer diarrhoea. The death-rate in London in 1867 was 23.0 per 1,000. Notwithstanding the great excess in the female population of London over the males, the male deaths exceeded those of females by nearly 2,000; the death-rate for the year among males being 25.3 per 1,000, and of females only 20.9. To the dwellers in this metropolis, who have been somewhat groaning in recent years under the weight of the extra millions that have been added to the local taxation for the payment of the Main Drainage Works, it should at least be some satisfaction to be able fairly to assign some portion of the improved health of London to the operation of this vast system of sewerage. The worst part of London, by which we mean those parts most densely crowded with the poorest classes, such as St. Giles's, St. Luke's, Whitechapel, &c., enjoyed death-rates in 1867 which bore favourable comparison with some of our provincial towns. This is also in a great measure due to the effective working of the system of health officers, who, although in many cases overburdened by far too large districts, are surely effecting a radical improvement in the condition of some of the worst localities which formerly contributed so largely to swell the death-rate for London. We gave details, with reference to London in our last, and need not repeat them.

Of the total 70,538 deaths registered in London in 1867, the causes were recorded of 69,757. More than a fifth of the whole, 15,027, were referred to zymotic diseases, principally to one or other of the following diseases:—Typhus, small-pox, measles, scarlatina, whooping-cough, and diarrhoea. This class of diseases is almost entirely within human control. In 1865, the deaths referred to these causes were 18,058; and in 1866 (including 5,577 from cholera), 23,680. Not since 1860 have the deaths in London from zymotic diseases been so low as in 1867. The only disease of this class which showed an increase in 1867 was small-pox, which was fatal in 1,332 cases; this number although slightly below that in 1866, was far above the average of recent years. The mortality from typhus has shown an almost continuous decline since 1862.

On the whole, as far as London is concerned, the return for 1867 is certainly satisfactory, and seems to indicate a still greater prospective improvement in the health of its residents. The great sanitary problem remaining to be solved for the metropolis is, doubtless, the water supply. That Londoners will long be contented with the present systems is scarcely creditable, after the light which has recently been thrown upon the indubitable influence of the quality of water upon public health. There is little doubt but that with an adequate supply of pure water, London would be one of the healthiest cities in the world.

MANCHESTER TOWN-HALL COMPETITION.

THE following is a list of the designs sent in by the architects selected by the corporation with the assistance of Mr. Godwin, in the first competition, pointed to by mottoes or symbols only in the report of the referees in the second competition, which we append:—

1. "Arnolfo di Lapo," Mr. Cuthbert Brodrick (architect of the Leeds Town-hall).
2. "Faire sans dire," Mr. T. H. Wyatt (architect of the Liverpool Exchange).
3. "Fides," Mr. Lee (London).
4. "Sperandium," Mr. J. Scott (London).
5. "St. Valentine," Mr. Waterhouse.
6. The Masons' symbol of crossed triangles, Messrs. Speakman & Charlesworth (Manchester).
7. "True to the line," Mr. Thomas Worthington (Manchester).
8. "Valentine," Mr. Salomons, (Manchester).

Dear Sir,—We have been honoured by the instructions of the Town-hall Sub-committee for the erection of a new Town-hall in the city of Manchester, dated the 20th February last, and conveyed through you, requesting us to furnish our opinion generally on the plans sent in by the eight competing architects, and especially with reference to the matters therein specified. (Mottoes of designs)—1. "Arnolfo di Lapo," 2. "Faire sans dire," 3. "Fides," 4. "Sperandium," 5. "St. Valentine," 6. "Masons' symbol of crossed triangles," 7. "True to the line," 8. "Valentine." We have accordingly examined with very great care, the several drawings, and read the explanations of the designs drawn up by the architects, and we beg to report as follows:—

1. As to the comparative merits of the designs in an architectural point of view, having regard to the form of the sites, the lines of the adjacent streets, the climate of the district, and the purposes for which the building is

required, we are of opinion that the designs No. 6, No. 4, No. 7, and No. 8 are, as works of art, the finest designs of the whole series; and, with regard to relative merit, may be considered to stand in the order in which we have here placed them.

2. As to general arrangements and convenience, having regard (amongst other matters) to the simplicity of plan, the facilities of access to the different parts of the building, the entrances for the different streams of visitors, the position and conveniences of staircases with a view to the avoiding of unnecessary walking inside the building, the provision made for getting down and taking up visitors arriving or departing in carriages, and also for the entrance of carts, and for the loading and unloading thereof; also, the convenience and character of the Mayor's reception-rooms, and the arrangements made for keeping the same distinct from the business portion of the building; and also whether the whole of the accommodation asked for in the Corporation was being provided, and the extent of unappropriated space: we are of opinion that the first place ought decidedly to be given to No. 5; the two next best designs being those of No. 6 and No. 8.

3. As to the expediency of window light supplied throughout the building, we consider the design of No. 5 best.

4. As to the provision made for ventilation and warming, we consider that all the designs would admit of the adoption of proper artificial systems of warming and ventilation; and that, owing to the open arrangements of the interior courtyards in this plan, the design of No. 6 would be best as regards natural ventilation.

5. As to the acoustic properties of the large hall or room and the council chamber, we are not prepared to give any decided opinion on this head.

6. As to the cost of the design, and the probability of the same being carried out for the amount stated by the architect, we are of opinion No. 5, No. 8, and No. 7 are the least costly of the designs submitted; and that the expense of carrying either of them into execution would probably not exceed the sum named in the instructions to the competing architects.

The conclusion at which we have arrived, after a careful adjustment and comparison of the various designs, on the plan and arrangement, light, construction, excellence of the interior courtyards, and the position of the spare room, is, that the four best designs in order of merit are 1st, No. 5; 2nd, No. 8; 3rd, No. 4; 4th, No. 7. And we both concur in recommending that the design marked "St. Valentine" (No. 5) should be recommended by the sub-committee to the mayor and corporation for adoption. The architectural character of this design is, as we have said, not quite so good as that of the others; but the plan has such great merits, it is so admirably and simply disposed, and so well lighted, that we cannot but feel that it is thoroughly suited to the first place. The general disposition of the masses of the building is simple, compact, and there is much dignity about the treatment of the principal story towards Albert-square. We are bound to say that in some respects the design appears to us to require additional study and modification, of which it admits without difficulty. The great entrance requires better proportions, more light, and greater dignity, and the designs for the clock tower and the angles between them towards Albert-square will, doubtless, be modified and improved by the architect, before they are carried into execution. We regret very much that the interior courts of this building (as indeed those of almost all the designs) have not been more carefully designed in regard to their appearance. They will be seen by most visitors to the building, as the whole of the corridors open into them; and as they are all as spacious and open as could be carried on the site, it seems a fatal mistake to leave them entirely unadorned. Mr. Waterhouse's design, in this respect, character is what they require, and there is no reason why they should not have it. The character of the building as a work of art depends very much upon its being uniformly good throughout.

We cannot conclude without saying that all the competitors appear to have bestowed immense pains on their designs for this very important work, and that the requirements contained in the instructions have been generally very carefully attended to.—We remain, dear sir, your very faithful servants,

THOS. L. DONALDSON,
GEORGE EDWARD STREET.

To the Town Clerk,

SIR,—The subject of the new town-hall is exciting considerable interest down here; but the public in general seem to know very little as to the real state of the case, therefore rumour is busy in a thousand forms. The report of the appointed judges has appeared in the papers, and the name of Mr. Waterhouse has been given as the one recommended to the council for the carrying out of the work. It is to be hoped that (previously to the decision being come to by the council) as to whether they follow the recommendation of Messrs. Street and Donaldson or not) the designs of the architects will be thrown open to the public, so as to elicit the opinion of the community. A MANCHESTER CITIZEN.

SIR,—I am not an architect, have not seen any of the designs, nor do I know who are the competitors, with the exception of Mr. Waterhouse, whose name has been made public. My objections to the report, which seems very inconsistent, are, therefore, entirely resting upon the report itself. In No. 1 of my report, Messrs. Donaldson and Street place Mr. Waterhouse's design, No. 5, as the fourth best according to the merits of the designs in an architectural point of view, having regard to various important points named in the purpose for which the building is required. Now, I think that this admission ought to exclude Mr. Waterhouse altogether from the competition, as there are three other designs, according to the report, which have higher merit in an architectural point of view, and are better adapted for the purpose for which the building is required, these being, in my opinion, the two most points we have to look to. As to the greater merit of the design of Mr. Waterhouse, No. 5, as it is said in the report that all the designs would admit of the adoption of proper artificial warming and ventilation; and, in my opinion, it matters very little whether the ventilation is natural or artificial, as long as the artificial venti-

lation is as good as the natural. In No. 6 of the report, Messrs. Donaldson & Street express their opinion that the least costly of the designs submitted, and that the expense of carrying either of them into execution would probably not exceed the sum named in the instructions to the competing architects. May I ask Messrs. Donaldson and Street whether the architects of the other designs have exceeded the sum named in the instructions, and if not, why they are considered less honest or less competent to make correct calculations than the above-named three? We know from experience, of at least one of these, that he is not infallible in making estimates, and the new Assize Courts. At the conclusion of their report, Messrs. Donaldson and Street say, that Mr. Waterhouse's design, which they recommended for adoption, requires additional study and modifications (i. e., alterations and improvements)—1st in the great entrance; 2nd, in the great clock-tower; and, 3rd, in the angles of the principal front. Therefore the three most conspicuous points in the whole building, as far as the exterior is concerned, are considered bad. If the other architects would be allowed to make alterations of equal importance to their plans and designs, after the various defects had been pointed out to them, I think that the few advantages in Mr. Waterhouse's design, which are mentioned in Nos. 2 and 3 of the report, would very soon disappear.

COMPETITIONS.

Proposed Infirmary at Highgate, for the Parish of St. Pancras.—The designs by a selected number of architects, referred to in our pages recently, were sent in on Monday, the 2nd. The guardians have awarded the first premium (150*l.*) to Messrs. John Giles & Co. The building is to accommodate 500 patients, and the estimated cost is about 53,000*l.*, exclusive of external drainage, boundary-walls, and fittings. The second premium (100*l.*) is given to Mr. Burden; and the third (50*l.*) to Mr. E. C. Robins. A correspondent complains that "the designs were sent in on Monday; were opened on Tuesday; and the report of the committee was printed and confirmed by the Board by Thursday Board meeting." Certainly very quick work.

Asylum for Imbecile Poor, Levensden-Woodside.—The designs for this building (ten, we believe) were sent in to the officers of the Metropolitan Asylum District Board on the 2nd inst.

Designs for a similar building, for a similar purpose, to be erected at Catterham, were sent in on the 9th inst.

Darlington Workhouse.—Eighteen sets of designs, in all 116 drawings, were sent in for this workhouse, and the guardians, after consulting with an independent architect from London, awarded, as we have already mentioned, the 1st premium, 40*l.*, to Mr. Adams, Stockton. The 2nd premium, 30*l.*, has been awarded to Mr. Stanger, of York; and the 3rd, 20*l.*, to Mr. R. B. Dixon, of Darlington. A correspondent asserts that "to carry out the selected plan will entail a cost of about 14,000*l.*, instead of the 10,000*l.* proposed."

Worcester Orphan Asylum.—The competition for this building, the advertisement of which appeared in the *Builder* of August 17, 1867, has resulted in the selection of a design, the joint production of Mr. William Watkins, of Lincoln, and Mr. S. Dutton Walker, of Nottingham. There were twenty-three competitors. As regards external treatment, economy being a great consideration, the little stone-work has been introduced, but the effect had been sought by means of a broken "skyline," and by the introduction of Staffordshire blue brick bands or strings of character being given to the building by the adoption of the Early Gothic style. The building is designed to accommodate twenty-five girls and twenty-five boys, with arrangements for extension, so as to receive conveniently double that number when required. The material chosen is red brick and Bath stone. The estimated cost is 4,000*l.*

St. Andrew's, Hertford.—Fourteen designs have been submitted, and are now in the Shire Hall. A meeting will be held on the 20th to make the selection.

New Cemetery, Diss.—The amount already expended in purchase of land, drainage, and other matters connected with the new cemetery is 850*l.* The design of Mr. J. T. Musket has been accepted, and the premium of 10*l.* awarded to him, and he has received instructions to prepare specifications for the chapels in accordance with his design: the cost not to exceed 850*l.* A premium of 5*l.* has been awarded to Mr. H. G.

* *St. Pancras Infirmary.*—Mr. Knightley writes,—"Will you kindly say that I was one of those chosen to compete, and that my design was selected for the first premium and for adoption; but, it being found that my estimate and description were not sent in till Tuesday morning, instead of Monday evening, the chairman ruled that I had put myself on foot, and so it was decided. It seems hard to be turned out for so small a matter." † See p. 167, ante.

Bishop, for the pains he has taken in preparing plans.

Slough New Parish Church.—According to the *Parish Magazine*, the following architects have been selected to compete for the design of the proposed new church.—Mr. Alfred Bedborough, Southampton; Mr. R. Brandon, London; Mr. Biggill, London; Mr. Conybeare, Westminster; Mr. Edgington, Windsor; Mr. Francis, London; Mr. Fowler, Louth; Mr. James, London; and Mr. Seddon, Westminster. It has been resolved by the committee to have the designs sent in under mottoes, and to offer 50*l.* premium for the best design, and 25*l.* for the second.

Kensal New Town.—An anonymous gift of 4,000*l.* was recently made to the Bishop of London's Fund for the purpose of erecting a church in Kensal New Town. The carrying out of the donor's intention was undertaken at the request of the Bishop's Fund Committee, by the London Diocesan Church Building Society, who invited a few architects to submit designs. Out of four sets of drawings sent in, the committee have selected the design submitted by Mr. Basset Keeling, under whose superintendence it will be at once carried out. The church will seat 800 adults, and the inclusive cost (site only excepted) will be covered by the amount above stated.

WAKEFIELD FINE-ART AND INDUSTRIAL INSTITUTION.

THIS Institution is to be opened in April. It is the outcome of the Exhibition of 1865. There were, as our readers will remember, many suggestions as to the application of the 3,000*l.* surplus which the Exhibition left in the hands of the committee of management, and for a full year they were all carefully considered, and the result was a determination to found a Fine-Art and Industrial Institution. The purchase of the old national school and the adjacent land, in Bell-street, followed; and the assistance of Mr. Watson, architect, was obtained to adapt the building to its new purposes; and contracts were entered into for the alterations. The building has good street frontages. The old national school had not much architectural beauty to recommend it. Notwithstanding its massive portico, ugly woodwork had been too barge-board to apply to it; but the alterations that have been made, and are making, promise to render its aspect, externally, not wanting in congruity with its uses. The portico is retained; and round-arched windows are opened, one on each side; and the roof is finished off with light ironwork. Opening out from the hall, one on each side, are rooms—the one to be appropriated to the library, and the other as the council-room. Passing forwards through the entrance-hall we enter a spacious hall, which is to be the museum; and beyond that again is another hall, to be used as the School of Art. These rooms have no side windows, but are lighted from the roof. The contractors for making the alterations are, Mr. George Fawcett, mason's work; Messrs. Heaps & Robinson, Leeds, ironwork; Mr. Speight, joiner's work; Mr. T. C. Tattersall, the plaster work; and Mr. Craven, the plumbing. The committee have obtained a master who will give the Wakefield School of Art a position.—Mr. Walter Smith, the head master of the Leeds School of Art, who is well known as a successful teacher, and who is an earnest student, of his art.

THE CASTLE OF COUCY.

COUCY-LE-CHATEAU, LOWE BIRD CASTLE, are built upon and completely occupy the somewhat irregularly-shaped but level summit of a promontory of chalk, the eastern part or root of which is connected with the high land of the upper forest of Coucy, while towards the north and west the termination of the platform stands out boldly and abruptly, from 150 ft. to 200 ft. above the fertile valleys on either hand, whence spring the tributary waters of the Lette, a stream which flows down from the ancient city of Laon to reach the Oise at Manicamp.

The valleys immediately below and commanded by the castle bear marks of high and early cultivation, and no doubt contributed largely to its support. More distant, chiefly on the eastern and northern sides, are the immense woodland tracts of the high and low forests of Coucy, St. Gobain, and Monceau, while to the

south are those of Pinon and Mostier. Occupying fertile spots amidst these forests were the abbies of Nogent, St. Nicolas, Barizy, and Prémontre, where was the burial-place of the de Coucys, and the remains of which religious houses are interspersed with those of the castles of St. Gobain, Folembray, Anizy, La Fère, Pinon, and many others, showing the value attached to this tract of country by the jealousy displayed in its defence.

The etymology of Coucy has not been explained. The district in which it stands was known as Le Meze in the sixth century, and Coucy was probably included in that part of it granted by Clovis to St. Remi for the archiepiscopal see of Reims A.D. 500. In 909 it was piscopal see of Archbishop Hervé, who, moved in the hands of the Norman, here first built the castle known henceforward as Coucy.

Whatever may have been the particulars of this fortress, its area must have been identical with that of the later work, governed by the configuration of the ground; and, whatever may be its construction, its position could not but endow it with strength and importance. It became at once a place of note, and was so coveted by Herbert Count of Vermandois, that he caused his son of five years old to be elected archbishop, and administered the temporalities of Reims in his name. Here he imprisoned Charles the Simple, whom he sold to his rival king for the county of Laon. Nevertheless, in 930 Hervé was forced to give up Coucy to Boson, brother to Raoul, king of France. Boson was slain before St. Quentin in 931, and, after a century of vicissitudes, the domain, held by a more quiet-temper of the church, was in 1037 the signory of Alberic, the founder of the heronial name of Coucy. It is uncertain whether Alberic was of the family of Eudo de Chartres or that of the Counts of Vermandois. By marriage he added Amiens and its grand adjacent castle of Boves to Coucy, and is thought to have founded the abbey of Nogent-sons-Coucy.

Alberic was succeeded by his son Enguerrand, Sieur de Coucy, Count of Amiens, and Lord of Boves. He married Ada, heiress of Letard de Roucy, Lord of Marle, second son of Gilbert, Count of Reims, with whom he acquired Marle and La Fère. He is thought to have first assumed the well-known armorial bearings "Barry of 6, vairé and gules." He died 1116, leaving Thomas.

Thomas de Marle, de Coucy, his son and successor, long in rebellion against his father, bore a bad name for violence. He lost Amiens; but, again by marriage, acquired Crécy-en-Serre and Nogent. He died 1130.

Enguerrand II., known as Le Sire de Coucy—this title, it is said, denoting the lord of an allodial fief,—beld also Marle, Crécy, Verme, Pinon, and La Fère, in which latter castle he defended himself with success against Louis le Gros and Raoul, Count of Vermandois, in 1132. His reign was one of peace and justice.

This Enguerrand is said to have slain in personal combat a ferocious beast, called a lion, that infested the neighbourhood; and this tale is no doubt the origin of the lions which were used by the family as crest and supporters. Such tales were common in the twelfth century, only the scene of the exploit was usually more safely laid in Palestine. This combat was commemorated in a bas-relief over the door of the keep at Coucy, and was probably the foundation of a singular ceremony which only ceased at the revolution. "Thrice annually, at Easter, Pentecost, and Christmas, the Abbot of Nogent, or his attorney, entered Coucy by the lower gate, a whip in his hand and mounted upon a croppered and doctailed bay. On his pommel was suspended a seed-bag of white linen filled with wheat, and in a basket certain crescent-shaped cakes stuffed with minced veal, cooked in oil, and called rissoles, probably the earliest mention of a dish which has descended to our own times.

Behind the abbot came a red dog, also with cropped ears and tail, and having a rissole suspended from his neck. This singular procession then entered the castle, and at the base of the keep the abbot made the circuit of a central and three lesser couchant lions there carved in stone, and afterwards embraced the larger beast. This done he offered the cakes in homage to the lord, who distributed them to the people, and then witnessed the record of the homage by affixing to it a special seal, representing a mitred and crosiered abbot, having for feet the hoofs of a huck. A representation of this ceremony in tapestry long adorned the walls of the

castle, and is thought to have been taken into Lorraine after the marriage of a later Coucy with a daughter of that house.

Enguerrand II. died while on a crusade in Palestine about 1145; but his body was laid in his abbey of Prémontre, near the castle, where his effigy remained in 1632.

Raoul de Coucy, son and successor, was under age at his father's death. He married, about 1169, Agnes of Hainaut; and secondly, Alix, niece of Louis-le-Jenne, and sister of Robert de Dreux. By this match he connected himself with the blood royal. He accompanied Philip Augustus to Palestine in 1188, and fell before the walls of Acre in 1191. He was buried at Foigny, and his son by Alix was his successor.

Enguerrand III., called the Great, Lord of Montmirail, Oisy, Crèvecœur, la Ferté-Ancueil, la Ferté-Gaucher, Vicomte de Meaux, and Châtelain of Cambray. He was the founder of the present castle, and at the same time walled in the considerable town that had risen under the protection of his ancestors. As he was a child at his accession, his mother administered the signory, and conceded a charter of liberties to the town in 1197; which he confirmed upon age. In 1200, *more majorum*, he attacked the property of the Church of Reims. In 1210, he joined the Count of Vermandois in the first crusade against the Albigenses, which he repeated in 1219 and 1226; then assisting at the siege of Toulouse and the taking of Avignon. He distinguished himself also at the battle of Bovines.

Enguerrand, though not wanting in territorial power, exercised an influence far beyond that due to wealth or breadth of possessions, and which was in great measure personal. He appears to have submitted with an ill grace to the government of Queen Blanche during the minority of St. Louis, and is said to have even contemplated regal power. However this may be, the consciousness of his influence no doubt led him to erect the Castle of Coucy, it is thought, between 1225-1230; and it may be that in so doing he proposed to himself to cast into the shade the grand tower of the Louvre, the work, a few years before, of Philip Augustus. He is also said to have rebuilt his other castles of St. Gobain, Assis, Marle, Folembray, and St. Aubin, and the Hôtel Coucy at Paris.

In 1244, he was in the confidence of St. Louis, and attended a conference of nobles at Chinon, where he supported the plan of a descent upon England; but while assembling his vassals for this purpose he was stung from his horse and killed by his own sword. Of his children by Marie de Montmirail, Raoul II., who fell in the crusade of 1250, and Enguerrand IV., became successively Sieurs de Coucy; but both died childless; and with the last closed the male line of these great barons. Alix, half-sister to the last lords, married Arnoul, Count de Cuiues. Enguerrand the Great had also a daughter, Mary, who was the second wife of Alexander II. of Scotland, and the mother of Alexander III. Mary was a very remarkable person, and exercised the duties of guardian to her son in difficult times in a very efficient manner, devising and executing a vigorous policy of her own.

Arnold Comte de Cuiues sold Cuiues to Philip le Hardi in 1282. Alix de Coucy, his wife, was daughter of Enguerrand III. by Marie Dame d'Oisy, his third wife. They had Enguerrand V. de Cuiues, Sire de Coucy, &c., who lived at the court of his cousin-german, Alexander III., in Scotland, where he married, before 1235, Christine de Baliol. He died 1321.

William, his son and heir, married Isabel, daughter of Guy de Châtillon, Comte de St. Pol. He died 1345, and was succeeded by Enguerrand VI., who married Catherine daughter of Leopold, Duke of Austria. This baron took part in the defence of his province against Edward III., and fell at the battle of Crécy, in 1346, leaving his son an infant.

Enguerrand VII., better known in England as Ingelram de Coucy, was one of the greatest and most powerful barons of his race and age, and, in a warlike age, celebrated as a military leader. He commenced his public life by a war of extermination against the insurgent Jacquerie. He was then one of the hostages in England for King John, and there married Isabel, daughter of Edward III., became a Knight of the Garter (30th on the list), and in 1366 was created Earl of Bedford. The effect, perhaps the price, of these honours was his neutrality in the war between France and England. He claimed the duchy of Austria, and raised 60,000

condottieri to support his rights, but in this he was unsuccessful.

After the death of Edward III. he returned the insignia of the Garter to his successor, and took part with France. Upon Du Guesclin's death, he was offered, and declined, the sword of Constable of France, but became governor of Picardy. His advice to the king was to anticipate the English attacks.

His second wife was a daughter of the Duke of Lorraine. In 1382, he composed, by fair words, the insurrection of the Maillotins, at Paris. In Picardy he was scarcely less lenient. Doutard, one of their leaders, he sentenced to death, but at the gallows foot he was pardoned, by the custom of Picardy, because a woman from the crowd consented to marry him,—a singular legal juxtaposition of hanging and matrimony. Enguerrand took part in the campaign of Charles VI. against Ghent, in which Van Artevelde was killed; and in the following year, after putting down an insurrection at Paris, he joined the war in Flanders, where he won the high approbation of Froissart.

He then went to Italy, and fought at the battle of Arezzo, for which he received the charge of Grand Butler of France. Shortly afterwards, he was prominent in the military and naval preparations for a descent upon England, and seems to have commanded a division of the fleet, and to have been driven upon the coast of Scotland.

In 1390 he took part in the African expedition, landing at Carthage. The closing act of his life was the unsuccessful crusade against Sultan Bajazet, upon his invasion of Hungary, where Enguerrand was defeated and made prisoner, and so died in 1397, aged 57, the last male of the second line of the Sires of Concy.

Upon his death, Louis Duke of Orleans, by a mixture of force and fraud, obtained possession of the Concy estates, to the exclusion of the heir female. Upon the death of Louis, in 1465, Duke Charles succeeded, and upon his accession to the throne of France as Louis XII., in 1498, Concy became Crown property, and ceased to retain any individuality, or to be the seat of an independent family. As an appanage of the Crown it was granted to the successive families of Orleans, and was thence held by *égalité* at the revolution. It is at present vested in the Crown, and has in consequence received a share of the consideration with which the Emperor regards all public monuments, and has been most judiciously preserved from further decay by M. Viollet-le-Duc, from whose survey the annexed engraving has been made.

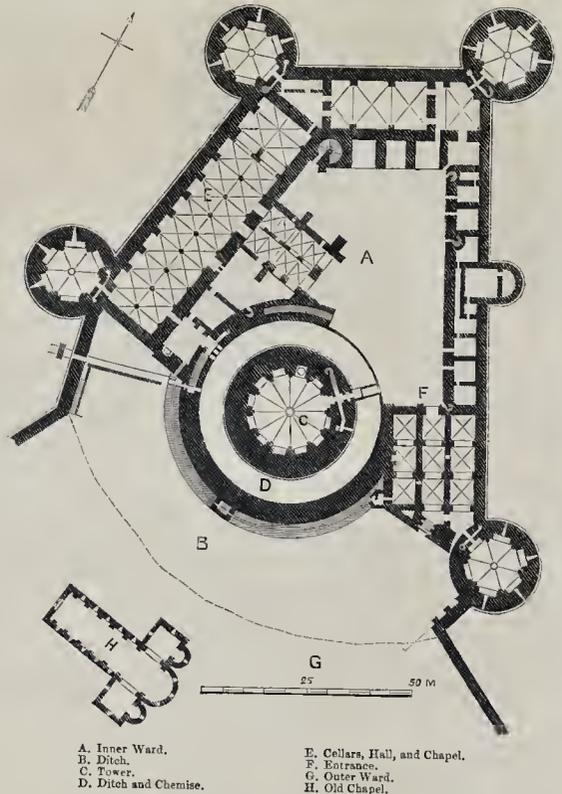

The Castle occupies the north-western extremity of the platform, of which the remainder is occupied by the town. Upon three sides the natural defence is the steep hill-side, the upper 30 ft. or 40 ft. of which are rendered vertical by art, and faced with masonry. (The wholly artificial) defences of the town on the south front are a deep ditch, extending from cliff to cliff, and dividing the town from the castle, within which is a curtain wall, flanked at its ends by two round towers, containing vaulted chambers, and with a central gate-house, also so flanked*.

THE NEW CHURCH OF ST. JUDE, EAST BRITXON.

On the 8th of December, 1866, a few gentlemen met at the Parsonage of the parish of St. Matthew, Brixton, when the Incumbent drew attention to the rapid increase of the population of the parish, which now exceeds what it was before the portions of it now belonging to St. John's, Angel Town, Holy Trinity, Tulse Hill, and All Saints', Clapham Park, were separated from it. The subject was maturely considered, and it was resolved to erect a new church. A plot of ground in Dalwich-lane was purchased at a cost of 736*l.*, and designs were received in competition from twelve invited architects for a church to accommodate 1,000 adults and 100 children. From these the design sent by Mr. E. C. Robins was adopted, and we publish a view of the interior in our present number.

The foundation stone was laid in August last, and the building has rapidly progressed since. The whole of the exterior is now complete, with the exception of the upper stages of the spire; and great efforts are being made to raise the remaining 2,000*l.* required to complete the interior.

* To be continued.

COUCY CASTLE, FRANCE.—Plan.

The church is designed in the Early Decorated style, and consists of a nave 96 ft. long by 24 ft. wide, and 48 ft. high to the internal apex of the open-timber roof, and north and south aisles, each 96 ft. long by 17 ft. wide, 36 ft. high, with shallow transepts at the chancel end. The total internal width of the church is 62 ft., and across the transepts 78 ft.

The chancel is 27 ft. deep by 20 ft. wide, and 30 ft. high from the raised pavement to the highest part of polygonal boarded roof. There are nave and north aisle porches. The tower is situated in the north side of the chancel, at the end of the north aisle. It is divided into four stages, the lowest story forming a third porch, and is surmounted by a Bath-stone spire, 105 ft. from the ground to the top of the vane. The vestry, with hot-water apparatus chamber beneath, is situated in a corresponding position on the south side of the chancel.

The church is faced externally with Kentish rag and Bath stone dressings. The windows generally are divided by mullions, with three lights, and the heads filled with geometrical tracery. The transept and nave end windows are in four lights, and the chancel window is in five lights. The roofs are of steep pitch, set to an angle of 60 degrees with the horizon. They are covered with purple and blue Welsh slates in bands, with serrated edges to the lowest course of each band. There are ornamental iron ridges to all the roofs, with crosses of iron or stone to all the gable ends, the large wrought-iron vane and lightning conductor being supplied by Messrs. Richardson, Slade, & Ellison.

There is a good deal of carving included in the contract, both externally and internally—externally, chiefly in label end bosses, and ball flowers to the corbel tables and angles, cornice to parapet of tower, and gargoyles for each angle of the tower. Internally the circular

columns of the nave arcades are surmounted with square abaci with carved capitals.

The chancel arch is double, the lower, receding 6 in., and supported on red Mansfield stone shafts, with foliated capitals on carved corbels. The nave arcade and the chancel arches are of stones, alternately with red and white bricks. The rest of the interior walls are plastered with rough stucco face. The aisle roofs are of trussed rafters, circular-saw cut, and stained. The nave roof is in addition provided with mot trusses, with curved braces, and pierced cusping resting on moulded corbels. The space between the nave and aisle roofs is plastered for ceiling. Between the nave and aisle roofs are sixteen dormer windows provided for light and ventilation, chiefly the latter. The pewing is of stained deal varnished. The pulpit and reading-desk are intended to be of stone. The pavement of the chancel and the recesses will be of ornamental tiles. The chancel will be heated with warm water.

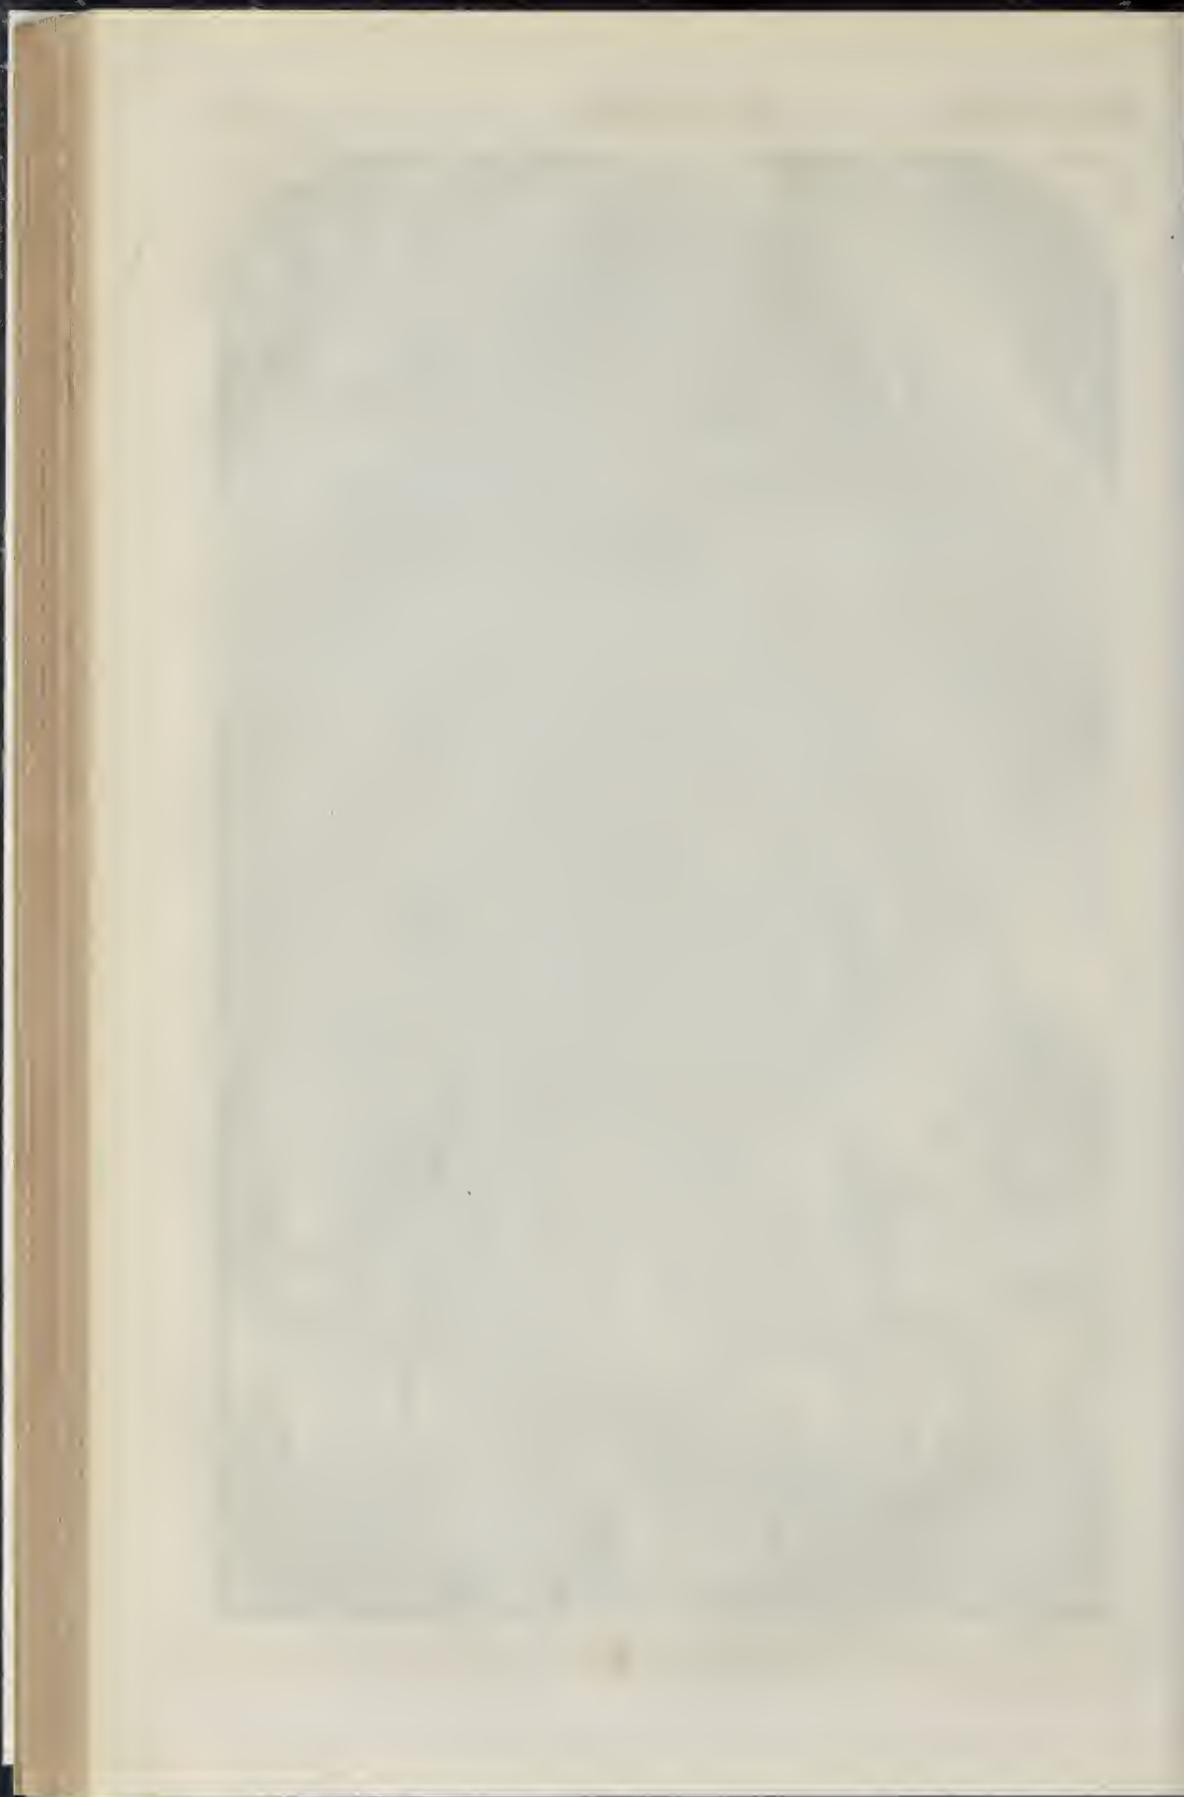

The amount of the contract for the whole is 6,000*l.* The contractor is Mr. John Kirk; the clerk of works, Mr. Leach.

THE ARCHITECTURAL MUSEUM.

We understand that a contract for the new building, Westminster, has been signed, and that the works are in progress. A considerable sum of money is still needed to insure completion of the undertaking. Would-be students should remember that there are large architectural collections in the South Kensington Museum, and that they need not wait until the new building is up. The fact is, it is much easier to talk about studying, and to find reasons for not doing it, than to go to work in earnest.

THE CHURCH OF ST. JUDE, EAST BRIXTON.—MR. E. C. ROBINS, ARCHITECT.

THE TECHNICAL INSTRUCTION MOVEMENT.

At the Society of Arts last week a paper on Technical Education was read by Mr. John Randall, F.G.S., one of the artizan reporters on the Paris Exhibition. In referring to French progress in art, as evidenced at last year's Exhibition, he said:—

This progress was witnessed by a large number of our countrymen, including a goodly sprinkling of artisans, who expressed their surprise,—a surprise, however, which subsided on looking into the facilities foreign workmen enjoy for obtaining a knowledge of the principles of their art, and of the theory of their several crafts. Many of those who have written on the subject tell us that they found light and easy styles of ornamentation, founded upon a close observance of nature, and adapted to various materials in almost endless devices; and this not altogether as applied to rich and costly articles coming within reach of the luxurious classes, but in connexion with multifarious objects of elegance, produced at little cost, and intended for common consumption and general use.

They saw French workmen working less hard than ourselves, but producing higher effects with greater ease,—working with less energy, but with a greater familiarity with the science and tendencies of their art; they found these workmen acting out their part under the direction of intelligent foremen and chiefs—themselves the higher creations of the same excellent system of technical training; and they found these results the matured fruitage of indigenous institutions which had taken firm root on French soil. They found, on instituting a comparison, in very many instances, British workmen imperfectly taught, and to a great extent ignorant of the economy of human effort,—often working under foremen chosen more for ability to keep accounts than from any superior knowledge or power to direct. In either case, they found few reaching above the level of mediocrity, or receiving any stimulus beyond mere wages to develop the facilities with which God has enriched them, and which, if fully cultivated, would increase the means of individual happiness, and add to the prosperity of the country.

I heard an English workman observe in Paris that there is much more credit due to an English workman if he is clever; for a Frenchman has so many advantages that, if he only have moderate talents, he can scarcely help but be a good workman. He has excellent schools to give him a technical education, and, go where he will, there is something to educate his eye, and elevate his taste.

It is my decided opinion that, whatever the means suggested for supplying the deficiencies of technical instruction, they should be in the hands and under the control of Government. The voluntary system with regard to education, notwithstanding the sectarian stimulants applied, has signally failed; and the part-voluntary scheme of art-education has proved inefficient. In few places, if any, are art-schools supported as they ought to be, whilst in some they have been closed altogether, or those still open are chiefly attended by amateur ladies and others above the class of artisans. Government has hitherto been in advance of the people to a certain extent on these points; and it really is to the governing power that we must look, rather than to local effort, for the means of placing the art-workmen of this country on an equal footing with their rivals on the Continent. Give to the Englishman the same opportunities of enlightenment and instruction as to the foreigner, and there is no branch of art and science, no human industry requiring taste and skill, in which he will not shine pre-eminent.

The conclusion seems natural that the seed of a scientific and art-education, such as the country requires, must be sown in the national or primary school, either by the schoolmaster or by supplementary teachers. What we complain of, and what the country, raising the taxes to support the present system, complains of most, is that it is too much in the hands of the clergy, and under inspection by men drafted from them,—men who are neither qualified by their education, their callings, nor their sympathies, for appreciating the importance of that secular knowledge which is so essential to the social well-being of the children committed to their care, and who are under a temptation to use it as a proselyting scheme, rather than an engine for fitting children for their duties. What we

want is for the State to carry out its own admitted principles; to furnish that education which it professes to give, which it admits is essential to the commonwealth, instead of going a round-about way and giving something else. Government in effect now says: Education is all-important; it is essential to your welfare, and to that of the public; you want it, and we undertake to give it upon condition that you take something else along with it. It is the old plan of cheating the law by selling the straw and giving the hook.

The new minute of the committee of council for the advancement of technical education in connexion with art and night schools, by payments and scholarships, is a step in the right direction, and will give a stimulus to the good work of technical training; but it will even require something more than this to overcome the inertia of existing indifference and general apathy.

In the discussion which followed the reading of the paper, several workmen, chiefly artizan-reporters on last year's Paris Exhibition, took part. One of these, Mr. Connolly, mason, whilst assenting generally to Mr. Randall's view as to French progress, said that in his own trade—that of a stonemason—he had often seen a shop-foreman spend hours over a stone, showing the man who was to work it what was required, and drawing lines upon it for that purpose; and it was often quite a puzzle between the man and the foreman what direction these lines should take. There was not more than one foreman in twenty that could take a pencil and make a plan and section of what was required to be done; and if there were more, not one man in a hundred would know what was meant. If the foreman had sufficient education to be able to communicate his ideas to the workman by drawing, and if the workman were able to understand the drawings, an immense deal of time would be saved, and work would be better done; but at present they both had, to a great extent, to grope their way in the dark. He contended that the nation ought to supply this education, and that it would be economy on its part to do so. He must differ in one respect from the reader of the paper, and that was as to the religious element in teaching. He could not ignore the benefits which art had received from religion. Everything grand and noble in it had been the result of the action of religion upon the human mind. The noble buildings which studded the face of the country like gems in a diadem, arose out of the religious enthusiasm of the Middle Ages; and were they to believe that that same spirit was dead in the people of England? No, it only slept; it only required to be once more aroused to zeal and enthusiasm.

Mr. Jacob (cabinet-maker, one of the artizan-reporters) remarked, that one great advantage which it had struck him during his visit to Paris, the French workman had over the English, was the opportunity of visiting museums and galleries of art at times convenient to himself. They could only visit the British Museum on certain days in the daytime, which was practically impossible to excluding working men. The influence of the clergy would probably be exerted to prevent the opening of such institutions on a Sunday. If they were even open of an evening, he would ask any one who worked for eight or ten hours a day as he ought to work, if he then felt fit to go to a museum and study. He had tried it, and found great difficulty in deriving much benefit from his visit. The museum of South Kensington had certainly done more than anything else to improve the artistic taste of the working classes; but much more might be done, and, as one means, he would suggest the supplying copies of plaster casts at cost price. Again, the knowledge of geometry and orthographic projection was difficult of attainment, and the hooks from which it might be learned were costly; yet, without some acquaintance with these subjects, it was difficult to make a workman understand a working drawing. He suggested that sheets of such projections should be issued at a low price, so that they might be introduced into workshops, and that men might become familiarised with them.

Mr. Randall, at the close of the discussion, said he wished to correct a wrong impression which seemed to have been produced—that he was not a friend to religion. It would be sufficient to show that this was not the case, if he mentioned that he and his wife were members of the Church of England, that he had three daughters school mistresses in national schools, and one son a pupil teacher. He, therefore

knew something of the system of which he had spoken, and he knew that religious prejudices did interfere with the proper education of the country. It was quite usual, especially in country parishes, for a clergyman to speak of "my school," and "my schoolmaster," just as if the whole establishment were under his sole control. He quite agreed with the idea that district museums and colleges should be established. He thought it would be well if these district colleges had the power of conferring honorary distinctions. He had been made a fellow of the Geological Society, in consequence of his studies in that science, which he looked upon merely as a recreation; and if some similar distinction were awarded to men who devoted their energies to the attainment of excellence in their own particular business, it would be likely to have a very beneficial effect, especially on the rising generation of artisans.

EXHIBITION OF THE ROYAL SCOTTISH ACADEMY.

THE forty-second exhibition of the Royal Scottish Academy was opened to the public on the 15th ult., the number of works displayed being 1,086. Amongst this number there are a few excellent productions, a larger number of secondary merit, and a still larger residuum of inferior quality.

Of well-known works there is, as usual, a small admixture. These include Debufo's portrait of Rosa Bonheur, Philipp's "Letter-writer of Seville," "Marriage of the Princess Royal," and several of the sketches for his larger works; "The Finishing Touch," by Erskine Nicoll; "A Winter Night's Tale," by MacIver, and others.

The figure subjects are more numerous than has been the case for the last few years, the number of large obtrusive portraits fewer, and landscapes still continue to receive more favour than in the Royal Academy. The president has only one picture, No. 495, a "View of Glenfalloch, looking towards Loch Lomond." It is possessed of the qualities of health, air, and repose which more or less characterise his former landscapes, with less of the peiny glitter which so greatly detracted from their value.

The agony of the "Man of Sorrows," in Gethsemane (No. 622, Sir Noel Paton), is one of those subjects upon which modern painters should hardly venture. It jars against our ideas to criticise such. In this work we can trace nothing superhuman in the agony depicted. The picture is pretty rather than affecting. There is the calm moonlit sky, with the single star, which the artist delights in reproducing, and the carefully-painted grass and flowers, which could hardly be so distinctly seen under such a light. The drapery is gracefully disposed, and possesses considerable depth of colour.

More to our taste is the small picture (No. 454) of the ancient mariner obtaining relief by sleep from the strange grief that oppressed him. The aerial figure floating overhead is treated with the grace and elegance pervading the fairy subjects which are the artist's strong point.

No. 515, "Among the Cliffs," by Peter Graham, is not a very good subject; as a study from nature it is excellent; but we miss in it the poetical suggestiveness displayed in some of the former works of the artist. There is more in No. 497, "Billowness," by W. F. Vallance, where the peculiar swing of a ground-swell breaking against a sharp ledge of rock is happily rendered, as well as the gradual recession of the sea towards the horizon.

No. 542, "Tomb of the Bruce," W. H. Paton, is a view of Dunfermline Abbey, under the soft and mellowing influence of moonlight,—the salient points of the building being well brought out. We, however, prefer this artist's water colours: that medium seems better adapted for his style of work, which is pretty rather than forcible. No. 86, "Loch-in-Daal, Skye," is a good example.

No. 537, "Loch Torridon," A. Perigal. Mr. Perigal has the merit of choosing fine subjects from a good point of view, and these he delineates in a hard and formal manner: the same sky with billows of heavy clouds overhangs the metallic mountains which appear in all his views of Highland scenery.

No. 550, "A Rainy Day in the Country," Charles Lees, shows us a room in a country-house where the inmates are engaged playing chess, bagatelle, &c. Mr. Lees does not inform us whether this country-house is one of those esta-

blishments for the care and safe custody of the insane, yet certainly the inmates seem beside themselves: the half-emptied decanters on the side-table may account for this.

No. 651, "Borrowdale, Cumberland," Sam. Bough. The view is fine and excellently treated; nothing is shirked, all the details being carefully elaborated, yet in such a manner that they blend into a harmonious unity. The gradation of light and shade from the strongly-pronounced foreground onward till the distance vanishes in pearly gray behind the closing vista of hills, shows the work, if not of a master-mind, certainly of a very clever artist.

In a different style, and yet fine in their way, are the works of Mr. E. T. Crawford. No. 623, "A Lowland Strath," is one of those placid, sunny bits of nature where one lingers to linger, and the artist has succeeded in imparting that character to it. He is equally successful in his sea-piece, and has produced a warm and hazy atmosphere and sparkling translucent water in No. 679, "Hay-boats off Doedrecht."

Mr. W. Douglas used to produce works of some importance which told a particular tale of their own. The accessories of these works were always carefully studied, and displayed antiquarian research. Now, however, he allows his love of nick-nacks to carry him away, and the human element introduced is a mere excuse for their display. This is obvious in No. 668, "The Antiquary's Daughter," and appears more or less obtrusively in his other exhibits.

No. 520, "Portrait of Mrs. Shand," by R. Herdman, is the portrait of a lovely woman, painted with delicacy and grace.

There is always something in the works of Mr. W. B. Scott to arrest attention; this may arise in some degree from the peculiarity of the subjects he chooses, but also from the manner in which they are presented. No. 300, "A Messenger of the New Faith," represents a scene in Roman life in the middle of the second century; a Christian maiden with the "Book of Life" in her hand is entering a temple of Venus intent upon rescuing from the wiles of the priestess a simple-looking girl, whom she is initiating into the mysteries of the worship of Aphrodite. In the courtyard of the temple (a good example of Roman coloured decoration) are two girls prattling with a chubby little fellow equipped as a Cupid. Beside the priestess a woman reclines on a couch in a state of semi-nudity, who seems scared at the entrance of the visitor, but the aged priestess is in a state of vehement wrath at the intrusion. The most unsatisfactory thing in this picture is the chief figure. In his desire to impart to the messenger an air of purity, he has run into the extreme of making her appearance.

310, "An Eastern Lady," M. J. Portales, is one of those specimens of soft mezzo colouring which find many admirers. The lady has the large liquid eyes, rich brown skin, and full ripe lips which characterize the beauties of the harem.

340, "The Alarm," J. B. Macdonald, represents one of the followers of the Pretender, after Culloden, alarmed by the approach of an enemy. He is accompanied by his wife or sweetheart, who urges him to seek safety in flight, but he appears more inclined to face the danger. This is, in our opinion, the finest piece of work the artist has produced. The figures are boldly and vigorously drawn, and the texture and colour far surpass his former efforts.

Mr. Macgarrath's "Dora in the Wheat-field" (No. 404) is in many respects a fine picture; the figure of Dora is simple and graceful, and that of the boy childlike and natural, and the reapers in the distances are skillfully introduced. We are not quite sure of the colour of the ripe wheat, but we feel convinced that "the mould that was unsown, where many poppies grew," requires much more work upon it than has been bestowed upon it by the artist: the poppies and other wild flowers are carefully enough wrought out, but they grow individually, each by itself, without the accompaniments which are found in nature. Detail of this sort should either be distinctly wrought out or suggested: in this instance neither course has been adopted. The sky in this picture seems rather tame, but this may arise from its proximity to the glowing sunshine of Bough's "Thames from Greenwich" (No. 410). 448, "A Pine Forest," by J. McWhirter, is solemn and grand in conception, and vigorous in execution.

488, "The Ballad Singer," Geo. Hay, has a thoroughly Medieval look about it: the characters do not seem like moderns dressed up to play

a part, as they do in No. 793, "The Captured Banner," by J. A. Houston.

684, "Waiting for a Reader," J. Drummond, represents a scene common after the Reformation. A number of the early Protestants are waiting for some one to read to them from a large Bible chained to a desk in a church porch; it is one of the best pictures Mr. Drummond has produced for many years.

694, "Checkmate," R. P. Bell, introduces us to two cavaliers engaged at chess. The crest-fallen puzzled look of the one and the self-satisfied triumph of the other are given without exaggeration.

Mr. J. Farquharson is a young landscape-painter whose works are full of promise. No. 708, "Pass of Aberglassly," is sunny and bright; and 947, "Llyn Idval, North Wales," sombre and appropriate.

There are other two young aspirants to fame, whose works are deserving of special notice.—Mr. W. E. Lockhart and Mr. E. J. Douglas. The former is of the school of Philip, and the latter is a follower of Landseer.

Mr. Archer exhibits two pictures, both displaying good drawing, texture, and colour.

Want of space prevents us from noticing in detail the figure subjects of Messrs. Chalmers, Halswell, T. Graham, and others, and the landscapes of Messrs. Cassie, Beattie Brown, Burton, &c., which are all deserving of notice; but at the same time it saves us the pain of writing in terms of censure of the productions of others of whom better things might have been expected.

In our next we shall take up the architectural drawings, as in duty bound.

MEMORIAL OF STOTHARD.

The memorial bust of Stothard, recently executed by Mr. Weekes, R.A. (for presentation to the National Collection as a *pendant* to that of Mulready by the same sculptor), will be included in the ensuing exhibition of the Royal Academy. The promoters of this memorial to the gentle, gifted artist it so happily represents, have well earned the grateful thanks of all classes of our art-loving public; for, previously to its execution, no such tribute had been awarded to his name and memory.

LOCAL BOARDS AND TOWN SURVEYORS. CREWE.

WHERE all local boards to follow the example of Crewe, the office of town surveyor would not be an enviable one. Crewe is what may be called a working men's town, of about 16,000 inhabitants, the majority of the adult male population being employed at the locomotive works of the London and North-Western Railway Company. The local board is composed of fifteen members, whose views appear to be not very liberal. From the accounts in a local paper, it seems there are extensive sewerage works in operation in the town under the superintendence of the surveyor, who had, until recently, the assistance of a foreman, whose duties were to keep the time of the workmen employed in the streets, and generally to assist the surveyor in his outdoor duties, also to act as turncock and water-inspector.

The Board have recently deemed it necessary to take away this man, in order that he may devote the whole of his time as inspector at the outfall sewerage works, thus depriving the surveyor of his services, who has now not only to perform his own professional duties (the construction of the main outfall sewers entailing a great amount of additional work), but the duties of the water inspector and ganger. He asked to be allowed to appoint one of the other men to keep the time and to have charge of the remainder of the workmen during his (the surveyor's) absence, and he paid 2s. per week extra for such work; this was passed in the general purposes committee, but over-ruled at the last general meeting of the Board. It is amusing to read the arguments against such an arrangement. The chairman, who is described by one of the members as "a close and cheese-paring man," thought that the surveyor ought to pay it out of his own pocket. The following resolution was passed:—"That the surveyor be informed that it is his duty to look after the men in the streets, even if it necessitates his attendance at six o'clock in the morning."

Now, had the surveyor been "informed" of such being his duties when he was appointed, he probably would never have engaged to perform such work, as he states that he was never called upon in his previous engagements to be in attendance before nine o'clock except on particular occasions. It was admitted that he is frequently required to attend committee meetings up to ten o'clock at night, and now he is required to be out at six o'clock in the morning.

A few months ago the surveyor was "informed" by a resolution of the Board that it was his duty to make a survey and plan of the whole town and district. What will be the next duty of this unfortunate town surveyor?

APPOINTMENT OF AN OFFICER OF HEALTH FOR MANCHESTER.

At a meeting of the Manchester City Council, on the 4th inst., a resolution was passed appointing Mr. John Leigh, M.R.C.S., Officer of Health for that city, at a salary of 500l. per annum.

The importance of this appointment to the cause of sanitary progress can scarcely be over-rated. Not only may the close upon half a million of inhabitants living in Manchester reasonably expect to derive advantage in the shape of reduced death-rates, and the enjoyment of a higher standard of health, but this appointment, in the third city of England, will strengthen the hands of the sanitary party in those of our large towns which have not yet acknowledged the necessity for the services of such an officer. Birmingham is now by far the largest town in England unprovided with an officer of health; and although, from natural advantages of situation, this town has enjoyed a comparative immunity from epidemics, and a generally low death-rate (for a large town), evidence is not wanting in recent returns to show that Birmingham is being left behind by the greater sanitary activity of other towns. Since the beginning of the year Birmingham has not stood so well in the list of towns, arranged in the order of the weekly rates of mortality, as formerly. This is not so much because Birmingham is less healthy, but that it is standing still, while other towns are rapidly reducing their excessive death-rates.

The appointment of an officer of health for Manchester has been the result of a long-continued struggle between two almost equally balanced parties in that city and its council; and long since such an appointment had been decided upon, the selection of the officer has been keenly contested. Mr. Leigh, from the first, had been mentioned as the most eligible candidate, from having long been known to possess many of the most necessary requirements for an efficient officer of health. He had devoted much time to sanitary research; he was well-versed in the subject; was a chemist of undoubted ability; and had for years held appointments under the council, entailing duties of an analogous character to those which should be performed by an officer of health. Early in September last, at a meeting of the Council, when the appointment was brought forward, its opponents succeeded in referring it to a committee, which was empowered to advertise publicly for candidates for the proposed appointment. Six months were apparently consumed in the labours of this committee. The advertisements setting forth that the Corporation of Manchester were prepared to receive applications from gentlemen, medical or otherwise, willing to undertake the duties of officer of health for that city, the salary being 500l. per annum, as might be supposed, resulted in numerous applications.

In addition to Mr. John Leigh, and Dr. Reed, of the Royal Infirmary, Manchester, between whom the choice of the council eventually rested, ten other medical gentlemen, three officers of the army, one clergyman and schoolmaster, an Inspector-General of Army Hospitals, the Officer of Health of Southampton, two sanitary inspectors, and three other gentlemen, whose qualifications are not stated, were among the applicants. As before stated, these candidates were finally reduced to two, Mr. Leigh and Dr. Reed; and when the selection was finally put to the vote, thirty-three of the council were found to be in favour of Mr. Leigh, and twenty-six for Dr. Reed, the former being thus elected by a majority of seven. The recent unsatisfactory sanitary condition of Manchester, as shown in the published re-

turns of births and deaths, has probably influenced in some measure the council to the appointment just made. The following few figures will show that it has been made none too soon. In the city of Manchester the death-rate in 1867 was 31.4 per 1,000 persons living, and higher than in any one of the twelve other large towns of the United Kingdom, furnishing weekly returns. The average rate in the thirteen towns for the year, was 25.3 per 1,000. In the past ten weeks of this year (ending 7th inst.), the death-rate in the city of Manchester and the borough of Salford, has averaged 31.5 per 1,000, whereas in eleven large towns of England, including London, the rate has not exceeded 25.3 per 1,000.

ARCHITECTS' BENEVOLENT SOCIETY.

The annual general meeting of the subscribers to this Society was held on Wednesday, at the House, in Conduit-street, at which were present Mr. Sydney Smirke, R.A. (president), in the chair, and Messrs. B. Ferrey, F.S.A., George J. J. Mair, F.S.A., C. C. Nelson, F.S.A., E. Roberts, F.S.A., E. Nash, F. Good, S. Wood, James Lockyer, and others.

The balance-sheet and general report, which was read by Mr. J. Turner (hon. sec.), and unanimously adopted, showed that, including the previous balance of 104l. 13s. 6d., together with subscriptions, donations, dividends, &c., the total amounted to 366l. 7s. 2d., of which, after paying in gifts to applicants 192l., and defraying the other expenses, a balance remained of 41l. 11s. 8d., in addition to 1,367l. 15s. 8d. invested in the New Three per Cents. The council had to deplore the insufficiency of their means, especially as during the past year the demands had been more numerous than in any preceding year. The general financial depression had been severely felt by the profession, many great works having been postponed or abandoned, and a great number of private undertakings checked. The applicants relieved had been 14, of whom 3 had been particularly distressing cases; but, in consequence of the exhaustion of the funds, several most deserving claims had been of necessity rejected. Since the last report, 18 new members had joined. The council had most specially to regret the decease of Sir Robert Smirke, their first patron. The Report proceeded to urge upon the members to use their utmost exertions to augment the number of subscribers, and generally to promote the efficiency of the Society. During the year there had been a great accession of members in Manchester; and it was heartily hoped that this noble example would encourage and promote the extension of their brotherhood in other districts.

The list of subscriptions was read, and donations of 5l. 5s. each, handed in from Messrs. Ashton and Mair.

After the appointment of council and other officers for the year ensuing, thanks were accorded to those of the past year, as also to the Chairman of the day and the Hon. Secretary, and the proceedings concluded.

THE SOIRÉE AT THE ROYAL SOCIETY.

The *soirée* at Burlington House on Saturday last was largely attended. The Prince of Wales was present, and the Master of the Mint (Professor Graham), the Chemist, and Professor Tyndall exhibited some exceedingly curious experiments—the former the dialytic separation, by a septum of palladium, of pure hydrogen from coal gas, and the extraction of occluded hydrogen from palladium; and the latter Faraday's famous magnetization of light. There were many other objects of interest, among which were two simple means of increasing the luminosity of ordinary gas-lights. In one case increased amount of light was obtained by placing a simple self-regulating valve over the top of a glass chimney, the increased pressure and heating of the air within the chimney causing perfect combustion in the flame, with increased steadiness and softness as well as volume of light. In the other case the increase of light was obtained by an equally simple expedient, not new but important, namely, by placing over and across the two holes of an ordinary burner a small thin plate of platinum. In this case the size as well as the illuminating power of the light was greatly increased. It is stated that there is less consumption of gas

effected by this simple means, in the proportion of 2.92 with platinum perfecter, as against 3.02 cubic feet per hour without it, the illuminating power in standard sperm candles being as 6.41 to 4.06, or an increase of light, per foot of gas, of 63 per cent. The platinum disc used was the invention, it is said, of Mr. Scholl, and it was placed by a little cup over the burner. The self-regulating valve was exhibited by the Gas Economising Company.

To the art collections the Queen contributed original drawings by Fra Bartolomeo and the scholars of Raffaello. Photographs of Palestine, by the exploration party; photographs of the scenery, people, and animals of India, by Mr. W. Douglas; drawings made in the regions beyond Behring Straits, by Mr. Frederick Whymper; and the rotary induction machine for statical electricity, by Sir William Thomson, were also exhibited.

INSTITUTION OF ENGINEERS IN SCOTLAND.

At the fifth general meeting of this Institution, held on Wednesday, the 12th of February, Mr. James M. Gale, C.E., president, in the chair, the report of the Committee on Institution Buildings was read by the secretary. After discussion, it was agreed that the report be printed and distributed among the members, and a special general meeting called further to consider it and decide, on Tuesday, the 18th of February, at two o'clock, p.m.

The discussion on Mr. Duncan's paper, "Remarks on the Proposed Amendments of the Merchant Shipping Act," was resumed and terminated.

A paper "On an Improved Bar-testing Machine, and Callipers for Testing the Thickness of Pipes" (designed by Mr. H. J. King), communicated by Mr. John Page, C.E., was read. A discussion followed and was terminated.

At the adjourned meeting, on the 18th February, it was unanimously carried that the recommendations in the report be adopted, and the matter remitted back to the committee to take the necessary steps to carry out the proposed arrangement with the City authorities, and secure accommodation in the Corporation-buildings, South-shall-street.

Mr. Peter Denny intimated that he was willing to give 250l. (being one-half of what he had subscribed towards the scheme for obtaining a suitable building for the institution), on the understanding that the recommendations in the report be carried out, and the sum of 2,000l. obtained.

THE INSTITUTION OF CIVIL ENGINEERS.

On March 3rd, the paper read was "On the Manufacture and Wear of Rails," by Mr. C. P. Sandberg. It was divided into three parts. First, as to the best method of manufacturing rails out of common iron, and as to the time they would last. Secondly, as to the disposal of the iron rails when they were worn out. And thirdly, as to whether iron or steel, or a combination of the two materials, was the most economical to use for rails.

Assuming that, under a very heavy traffic, common iron rails would last five years, steel-top rails fifteen years, and solid steel rails thirty years, and that iron rails would cost 7l. per ton, steel-top rails 10l. per ton, and solid steel rails 15l. per ton, and that the old steel-top and iron rails were valued at 4l. per ton, and the old solid steel rails at 8l. per ton, then, with a rail section of 84 lb. per yard, 250 tons of rails would be required for one English mile of double line, and the cost of laying the rails might be estimated at 1l. per ton. On these assumptions the author gave various tables, the result of which was to show that the amount of traffic must decide which material it was the most economical to use for the maintenance of the permanent way. For all railways where ordinary iron rails were worn out in five years, or in a shorter time, solid steel rails were the most economical, at the prices quoted. Where ordinary iron rails lasted over five and up to ten years, steel-top rails would be the cheapest; iron rails in these cases being proved to be the most expensive, although the cheapest where they lasted from fifteen to twenty years.

One table indicated that the iron rails were in no instance the cheapest; but, on the contrary, that when iron rails lasted only five years, solid steel rails had the advantage, and where iron rails had a longer duration, than that steel-headed rails were the most economical.

HOGARTH'S MONUMENT.

HAVING passed many hours of instruction and admiration over the engravings of Hogarth, I wish to draw your attention to the state of his monument in Chiswick Churchyard. Every person who has gazed on his picture, and that are handed down as heirlooms from generation to generation in the mansions of the rich and noble, and our public galleries, cannot but admit that his grave, if he visit it, is treated with great neglect. It was restored by William Hogarth, of Aberdeen, in 1856. After eleven years' service, at the present time the black in the letters on the stony panels is completely gone, and the face of the marble itself is perished. But no notice is taken of the spot where lies the man whose pictured morals charm the mind. At the present time, when the name of Garrick is posted on placards over London, and with your aid, could not something be done so as to render the epitaph that Garrick wrote legible on the spot where his friend lies buried. The myrtle by the side is green and fresh, and to the reflecting mind the thought must come that Nature is more kind than his countrymen. I was a witness in the picture-gallery of the Exhibition of 1862 of the pride with which men pointed out "Marriage à la Mode" for the painting of an Englishman, and yet few seem to know or care about where the artist lies buried. Artists, actors, literary men, if only aware of it, I am certain would all willingly contribute to have the words placed on that monument in Chiswick churchyard. P. P.

THE SCIENCE AND ART DEPARTMENT EXAMINATIONS.

Sir,—While the important subject of education is occupying so large a portion of the public attention, permit me to direct the attention of your readers to a great defect in the examinations of the Government Department of Science and Art. A large amount of the public money is annually expended on these examinations, and it may, therefore, be well to consider for a moment the trial to which candidates are therein subjected, and the success attending these examinations. As one who has been awarded first-class certificates of competency and Queen's prizes under the Department, I speak from my own experience.

Considering the importance attached to these competitions, it might reasonably be expected that in such a subject as "Building Construction and Naval Architecture," candidates would be subjected to an examination as to the orders and principles of architecture, the construction of buildings, and naval construction; but, instead of this, the entire examination consists in copying, in a certain time, a few lithographs of building elevations, sections, &c., of the construction and technical terms of which the candidate is totally ignorant. This is all! There are no questions whatever asked relative to the subjects which head the examination papers, and no attempt is made to ascertain whether the candidate understands anything about the constructions in which he is supposed to be examined.

These remarks apply also to the examinations in "Mechanical and Machine Construction," &c. Should the candidate successfully pass this "terrible ordeal," he is invested with a Government certificate of competency, and rewarded with a "Queen's Prize," or even a Gold or Silver Medal at the public expense! Now, I consider this kind of education (?) not only a mere sham, but also a double deception. Firstly, the Government is persuaded into voting a large sum of money annually to support an educational movement, which, as it is now conducted, can be productive of no lasting good; and secondly, the successful candidate is led to consider himself competent in subjects of which he has no real knowledge.

It may be said that were a more searching mode of examination adopted, the remuneration of science and art teachers under the Department would be seriously affected; but it is only reasonable to expect that were the standard of excellence raised (which would necessarily result in a great decrease in the number of successful candidates) teachers' premiums, as well as the value of prizes, would be proportionally increased.

I am persuaded that had a form of examination such as I have hinted at, comprising questions in construction, technical terms, &c., with illustrative diagrams, been adopted in the May

examinations of last year, instead of between 400 and 500 students passing, not a fifth of that number would have been successful. In my opinion this is a subject which those who are now taking such an active part in the question of educational reform would do well to take into their serious consideration. Such an apparent defect in our Government educational department ought not to be passed over in silence.

I hope that the want of a reform in these examinations may soon be considered by those at head-quarters too apparent to be any longer disregarded.

A. E. P.

“USE OF HOME-GROWN TIMBER.”

UNDER the above heading, in last week's Builder, was given notice of a paper referring to several British timber-trees. In the list appeared “the howler,” “the vine-prop alone,” and the “plum-tree.” These three additions to our Flora were evidently discovered by the non-botanical contributor. It is not easy to say what “the howler” is meant for, but it should probably read “osier,” or “holm;” “vine-prop alone,” should be “vine-prop elm;” and “plum-tree” should give place to “plum-tree” (plums, intimately allied as they are to the building trades, do not yet grow upon trees). As the other quotations in the article are morsels of the following exquisite lines from Spenser's “Faery Queen,” perhaps you will allow me to quote them out:-

“Much can they praise the trees so straight and high,
The sailing pine, the cedar proud and tall,
The vine-prop elm, the poplar never dry,
The bulder oak, sole king of forests all;
The sprin good for staves, the cypress inneral;
The laurel, need of mighty conquerors;
And pines sage; the fir that weepeth still;
The willow, worn of forlorn parsons;
The yew obedient to the hand that wills;
The birch for shafts, the saw for the mill;
The myrtle sweet bleeding in the bitter wound,
The fruitful beech, the ash for nothing ill,
The fruitful olive, and the plantain round,
The carver holme, the maple seldom inward sound.”

W. G. S.

THE DRAWING OF THE THRONE, HOUSE OF LORDS.

ERRA.—Having seen some strange assertions of Mr. Herbert, R.A., in the Standard, I wrote to that paper, but was refused the insertion of my letter; I therefore hope you will allow me to state in the Builder that I have thought it my duty to ask to see the drawing from which the photograph in Dr. Barry's pamphlet was taken.

Having seen it, and from my long connexion and friendship with Mr. Pugin, being necessarily very familiar with his touch, possessing, as I do, many drawings of his, I am certain that the drawing in question is not Mr. Pugin's. The touch is different, the style is different, and it has nothing in common with his handwork. The photograph from its small size gives an idea of fineness of line, which the original does not possess, and it is different in every respect from Mr. Pugin's drawing. Having examined it very carefully, and compared it with other drawings of Mr. Pugin's and Sir C. Barry's, I am confident that it is wholly the work of the latter.

I may remark, that though I have seen Mr. Pugin make hundreds of drawings, I never saw him put his initials upon them as separate letters. He used a well-known cypher, combining his three initials, with letters of a totally different form from the marks on the photograph. He used to put this cypher in one corner, and not in the body of a drawing, and certainly not in drawings made for other people.

TALBOT BURY.

ST. JOHN'S CHURCH, WEYMOUTH.

LOCAL SUPERINTENDENTS.

ERR.—I should not have troubled myself to take any notice of Mr. Bennett's letter (published February 28th) if my veracity had not been impugned, and a flat contradiction given to a statement I was obliged to make, in consequence of misapprehensions published respecting the alterations to St. John's Church.

Mr. Bennett states that I am “not correct” in my statements, and that “I am labouring under a mistake,” yet he does not name the nature of my incorrectness, or where I am “under a mistake,” and refers me to the Rev. J. Stephenson. This I will do, as he desires it, and give extracts from several of his letters from the beginning, which will fully explain my position as “architect to the church,” both originally and now, and how this Mr. Bennett was mixed up with it.

In my letter to you of February 15th, I stated that I am architect to the church, which was erected fourteen years since, from my designs, and under my inspection; that I have made all the designs, elevations, plans, details, working drawings, and specifications for the alterations of the church, at present in progress; and that I have been in constant communication with the Rev. J. Stephenson, the incumbent, as the architect. Now, as regards these matters, I cannot be “under any mistake.” I think having made these drawings, &c., must make me the architect. To save travelling expenses and look after the construction, a local man was to be employed, “to superintend the execution of the work;” and Mr. Bennett has thus been brought into connexion with the church. I do not question what he may be, or if he is or is not an architect, as I never heard of him before this; but his claims in this case are not justifiable, and, on principle and honesty alone, I am bound to defend myself, or else there

is no architect who has a clerk of works employed under him but may be subject to the same injustice. If Mr. Bennett had built churches, or was capable of doing so, why was he not engaged? Even the working drawings and specification seem to have been beyond his capacity, and Mr. Stephenson's letters of the following dates confirm my assertions. January 24, 1867, I was applied to as architect to prepare all the necessary working drawings, specification, and an entire set of plans needful for carrying out the work, leaving the supervision of the actual building to a person to be appointed for the purpose, reference, of course, to be made to you should any difficulties arise during the progress of the works in carrying out your plans.”

I presume that “person” was to see my designs carried out in their “integrity.” Again (July 10, 1867), “What we want is this, that the plans, drawings, &c., mentioned in my last letter be prepared by you in such a way, that the work of engagement can be carried out according to them by a person we appoint to superintend the building; and that you shall be responsible for accuracy, practicability, and completeness of the plans and drawings.”

Again (July 15, 1867), “We shall not require you to superintend the work or make up accounts. We want the specification, designs, drawings, &c., &c.; in fact, we want the work placed entirely in your hands.”

October 7, 1867.—“We shall be obliged if you will send us, as soon as you can the drawings and drawings of the pier as it will enable us to get tenders for the new work at St. John's.”

October 9, 1867.—“Pray let us have the plans and specification that we may get tenders.”

November 20, 1867.—“Will you send the working drawings as speedily as possible? They are much wanted.”

I could give extracts of other letters to the same effect; but I think there is quite enough to prove my assertions and nullify the pretensions of Mr. Bennett; besides, as it is not a matter of general interest, I wish to make this explanation as short as possible.

TALBOT BURY.

HERNE BAY PIER.

SIR,—Your correspondents on this subject will, I dare say, be glad to know that something is likely to be done towards restoring and opening the pier.

It has been a disgraceful situation long time, and now it only remains for the proprietor and the public to come forward with a good heart: then, no doubt, a contractor can be found who will be disposed to meet them on fair terms. I think anything short of restoring the pier as it exists, so that it may be made a stopping-place for steamers as well as a promenade, as it used to be, will be most absurd. It is high time the Herne Bay people were roused. Why should the place not be one of the favourite resorts instead of being neglected and almost despised because of its forlorn condition? I hope that the parties who have the matter in hand will light through successfully the difficulties which seem placed in their way, and so redeem the lost prestige of Herne Bay.

ONE OF THE PIERS.

COMPARATIVE ALTITUDES.

SIR,—Comparative altitudes are very useful and interesting, but only when they are clearly defined as to position and exact spot; to say many drawings of his, I am certain that the drawing in question is not Mr. Pugin's. The touch is different, the style is different, and it has nothing in common with his handwork. The photograph from its small size gives an idea of fineness of line, which the original does not possess, and it is different in every respect from Mr. Pugin's drawing. Having examined it very carefully, and compared it with other drawings of Mr. Pugin's and Sir C. Barry's, I am confident that it is wholly the work of the latter.

It may save the time of some who are struck at the altitudes if I remind them of Sir Henry James's abstract of the principal lines of spirit levelling in England and Wales taken during the Ordnance Survey. It is a hook containing 624 pages, and gives the levels and bench marks all over England and Wales up to 1861.

F. E. H.

A SOCIETY FOR DECORATORS.

SIR,—It has often occurred to me, and more especially at the present time, when so much is being said about art education, to ask whether or not there is in existence a society of which a country decorator may be a member, and through the publication of its essays and lectures, a report of the more important works executed in England, and an occasional visit to some of the meetings, may derive some advantage from association with more favoured brethren living in the very centre of industry and wealth, and the public thus be benefited by an interchange of ideas. Most of the higher professions have their associations, and none but those who are qualified are admitted as members, or considered by the public to be up in their respective occupations. If there is not a society, then why so important a profession as that of the decorators should be so far behind I cannot conceive.

In your impression of November 30th I sent a lecture by Mr. J. G. Crane, before the “House-painters' Association.” I know not if the society is such as I describe; if so, I should like to know more of it, through your publication or personal correspondence with any interested in the matter.

G. H.

GIVE VICTORIA STREET A MOVE.

In the commissioners of the Westminster Improvement and Encumbered Estate Acts of 1861 and 1865, would spend about £200, which by the 15th section of the Act of 1865, they are empowered to do, they might get Victoria Street, Westminster, finished off in a “jiffy.”

The plan is this: give an air of freshness to the whole street, follow:—

- 1. Employ about a dozen men for a month or so in clearing, and digging to a level, the surface of all the unoccupied ground, and in clearing away the rubbish from the roads, &c.
- 2. Put up several great fresh notices-board, with large black letters, on white grounds,—not many words,—and announce where particulars of the building plots can be obtained (see No. 4), and take all the old notices-board away.

3. Remove all posting-hills from every part of the street, and allow no more.

4. Erect in a conspicuous position, say about opposite the distillery, in the vacant ground, and close to the street, a one-story, fresh looking, cheap, temporary building, a corrugated iron building; painted some clean colour might be best; and in it have a large, fresh-looking plan of the street, and the plots to be let, and some person in attendance to explain. There should be a second room for private conference. It is almost certain that this plan room should be quite on a level with the street pavement, so as to be very easily entered.

5. Office of Victoria-street lands, should be conspicuous on the two sides.

6. Have the plan and particulars printed, so that any applicant could take one with him, or send for one.

7. Advertise the street a little.

AN XX-LAND AGENT.

UTILIZATION OF SEWAGE.

SIR.—The writer of the article in last week's Builder on the utilization of sewage has included Carlisle in the list of towns where sewage filtration through artificial beds has been tried and failed. Allow me to state that neither the Local Board nor the lessee has ever tried any method other than irrigation for the disposal of the sewage.

EDWARD T. MORLEY, City Surveyor, Carlisle.

THOUGHTFUL MANSIONS.

SIR,—We fully concur in the character our friend Mr. Cross has given the Cornish mansions, but at the same time he is hardly correct in stating that they have memorialised us for a reduction in their rate of wages.

Changes consequent upon the altered condition of the labour market have been made, but were anticipated by the men, who have recognised their propriety and necessity.

JOHN FREEMAN & SONS.

THE ALLEGED INSTABILITY OF THE NEW FORTIFICATIONS.

In reply to questions put by Colonel Sykes in the Commons, Sir J. Pakington said that two of the forts near Chatham, having been built on marshy ground, had in some degree subsided, but nothing would prevent the forts from being satisfactorily completed. At a fort at Warrington, in consequence of a changing in the soil, part of the retaining wall had shown some signs of weakness, but nothing would prevent that also from being repaired satisfactorily. He could not consent to accept Mr. Hawksley's authority as conclusive, compared with that of naval and military men of the highest standing, upon whose advice the Government of Lord Palmerston determined to carry on the fortifications. We are sorry to be forced to say that our own experience fully bears out the opinion expressed by Colonel Sykes. Some further supervision is absolutely necessary.

FROM MELBOURNE.

PRINCE ALFRED has had a splendid reception here. The town was decorated in every possible way for the occasion, with triumphal arches, flags, illuminations, fireworks, and torch-light processions. His Royal Highness also visited Ballarat and Geelong, and was received with similar manifestations of loyalty and rejoicing. Some of the triumphal arches were very tasteful. The Chinese displayed their loyalty by means of illuminated arches, Chinese lanterns, flags, and Chinese inscriptions. The Geelong Fire Brigade erected a triumphal arch of their own for the occasion of his Geelong visit. Advantage was taken of the Prince's visit to Melbourne to get him to lay the foundation-stone of the new Town-hall, which was done with great ceremonial. The trowel was of gold, and so splendid an article that his Royal Highness smilingly said it was almost a pity to use it. The design was by Mr. Ralph Wilson, of the firm of Cronch & Wilson, architects. Messrs. Reed & Barnes were the architects of the selected design for the Town-hall, which will be a really handsome Italian edifice. The design was obtained by competition, and was chosen from about thirty sets of drawings, more than a twelve-month since. The erection has been undertaken by Messrs. Lawrence & Cain, builders, for 65,000.

Ballarat.—Prince Alfred also laid the chief stones of the Victoria Temperance Hall, Ballarat, of which Mr. Poeppel is the architect. The general style of this building is Norman. The front elevation will consist of three stories, and the hall will be a spacious one. The trowel, here, too, was a handsome one, of gold gathered on the spot, and was designed by Mr. Poeppel.

An untoward episode of the Prince's visit to Melbourne was a robbery of some jewelry belonging to him, the thief being a person appointed by the Governor to attend His Royal Highness temporarily as his valet. The name of this scamp, who ought to be whipped for so disgraceful an act upon such an occasion, was Osbaldeston. He had been keeper of a Turkish bath, and promoted to the office of shampooer to his Excellency the Governor; hence his further promotion to be valet, *pro tempore*, to the Duke of Edinburgh.

ACCIDENTS.

ONE of the houses which still remained to be pulled down on the Law Courts site, near Temple Bar, has fallen of its own accord. It was the well-known shop occupied by the Holloway's ointment people, of advertising notoriety. The primary cause of the fall is said to have been the burning some time since of a beam in the basement, which was not replaced, and when the upper floors were being removed the want of its support led to the fall of the whole building.

A dilapidated building of four stories at Osburn, Newcastle, has partly fallen while under repair, killing one of the workmen and severely wounding another. One of the beams supporting a floor, on which was a quantity of cement, had snapped, causing the flooring to give way.

Another cement warehouse has fallen. It was situated in Hope-street, Glasgow, and was a one-story brick building.

Books Received.

Half-hours with the Telescope. By RICHARD A. PROCTOR, B.A., F.R.A.S. London: Hardwicke.

THE author and publisher of this little work had in view, in its preparation, the production, at a moderate price, of a useful and reliable guide to the amateur telescopicist; and the result is an excellent little treatise, which was much wanted by amateurs, who will here find just the sort of practical instruction which they specially require. The volume is illustrated by diagrams on stone and wood.

Papers on Subjects connected with the Duties of the Corps of Royal Engineers, contributed by Officers of the Royal Engineers. New series. Vol. XVII. Printed by Jackson & Son, Woolwich, 1868.

THIS volume of transactions of the Royal Engineers contains some interesting papers, and especially one titled "A Comparison between Free and Convict Labour," by Captain Harvey, Deputy-Governor of Portsmouth Prison. This is a subject we have for years occasionally treated of, and we are glad to notice how favourably it is considered by the Deputy-Governor of Portsmouth Prison. The waste of manual power in the general treatment of convicts is enormous, and the expense to the country is very great. A subject akin to this, as regards waste of power, is also treated of in this volume—namely, military labour, on which, as well as on convict labour also, there is a paper by Captain Percy Smith.

VARIORUM.

"The Reliquary: Quarterly Archeological Journal and Review." No. 31, Vol. VIII., January, 1868. Edited by Llewellyn Jewitt, F.S.A. London: Bemrose, Paternoster-row.—The two first papers in this very interesting quarterly are on the tile-kiln discovered at Repton, in Derbyshire; one by the Rev. Stuart Adolphus Pears, D.D.; and the other by the Editor. A version of the amusing ballad of the Derby Ram is given, regarding which the writer of this notice would suggest that the nonsense of the chorus might be avoided, as it was in a version which he was taught fifty years ago in Scotland, and wherein the last verse given in the Archeological Quarterly forms the chorus between the verses.—"Report to the Hon. the Commissioners of Sewers of the City of London on the Projects of Companies, Session 1867-8, affecting the City." By William Haywood, Engineer and Surveyor to the Commission.—From this report it appears that

the railway projects affecting the City are very much fewer this year than the alarming lists which threatened to swallow up the City altogether of late years. The only new ones now are the Eastern Metropolitan (Underground); the Islington; and the Metropolitan (Smithfield Junction). Two or three others want extension of time. The Tower Subway and the London Corporation Gas Bill are the only others; in all there are seven Bills. Mr. Haywood recommends a cautionary dissent from the whole of these projects, so as to enable the Commissioners to retain a *locus standi* before the Parliamentary Committees.

Miscellanea.

ARTISANS' AND LABOURERS' DWELLINGS BILL.—Mr. Mac Cullagh Torrens's Bill has been read a second time in the House of Commons.

EXPLOSION AND BURNING THROUGH NAPHTHA.—The English schooner, *Mary Ann*, Captain Marshall, laden with naphtha and petroleum, caught fire at Antwerp, in consequence of an explosion on board. The ship was entirely destroyed, and the captain and crew perished.

DESTRUCTION OF A CHURCH BY FIRE.—The parish church of St. George, Wemdon, near Bridgewater, has been destroyed by fire. During divine service, and just after the vicar had given out his text, a loud knocking was heard at one of the doors, and on its being opened, a man alarmed the congregation by exclaiming, "Make haste out, the church is on fire." Great consternation prevailed, although no fire or smoke was then observed inside the building. Outside, however, it was seen that one portion of the roof was in a blaze. It was evident that the flue belonging to the stove had either become overheated, or that there was some defect in it, which had caused ignition of the rafters between the ceiling and the roof. Except the tower, which was saved, together with a peal of five bells, and the chancel, the whole of the building was entirely destroyed, together with an organ, almost new, and the carved oak pulpit. Until a few years past the church was insured in the sum of 500*l.*, but was now uninsured.

THE NEW TOWN HALL FOR GATESHEAD.—At a recent meeting of the town council, according to the local paper, the committee reported that Sir W. James had signified his approval of the Gateshead Town-hall and Corporate Buildings; that the draft contract with Mr. Thomas Bulman and his security had been prepared; and that the matter only wanted the completion, by Mr. J. Johnstone, of the specifications and details. Messrs. W. & R. Reed were the contractors selected for the erection of the buildings proposed to face the High-street. When it was arranged that they should be erected in West-street, it was suggested that the Messrs. Reed should be employed to do the work, at the schedule of prices attached to their original tender. It was not now intended to employ Messrs. Reed in any part of the work, and the committee recommend that 200*l.* be paid to them in full of all compensation. Messrs. Reed have signified their willingness to accept the sum named in full of all claims. The report was adopted and confirmed.

DRAINAGE.—We understand that Mr. Codrington, Associate of the Institution of Civil Engineers, has addressed a letter to the Mayor of Reading, proposing to submit a plan to the local Drainage Committee for the disposal of the sewage of the town. Irrigation of a sufficient area of land at Lower Caversham, above flood level, and an outfall from the irrigated land, aided by pumping, are prominent points in the plan. A saving of 7,000*l.* in cost of works, and a large sum in annual working expenses, is anticipated.—The tenders for executing the necessary works for extending the sewerage and water supply to the White Cross district, Hereford, have been opened by the District Drainage Committee of the Town Council. There were seven competitors, who tendered as follows:—Messrs. Jones & Jepson, 2,649*l.*; Mr. Charles Sterry, 2,860*l.*; Mr. Richard Pritchard, 2,280*l.*; Messrs. R. Welsh & Son, 2,137*l.*; Mr. William Bowers, 2,135*l.*; Mr. Edward Bigglestone, 2,075*l.*; and Mr. James Bowers, 1,937*l.* 10*s.* The tender of Mr. James Bowers, being the lowest, was accepted, and the work will be immediately commenced, and is to be completed within six months.

TURRET CLOCKS.—Mr. Benson sends us a long list of turret clocks erected by him during the year 1867, as well in India as in the United Kingdom. It serves to show the esteem in which the maker's works are held, but would scarcely interest our readers.

SALE OF CARVINGS AND CASTS.—Mr. W. G. Rogers, the carver, unable, as he says, to fight against the weight of seventy-six years, is about to sell by auction the whole of his collection, consisting of several hundred specimens of old Italian, Flemish, Venetian, and French works; works by Gibbon and Chippendale; and many of his own works of original designs and working drawings. Some of our readers will doubtless take advantage of the opportunity.

TUNBRIDGE WELLS INFIRMARY.—A movement is in progress for the erection of a new infirmary for Tunbridge Wells, at a cost of somewhere about 10,000*l.* This is thought by some to be preferable to any enlargement or improvement of the present infirmary, which only contains accommodation for twenty-four beds. It is suggested that the new infirmary should be called the Victoria Hospital, and that perhaps her Majesty, who spent much of her childhood in the neighbourhood, might be induced to lay the foundation-stone.

BURIED COVENTRY.—At a recent meeting of the Warwickshire Naturalists' and Archeologists' Field Club, held at the Museum, Warwick, Mr. P. Wykeham Martin, M.P., in the chair, an interesting paper was read by Mr. W. G. Fretton, on "Buried Coventry," descriptive of the various indications of edifices, &c., which have passed away, and especially noticing the crypts. Old Coventry, as known to the earliest inhabitants of the district, said the lecturer, is, in fact, buried; and, with its assemblage of wattle huts, timber houses, and stone hindings of greater note, all has disappeared; a new and fashionable resort of the wealthier citizens has usurped its place, and if we were to seek for indications of the former town we should find them round and about the vicarage of Holy Trinity, where, beneath the surface, old foundations of the church of St. Nicholas are still to be met with, and human bones have been found. Closely adjacent is a portion of the old pack-horse road to Leicester. The traces of the monastery founded by Lady Godiva in 1043, on the ruins of the Saxon nunnery of St. Osburg, that had been destroyed by Edric the Traitor nearly thirty years before, formed a special subject of notice in the lecture.

NEWCASTLE ANTIQUARIAN SOCIETY.—The monthly meeting of this society has been held in the Old Castle, Newcastle-upon-Tyne, the Right Hon. Lord Ravensworth in the chair. His lordship, on taking the chair, said that some two or three years ago he promised to write a memoir, on the suggestion of his friend Dr. Charlton, on an enigmatic tablet called the Corbridge Lanx. There was one point which he then stated, namely, that the female figure, which had been represented by different commentators in different guises, was Latona, the mother of Apollo and Diana, the two prominent figures in that Lanx. And he also mentioned that the worship of Latona was practically conjoined with the worship of Apollo and Diana; also that one of the symbols in the borders of the Lanx was a palm-tree dedicated to Latona, on account of (according to the ancient mythology) her clasping, at the time of the birth of Apollo, a palm-tree and an olive-tree. A report had just been handed to him by a gentleman who had been sent out by the Dilettanti Society of London (of which he was a member) to take measurements and make a report of the remains of a temple of Apollo Sminthena in Asia Minor. An altar had been discovered by the gentleman (Mr. Pullen), of which rubbings had been taken. The temple was dedicated to Apollo, Artemis, and Latona—Artemis being the Greek Diana, and Latona being the mother of the god and goddess. He mentioned these circumstances as it was in some degree corroborative of the opinion which he then ventured to state. Dr. Bruce said that he had been informed by Sir E. Blackett of the finding of a Roman altar at Hulton Castle, near Matten. On the top of it was discovered the word "NVMINIUS," but what followed he could not tell; they expected it would be the word AUGUSTORUM. He would take care to make a journey out, and endeavour to see it before the next meeting. Lord Ravensworth read an interesting paper on "The Roman Wall."

LEAD-WORK.—It is fair to mention that the lead-work of the new spire, St. Nicholas's Chapel, Lynn, as also that for the new lantern, Ely Cathedral, was executed by Mr. Matthew Hall, of London.

CHEMICAL SOCIETY'S SOIREE.—A very charming entertainment was given on Wednesday evening by the President and Mrs. Warren De La Rue to a large company, at Willis's Rooms. The reception-halls were crowded with new and important philosophical and other apparatus, and a host of other objects of interest, many of them chemical and metallic, and the walls were hung with pictures, photographs, &c.

DESTRUCTIVE FIRE.—The extensive premises of Messrs. Farmico & Sons, window-glass and lead merchants, St. John-street, Smithfield, have been destroyed by fire, which also seized on adjoining buildings, eight of which, besides Messrs. Farmico's, but including Messrs. Brownings, oil merchants, have been destroyed. Messrs. Farmico announce that their business will continue to be conducted as before at the same place.

CAITHNESS INDUSTRIAL EXHIBITION.—The Caithness Industrial Exhibition has been formally opened at Wick. It has proved a great success. The hall, on the day of opening, was well filled by a numerous and highly respectable gathering from all parts of the county. The exhibition is held in the Temperance Hall, which is completely filled with a varied assortment of objects of industry and art. Her Majesty conferred a hush of the Prince Consort, escorted by the Crown Princess of Prussia. The ceremonial of opening the exhibition included the unveiling of this hush, which has been the principal attraction in the exhibition.

RESTORATION OF DECAY.—A new form of falsification in the restoration of an old building is reported from Italy. The Archive Office at Pisa is being restored, and the finished portions are said to display considerable archaeological study. It was decided, however, that the work was not to look like a restoration, but should wear the appearance of a genuine relic of antiquity; and so the workmen and artists employed were directed to anticipate the injuries of time by smudging their work here and there, by chipping pieces now and then out of the new walls, by toning down their tints, and by introducing artificial discolourations, importing to be the result of age and damp.

THE GLASGOW SEWAGE ASSOCIATION.—At the last ordinary meeting of this association Mr. Smith briefly sketched the leading features of the paper which he read at the previous meeting, and the discussion thereon was resumed, after which Mr. Sim read a paper, in which he proposed a plan to prevent the sedimentary matter which issues from the sewers of the city from passing into the river. This was simply by intercepting it at the outlets in sediment receptacles and barging it regularly away. Mr. Sim said that on reading his paper to Mr. Roy, the Glasgow representative of Messrs. Brassey & Co., he suggested an intercepting sewer on each side of the river, to lead down past the city to some convenient place for settling ground where the sediment could be deposited and carried away in barges as proposed. No one seemed much to appreciate Mr. Sim's scheme.

THE GREAT TRIENNIAL HANDEL FESTIVAL, CRYSTAL PALACE, 1868.—Extensive preparations are being made to render this celebration, in June, the most complete illustration of English musical progress that has yet been witnessed. An able programme has been published. The London division of the chorus will be more numerous even than on previous occasions; application for admission thereto having proportionately increased. An interesting feature in connexion with this festival is the publication of a photo-lithographic fac simile of Handel's own manuscript score of the Messiah, which has been lent for the purpose by her majesty the Queen from the royal library. Handel's scores were bequeathed by him to John Christopher Smith, his amanuensis, who in his turn presented them to George III., after the death of the Dowager Princess of Wales, the mother of the king, upon the latter continuing the pension which Smith had received during the lifetime of the princess. The date of the commencement of the work is August 22nd, and at the end, September 12th, thus proving that this immortal production was penned by Handel in the short space of twenty-one days.

PERSECUTION OF A NON-UNION MAN.—We have forwarded to the "Country Clergyman" three offers of an engagement for the young brick-layer.

METROPOLIS SUBWAYS BILL.—This bill, which is a reprint of that of last session, as amended in committee, has passed the second reading in the Commons.

RAILWAYS IN MEXICO.—We hear of various great projects being now before Congress, which will place the city of Mexico in direct communication with the United States, and with all the salient points of its own territory. One company, the Mexico and United States, proposes a line which shall place this city within ninety hours of New York.

IMPORTANT PUBLIC QUESTIONS IN BRIGHTON.—A committee of influential residents in Brighton, including Mr. White, M.P., and Professor Fawcett, M.P., has been formed with the view of bringing before the inhabitants opinions on some of the more important questions of the day. The inaugural lecture was given by Mr. W. Hepworth Dixon, on "The True Theory of Representation," and was regarded by the committee as a complete success. Mr. Dixon's address has been printed and circulated. Mr. Godwin Smith has since lectured; and on Friday, the 20th instant, Mr. Godwin is to deliver an address in the Town-Hall, on "The Health and Happiness Question." Mr. Henry Willett and Mr. J. E. Mayall act as honorary secretaries.

TENDERS.

Table with columns for work descriptions and amounts. Includes entries for Lake, Henshaw, King & Sons, Wills, Dubbin, and various construction projects.

For the erection of a warehouse and offices at 41, Coleman-street. Mr. G. Loe, architect:—

Table listing tenders for Coleman-street warehouse project, including Adamson & Son, Axford & Whillier, Hart, Hyder & Son, Winder, Gammon & Son, King & Sons, Wills, Hill & Keddell, Conder, Wells, and Crab & Vaughan.

For workshops, Marlboro'-place, Brighton. Mr. J. Berney, architect:—

Table listing tenders for Marlboro'-place workshops, including Oliver, Loader, Dobson, Dalhimore, George, Sawyer, Farr, Hall, Jackson, and Lockyer.

For the erection of four houses at Barking, Essex. Mr. J. W. Dennison, architect:—

Table listing tenders for Barking houses, including Stokes, Brett, and Withers.

For detached villa, on the Stonebridge Park Estate, Willesden. Five to be erected. Mr. Bassett Keeling, architect. No quantities supplied:—

Table listing tenders for Stonebridge Park Estate villa, including Woodbridge, Linn, and Suowden.

For new infirmary and dispensary, Barton-on-Trent. Mr. Edward Hulme, architect. Quantities supplied:—

Table listing tenders for Barton-on-Trent infirmary, including Jeffrey & Fritchard, Webb (too late), Hewley, Brothers, Lovatt, Matthews, Gregory, Maddocks, Trow & Sons, Wileman & Wigley, Hadfield, Smith & Chamberlain, Bowler & Beck, Clarke, Mason, Lilley & Son, Nelson, Neale & Son, Hardrick & Son, Lowe & Son, Lilly & Son, and Hunter & Bennett.

For new schools and parochial meeting-room, Newhaven, Sussex, for the Rev. E. P. Southwood, Messrs. Halsey, Brock, & Wicks, architects:—

Table listing tenders for Newhaven schools, including Parks, Simpson, Card & Son, Lee, Kirk, Holloway & Son, and Moring.

For new market, for Clevedon Local Board of Health. Mr. Hans F. Price, architect:—

Table listing tenders for Clevedon market, including Bennett and Newman.

For weigh-bridge house, for Clevedon Local Board of Health. Mr. Hans F. Price, architect:—

Table listing tenders for Clevedon weigh-bridge house, including Bennett and Newman.

For new house at Bathford, for Mr. Bath. Mr. Hans F. Price, architect:—

Table listing tenders for Bathford house, including Newman.

For the erection of a Roman Catholic church and presbytery, London, Staffordshire, for the Rev. J. Massey. Mr. E. W. Fugin, architect:—

Table listing tenders for Staffordshire church, including Collis & Hodgson, Eaton, Barlow, Hughes, Hall & Son, Hodgson, Heveningham, Trow & Son, Richardson, and Crutchley.

For erecting four houses at Crown-hill, Lower Norwood, for Messrs J. & J. Allen. Mr. Albert Bridgman, architect:—

Table listing tenders for Crown-hill houses, including Gunning.

For the Holyhead drainage:—

Table listing tenders for Holyhead drainage, including Hardacre, Jeffrey, Messrs. Hughes, Chester, Owen & Williams, Owens & Evans, Messrs. Fogg, Bugbird (accepted), and Thomas & Sons.

For carcasses of house and stable offices, at Castle Hill, Blechingley, Surrey, for Mr. James Norris, exclusive of bricks, rubble stone, and sand. Mr. James Wylson, architect. Quantities furnished by Mr. Dan Cubitt Nichols:—

Table listing tenders for Castle Hill offices, including Little, Bowman, Rentmore, Patman & Fotheringham, Barnes, Macey, Carruthers, M. Regis, sen., J. & W. Sanders, Myers & Sons, Hill & Keddell, Conder, Jackson, Shaw, Piper & Wheeler.

For alterations and additions to residence, Brigadier Hill, Epsfeld, for Mr. F. G. Carling. Mr. Thomas J. Hill, architect:—

Table listing tenders for Brigadier Hill residence, including Saunders, Salford, Patman, Brox, Field & Sons, and Bayes.

For St. Augustine's Church, Wisbech. Mr. William Smith, architect:—

Table listing tenders for St. Augustine's Church, including Cave & Halliday, Bell & Sons, Cooke, Bennett, Brown, Rust, and Law.

For addition of new aisle and entire reseating of St. Mary's Church, East Barrow, for Mr. Rowland Barker, architect. Quantities supplied by Mr. F. W. Hunt:—

Table listing tenders for St. Mary's Church, including Rhodes & Roberts, Carter & Son, Dove, Brothers, and Brass.

St. Peter's Schools, Hammersmith.—Mr. Stimpson's tender was 4,063l., not 4,863l.

TO CORRESPONDENTS.

H. T. (to give plaster casts "the appearance of ivory," they are intended, we believe, in bolting stearine).—T. F. C. (Mr. Rothchild Cooke's rights have been often admitted and argued in the Builder).—J. D. P. (unnecessary).—J. R. (forwarded).—B. B. (ditto).—H. F. (not worth while).—E. V. (next week). O. V. Note.—Architects who are unwilling (as we are) that their names should not accompany lists of tenders with which they are concerned, may prevent the omission by sending lists themselves. We cannot repeat lists in the ground of such omission.

We are compelled to decline pointing out books and giving addresses.

All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

TO SUBSCRIBERS.

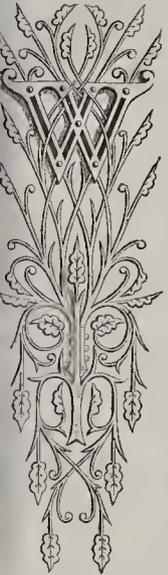

NOW READY, THE TWENTY-FIFTH VOLUME OF "THE BUILDER" (bound), for the year 1867, price One Guinea.

CLOTH CASES for binding the Numbers, price Two Shillings and Ninpence. COLOURED TITLE-PAGE, Gratis.

The Builder.

VOL. XXVI.—No. 1311.

Machinery for Joiners' Work.—The Redcliffe Estate, Brompton.

I propose to devote this page to a little bit of advertising, but it is advertising with a view to what seems to us public advantage. We want to make better known what can really be done in one branch of building by means of machinery than it is at present. It would seem curious, if we did not know how often a new thing must be said before it is heard and acted on, to find that even at the present time some of our leading builders, each paying hundreds of pounds weekly for joiners' wages, shut their eyes to the enormous economy that can be effected in this class of work by the employment

of some of the machines which have been perfected within the last few years. It seems a general idea among builders, even among those who admit the saving effected by machinery for joiners' work, that machinery can pay only in very large establishments, and that unless a builder can afford to expend a great sum of money upon an extensive plant, and have separate machines for each operation, he had better be without machinery altogether. Our inquiries, however, had us to the belief that by a moderate outlay on machinery, which would be within the means of any man employing a dozen men, a great saving may be effected. Desiring by all means to lessen the cost of houses, and knowing very well that machinery benefits in the long run even those who may seem for a time to be injuriously affected by it, we have looked more carefully into the subject, and will give some of the results. These are taken from the accounts kept of the work actually turned out by a small plant of machinery erected by Samuel Worsam & Co., of Chelsea, for Messrs. Corbett & McClymont, who are building largely upon the Redcliffe Estate, West Brompton. And first let us say a few words about the rather remarkable building operations that are being carried on here. The Redcliffe Estate, which is something less than two miles from Hyde Park-corner, consists of about seventy acres. The Fulham-road bounds it on the south side; the Old Richmond-road, leading from South Kensington to Hammer-smith, on the north side; Honey-lane, leading from the Fulham-road to the Richmond-road, forms its western termination; and The Grove, Boltons, and Redcliffe-road, are its bounds on the east side. Not five years ago the whole of this estate was used as market garden-ground, a considerable portion of it belongs to Capt. Hunter and Capt. James Gunter, Messrs. G. &

H. Godwin acting as their architects. For the freeholder of another part of the estate Messrs. C. Lee & Son are the architects.

When Messrs. Corbett & McClymont first went on to the land there was no carriage-road from Fulham-road to Richmond-road, but they have now made a handsome road, called Redcliffe-gardens, upwards of 60 ft. in width, and about half a mile in length (on the site of Walnut-tree-walk), on either side of which very capital semi-detached villas are being erected. Near the north end of Redcliffe-gardens a square has been formed, through which Redcliffe-gardens pass, and in the western half of the square a site has been set aside for a church. The builders have carried out their operations with great spirit and activity; they have constructed the whole of the roads and sewers, and there are now erected on the estate, standing upon a bed of gravel and sand for upwards of 20 ft. in depth, about 550 houses, shops, and stables. The houses have been built with a view apparently to suit a variety of tenants, as the rents commence at 50*l.*, and range from that amount up to 160*l.* per annum. About 400 more houses, we learn, are yet to be erected, many of them of large size. With a good service of omnibuses, and two railway-stations, viz., the Chelsea Station, at the south end of the estate, and the West Brompton Station, at the north end of the estate, which afford ready communication with the City, this district can scarcely fail to come into good use, and give a good reward to the builders for their enterprise and skill.

To return, however, to our subject. The whole of the joiners' work for the houses on this estate is prepared from deals and battens, which are purchased at the docks, and stacked in the yard adjoining the mill until seasoned.

The machinery is fixed in a temporary building on a convenient part of the land, and comprises:—

1. A Worsam's portable deal frame, capable of sawing at one time two deals or planks, up to 14 in. wide by 4 in. thick, into hoards of any required thickness. This machine is so constructed as to require no excavations below the floor, often inconvenient. It is entirely self-contained, being all fitted to a strong cast-iron foundation plate. The swing frame being made of steel, it combines great strength with lightness, and can be driven at the rate of 250 strokes per minute with twelve saws working at once without perceptible vibration. The saws used in this frame are very thin, so as to reduce the waste of wood to the minimum.

2. A self-acting saw-bench with a feed motion by means of a rope for bringing forward the timber to the saw. The rate of feed, it seems, can be varied from 12 ft. to 60 ft. a minute, according to the nature of the work. This bench is used chiefly for sawing single cuts in deals, planks, or battens; for cutting feather-edged hoards or ripping out scantlings of various sizes; and it is provided with a pair of timber-carriages or "hogies" running on rails for carrying the ends of a long piece of timber.

3. There is a planing and "trueing up" machine for planing and "trueing up" the stuff after it leaves the sawing-machines. This, they say, is the only machine which has ever been brought out which will set a piece of twisted timber true, and at the same time give it a planed face fit for gluing up without requiring to be touched by a hand-plane. The stuff to be planed is laid upon a planed travelling-table of cast-iron, and is held by a series of screw cramps, which retain it in one position when under the action of the cutters. It is worked by a labourer at 2*s.* a week, and some notion may be formed of the economy effected by the use of this machine when it is mentioned that it will plane up the whole of the stuff for fifty 2-in. doors in ten hours. The work performed by it in our presence seemed very good.

4. The "General Joiner" is a singularly useful machine, which appears to do almost all the different kinds of work usually executed by hand in a joiner's shop, amongst which may be reckoned sawing, planing and thicknessing, mortising, tenoning (single or double), cross-cutting and squaring up, grooving, tonguing, rebating, moulding and heading, chamfering, wedge-cutting, boring, and a great variety of other operations. With a little practice any joiner can work it. The mortising apparatus is fitted with a self-acting feed motion, by means of which the piece being mortised is moved forward at each stroke of the hand lever. The table is fitted with stops which regulate the depth and length of the mortises, and the bed has an independent rising and falling motion, so that a lad can be mortising or boring while a man is at work at the other table. The mortising apparatus is usually worked by a young lad, who will make from sixty to eighty ordinary mortises in an hour.

After the stuff has been planed at the trying-up machine, it is taken to the "general joiner," at which it is mortised, tenoned, grooved, moulded, and otherwise prepared for putting together and cleaning off in the joiners' shop.

All these machines, in full work, are driven by a Ransome's 12-horse power portable steam-engine. The fire-place is of extra size, to enable it to use up the sawdust and waste wood from the different machines, which, mixed with a little small coal, is found sufficient to generate an ample supply of steam. The road-wheels and axles of the engine are removed, and the boiler is set upon two cast-iron saddles: by this arrangement all oscillation is avoided, and it becomes as it were a stationary engine, with a quick draught, occupying a very small space. The smoke from this engine is not much more than that from an ordinary house chimney, and it works almost noiselessly.

Of course there is a grinding apparatus for grinding and setting the plane-irons, and a moulding-iron grinder, with small Bilston stones of various forms for sharpening moulding-irons; and in order to keep the grit and sludge from the grinding machines from spoiling the other machinery, the former are fixed in a small "lean-to," built out from the main building.

The whole of the machinery is driven from a single line of main shafting which runs across the mill. This shafting, we observe, is fixed below the floor in a tunnel, and thus all the driving-hands are kept out of the way, which is a great advantage where long pieces of timber are being constantly carried about, and where, consequently, overhead driving gear would be dangerous. All the machines are placed on stones, set on a few courses of brickwork: being thus solidly fixed, they can be driven at a very high speed without vibration; and being entirely independent of the building, a light cheap erection to keep out the weather is all that is required.

The entire cost of the plant in the shop we are describing, including steam-engine, shafting, hands, and a complete set of saws and cutters for each machine, was 1,000*l.*, including fixing and starting it to work. Of this sum one-half may fairly be taken as chargeable to the sawing department, leaving the cost of the joiner's machinery with its proportionate share of the engine and shafting at 500*l.*

And now comes the question of saving. The net earnings of the deal-frame and self-acting saw-bench, estimated from the prices charged for cutting at the mills, have averaged, we are assured, 72*l.* per month, after deducting all working expenses. This result has been obtained from the books of the mill, dating back from the time when the machinery was first started, about six months since.

The following facts will illustrate the saving

of labour effected by the Trying-up Machine and the "General Joiner"—

Cost of Labour upon Thirty 2-in. Four-panel Doors, 6 ft. 10 in. by 2 ft. 10 in.

Planing and truing up the whole of the stuff, and planing and thickening the panels. Man's time at trying-up machine, 7 hours	£ s. d.
Mortising, tenoning, grooving, and otherwise preparing the work ready for putting together at the "General Joiner," two lads ten hours each	0 3 2
Half the time of the foreman of the mill setting out the work and adjusting the cutters, &c., five hours	0 3 6
Total cost of labour at the machines ...	0 10 10
Putting together, wedging, and gluing up and cleaning off by hand, but not including mending, 7½ hours at 6d. per hour	1 18 3

Total cost for labour on thirty 2-in. doors

Total cost for labour on one 2-in. door, equal to 1s. 7d.

Cost of Labour upon 36 Pairs of Sashes, 7 ft. by 4 ft., with four Panes.

Planing and truing up the whole of the stuff. Man's time at the trying-up machine, five hours	0 2 2½
Mortising, tenoning, mending, and rebating, scribbing, sticking the sash-bars, &c., at the "General Joiner," two lads ten hours each	0 4 2
Half the foreman's time setting out the work, and adjusting the cutters for the lads at the "General Joiner," five hours	0 3 6
Total cost of labour at machines	0 9 10½
Putting together, wedging, and gluing up and cleaning off after leaving the machines, sixty hours at 6d. per hour	1 10 6

Total cost for labour on thirty-six pairs of sashes

The total cost for labour on one pair of sashes, equal to 1s. 8d.

Cost of Labour upon 28 Sash Frames for 7 ft. by 4 ft. Sashes, including the Sills.

Planing up the whole of the stuff for twenty-eight sash frames. Man's time at trying-up machine, five hours	0 2 2½
Sticking parting beads, grooving the pulley stiles for putting bead, cross-tonguing and sinking heads of pulley stiles, bevelling, grooving, and sinking sills, and tenoning to receive pulley stiles, at the "General Joiner," two lads ten hours each	0 4 2
Half the foreman's time setting out the work, and adjusting the cutters for the lads at the "General Joiner," five hours	0 3 6
Total cost of labour at the machines ...	0 9 10¼
Putting together and cleaning off by hand after leaving the machines, fifty-six hours at 6d. ...	1 8 0

Total cost for labour on twenty-eight frames

The total cost for labour on one frame, equal to 1s. 4d.

In all the above instances the stuff was snwn to the right thickness at the deal frame and saw-hench, and cross cut to lengths; but the ripping out was done at the "General Joiner," the cost being included in the above figures. Interest on the cost of the machinery would have to be added, together with a proportion of the engine-man's wages; but this would give but a very small increase to the cost of the items in question. We believe that a section of our readers will find it worth while to inquire for themselves into the correctness of these details.

We saw at the manufacturers' some specimens of the higher kinds of joiners' work, such as circular panels and embossed and snnk ornamental panels, such as, it has hitherto been considered, could not be done by machinery, but which, in reality, are produced by a newly-invented machine at less than one-fortieth part of the cost of hand labour; and into this part of the subject we will not now enter, confining ourselves to the results of the plant set up for one particular firm of builders.

TECHNICAL INSTRUCTION FOR ARTISANS.—At a conference on this subject at the Society of Arts, arranged by the Working Men's Club and Institute Union, a committee was appointed to ascertain how far existing institutions may be rendered available as industrial museums and trade colleges in London, to be set on foot on the principle of combining voluntary effort with aid from the State; to ascertain in what district of London such colleges and museums may best be established; to communicate with employers and manufacturers on the subject of providing technical instruction in the workshops; and to take such further steps as the committee may think desirable with reference to the object in view.

ON THE UTILIZATION OF SEWAGE BY IRRIGATION.*

It has already been demonstrated that in pouring the impure contents of our sewers into the nearest water-courses, we are not only imperilling the health of the community in more ways than one, but we are wasting, to produce this baneful effect, a commodity of inestimable value to our fields. That such is the case is due partly to the looseness of the laws referring to the pollution of rivers; partly to the narrow policy of private manufacturers, who in many cases, from ignorance or want of energy, will take no means to rescue ingredients of considerable worth, such as are now aiding in the discoloration of our streams; and partly—perhaps chiefly—to the apathy of the great body of the public, which, ever slow to the appreciation of a nuisance which has been of a gradual and insidious growth, has at the same time no just idea of the benefit which would accrue from the application of sewage to the land. That this benefit would be solid and permanent, is a truth which cannot fail to be extracted from the great mass of evidence which has from time to time been placed before the nation, and it is now our duty to give a sort of digest of this evidence, which, however crude and incomplete, at any rate may claim to possess the merit of being faithful. In this statement it is proposed to include an analysis of the principles of sewage irrigation; its estimated benefits to the country; a careful examination into its different methods of application; its comparative merits under the combined and separate systems of drainage; the nature of the land and the crops concerned in its application; the sanitary effects; and its practical results as recorded in the most eminent examples.

Comparative Novelty of Sewage Irrigation in this Country.

When the word novelty is used in reference to the cultivation of land by sewage, it is to be understood that, although in one or two isolated cases—such as Edinburgh, where we are credibly informed† that even from so far back as two centuries ago, sewage has been applied to the soil—it is only within recent times that it has been reduced to an organised system.

On the other hand, in the southern parts of Europe, the principles and practice of this important branch of agricultural science have long since attained considerable perfection, evidence of which may be derived from the numerous and costly works which have been profitably constructed in the vicinity of large towns. And, as has already been said, in all hot and dry countries in every part of the globe, water irrigation has from the remotest ages supplemented the forces of nature. For this purpose, we are told that systems of reservoirs, similar to those of our modern waterworks, were constructed by the engineers of ancient India, Assyria, and Egypt, on a scale of magnitude corresponding with the powerful grandeur of those nations. The *norias* of the Moors, the bucket-wheel of the Persian, and the *fadoud* or rudo water-lever of the Egyptians, were appliances used in irrigation for raising the water to the desired height, and are still to be seen in those countries.

In Spain, where this art was carried to perfection under the enlightened dominion of the Moors, schemes of irrigation at the present day form a most important branch of public and private enterprise, some of which are in the hands of English engineers. These works do not resemble the river-warpings which have from a very ancient date been practised in this country, more particularly upon the banks of the Ouse, in Yorkshire, but rather those river-meadows such as in Devonshire illustrate the value of a large and regular supply of water on a free and well-drained soil.

To the humidity of our climate, and consequent abundance of water, is due the rarity of irrigation works in this country; and to this it may be added, that until very recently, the defective drainage of cultivated lands prohibited anything like irrigation on a large scale, where such works were feasible and most to be desired. Now, however, that good drainage has become general, and the soil rendered dry and porous, and capable of absorbing additional moisture, the latter drawback no longer exists, and it is generally admitted that light and well-worked soils are adapted for irrigation under ordinary circumstances. Experience also has demon-

strated that the moisture of our climate is so far from marring the effect of irrigation, that enormous quantities of water or sewage may be applied with the happiest results.

It has been computed that the annual depth of sewage applied to the Craigentinny meadow, Edinburgh, which bring a rental of from 15*l.* to 20*l.* per acre, is not less than 64 in., and that under a climate far more humid than that of England generally.*

Analysis of the Principles of Sewage Irrigation.

In treating of this section of our subject, we must consider, firstly, the elements of vegetable growth; secondly, the form in which such elements are best applied to the plant; and thirdly, whether, in matter and in form, the sewage of towns comprehends those qualities essential to application and increase. Although the diversity of the combination of the elementary constituents of plants is almost infinite, yet these constituents are actually reducible to four, namely, oxygen, hydrogen, carbon, and azote or nitrogen. From these elements are derived, through the medium of chemical combination, certain compound constituents, some of which are combustible, and some of which are incombustible. The latter, which are simply the ash which all vegetable substances leave on combustion, are chiefly phosphoric, sulphuric, silicic acid, potash, soda, lime, iron, magnesia, and chloride of sodium. The former are derived from carbonic acid, ammonia, sulphuric acid, and water. These, whence we have the ammonia, starch, sugar, gum, and other substances composing the fabric of a plant, are in point of fact the food which is supplied to it by the decomposition of the atoms of manure in which its roots are embedded, so that to a certain extent, the medium which is calculated to effect most speedily and completely such decomposition must be productive of most benefit. Now it is a well-known fact that no manure, be it what it may, is freed from the enriching elements it may contain without the intervention of moisture. For the roots of plants to absorb their food in a dry state is an impossibility; therefore, until a shower of rain or some other watery agent has decomposed the sources of fertility, an application of manure is of no benefit. Cowley has said—

"The plants suck in the earth, and are
By constant drinking fresh and fair;"

and it would be difficult to find a more fitting expression in which to convey a definition of the process of their growth. Liebig says: "The presence of moisture, a certain degree of heat, and free access of air are the proximate conditions of those changes by which the nutritive substances in chemical combination are made available for the roots. A certain quantity of water is indispensable to transpire the soil constituents when rendered soluble; water, with the co-operation of carbonic acid, decomposes the silicates, and makes the undissolved phosphates soluble and diffusible through the soil."‡ Again—

"Dung and other manuring agents act only through the medium of the earthy particles that have become saturated with the nutritive substances contained in the manure."‡

If, therefore, we can discover a manure which, while it contains the elements of fertility, contains them in that form which most readily assimilates them to the structure of the plant,—the form of solution,—it will be admitted that, provided the application of such a manure be commercially practicable, it must be productive of immense benefit to the country. From the analyses and opinions of our most enlightened chemists and practical agriculturists, we have shown that the sewage of cities is rich in manurial properties, the greater part of which are held in solution, and are thereby most available for vegetable increase. And we shall hereafter place before the reader proof that its application in such form is consistent with the most satisfactory pecuniary results.

The chairman of the Metropolitan Board of Works is of opinion that the application of sewage in a liquid form is the best. §

Sir Charles Fox says that sewage can be remuneratively applied in a liquid form only. ||

The Rivers Pollution Commissioners, speaking with reference to the application of town sewage to land, say in their third report (Aire and

valder rivers), that "the produce of properly irrigated land will be from five to ten-fold that of the same land under ordinary cultivation." The Commissioners also state that, in the course of their inspection of the Aire and Calder district, they had no experience of any town or locality where the application of sewage irrigation would be impracticable.*

† Professor Wey considers that the liquid form is the only proper form of dealing with sewage. † Mr. R. Rawlinson thinks the best mode of dealing with sewage in all cases is to carry it rapidly on to the land. ‡

§ The Report of the Commissioners on Metropolitan Sewage, 1864, states,—"Your committee have come to the conclusion that it is not only possible to utilize the sewage of towns, by conveying it in a liquid state through mains and pipes into the country, but that such an undertaking may be made to result in pecuniary benefit to the ratepayers of the town whose sewage is thus utilized." "That soils and the roots of growing plants have a great and rapid power of abstracting impurities from sewage-water, and rendering it again innocuous and free from contamination." And, "That if it is no longer to flow into rivers, the only alternative which remains is to dispose of it on the land." §

1. The Different Methods of Sewage Irrigation.

¶ Having described the principles of the action of sewage upon the soil, we will now proceed to give a brief account of the various modes of its application. These are as follow:—

1. By bed and catch-work from open conduits.
2. By hose and jet distribution from iron pipes.
3. By flat-flooding or submersion.
4. By sub-irrigation.

1. Bed and Catch-work.

¶ So far as our present experience extends, there is no little doubt that this method of applying diluted liquid manure is by far the most successful, and its extreme simplicity as compared with other modes would appear to mark this as a natural result. Bed-work is adopted generally in preference to catch-work, but this arises chiefly from the fact that where irrigation is being carried on the configuration of the ground is more generally adapted to the former method. In the selection of a site for an irrigation farm, a level or gently rising meadows on the banks of a stream below the outfall are considered as the most favourable to the principle of gravitation; preference being always given to ground with a double inclination,—that is, with a slope perpendicular to, as well as parallel with, the stream. When these slopes are sufficiently moderate, or when the ground is level, the following is the system of preparing it by bed and catch-work. The sewage, after being strained, by means of a very simple and effective grating, from those grosser impurities which would impede the easy flow of the liquid over the soil, is brought to the highest point in the field, in a subterranean open conduit; thence it is conveyed through the head of the enclosure, maintaining a superior elevation. The surface of the field is divided into parallel beds of the width of from 16 ft. to 40 ft., running perpendicularly to the conduit. These beds are carefully arranged on a ridge and hollow plan, so that they present a series of gentle declivities, falling away on both sides from the centre of each ridge, which longitudinally intersected by a narrow gutter a few inches deep. Communication is effected between these gutters or feeding canals and the main conduit by means of little stop-gates, which, being removed, allow the feeders to be filled, and to shed their overflowing contents in a gentle, constant stratum, in and about the roots of the plants, which absorb the properties in solution through the digestive medium of the soil. The action of the latter, thus quickened by the transmuting process of vegetable growth, tends directly to clarify the liquid, which drains off in a comparatively pure state.

¶ In the centre of each hollow, between the beds, is laid a shallow drain of just sufficient depth to receive and carry off without reference to subsoil drainage, the clarified water after irrigation. In some cases it is deemed necessary to pass this water more over the soil. By these minor drains the liquid is carried into a large intercepting drain at the bottom of the field, which, taking a general inclination of the valley, may be

¶ Third Rep. (Aire and Calder, 1867), vol. 1, pp. 15, 64.
 † Rep. Met. Sewage, 1864: 4710.
 ‡ Rep. Met. Sewage, 1864: 4100.
 § Rep. Met. Sewage, 1864: pp. 5, 6, Preliminary Report.

brought to the surface at a lower level, and its contents once more utilized. The completeness with which this plan is carried out is a striking feature in the irrigation works at South Norwood.

¶ In water irrigation, open receiving-canals are often substituted for shallow drains, into which the liquid is drained off, percolating to the root-fibres; but this method cannot be considered as adapted for the treatment of sewage. When, as often happens, the inclination of the ground in the direction of the feeding-canals is too great to admit of their being filled to one level throughout, it becomes necessary to ensure a uniform distribution of the sewage by dividing them into level reaches with sudden drops, as in ordinary canals. This is effected by the simple expedient of wooden slopes or sods of turf, which may be put down or taken up at will, and between which the sewage overflows equally on both sides. In order to receive the highest benefit from the utilisation of sewage in this mode, it is requisite that the land selected should be naturally free and porous, well drained and pulverized, so as to render it thoroughly absorbent and to avoid stagnation, the bane of irrigation. Beneath the surface-drains specially laid to collect the purified sewage-water, a perfect system of irrigation demands efficient deep drainage of the nasal kind; otherwise, unless the soil happens to be unusually dry, it will tend to become water-logged and soddened: this, of course, should be the first operation. The quickest method of making the small feeding-canals is to run the plough along the ridge of each bed, taking a tolerably deep furrow; after which, a labourer with his spade can finish them off with great facility.

¶ Messrs. Napier & Hope, in their scheme for the utilization of the northern sewage of London on the Maplin Sands, have proposed to line their feeding-canals with clay tiles having a double lip; this lip extending 2 in. or 3 in. over the ridge on either side.* This is with a design to prevent the supposed nuisance arising from the accumulation of decomposing solid matter upon the "ragged edges" of ordinary feeders,—a supposition wholly inconsistent with the fact. In Messrs. Napier & Hope's scheme, as laid before the Metropolitan Board of Works, no provision appears to have been made for straining or settling the solid portions of sewage prior to conducting it upon the land. In this case it would be doubtless necessary to adopt tiles of the kind mentioned; and, as stated by the projectors, to have them swept out daily. But those conversant with the practical application of sewage to agricultural purposes would hardly think of allowing such solid refuse to enter and choke up the feeders. By the simple and inexpensive grating before mentioned, which retains all the papers and heavy matters, the sewage is rendered so easy of flow that all fear of such nuisance is entirely avoided. The plan, therefore, of tiled gutters would add considerably to the prime cost of irrigation works without presenting any corresponding advantages. Bed-work is alike adapted for level meadows, and for gently-inclined ground with a tolerably uniform surface.

¶ The method of catch-work is usually adopted when bed-work is rendered impossible by the steep inclination of the land, under which circumstances no equal distribution of the liquid could be effected by feeders running with the slope. Land, therefore, possessing this abrupt inclination, should be intersected transversely with the slope, and parallel with the main conduit, by level lines contoured one above another along its surface, which lines mark the position of the feeders. These may be of more or less distance apart, and should have direct communication with the main conduit by means of side-channels, and when filled, their contents flow evenly over the lower side, down the intervening slope, fertilising the soil in its progress. What is not absorbed by the ground is caught by the next feeder, whence it is again discharged, and this process is repeated until, having reached the bottom of the declivity in a state of comparative purity, the water falls into a catch-drain. It must be observed that as the lower parts of the ground are reached, the direct supply of sewage to the feeders should be materially diminished, so that no portion should receive more than its requisite share, and that none of the sewage should escape without traversing a sufficient purifying area. A very slight fall should also be given to the contour canals to

* Report Met. Sewage, 1864: 556.

admit of their cleansing or emptying themselves, when the process of active irrigation is discontinued. As to whether it may be deemed sufficient not to effect communication in every case between the main supply and the feeders, this point may be ruled by circumstances.

¶ If irrigation by catch-work is not so thoroughly perfect in the purification of sewage as bed-work, inasmuch as a certain proportion must pass over the surface of the ground without percolation to the roots of the plant, yet there can be no doubt that it is very effective, and may be accomplished at a far less cost. By these methods of irrigation, sewage may be applied to grass crops once in ten or fourteen days, almost up to the moment of cutting the crop.

¶ At Croydon, 3l. to 4l. per acre were allowed by the local Board to its tenant, Mr. Marriage, for the preparation of the ground into bed-work, in the execution of which many woods and shaws were grubbed up.*

¶ Edinburgh, Aldershot, Norwood, Croydon, Rugby, Bury St. Edmund's, Barking, and almost all those irrigation works which are prominently associated with the progress of the utilisation of sewage, have adopted the open conduit system. Mr. Baldwin Latham, the well-known engineer to the Croydon Board, whose connexion with the Croydon and Norwood works entitles his opinion to very considerable weight in this important question, considers this the simplest and most effectual mode of application, and this opinion is borne out by the Rivers' Pollution Commissioners, Mr. Bateman, Mr. Rawlinson, Mr. Walker, of Rugby, Messrs. Napier & Hope, Mr. Lawos, and others. †

2. Hose and Jet Distribution from Iron Pipes.

¶ The power requisite for forcing sewage on to the land, by means of leathern hose affixed to hydrants, is obtained either by pumping or by constructing certain summit reservoirs or tanks, which shall have the necessary head of pressure.

¶ Pipes of cast iron convey the sewage to the land, and are provided with hydrants at proper intervals, to which may be attached the distributing-hose. Glazed pipes of stoneware have been tried at Worthing in lieu of cast iron, but without success. ‡ The ground requires no special preparation, but is irrigated through the medium of the hose, which is directed over the area within its compass by a labourer, who carries it to and fro until the operation is complete. Care must be exercised lest any hollow part of the ground should become swamped. About five acres daily may be covered by one jet.

¶ It will be seen that by this method sewage, instead of being applied in a smooth and uniform current to the roots of the crop, is propelled forward with considerable force, and drops in a heavy vertical shower upon the stem or blade,—a process which, in the case of long thick grass, tends to beat down and injure the plant. Whilst the crop is still young, little harm results on this score; but after arriving at a certain stage and growth, the sewage must be applied with great caution, if not altogether discontinued. The strongest recommendation which is urged by the advocates of the jet and hose principle, is its low cost as compared with the expense of throwing the soil into elaborate artificial beds. From 3l. to 4l. per acre is the estimated cost for submains, hydrants, hose, &c., given by Mr. Ellis, who, quoting the Report of the Board of Health, states, "that whereas the average cost of the distribution of bed-work has been 31l. 14s. 7d. per acre, with annual working expenses amounting to 3l. 7s. 1d., the average cost of distribution by underground pipes and hose has been 3l. 5s. 1d. per acre, with annual working expenses of 5s. 11d." § But, as we have already seen, that in the case of Croydon, where the ground was not unusually favourable, 3l. or 4l. sufficed the tenant for laying out the land, we may not unfairly conclude that the statement of the Board of Health is not founded upon a careful examination of facts, and may be suspected of some degree of partiality. Mr. Pusey has stated that catch-work water irrigation has been adopted with great success in Devonshire, at a

* Rep. Met. Sewage, 1864: 2245.
 † The Rivers' Commissioners (Aire and Calder Report) state that the cost of preparing the ground on the open carrier system may be 6l. per acre.—Third Report, vol. 1, p. 14. "Where main open carriers may be considered a nuisance, as near houses, roads, or foot-walks, they may have covered conduits having cheap outlet-valves at a chain apart."—*Ibid.*
 ‡ Rep. Met. Sewage: 4105.
 § Report Met. Sewage, 1864: 2450-1-2.

cost of from 2l. to 5l. per acre.* The very elaborate works at Mansfield, on the Duke of Portland's estate, which are usually cited by the opponents of the open conduit system as illustrative of its great cost, form a wholly exceptional case, having been executed without regard to expenses. These included the reclamation of waste land, drains, bridges, carriers paved with brick, and items of the like unnecessary nature.

It must also be recollected that in many cases sewage, which may be easily gravitated to its destination by means of open carriers, would, under the hose-and-jet system, require pumping up to an artificial head before the pressure could be obtained sufficient to overcome the friction of several hundred feet of earthen piping, so as to admit of its free and efficient discharge. Such additional expense has evidently not been included in the statement of the Board.

It is, however, in the principle of the application of the sewage to the plant that the special defect of this system is held to consist. The vertical discharge from a hose may be likened by its admirers to that of a natural shower of rain; but the comparison hardly holds good by reason of the different degrees of density. It is far likelier one of those heavy flood rains, which do so much damage in advanced seasons, such damage being increased by the deposition of a gritty substance upon the stem or blade of vegetation, very injurious to the value of the crops. But, it may be argued, it is not intended to apply sewage to grass of long growth. The result of this would be an enormous increase in the quantity of land required to utilise the sewage, thus enhancing what is under any circumstances felt to be the great difficulty attending this question. By open carriers active irrigation may be carried on in the hours of night without the supervision of attendants; but with the hose and jet this would be impossible. One of three contingencies would be inevitable,—firstly, hand-distribution by night; secondly, the construction of a costly reservoir; or, thirdly, the nightly use of an overflow with its attendant waste.

Amongst those who have declared in favour of the hose-and-jet principle of distribution are Sir Charles Fox, Alderman Mechi, Mr. Ellis, &c. It is used at Aldershot by Mr. Blackburn, but to a very limited extent, the irrigation there being for the most part carried on by open conduits; by Alderman Mechi, on his own land at Tipney Hall; by the Earl of Essex, at Cassiobury Park, near Watford; and on Mr. Harvey's Farm, at Portobello, near Glasgow.

On the other hand, Mr. Walker, of Rugby, first tried the hose-and-jet principle, but found open gutters more satisfactory.† Mr. Latham, in his interesting paper, read before the Society of Engineers in 1866, says, in reference to this system, that it may be viewed as a scientific toy, which is outwardly more attractive than useful.‡

NON-EDUCATING ENGLAND.

REPORT OF THE EDUCATION COMMISSIONERS.

THE edifices of any period of history afford the most distinct, as well as the most permanent, indication of the character of the age. In the ever-changing eddies of that vast secular transformation of the human race which we know as history, we are apt to lose sight of the movement of the day, from the fact that we ourselves are included in it. But if we can divide our own memory into intervals,—if we recall the phases of life presented, for instance, decade after decade,—the rapidity of change forces itself on the contemplation. Dress, manner, phraseology, tone of conventional intercourse, method of regarding the great problems of life,—what changes have been witnessed in each since, for example, the flight of the Orleans family from France. But the records of these changes are only to be found either by the student, in the form of literature, or by the observer in the form of architecture.

In structural embodiment, the genius of the day is ever reproducing its own image. It may be an age of great power, represented by great structures, which preserve the impress of their character through more changeable times; it may be an age of servility or of degradation, witnessed by the feeble reproduction of the past.

But in any case the handwriting of the genius of the time is plain to those who know how to read it.

Our own contemporary time is one of unprecedented structural activity. All over the civilized world the cities of the past are being transformed into those of the present. Paris is being rebuilt; Marseilles is a new creation; the old Italian cities are instinct with a new life; London itself is rebuilding. With all this activity there is a want of guiding architectural genius. Reproduction or adaptation of the past meets us all around. Architects are discussing questions as to the authorship and the origin of style. It is rather the social and the political movement of the day that is forcing the hand of the builder, than the builder who is anticipating and guiding the wants of the public. We have more street building than architecture.

But in one respect the period which has elapsed since 1830 has left records of its fight, such as no preceding age of history has witnessed. If the architect has not been showing original genius, the same blame will not attach to the engineer. First the country, and now the cities, are covered with great works,—unornamental, no doubt; at times even devoid of the truest style of ornament, structural adaptation to their object, but still great works. It is in such structures as the Menai Bridge, the new viaducts that span the Thames, the mighty wagon roofs of our terminal metropolitan stations, that we see the true signs of the times. The immense revolution inaugurated by the steam-engine, has already become commemorated by structures, before which the mouldering relics of the feudal ages are being swept from the face of the country.

We have thus written with a pen of iron and of stone upon the face of England the great characteristics of the times. So far as we hold to the past, there are signs of incertitude and of confusion; so far as we have been compelled to provide for a new future—a future so new that it hardly seems to be the product of the past,—we have evidence of vigor, of originality, of skill; and we have just been called on, in a tone as loud as thunder, to detect the same difference in that which underlies all external structures, the very framework of society itself.

Our attention has long been directed to the subject of education. Three commissioners have been appointed within the last ten years to attest facts, as to the state both of our own schools and of those of Europe and the United States. The commissioners have had a patience worthy of their task. Reports of the utmost value have been in print since 1856; but it is only during the past month that the first of the twenty volumes which the commissioners are preparing for publication is presented to the public.

It is not using exaggerated language to say that the aspect of the facts, collected under the direction of the several commissioners, is such as to take away the breath of any one to whom they are presented in thrilling novelty. Uneasy feelings have been present in the minds of most thoughtful men; but when a careful study of the information now in course of issue to the public shall have made them masters of the salient outlines of the case, these feelings will be replaced by mingled wonder, alarm, and humiliation. Not that these feelings will be unquenched by a solid ground of hope. There are bright, very bright, points, amid our insular darkness.

An abstract of the reports now in course of publication would in itself exceed any reasonable limits that our pages could afford, and an abstract could have but little value were it not of considerable length. The study of a single detailed report would do more to bring home to the mind the impression under which we write, and which we would gladly communicate to our readers, than a far wider range of information thus acquired at second-hand. Those who believe that in the education of the young lies the key to the future of the country, will not fail to consult the reports for themselves. If they cannot see with their own eyes, they will at least desire to look through the glasses of the assistant commissioners.

The grand outlines of the case are these. Europe and America, in all parts that can be spoken of as progressive, almost in all that can be called civilized, are educating the youth of the respective States on some definitely organised, provident system. To this general rule there are certain exceptions,—chiefly Spain, Austria, Rome, and the United Kingdom. Spain we may for the moment disregard, as a country which, since 1830, has been continually on the verge of

a volcano. Austria is undergoing transformation, and since Mr. Arnold compared the institutions of that great geographical agglomeration with those of this country, the Legislature of Hungary have determined that the school shall no longer be left beneath the blighting shadow of the priesthood. In Rome, so long as the tripod crown is propped up by the Chassepot rifle education of course means excommunication, exile, imprisonment. Priestly government and popular education are irreconcilable even for a week.

Amongst those countries, then, which may with more or less justice suppose themselves entitled to compete for the leadership of Europe or at least for one of the highest seats in its council, England stands alone as a non-educating country; and it is tolerably clear that unless she entirely frees herself from this inconvertible reproach, that her claim to a position in the world will soon become a mere empty boast.

It is impossible to investigate the state of things now laid bare by a patient and searching inquiry, without admitting the conclusion that we have neither high nor secondary education organised in this country. We have some few admirable schools, in which secondary education of a high order may be obtained. But such schools are rare and brilliant exceptions. On universities, it is hard to deny, are unfitted the state of knowledge of the day, although fitted to that of our usual style of education. High instruction is only to be attained in the some branches of study, at the personal expense of the under-graduate, by paying spectators, and in other branches not at all. It is not that we have no learned men,—no able men,—but the system is such as to render these men as inefficient as possible.

The secondary education which is now offered to the choice of parents is provided by private schools, proprietary schools, and public schools. Of the latter, all that can by any stretch of courtesy be spoken of as deserving the name, contain 15,000 scholars. The French public secondary schools, with a population exceeding our own by 45 per cent., contain 66,000. The public secondary schools of Prussia, with a population of a million and a half less than our own (in round figures) the same number contain 66,000. The universities of England contain 3,500 students. The universities of Prussia contain 6,362. But all the Prussian students are admitted by a real examination, not a test of power of retaining cram for a few days or weeks, but a serial set of tests of having passed through a serious education. For many of our students Oxford and Cambridge are mere agreeable clubs; for all Prussian students the gymnasiums and universities are admirable preparatory schools for the real business of the life of highly-educated men. "An admirable English mathematician," writes Mr. Arnold, "told me that he should never recover the loss of the two years he wasted under schoolboy-instruction at an English university, when he ought to have been under superior instruction, for which the present university course in England makes no provision." "Who can estimate the loss to the country from an absence,—so complete that it needs genius to be sensible of it, and cost genius an effort to repair it,—of all regular provision for the scientific study and teaching of any branch of knowledge."

No country in the world has organised a scheme of universal education, that is to say universal in the sense that different boys at girls should only differ from one another, in the course through which they pass, in the number of years which they spend at school. We are not arguing that this is desirable, or even affirming it to be possible. But if not, it is clear that a first requisite in drawing up any plan of systematic education, must be the classification of the subjects of that education according to the number of years which they may be able spent under schooling. Hence the first important division of education into primary, secondary or middle-class, and high. The line in this country appears to be drawn at the twelfth or thirteenth year as the upper limit of the first, and at the eighteenth or nineteenth as that of the second.

Now, if we regard the sixth or highest standard of the Revised Code, as stated in the Report of the Committee of Council on Education for 1865, as defining the natural limit of primary education, we shall come to the conclusion that we are thankful for small mercies. The child educated up to that sixth standard must be ab-

* Royal Agricultural Journal, vol. 1, p. 367. It is but fair to state, however, that Mr. Pusey places the cost of his works at from 20l. to 30l. per acre.

† Rep. Met. Sewage, 1864, 4697-5.

‡ To be continued.

read correctly "a short ordinary paragraph in newspaper or other modern narrative." He must be able to write correctly from dictation another short paragraph in a newspaper or other modern narrative slowly dictated once by few words at a time." And he must be able to work "a sum in practice or bills of parcels." In the City of London School, which justly claims to be regarded as one of the best organized and most successful of our educational establishments, the second division of the junior department contains boys of the average age of 11 years. This class may, therefore, be taken to represent the highest phase of primary education in England. The subjects taught are,—Bible, Testament, History, Geography, Grammar, Arithmetic, Writing, Dictation, and Chemistry. A mere enumeration of the studies does not, of course, give much information as to the proficiency of the students; but it must be observed that this division consists of boys who are in their third year of instruction on the same subjects, and that those who pass to the first division of the junior department containing boys of seven years' average age, only add lessons in French to the above list. There is also a separate grammar class, containing boys of 12½ years in which Latin is commenced.

In the French public schools, the children are admitted to the eighth or lowest class as young as seven years of age, if they can read and write. There is a lower and unnumbered class, in which children are admitted as early as five years of age. Latin is commenced in the first year after two years' schooling. The education of the French boy is thus from two to three years in advance of that of the English boy. We do not consider this an advantage. A general adoption of a system resembling that of the City of London School would, in our opinion, other things being alike, turn out a far more vigorous, healthy, and helpful race of English citizens than the severer course adopted in France. But it is not with us yet come to the choice of the best system. We have first to determine the necessity of the adoption of any system at all.

In Prussia, a nine years' course of education is required to be regularly gone through before obtaining admission to the university at eighteen or nineteen. In the *Realschulen*, or schools which aim at preparation for business life, there is a course of nine years, in which Latin is compulsory, or one of seven years, in which it is optional. Drawing is obligatory throughout all the Prussian secondary schools. In Switzerland, the school child between six and sixteen—one-fifth of the population—is under school discipline to a certain extent.

The question recently so much debated among ourselves as to the proper place and position of classical teaching in an education course, receives much light from the experience of the continent. It is important to distinguish between the two separate claims of the dead languages upon the attention of the organizers of education. Latin and Greek, by the general opinion of highly educated men, form an essential and even a dominant portion of the highest part of intellectual culture, such, for instance, as is the object of the Prussian universities to impart. Even in this highest form of classic education, however, there are two distinct views as to the object chiefly to be followed, some teachers giving chief attention to the mastery of the language, and others more especially regarding the literature of the classic times, and seeking to train the mind by intimate converse with the great writers of the past. Neither the one nor the other of these objects can be set before any youth whose school education is to terminate at the seventh or fourteenth year, and it is therefore not surprising that many, and even by some uneducated persons, why teach Latin at all to boys who are not destined, at all events, to pass through a full course of secondary education? Attempts have been made to meet the demand of the modern utilitarian spirit, and it is a curious fact that in Prussia, in France, and in Italy the proportion of non-classical to classical students is almost identical, the former constituting rather less than the latter part of the total number. But the reply to the question, the truth of which seems to be borne out by the balance of the evidence, is this. Latin is not taught to the primary or elementary student for its own sake, neither the philosophy nor the literature of the language is regarded by his education as a means of mental discipline,—a means

of opening the mind and of communicating to it,—not knowledge, but the power of acquiring knowledge,—the rudimentary study of Latin is the best method known to experience. As a rule, this would seem to be the case. Something must depend on the pupils, more on the masters. Some children may aptly learn, and some masters may aptly teach, whatever be the selected study intended to act as a sort of skeleton key to the mind. Arithmetic, as taught in the City of London School, seems to have been successfully used for this purpose. As yet, however, it would seem that the balance of opinion is in favour of the retention of Latin as a basis of general education, abandoning Greek, when a technical training is rather the object of the scholar's parents than a more liberal and complete culture.

It deserves careful reflection that a study which might well be made use of as an advantageous substitute for rudimentary Latin, a study which, more than any other, would tend freely and spontaneously to open the mind, a study, the importance of which was dimly indicated by Bacon himself, is to be found only among the higher forms of the secondary schools. If natural history were taught with the scrupulous exactitude that seems to be the first requisite for primary education, and with the life and fire that is the glory of the best American teachers, it would soon become apparent that no equally advantageous branch of study could be selected for the commencement of tuition. The interest would be aroused, the habit of attention formed, exactitude of observation would be enforced, the memory strengthened, the idea of a foreign language would be produced in the mind, and explained as far as least as the nouns; the idea of number would be illustrated by the happy labours of the genius of Linnaeus; and the child, while his unflagging attention was fixed on the contemplation of a series of natural objects, would be receiving a real training, of a nature to call out all the slumbering faculties without strain or distress. Were this basis of education introduced into the primary school, we might well afford to defer the rudiments of Latin until after the twelfth year, or to omit them altogether from technical or purely commercial schools.

As we turn from the subject the warning voice of Mr. Matthew Arnold lingers in our ears:—"France, Germany, Italy, Switzerland, Holland, have a civil organization which has been framed with forethought and design to meet the wants of modern society, while our civil organization in England still remains what time and chance have made it. The states which we really resemble, in this respect, are Austria and Rome." "Organize your secondary and your superior instruction."

THE CATHEDRAL OF BAMBERG.

In a paper on "The Medieval Architecture of Central and Southern Germany," read at the Institute of Architects on the 16th instant, Mr. H. W. Brewer gave particulars of Bamberg Cathedral, which we quote:—

The ancient ecclesiastical "Free City" of Bamberg is about 50 miles from Würzburg. Bamberg from a distance presents a grand appearance, though less striking than Würzburg. The city is built upon seven hills, each of which is crowned by a large church, the most remarkable of which is the cathedral. This noble church consists of a nave and aisles, with a choir and polygonal apse flanked by tall square towers, surmounted by octagon lanterns and spires at the east end, and transepts, apsidal choir, and two lofty spires at the west end. Each choir has a large crypt under it, and is raised 10 ft. or 12 ft. above the level of the nave. They are approached from the nave by double flights of steps, between each of which is an altar on a level with the nave floor. These altars are isolated from the wall in such a way as to leave a space at the back, from which there is a large opening looking down into the crypts. A large chapel with aisles forms a kind of continuation to the south transept. The church was originally founded by St. Henry in the year 1004, and was consecrated in 1012. This building was entirely destroyed by fire in the twelfth century. Of the present church the earliest portions are the eastern choir, lower portions of the two eastern towers, and the three first bays of the nave: these were not completed until 1237. The great eastern apse, the earliest portion of the existing church, is a remarkably fine

Romanesque work. It is covered with zig-zags and all kinds of ornament. The nave of the cathedral originally had a flat timber roof, and the present quadripartite vaulting has caused the blocking up of the alternate clerestory windows. This portion of the church is Transitional in character, but the pointed arch is only very sparingly used, showing how very far Germany was behind France and England in adopting Pointed architecture. Nor is this a solitary example; for the church of Kloster-Ebrach, near Bamberg, which is quite Romanesque in character, and exhibits scarcely any use of the Pointed arch, was completed as late as the year 1285. It is a singular fact that the further east one goes in Germany the longer the Romanesque style seems to have been retained. In the south-east of Austria and Hungary there are several Romanesque churches built after the year 1300; for instance, that of Seebisler Reen, on the borders of Hungary, on the doorway of which is an inscription recording its foundation in the year 1330. In the east of Hungary and parts of Servia the Romanesque style existed even to a later date; and the churches of Manassis and Ipek were both erected after the year 1400, and neither of them possess any Pointed arches. This would seem to argue strongly against Gothic architecture having been introduced from the East.

The next portions of Bamberg Cathedral in point of date are the transepts and western choir, which were completed in 1274; they are very fine Early First Pointed, but with the round arch still used, though sparingly. The two western towers, which are the most beautiful portions of the church, were erected after 1274. These exquisite towers bear such a resemblance to those of Laon, in France, that one is almost led to believe they were copied from the French church. Here we have another proof that the Germans were far behind the French, for the towers of Laon were built between the years 1225 and 1235; whereas those of Bamberg, which appear even earlier in character, were not commenced until after 1274. These towers are square to the level of the choir-walls, and are then carried up octagonally, with octagonal buttresses, consisting of beautiful open arcades, supported upon slender columns. The towers themselves are pierced in all their stories. These stories are marked by bold projecting cornices. The pinnacles and spires which crown and disfigure these noble towers are either modern or have been altered during the seventeenth century. The interior of this cathedral is very striking and solemn, though plain and severe. The beautiful warm colour of the stone adds greatly to the effect, and the grand quadripartite vaulting of the nave and the eastern choir directly attract admiration. The eastern apse is vaulted with a semi-dome, and the arcade running round the lowest portion is very singular. The arches are supported upon intertwined columns, some of which are tied together with great knots in the centre. In front of this apse stands a modern high altar of very objectionable design, surmounted by a large bronze crucifix, by Thorvaldsen; the stalls are fourteenth-century work. Against the south wall is a bronze effigy to Bishop Ebeuett, by Peter Vischer. In the centre of the choir are two other monuments, both thirteenth-century work. As before mentioned, this choir is raised about 12 ft. above the level of the nave, and at the back of the stalls are solid stone walls, separating it from the aisles. Towards the aisles these walls are divided into two stories by beautifully-carved cornices. The lower story is occupied by an arcade of pointed arches, supported upon detached shafts, with richly-carved capitals, quite French in character. The upper story consists of an arcade of trefoil-headed arches, filled with remarkably fine statues, representing the Twelve Apostles and the Twelve Prophets, the Annunciation, and St. Michael and the Devil. The heads are most noble, and the whole sculpture reminds one of the western doorway of Amiens. The spandrels are filled with most charming conventional foliage. These screens are probably of the same date as the western towers.

The two doorways in the eastern towers have very fine statues inserted, of a later date than the doorways themselves; the canopies over them are good specimens of the conventional representations of the Heavenly Jerusalem so common in France and Italy during the twelfth and thirteenth centuries. The great north doorway contains figures of the Prophets supporting the Evangelists upon their shoulders. Under the eastern choir is a large crypt, the vaulting

of which is supported upon two rows of cylindrical columns; it contains a holy well. The nave is very simple internally, and possesses no triforium; the western choir is more rich, and the vaulting ribs are ornamented with small "sigææ." The western apse is singularly beautiful; it is pierced by two tiers of lancet windows, with groups of shafts in the jambs and rich moldings. The western choir crosses the transepts, and is separated from them by solid stone screens similar to those of the eastern choir, except that they are decorated with thirteenth-century frescoes instead of statues: these frescoes are very much faded, but still are very interesting. The western choir contains a modern high altar, and a fine set of fourteenth-century stalls with canopies over them. In the centre of this choir is a most singular monument, consisting of a classical sarcophagus of white marble, standing upon a thirteenth-century base, and with a twelfth or early thirteenth century effigy lying upon it. This remarkable monument covers the remains of Pope Clement II. who died in the year 1047. He was formerly Archbishop of Bamberg, and is one of the very few popes who lie buried on this side of the Alps. Nothing whatever is known about the history of this most singular monument; the sarcophagus, which is ornamented with centaurs and other mythological figures, cannot well be later than the third or fourth century, and may be very much earlier.

In the western choir are two other remarkable monuments; they are large bronze effigies placed in an upright position against the walls; they are in very low relief, but perfect marvels of workmanship; they are works of Peter Vischer, and represent Archbishops Gross von Trochan and Truchses von Pommerfelden. The transepts are similar in architecture to the western choir. The north transept has a fine rose-window of plate tracery; the walls are arcaded within. In the south transept over an altar is an ivory crucifix, given to the church by the Emperor St. Henry II., and consequently dates as far back as the eleventh century. Attached to the piers of the nave are several remarkable bas-relief monuments of archbishops, two of them are as early as the twelfth century; there are also several frescoes in similar positions, which probably served as monuments. In the centre of the nave stands the magnificent altar-tomb of St. Henry II. and St. Cunigunda: it is entirely of white marble; the sides are ornamented with panels containing representations of various events in the lives of the two saints, and their effigies lie upon the slab of the monument: the workmanship of the whole is very delicate and refined. It is in a most wonderful state of preservation; was executed between the years 1499 and 1505, and is the masterpiece of Tilman Riemenschneider.

As this is the last time I shall have to mention the name of this great master, I cannot help expressing a regret that we know so little of his works in this country. To my mind he was one of the greatest sculptors Germany ever produced; his works are far more severe and simple in spirit than those of Adam Kraft or Peter Vischer, and indicate a great deal of that quiet religious feeling which is so noticeable in works of the thirteenth century.

Attached to one of the great piers of the chancel arch of the eastern choir is a most remarkable work of the thirteenth century. It is simply a life-sized equestrian statue of St. Stephen, King of Hungary. The horse has a wonderfully classical look about it, and might almost have walked out of the "Elgin marbles." The rider is very inferior as a work of art to the horse; he is represented as clothed in chain mail, and is rather stiff and cramped.

In a very small chapel leading out of the south aisle of the nave is an altar with a carved wooden reredos of the fifteenth century; it is the work of Michael Wolgemuth, and represents the separation of the Apostles: it is richly decorated with gilding and colour. Leading out of the south transept is a large chapel, dedicated to St. Andrew. This chapel is divided into a nave and aisles of equal width and height by two rows of columns. The northern portion is superb First Pointed work, thoroughly French in character, and the southern Late Second Pointed, rather plain. There are three altars, two of which are ancient; the reredos of one of them is a large triptych inclosing a picture by Lucas Cranach, containing more than 300 heads. The walls of this chapel are entirely covered with bronze monuments, representing archbishops, bishops, and priests; they are in low

relief, and consist of life-sized effigies standing under canopies. The earlier ones date from the end of the fifteenth century, and the latest the commencement of the sixteenth. The earlier ones are very spirited and fine, the later ones are poor and flat. In this chapel and other parts of the cathedral there are more than 130 of these monuments. The sacristy, which is very interesting, is entered from the chapel; it contains a superb pascal candlestick of silver, about 5 ft. high, bearing the date of 1216; it is covered with foliage, birds, beasts, and all kinds of ornament, and bears a strong resemblance to the "Glocestor candlestick," exhibited at the Loan Collection, except that in the Bamberg candlestick the work is more delicate and refined. There is a large reliquary of silver and crystal, about 8 ft. high, enclosing a smaller one presented to the church by St. Henry in the year 1004; this contains a third reliquary, of probably a still earlier date, entirely of cut crystal, within which is one of the largest relics of the true cross known to exist; the relic itself is in the shape of a cross, about 9 in. long and 4 in. across the arms. Whatever opinions may be entertained respecting relics, whether we believe that this piece of wood is a portion of the true cross or not, few can look without interest upon an object which caused the foundation of one of the grandest churches of Germany, of a city belonging to the most powerful and most ancient prince archbishops in Southern Germany, and second in historical interest to none in Central Europe. It was to enshrine this relic that St. Henry erected the first cathedral on this spot. Subsequently he gave the town to the archbishop and his successors, and the town of Bamberg owed its importance to the pilgrims of all nations, many of them kings and princes, who came to visit this relic. In so great reverence was it held that the town, although at one time containing nearly 40,000 inhabitants, was never fortified, and it is probably the largest ancient town in Europe which has never had any means of defence. The sacristy also contains a remarkably fine remonstrance of the fifteenth century, two reliquaries of the same date, and a vestment of the fourteenth or fifteenth century.

Bamberg Cathedral, as before stated, stands upon the top of a hill, and round the church is a terrace with a curious fifteenth-century work parapet, and a kind of stone reading-desk at the east end.

THE CASTLE OF COUCY.*

The castle is composed of a keep, an inner and an outer ward. The outer, about thrice the area of the inner ward, intervenes between the inner ward and the town. Its narrow south front has been described. Towards the north-east the hill is very steep, and the revetment wall on this face is not reinforced by buttresses or flanking towers. On the opposite face the ground is far less steep, and the platform projects in a bold salient towards the south-west, the revetment of which is strengthened by eight mural towers or bastions, some half-round and the others rectangular. The south wall is lofty, the others were probably mere parapets. The great gate-house, or "Porte de Maître Odon," is now much broken down. The portal arch was pointed, as are two lateral arches for the guard. The square grooms of one porticulis remains. The gate-house seems to have been of the usual rectangular plan, having a central portal arch and passage, and two exterior half-round flanking towers. In this outer ward are to be traced very considerable foundations, and here are found fragments of piers and arch stones, and carved blocks, showing that the buildings erected as stables and barracks for the castellan, and probably, in times of peace, for the lord, were very considerable, and of a handsome character. Here also are the foundations of a church, recently cleared out. They show a single nave, with a semicircular apse, and a transept, the two arms of which have, on their eastern sides, two smaller apses, the three ranging nearly in a line. The building is about 100 ft. long by 30 ft. broad; has a double west door, and five windows of a side, besides three in the apse and three in each limb of the transept. From its plan and proportions this church has been regarded as part of the original castle, and the only part now remaining. Its actual date is, however, probably of the eleventh century.

The inner or north end of this ward abuts

upon the inner ward. This front is occupied by a broad and deep dry ditch, concave towards the outer ward, having a walled concave and counter-scarp, and crossed at each end by the exterior encainte wall of the place.

The inner ward, or castle proper, is four-sided. The east face, of 130 yards, and north face, 60 yards, are both straight, and set at right angles. The east front, of 70 yards, is set at an obtuse angle to the north, but is also straight. Thus breadth is given to the south front, which is 130 yards. This front is also straight, but about five-sevenths of its central part is occupied by the convexity of the great tower and a chemise, which are placed upon the line of the curtain.

The east, west, and north fronts are towards the field, and are formed by facing the scarp rock with masonry, so that they stand 30 ft. 40 ft. high to the level of the *terre-plein*, above which rises the curtain-wall. The south front is covered by the ditch already described, and which is segmental in plan, with vertical sides. Near its east end this ditch is expanded from 60 ft. to 90 ft., and was there traversed by long drawbridge, which rested upon three detached rectangular piers, of which the inner one was the largest, and contained two lateral places of arms, and no doubt carried a tower. The bridge led up to the main gate. It is now replaced by a causeway.

At the four angles of the ward are four equidistant towers, 60 ft. in diameter, and 105 ft. high for the exterior base. They are remarkable for their size and boldness, being engaged on by one-fifth of their circumference. The towers rise from the rock, and contain two domes stages below the terre-plein level. These are entered by a circular hole or eye in the centre of each vault. The terre-plein level of each is hexagonal chamber, vaulted, having five recesses, of which four are pierced as loops. The entrance is in the gorge, with two lateral passages, one leading to a garderobe and one to a well-stair, ascending to the summit.

The chamber above is similar, but the loops are placed between instead of over those below, and thus the towers have been preserved from these vertical fissures so common when a series of loops or windows occur, as they usually do, on one vertical line. By this arrangement, although the archers defending the tower much increased, every point within arrow range was exposed to fire. There are three floors above the ground-level, or five in all. All are vaulted. A line of corbels at the present summit shows that they were originally defended by bretasche.

Nearly in the centre of the east face was a small half-round bastion with flat sides, 30 ft. diameter, and about 20 ft. projection.

Standing in the court, no part of the curtain is visible. Along the central 180 ft. of the eastern face is a range of buildings, called offices, about 30 ft. deep, and having three well-staircases serving the first and second floor, now destroyed. At the south end the space between the curtain and the tower chemise, about 60 ft. by 80 ft., occupied by three aisles of vaulting, each three bays. The centre of these is the main entrance, or continued portal arch. The lateral bays are for warders and soldiery in charge of the gate. There were two stories above the now destroyed.

Along the north front was originally a vaulted arcade, 45 ft. broad, composed of four bays. This has been added, in front, an arcade of three arches, open towards the court, and upon a platform thus gained have been constructed terraces and a range of state rooms, of which the principal is the ladies' hall, or *salle des princesses*, so named from the medallions of nine celebrated women which adorned the great chimney-piece. In the exterior was a sort of oriel bodice, or large windows towards the field. Above this was another story, to construct which the curtain was raised. These buildings were the addition of the Duke of Orleans. A large well-stair, also addition, led from the court to these apartments.

The west side also has a high curtain, again which is constructed a magnificent chamber 45 ft. broad by 470 ft. long, down the centre of which stands a line of ten columns, dividing the space into eleven vaulted and groined bays, which the northern pair are cut off as a privy cellar. On the east side of this chamber are four doors, two near the centre opening into the crypt of the chapel, one south of this, probably the main entrance, and one near the south end opening into what appear to have been kitchen, and which lie between this splendid

* See p. 191, ante. Also for Plan.

range of magazines and the great tower. Connected with the kitchens are three courts, and a staircase descending to the cellars.

Below the chamber is another of equal size, excavated in the chalk, as a cellar, probably about the finest and most spacious ever constructed.

Above, on the first-floor, or third stage, was the great hall of the castle, called from its nine effigies of heroes, *La Salle des Preux*. It had a wooden roof, two large fireplaces, and a large window at the south end, below which a small door opened upon a light wooden bridge, which dropped upon the curtain of the outer ward, just above the postern.

The chapel was a rectangular building, 60 ft. east and west, by 36 ft. north and south. It projected from the hall into the court. It was composed of two parallel aisles, vaulted, each in four bays. Its south-east angle was engaged with the chemise of the great tower. Its south-west angle was free, and had two buttresses set on at right angles. This chapel is now destroyed to its foundations. It opened from the great hall.

The keep, or great tower, is the boast of Coucy, and deservedly so, being one of the finest towers in the world, and no doubt the largest and most complete single military building.

It is a plain tower, perfectly cylindrical, of excellent ashlar workmanship, 100 ft. diameter at base and summit, and 200 ft. high. It rises out of a paved moat, the base being about 12 ft. below the level of the terre-plain, and is entered by a drawbridge from the level, all below being solid.

Including the hasement, the tower contains three stories. The ground floor, on the level of the terre-plain, is entered by a drawbridge laid across the ditch, and which, when raised, covered a small square-headed portal, under a pointed arch, the entrance to a passage directly piercing the wall. The passage has an interior machicolation and a portcullis, both worked from a small chamber in the wall above, which also received the chains of the bridge. Within the portcullis was a stout door barred within, and, on the left and right, passages, one to a mural garderobe with an exterior loop, the other leading to a well-stair which served the upper rooms and led to the ramparts.

The entrance-passage leads direct into a dodocagonal chamber of about 60 ft. diameter, having a recess in each floor for stores, one occupied by the entrance, one by a large well, now about 90 ft. deep and formerly 200 ft., and one by a chimney.

Each pier is faced by a column, from which springs a rib, the twelve meeting in the centre at an eye, and supporting the vault. Each vaulting cell has a pointed gable, of which two are pierced for light.

The first-floor is of the same figure and diameter, and vaulted in a similar manner. One of its recesses is closed by a fireplace with an oven behind it; one gives passage to a very narrow postern, the plank bridge from which drops upon the rampart of the chemise wall, and three are pierced by small windows. One of these window recesses is entered laterally by a small passage from the adjacent recess. This is of fifteenth-century work, made when the recess was walled up to serve as a separate chamber. Another recess has also a lateral passage, entering a small mural garderobe, looped from the outside. In one recess are two windows, one above the other.

The second-floor, resembling the other in plan and diameter at its floor level, has a different arrangement at a height of 12 ft. Here the piers cease, and behind, between them and the outer shell of wall, is a gallery, entered by the regular well-stair, but each of the eleven other compartments of which forms a box like that of a theatre, looking down upon the central pit or floor. Two of these boxes are occupied by the detached flues of the two chimneys from below, and two are lighted by windows, which, with the central eye, form the whole and very insufficient light. In this chamber, the next below the battlements, the commander could collect and address a very numerous garrison.

The third-floor, that of the ramparts, and open above, is contained within a thick and lofty parapet wall about 10 ft. high, and pierced by twenty-four lancet arches, and as many intermediate loops. Above these the wall is surmounted by a grand coping, which overhangs both ways about three times the thickness of the wall, and then slopes upwards into a ridge. It was upon this ridge that were laid the roofing rafters

of the *brétasche* gallery, which enclosed the wall inside and outside. The former was merely as a counterpoise. The latter was of two stories, and rested its main struts upon a line of forty-eight grand corbels, which remain on the exterior face of the wall at the rampart level. The flues appeared above the roof, and three large and highly crocketed pinnacles were placed astride on the crest of the wall. The stone vault of the upper chamber was covered with lead, with occasional gutter openings outwards.

Nothing can be grander than the conception of this tower, nothing more complete than the execution of its details. All is gigantesque, as though for a race above the ordinary stature of man, and the walls within were overlaid with a fine cement, and painted with care. The design of the sculpture is bold and masculine, as becomes a military building; but all is in excellent taste, and admirably executed.

The walls of the keep are tied with chain-courses of timber, laid in mortar, in the centre of the work, as was the custom in France in the twelfth and thirteenth centuries. The timber is exposed below some of the loops. In the upper floors were imbedded radiating ties, also of wood.

Two lines of square putlog-holes are seen on the exterior of the keep. They ascend in a spiral, or a right-handed screw, and indicate the manner in which the building was constructed. Horizontal beams, projecting from the upper row, carried the inclined plane or roadway up which the materials were dragged, and these were supported by struts, the feet of which rested in the lower row.

There remains to be described only the *chemise*, or work designed to cover the base of the keep from the operations of the miner. It has been seen that the base of the keep was solid, and that it stood in a paved fosse, about 20 ft. broad, with vertical sides. The exterior side, or counter-scarp, of this fosse was a wall, about 8 ft. thick, which divided it from the main exterior ditch of the ward, and rose to the level of the first floor of the keep, say 30 ft. The ordinary ascent to its rampart walk was by a stair within the wall, commencing on the right near the keep entrance. It was also reached from the first-floor of the keep by a slight bridge, such as was employed at Rochester, and probably in one or two places in the Tower of London. There was also an access from the other end of the wall, from the rooms over the great gateway.

Outside of and at the base of the salient half of this wall was built against it, at the level of the bottom of the exterior ditch, a covered way or gallery, intended to act as a countermine, and still more completely to frustrate attempts against the keep. The gallery is entered from either end, and in its centre rises a sort of buttress against the wall in which was contained a wooden stair, by which the people on the rampart could communicate with those in the gallery. In the gallery also was a well, for the use of the kitchens, and in the substance of the wall a garderobe.

From the bottom of the keep ditch issued a postern, defended by gate, portcullis, and machicolation, the two latter worked from a small chamber in the wall; from this a wooden bridge led, in the ditch, to a postern in the west and outer wall of the outer ward.

The castle and town being of one date, and from one design, may be regarded as representing a thirteenth-century fortress of the first class, and of the strongest character, in which the internal arrangements, though palatial, were made completely subordinate to the military character and security of the place. The great feature of the castle is the keep, which commands the whole, in every part, and from its size and strength could be held with confidence after all the other defences had been taken.

The additions of the fifteenth century, consisting of state-rooms, a hall, and various upper stories, intended for the state and attendants of a court, though not extending to the keep, in some degree injured the military character of the place, and took off from the predominating grandeur of that great central feature. These, however, have for the most part fallen away, and what remains is chiefly original work, so that the appearance of the keep and inner ward is in many respects as they were designed by the great haron, who contemned the titles of king and prince, and was content with the severe simplicity of that of "Sire de Coucy."

The castle in 1652 fell into the hands of Mazarin, who employed Metzcan, son of him who threw up the famous dyke at Rochelle, to render it indefensible. The engineer blew the

chemise wall outwards into the ditch, and exploded a heavy charge of powder in each of the towers. The effect of this upon the keep was to clear out the vaulted stages, and to leave the cylinder like the tube of a vast cannon. Thus, with one or two vertical figures, it stood till our day; but now these have been closed with great care and judgment, and the cylinder has been hooped with iron, in a manner that is scarcely to be observed, and will preserve it indefinitely.

Those who wish to understand the details of this most curious place, and to acquire a complete and comprehensive view of it as a military work, would do well to read the masterly exposition of M. Le Duc, sold upon the spot, and given also in this Dictionary, under the articles of "Château" and "Donjon."

The town is also worth a visit. It contains a good church, and its southern gate-house is a very massive structure. The portal is very narrow, about 9 ft., acutely pointed, and it opens between two drum towers of one-third projection, and of about 100 ft. diameter and 60 ft. high. The short curtain between them, occupied below by the gateway, above is convex in plan, and supports two hold brackets, upon which lies a stout beam, a part of the original *brétasche*, and a rare, if not a solitary, instance of a part of such a structure remaining in place.

The drawbridge is replaced by a causeway, but at the base of the gateway are two large square holes, nearly where the axle of the bridge would rest, but which closely resemble drains, which they can scarcely be. There are no marks of external defences, save the *brétasche*. Probably the bridge, when up, acted as a gate. Within the passage, on each side, is a large lateral loop, then two portcullises, and between them a large machicolation. Within the second grate is a gate, and within this the passage is vaulted for about 16 ft. Then follows an open space, of which the roof was of timber, and then a vault. The inner end of the passage is injured, and repaired. Above, over the portal, is a fireplace of enormous size.

This gatehouse is placed in the middle of the curtain which covers the very narrow south-east front of the town. On each side of the gate-towers is a curtain of about 100 ft. long, and beyond this a pair of drum mural towers, of half projection. The loops of these towers, like every detail in Coucy, are on a grand scale. Though mere slots, they are 10 ft. high, and in three tiers. In front of the wall is a fosse of unusual breadth, wholly artificial, and which, like that of the castle, is dug across the peninsula, from one lateral valley to the other. C.

PARIS.

THERE is some talk here of demolishing the Pont Royal, and reconstructing it in the axis of the Emperor's grand entrance to the Tuilleries, and in a line, almost, with the Rue de Banne. Up to 1632 the sole means of communication between the Faubourg Saint-Germain and the Louvre and Tuilleries was by a *bac* (hence the name Rue du Bac close by), or sort of large boats ferried across the river by means of a rope stretched from one bank to the other. At this period the bridge was a wooden one, but in 1664 it was carried away by an inundation, and the present one built of stone. It was here, also, that the first dredging-boat was used to prepare the bed for the principal pier, under which the coins, &c., of Louis XIV. were deposited, and it will be curious to see those authentic relics laid bare.

We gave some account at p. 659—1867, of the works undertaken to restore the ironwork of the central doorway of Notre Dame de Paris. It was opened anciently only on very rare religious occasions, and we find that it was opened for ceremonies foreign to the general church-service at the following epochs:—Philip IV., called the Bel, on his return from the war against Flanders, entered on horseback into the church to give thanks for his victory. In remembrance of this occurrence, an equestrian statue, as large as life, of Philip the Bel, was erected at the end of the nave. Louis XII., Louis XIII., and Louis XIV., also entered Notre Dame by this door. This last monarch paid a first visit to the church, with the Queen Marie-Thérèse, for the ceremony of the baptism of the celebrated bell, called the Bourdon (in the south tower), in 1655. This bell bears the names of Emmanuel-Louise-Thérèse. The second visit of Louis XIV. was in 1699, when he laid the first stone of the

altar. Behind the altar, under the centre arcade, there was at that period a marble group by Conston, and called *Le Vœu de Louis XIII.* This splendid work of art partly figures at the Versailles Museum since 1830. The Emperor Napoleon I., on the day of the *sacre*, and Pope Pius VII., passed likewise into the church by this door. Napoleon III. also entered by it on the occasion of his marriage.

The reconstruction of the Halles Centrales, and the disengagement of their neighborhood, have, for some years, been carried on at the west, the north, and the south sides; the underground stories of the two last pavilions of the second group were finished in the second half-year of 1867. The columns and framework of the roof are erected and the metallic carcass is being put together; so that in a short time these pavilions will be ready to be opened. Of the different thoroughfares projected for this great central market, those of the south (Rues du Pont Neuf and des Halles Centrales), are completely finished; that of the north-east (the Rue Turbigo) continues its diagonal line as far as the Place du Château d'Eau, and the Rue Berger, which is to form on the south a line symmetrical with that of the Rue Rambuteau, will be shortly opened throughout.

The second group of the Halles once terminated the houses surrounding the Halle au Blé are to be raised, and four pavilions erected in their place to serve as annexes to this vast rotunda. To the west of this group will pass the Rue du Louvre, prolonged upon which will debouch the Rues Berger and Rambuteau.

In place of the old fountain of the Château d'Eau, now removed to the new abattoirs of La Villette, the foundations are being laid for that to be erected in its place. It will consist of eight lions, from the mouths of which cascades will fall into an enormous basin, after having passed through two circles bordered with verdure and flowers; at night a brilliant candelabrum of vast proportions will light it up.

At the sale by auction of the collection of M. Roux (of Tours) at the hôtel Drouot, including a variety of artistic curiosities, the "bonnet" of the sale was a small mirror, of the hilt of a female, the size of a child's hand, of boxwood, profusely decorated with interlacings; groups of fruit arabesques; figures of geni, &c.; and a woman representing Justice;—on the reverse, Daniel in the lion's den; a little girl sounding the trumpet; a figure of a man playing the violin, &c.;—a true little *chef d'œuvre*, immitable, of composition and execution of the Flemish art of the sixteenth century. Its dimensions are 133 millimètres high by 108 millim. wide. The sum at which it was valued by the appraiser was 400l., and it was sold for 1,000l., plus the usual 5 per cent. auction dues. M. Roux had bought it for 3l. 4s. (1) fifteen years ago. The purchaser is said to be the Duc d'Angoulême, who deputed some one to buy it for him.

One of the best sales of pictures of this year took place at the same hotel, viz., the collection of the Count d'Aquila. The sale of forty-six modern paintings produced more than 8,000l.

ABRIDGED SPECIFICATIONS OF PATENTS.*

THESE portly volumes, of 1,400 pages each or so, four of which in number have been forwarded to us by Mr. Woodcroft from the Patent Office, contain each abridgments of a single order of patents, one, for example, relating to Hydraulics, from A. D. 1617 to 1865; another on the Preparation and Combustion of Fuel, dating from A. D. 1620 to 1865; and so on. The selection and issue in a printed form of these volumes cannot but be of immense service to all interested in the taking out or the resisting of patent rights, as they obviate the necessity for an endless search at the Patent Office amongst the heterogeneous mass of extended and often wordy patents of all sorts for some one special order of patents. The abridgments or abstracts are short and as explicit as possible too, thus saving additional time in search even through the volumes themselves, which afford still further facilities by the addition of a full index of names, and a still more valuable index of subject matter. In the volume relating to Hydraulics, for

* Patents for Inventions: Abridgments of Specifications. Printed by order of the Commissioners of Patents, London: Office of Commissioners, 25, Southampton-buildings, Chancery-lane, Holborn, 1868.

example, in the index of subject matter, everything is separated into distinct heads, such as Aëriated Waters, Baths, Beer-engines, Boring, Canals, Cocks and Taps, Culverts, Docks, Drains, Drinking-fountains, Filters, Fire-engines, and so on in a multitude of headings all through the alphabet. This volume, by the way, is all the more especially useful in our province that it includes a great many patents for sanitary purposes, as the following summary of its contents will show:—

"This series relates to raising, forcing, storing, filtering, applying, measuring, and regulating the flow of water; it also relates to irrigation and drainage, to apparatus for the employment of hydraulic motive power, and to the appliances for its domestic and sanitary use, such as joints for pipes, taps and cocks, fountains, baths, and water-closets; moreover, it includes improvements in the form or arrangement of sewers and drains, designed to facilitate the flow of water; in flushing or otherwise removing obstructions; in trapping; in excavating or cutting trenches, ditches, and drains. But it is not intended to include materials for or methods of manufacturing or constructing sewers or drains; these will be found in the series of abridgments entitled, 'Tunnels, Subways, and Sewers,' and 'Drain Tiles and Pipes.' Nor is it intended to include improvements in the collection and treatment of sewage; these will be found in the series of abridgments entitled, 'Manure.'"

The number of specifications printed and published at the time of the issue of this volume amounted to nearly 61,000; and the number included in the other volume on Combustion of Fuel was 59,000.

Each volume contains an Introduction, giving a rapid and brief *resumé* of the history of the subjects patented in each. There is thus a short historical treatise or essay on Hydraulics in the volume relating to Hydraulics; and one on Fuel and Combustion in the correlative volume.

So early as 1630, we see, from the volume on Hydraulics, a patent was got by one David Ramseye, "to make boats, shippers, and barges to go against wynde and tyde." The draining of water out of mines and marshes by hydraulic engines appears as the subject of various patents of about as early a date; and canals and water-works are also amongst them. The eighth patent on the list was granted to Hugh Middleton "for the wyning and draying of many grounds," granted "for the good opinion we have conceived of the said Hugh Middleton, or that worthy works of his in bringing the New River to our Citty of London, and his care and industry in busines of like nature tending to the publicke good." The second patent on the list, of date 1618, was granted to David Ramsay and Thomas Wildgosse "to ploughe ground without horse or oxen." John Gilbert, in 1618, got a patent for a "new engine or instrument called or termed a water-plough, for the taking upp of sand, gravell, shelles or hanches of the river of Thames," &c. In 1638 a patent was granted to Sir George Horsey, Dudd Dudley, and others, for "the making of iron with sea or pitt coale, peate, or turfe, and with the same to rost, melt, or refine all metalls of what nature soever." All these and the other patents in these volumes can be had separately, and not as mere abridgments, in a printed form, from prices varying from 4d. and 6d. to 2s. or 3s.

The volume on "Fuel and Combustion" shows that smoke consumption was a very early subject of consideration and experiment. In the Introduction to this volume a curious fact is brought forward from "Pennant's Tour in Wales," p. 17, that a "flint axe was found in an out-crop of coal in Monmouthshire, and similar discoveries have been made near Ashby. Of course it is not to be inferred, all at once, from this that it will form evidence of the existence of man in the carboniferous era, although even that would not be so startling an inference in these days; but that coal was probably used as fuel in exceedingly ancient times.

It is mentioned, in this Introduction, that of date 1686, a plan for making the fire gasses and smoke of a wood fire descend downwards through the fuel, was invented by Mr. Dalesme, and is alluded to by M. De la Hire, in his "*Reflexions sur la Machine qui consume la Poudre*," at p. 406, of vol. x. of the (1686) *Mémoires de l'Académie Royale des Sciences* (Paris, 1730); and that Dr. Franklin invented in 1785 a revolving grate, with a circular fire cage, and so made as to be capable of being turned round, after being lighted, in order to bring the fresh coal under the burning coals, and thereby prevent the development of smoke. (From "The Transactions of the American Philosophical Society," January 28, 1786, into "The Complete Works," &c., of Dr. Franklin, London, 1806, vol. ii., p. 314.) A down-draught stove, the construction of which is based upon that of Dalesme,

from which it was avowedly taken, is also described.

Altogether these volumes must not only be exceedingly useful, but they are of great interest historically and archæologically as well as scientifically speaking; and the work of compilation and condensation, which must have been a most formidable one, appears to be excellently well done. The other two volumes before us relate to Railways, and to Raising, Lowering, and Weighing.

THE ARCHITECTURAL EXHIBITION SOCIETY.

WE would remind our readers that the annual Exhibition in the galleries of the Houses in Conduit-street, will be opened on Monday, May 4th next, and that all drawings must be sent to the galleries on Wednesday or Thursday, the 8th and 9th days of April. The committee desire to give to the architectural profession, and the public at large, a convenient opportunity of exhibiting and inspecting well-executed representations of the works now being executed by individual architects and others interested in art. In furtherance of these objects, and in addition to the usual attractions of the Exhibition, they are desirous of receiving perspective and geometrical drawings of all new buildings, with such particulars as to plan, construction, cost, draughtsman, or artist, as may be desirable; and, in addition, photographs of buildings already executed, original sketches, working drawings, sketches of old works, and competition or other designs, which may recently have been prepared. The Committee have also decided upon accepting a limited number of purely artistic drawings of architectural subjects. They have published a list of towns in which honorary secretaries are desired. Some of our readers may be disposed to act in that capacity.

ARCHITECTURE IN THE ROYAL SCOTTISH ACADEMY.

THE architectural drawings exhibited this year are remarkable neither as to quantity nor quality. A few of the designs show some amount of thought on the part of the authors; but others not only exhibit an utter want of it, but a disregard of, or incapacity to appreciate, the laws of harmony and proportion. Notwithstanding all that has been written against the use of "constructed ornamentation," and the debased forms of the later renaissance, broken pediments, gables without roofs behind them, and detached columns supporting nothing, continue to appear. No. 192, "Langton House, Berwickshire," is the work of Mr. David Bryce, the leading architect in Scotland, and he has designed many mansions, and added to or reconstructed more; but we do not recollect of any instance save this where he has reproduced so much meretricious detail. The mansion is certainly a large and stately one, but it is ostentatious; and the portal is flanked by three tiers of detached pillars, which do no other duty than thrust themselves forward to be looked at, and the carving is mostly made up of large scrolls, which sprawl out wherever an opportunity presents itself. No. 118, "Free St. George's Church," as designed for the site ultimately chosen, is Palladian in style, and without the tower would be a poor production. The tower is, however, a striking feature, made up of a series of arched unglazed openings, and adorned with statuary. The style adopted is undoubtedly more in keeping with the surroundings than would have been the Gothic church (No. 162), designed for the site first fixed upon.

No. 57, "Free High Church, Partick," by J. Honeyman, is a gracefully proportioned edifice of fourteenth-century Gothic, and it has been skilfully adapted to the slope of the ground, the result being quietly picturesque, without the architect having gone out of the way to produce that result.

Mr. Pilkington's "Dundee Church," No. 270, is an effort at producing picturesque by the addition of many little adjuncts to the main building; these adjuncts detract from the dignity of the building, which would be better without them. The spire is a fine piece of composition, bold and gracefully proportioned.

No. 194, "Church of St. Michael and All Angels, Helensburgh," Robert Anderson, architect, is neither picturesque nor graceful, the

general effect being heavy and uninteresting; the detail appears to be faultlessly correct, but the little sills of windows, both in the aisles and clerestory, are rather primitive. Mr. Anderson seems to be more successful with his interiors than with his elevations. No. 210, "Interior of Church of St. John the Evangelist," at Alloa, is broad, simple, and well proportioned.

Nos. 211 and 231 are the first efforts at church-building of Mr. J. W. Smith. We prefer the former to the latter, the main gable of which is weakly treated. Mr. Smith will pardon us for advising him not to aim at giving too much for the money; his churches would be much better if more simply treated.

No. 120, "U. P. Church, Newtown, St. Howell's" by Mr. John Paterson, is liney and characterless, notwithstanding an effort at novelty in the arrangement.

No. 103, "Design for a Church in Glasgow in the Mixed Moorish and Lombardic Styles," by Mr. J. T. Roched, is quite out of the ordinary run, and is more peculiar than beautiful: the slender campanile is not a feature that would appear to advantage amongst the high chimney-stalks of Glasgow.

No. 160, "Perspective View of the Choir of St. Giles's Cathedral, showing the Improvements proposed by the Lord Provost;" B. Matheon. This does not pretend to be a restoration, the requirements of the Presbyterian form of worship being incompatible with the arrangements usual in a cathedral choir, and the only course left to the architect was to give the interior the semblance of such. This he has done by arranging the stalls against the walls of the aisles and across the east end, substituting open benches for the present heavy pews, and leaving an open railed-in space in which the pulpit and font are placed. The stalls are copied from those in King's College Chapel, Aberdeen, the best remaining example of ecclesiastical wood carving in Scotland. They are in perfect keeping with the style of the cathedral. The pulpit has a rather tab-like appearance; something of the nature of a platform would be more appropriate. The mutilated tracery is left as it was: as we stated in a former notice, all character has been knocked out of it by paring down; to place stained glass in it would be worse than setting a fine picture in a shabby martinet frame.

No. 42, "United Presbyterian New Church, North Berwick, in the Early English or Pointed Style of Architecture; the small Island of Craigleith and Firth of Forth in the distance," Robert R. Raehurn, architect. The intelligent reader may form a guess of what kind of church this is from the entry in the catalogue which we have quoted: *in form it is hideous, and in style execrable; the pinnacles which surmount the buttresses are certainly not Early English, and if of any style at all are of that which was in vogue a century ago.* We advance these remarks solely in the interest of art. It is sometimes necessary to speak strongly, and no one who knows nought of the art of building will, we venture to say, attempt to defend such a design as the one in question.

No. 61, "House at Weston, near North Shields, Durham," by Douglas & Stevenson, is Italian Gothic in style; the arrangement of the parts is pleasing and natural, and the detail good. There is a homely unostentatious look about this house, which suggests the idea that internal elegance and comfort have not been sacrificed to external effect.

No. 16, "Tenements at Heriot Mount," R. Thornton Shiells.—This is a bold and effective group of Scottish tenanted dwellings,—rather severe, perhaps, but well suited for the locality which they occupy on a height overlooking the Queen's Park and in the proximity of Salisbury Craigs. Had the other dwellings in this neighborhood been well designed, the views of the city from the craigs would have been greatly enhanced; as it is, they are "stale, flat, and unprofitable"—a rare opportunity of producing a fine effect, at small cost, has been missed.

No. 249, "Kingsknows House," Wm. Hay.—In the Scottish Baronial style. Stone was the invariable material used, and the detail was vigorous rather than refined. We have here, however, a building which has more the character of a brick than a stone structure.

Mr. Pilkington's "Dundee Club," No. 273, is unlike any other building of this class that we know of; it is marked by an individuality which characterises the designs of this architect. The style may be termed Byzantine; the openings consist of wide round-headed arches, and the

windows of the first-floor have an open-framed margin in stone. There is a certain vigour about this design, as well as in the mansion No. 228, similar to it, which would be highly commendable were it combined with elegance and gracefulness of proportion.

Mr. James Gowans exhibits a large view of part of Castle-terrace (No. 153), which is in course of erection. This terrace will form a marked feature in the architecture of Edinburgh; the broken and varied skyline is very different from the invariable straight-line of cornice in all the other terraces of the new town. If Mr. Gowans would only forego his peculiar notions of detail, and substitute a little carving for the profusion of notches and splay he delights in, his buildings would be less peculiar, but certainly more beautiful.

BUILDING MATERIALS AND THE PROPOSED PAUPER ASYLUMS.

THE question of building upon an extensive scale for the accommodation of pauper lunatics and pauper patients, afflicted with small-pox or fever, is assuming a very prominent and important feature in the social arrangements of the metropolis, under the provisions of the Poor-law Act of 1837. Measures are in progress for the erection of such buildings in various parts of the suburbs of London, the funds being provided by contributions from the several metropolitan parishes and unions, the whole being under the supervision of representatives elected by the several parochial districts, and constituting what is termed the Board of Management of the Metropolitan Asylum District. Sites for the proposed buildings have been already purchased at Leewesden and Caterham, and others are now under consideration for hospital purposes. The Board have already obtained power to borrow 200,000*l.* for the purposes of the two asylums sanctioned, and a much larger sum will no doubt be required before the system which has been thus commenced can be brought into practical operation. In the construction of these extensive buildings, if bricks be used, some 20,000,000 or 30,000,000 will be required for each, in bricks and mortar, consequently the third of the whole expenditure will be incurred. It may not, therefore, be unimportant to review some of the matters which bear a close relation to the subject, and especially those affecting the quality of the materials employed, it being highly necessary that such materials should be of the soundest quality possible, free from any admixture of ingredients which produce deterioration and generate disease.

The Legislature, it may be observed, has already assumed the responsibility of regulating the construction of buildings, by the Act of 18 & 19 Vict., c. 122, well known as the Metropolitan Building Act, 1855; and two amendment Acts, modifying and extending the provisions of the original statute, have since received the sanction of Parliament. These Acts contain provisions relating to the lines of walls, recesses and openings, parapets and bressummers, chimneys and flues, fireplaces and conveyance-pipes for heated air, steam and other products of production; but they make no reference whatever to the character and quality of the materials commonly used in the erection of such buildings. There are no regulations enforceable to insure the structure being perfectly dry in all seasons of the year, which is a very important consideration in this variable climate, and never attained when sand or any material impregnated with saline matter is used in the construction of the building. Many of our public structures give ocular demonstration of inherent defects which due precaution might have prevented. We need only instance the Hanwell viaduct of the Great Western Railway, in elucidation of the point to which we direct attention. This with its mil-dewy walls indicates a process of absorption and emission going on continually, rendering every part thereof damp. If saline particles be in either bricks or mortar they act like a sponge in absorbing moisture from the atmosphere, and giving it out again under the influence of heat. The new boundary-walls of Coldbath-fields' prison, near to Mount Pleasant, is another instance; and we should not be surprised if the costly erection of St. Thomas's Hospital, now in progress, should in after years awaken posterity to the fact that materials containing saline matter were used in the building. It is now upwards of twenty-five years since the Great Western Railway Viaduct was built, and there it

stands, a monument of indiscretion on the part of those by whom it was constructed.

The committee of the Board of Management of the Asylum District, who are entrusted with the selection of sites, the preparing of plans, and the drawing of specifications, very laudably direct their attention to facilities for drainage, salubrity of atmosphere, accessibility by road or railway, and other requisites of an obvious character, which ordinary business men could not overlook without displaying great want of attention; but there are many other considerations well entitled to notice in the formation of such buildings as are contemplated by the Asylum Board. While the Building Acts, as before stated, abound in rules applying to form of construction, they absolutely ignore the quality of building materials; and hence we have private dwellings, public schools, infirmaries and hospitals, workhouses and prisons, built of brick containing saline matter, kept together by means of mortar which has been mixed up with sea-sand or sand taken from the river Thames below Blackwall, where it is generally brackish, and becomes more and more so as we approach Gravesend, where the river flows into the sea. Buildings made in the way we have described never fail to exhibit the ordinary tests of dampness, which, if not recognized by the sensibility of the organs of smell, seldom remain undetected by those of vision. The walls of such buildings generally become flakey white outside, and frequently present a similar appearance inside through three or four coats of paint. The observant eye may have noticed blisters of paint upon a "flatted wall," which, if probed with a knife, will let moisture exude and trickle down, showing that it must have come from the material of which the walls are built. The Board-room of the mansion in Spring-gardens, where the Metropolitan Board of Works holds its weekly sittings, and which is at present temporarily occupied by the Asylum District Board, affords a striking proof of the correctness of these remarks.

Our object in directing attention to these matters is to obviate, as far as possible, in the construction of buildings projected by the Metropolitan Asylum Board, similar mistake to those already committed in other large building operations. We believe that, in many cases, builders err through sheer ignorance, and that architects—highly educated professional men—from want of practical attention, have failed to detect the hidden causes which are silently operating in producing the most disastrous results.

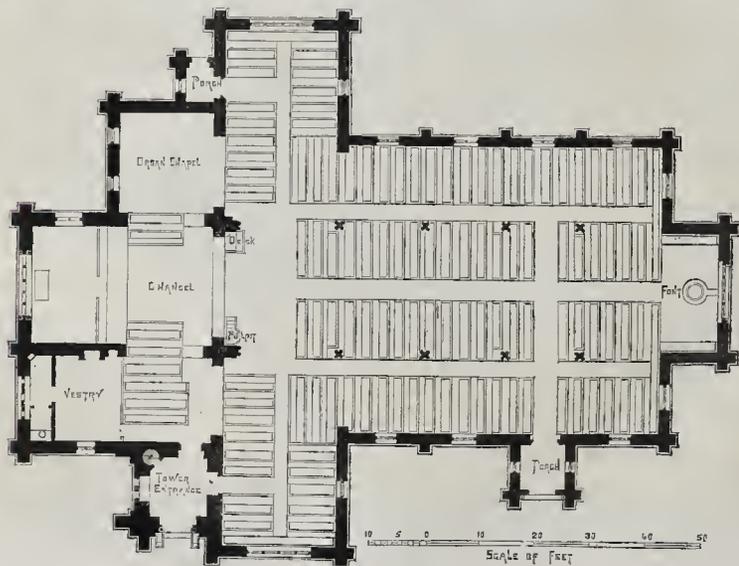

The infirmaries of our workhouses, and many of our large hospitals, contain very many patients, labouring under chronic diseases of a painful character, which there is every reason to believe originated from damp pervading the structures, and by consequence the atmosphere of the houses in which they resided. Chronic rheumatism, ague, intermittent fever, and many other affinitive forms of disease, which generally prevail in large establishments, especially when situated in close neighborhoods, or where the inmates are crowded together as in the dwellings of the poor and working-classes, owe their existence, in a great measure, to the faulty nature of the materials of which the dwellings are constructed; nor do these observations apply only to the houses of the poor; for the rich, whose residences wear a degree of splendour on their exterior, have the same canker-worm of saline damp, eating its way through every part of the structure, and seizing with irresistible force, albeit unobservedly, the physical frames of all who come within the sphere of its pervading influence. A METROPOLITAN RATEPAYER.

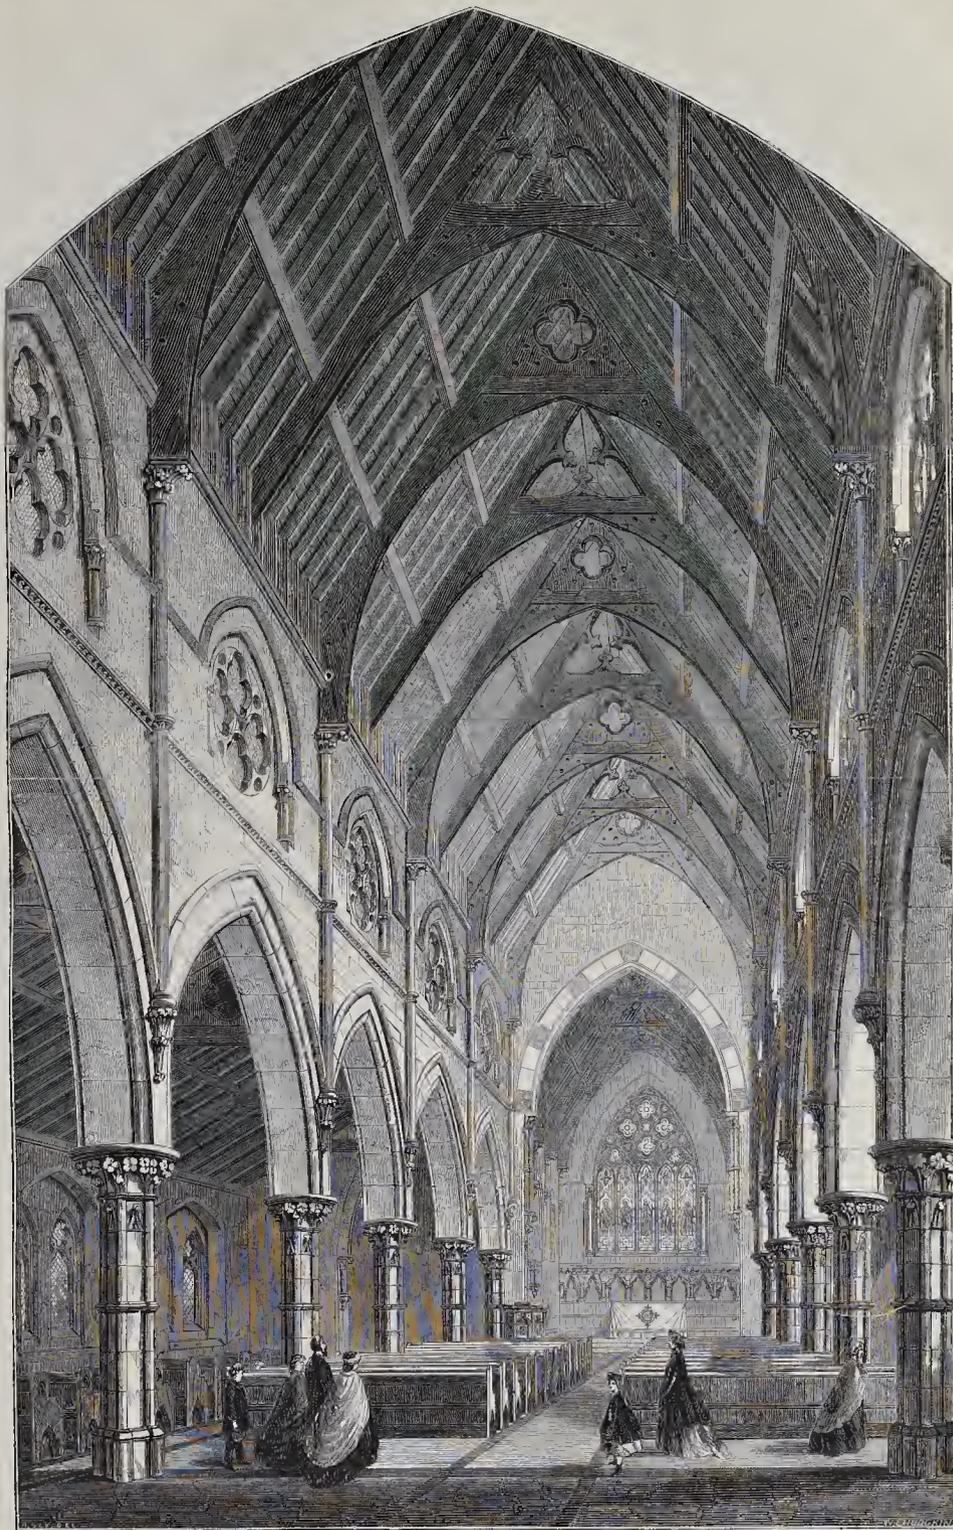

BISHOP'S CAMDEN SANITARY VALVE.

In thousands of cisterns the "waste pipe" leads direct into the house-drain; and, being untrapped, or so trapped as to be inefficient, permits the contamination of the water by foul and dangerous gases. Who can estimate the number of illnesses to which this has led? The best thing to do is to arrange the waste-pipe so that it may discharge itself without actual connexion with the drain; but, when this cannot be done, the Camden Sanitary Valve, patented by Mr. Bishop, of Pratt-street, Camden Town, may be very usefully employed. It consists of an air-ball, that opens a carefully arranged valve, when the cistern is too full, and it may be applied at small cost.

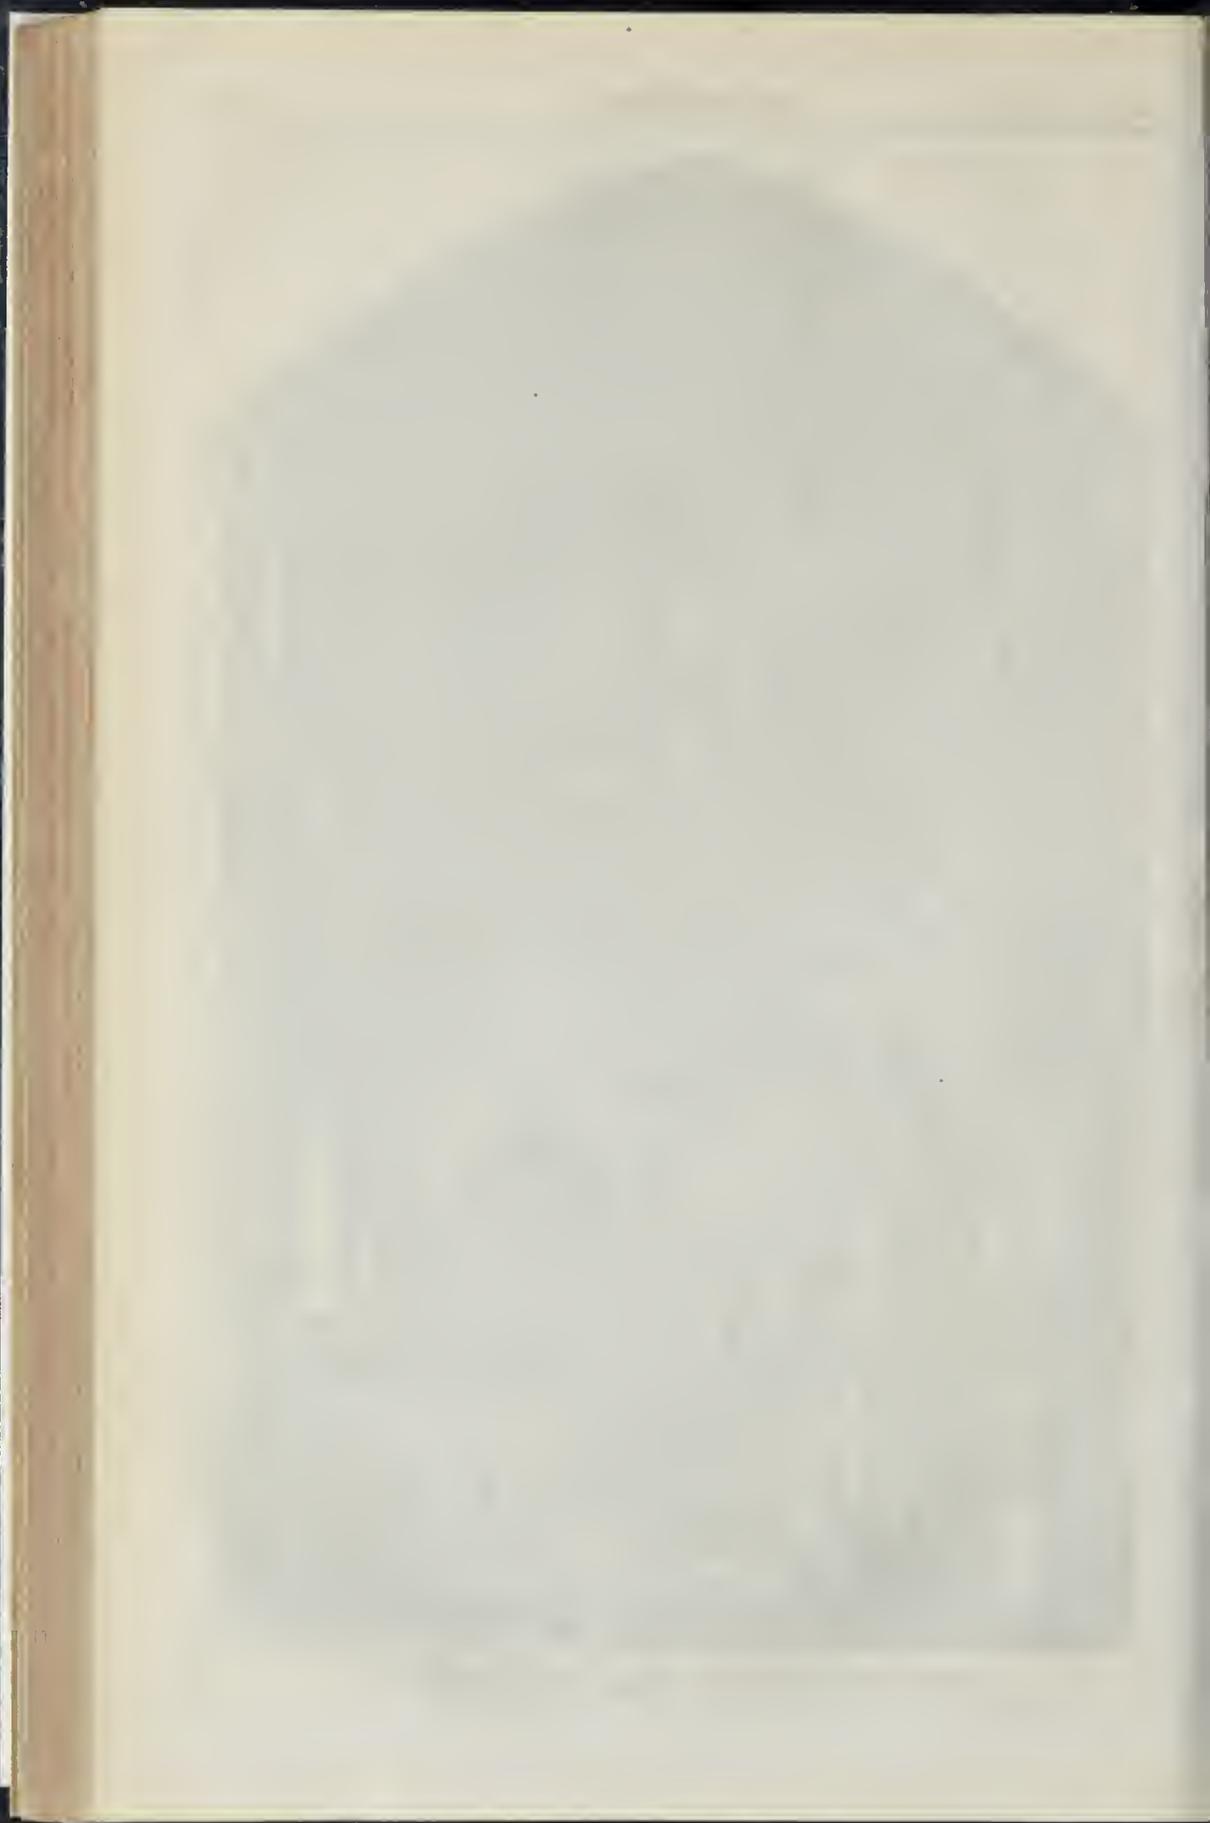

SHARROW CHURCH, SHEFFIELD.

SHARROW CHURCH, SHEFFIELD.—MR. J. B. MITCHELL-WITHERS, ARCHITECT.

SHARROW CHURCH, SHEFFIELD.

This church is being erected by the Sheffield Church Extension Society. The design was selected in open competition from those of about thirty competitors. The corner-stone was laid in June last by the Archbishop of York, the president of the society.

The building is erected with Whitlow well-stones and Eyan ashlar. The roofs and internal fittings are of stained deal. The contracts, exclusive of warming, lighting, boundary walls, architect's commission, and clerk of works, amount to about 4,200*l*. Accommodation is provided for 750 adults. The site was presented by Sir John Brown.

The east window will be filled with stained glass by Messrs. Clayton & Bell, the gift of Mr. Chas. Gould, and the west will be filled with glass, the gift of another friend.

The church will be ready for consecration in the autumn of the present year.

The architect is Mr. J. B. Mitchell-Withers, of Sheffield.

SONS OF THEIR WORKS.

UNDER this title, "*Les Fils de leurs Œuvres*," Mr. George d'Heilly publishes, this week, at Ronquette's, Paris, a curious little book, in which the origin of a few well-known persons of the present epoch is indicated. We learn from it that About is a grocer's son; Amber, son of a picture-dealer; Belmont, of a joiner; Coquelin, of a haker; Crozier, of a porter; Duprez, of a performer; Garnier, architect of the new Opera House, Paris (of which an illustration was lately given in the pages of the *Builder*), of a smith; Govaert, of a labourer; Gvoynard, of a farmer; Halevy, of a grocer; Houssaye, of a miller; Levasour, of a labourer; Victor Massé, of a dealer in nails; Monselet, of a bookseller. Mademoiselle Rachel is the daughter of a hawker; Rossini, the son of itinerant singers; Sorhe, of a silk dealer; and Verdi, of an inn-keeper. All honour to them for their self-creation!

TUBE WELLS.

A NUMBER of gentlemen met on Saturday last in a field near Thames Ditton station, for the purpose of witnessing the sinking of wells upon the tube system, which was used to good purpose in the American war, and is now being used in Abyssinia with success. The utility of this invention, of which Mr. Norton, of Ludgate-hill, is the sole patentee in this country, is not, however, confined to campaigning.

The simple contrivance by which it would appear, a well may be extemporised in some twenty minutes, is a few pipes about 3 ft. long—like gas pipes—two clamps, and a monkey. The first pipe, which makes the well, is perforated for about 16 in., and is shod with a steel peg top, which swells out beyond the pipe, and which fulfils the double purpose of providing a sharp point and easing from friction whatever lengths of tubing may have to follow it. A clamp is placed about the centre of this tube, and another clamp at the top, to which two pulleys are attached, and over these pulleys a cylindrical "monkey" is suspended, which, falling on the clamp below, drives the pipe into the ground. Then another pipe is screwed on, and the clamps being lifted higher, the same process is continued, and so pipe is added to pipe until the water stratum has been reached, which is ascertained by dropping a plummet into the tubing. Then a small ordinary sucking-pump is screwed on to the last pipe, which is allowed to protrude about a foot above the ground, and water thick with sand immediately comes up at the rate of about ten gallons a minute. After some time all the sand smaller than the perforations below to which the draw of the pump extends is eliminated, and the perforated portion of the pipe rests in a bed of shingle, the pebbles being necessarily small near the pipe, and growing larger in proportion to the distance at which they are removed. Thus a natural filter is formed.

The tube-well which attracted most attention was that which is in use in Abyssinia, the pipes of which are only 1½ in. in diameter. This well was sunk 15 ft. in 17½ minutes, and water was pumped in 19 minutes. Two men can carry this well, and everything connected with fixing it, and one is quite equal to anything the fixing requires. It was taken up by means of the

"monkey" worked upwards, in 7½ minutes, and in the apparently astonishing time of 1½ minute by means of a lever, which a mule easily carries in addition to half a dozen wells. These pumps can be made useful on farms, and in factories, as well as in the premises of private houses. When water does not come it is coaxed, as it were, by driving water down the tubing at a pressure of two or three hundred pounds to the inch, which searches the strata, and makes a water-way. Where the water stratum is sandy a filter of horse-hair is inserted in the tube. The water never freezes.

EARTHQUAKE-PROOF BUILDINGS.

At a recent meeting of the Scottish Society of Arts, in Edinburgh, Mr. David Stevenson read a paper on certain arrangements, designed for the preservation of structures in countries subject to earthquakes. Mr. Stevenson stated that his attention had been directed to the matter, not as a speculative question, but by the Government, as a problem of practical engineering. The Japanese had applied to the Government of this country to advise them as to what was necessary to light the coast, according to treaty, the difficulty consequent on frequent earthquakes being pointed out. The Board of Trade, in remitting the whole subject to Messrs. Stevenson, specially directed attention to this new feature in lighthouse engineering. Mr. Stevenson explained the device he had proposed for rendering buildings aseismatic, and illustrated it by diagrams and models. The new construction, as described in the *Scottsman*, is based on the principle of breaking the continuity between the earth, which is effected by the shock, and the superstructure which rests on its surface; and the break is effected by the aseismatic joint, which, in the case of lighthouse apparatus, consists in placing the iron table on which the apparatus rests on halls of metal, working in cups [of somewhat larger diameter, we presume, than the halls], formed in the underside of the table. These halls rest in similar cups formed on the upper side of a lower table. When the lower table is affected by a shock, it is at liberty to move freely, without affecting the apparatus above, which, by reason of its inertia, remains unaffected. The motion being *quas quæ versus*, also renders its action the same from whatever direction the shock may come. Mr. Stevenson stated that the aseismatic action had been successfully tested by experiments made at Messrs. Milne's works on tables of the full size for a first-order lighthouse. The Government have ordered the whole of the lights about to be constructed here for the Japanese Government to be made on this principle; and it may ultimately be adopted for architectural or domestic arrangements generally in countries subject to earthquakes of destructive character. The Japanese, who are an ingenious, mechanical people, will probably adopt it wherever it is applicable.

PROVINCIAL NEWS.

Brighton.—The foundation stone of a Turkish bath has been laid in West-street. Messrs. Cheesman & Co. are the contractors, and the architect is Mr. Gouley.

Hull.—The west dock, an important addition to the works of the Hull Dock Company, will be opened before the close of the present year. It is expected that the Prince of Wales will attend the opening ceremonial.

Bradford.—The new buildings at the corner of Bate-street, for the Commercial Joint Stock Banking Company, lately carrying on business in Market-street, have been opened. The style is French Gothic. The principal front looks towards the Exchange. It consists of two stories and an attic. A tower rises to a height of about 90 ft. from the corner adjoining the intended new street. The entrance door at the foot is deeply sunk, with polished granite shafts and moulded hands. The windows in the first story of this tower are sunk to a depth of 4 or 5 ft. Each of these windows has a projecting balcony, with balusters, and is surmounted by gables having carved crockets and finials. The double windows here are also pointed and deeply recessed. A carved cornice and pierced parapet, with angle pinnacles, surmount this story, above which rises a steep slate roof, with dormer windows, terminating in wrought-iron cresting and finials. In this frontage, there are on the

ground-floor four windows, with pierced panels underneath, and a door corresponding to that in the tower. These have shafts of polished granite. On the second floor are five double windows, with tracery heads. Throughout the carving has been executed by Messrs. Maw & Ingie, of Leeds. A cornice, supported on carved brackets in couples, runs along the front, and above it is a pierced parapet. A row of single-light stone dormer windows, with gables, is placed in the roof. The frontage to Piece Hall-yard corresponds in detail with that just described. The third side, commencing from the lower previously described, is, with the exception of a large central gable, treated in a similar manner, but is at present almost hidden by the adjacent houses. Mr. A. Mallinson has been clerk of the works, and under his superintendence the designs of the architects, Messrs. Andrews, Son, & Pepper, of this town, have been executed. The masonry was done by J. Burnley & Son; the joiners' work by J. Wilson & Sons; the furniture of the bank by Mills & Backhouse; the plumbing by J. Keighley; the slating by T. Nelson; the plastering by E. Dixon; the painting and decorating by H. Briggs; the cast-iron work by J. Cliff & E. Halevy; the ornamental wrought-iron work by W. Slater; and the gasfittings by Skidmore, of Coventry.

Shepton Mallet.—The almshouses have been recently built, and are designed to accommodate four persons. Each comprises a living-room, pantry, and bed-room with a bay-window and porch. There is a separate yard at the back of each house enclosed by a wall, with the necessary outbuildings. The walls are built of the local stone, hammer-dressed on the external face, with doubling quoins and dressings. The roofs are covered with Bridgwater tiles. The contractor for the masons' work was Mr. Fudge, and for the carpenters' and joiners' work Mr. Stock, both of Shepton Mallet. Mr. Ferrey, of London, was the architect employed.

SANITARY MATTERS.

Liverpool.—At a special meeting of the Health Committee of the Liverpool corporation, it has been decided to recommend the council to apply to Parliament for powers to enforce the conversion of all privies within the borough into water-closets, the cost to be defrayed by the corporation and the respective owners, in proportions afterwards to be decided. It has been satisfactorily shown that the conversion, so far as it has proceeded, has materially reduced the local rate of mortality.

Farnham Sewerage Competition.—A correspondent of the *Surrey Standard* says,—"It is now twelve months since plans were deposited with the local authorities for improving the sanitary state of the town, and, as yet, nothing is known, either by the competitors or the public, respecting the adoption of any of the numerous schemes submitted, agreeably with the advertised desire of the local Board. It appears very desirable that some immediate decision of the Board should be made known, especially so, considering the dangerous sanitary state of the town. An unsewered town, containing nearly 6,000 inhabitants, is certainly a place most likely to be visited by fevers, cholera, and other epidemics: should these fearful visitants arrive during the approaching summer, death must necessarily ensue, and then the authorities will feel they have been guilty of gross neglect and abuse of powers vested in them by Government. It is to be hoped that the local Board will set resolutely to work in improving the present defective sanitary condition of the town. Will you kindly inform us whether the Board is defunct, and what has been done with the various sets of plans?"

Seaford Drainage.—The plan of Messrs. Gotto & Beesley (estimated cost 2,400*l*.), which has been finally adopted, will consist of a main out-fall sewer along the front of the town, so as to convey the sewage to the Cliffe and about half a mile to the eastward, and discharge it, after being deodorised, into the sea at low-water mark. At and after low water, the current sets in to the eastward, towards Beachy Head: so that there will be no nuisance to bathers and others in front of the town, the whole being about a mile in extent. At the western extremity a large flushing reservoir will be formed. This will be filled by means of a self-acting iron pipe through the beach, at high water, and as soon as the sewage is emptied at low tide, the con-

tents of this reservoir, about 15,000 gallons, will be flushed through from end to end of the main drain, to keep it clear and free from deposit. Pipe sewers, communicating with the main outfall sewer, are to be laid in all the streets, with special provisions for inspection, cleansing, and ventilating the same, the latter object being attained by charcoal ventilators. There is also to be attached to the main sewer a tank and apparatus for deodorising its contents before its discharge into the sea. Provision will also be made at the outfall for, at a future time, as the town increases, pumping the sewage on the land at a distance from the town for agricultural purposes. The tender of Mr. W. Williams, of Swansea, to do the work for 2,283l. was accepted. The plan has been approved of by the Home Secretary, and arrangements made for repayment by rate in thirty years.

Fever at Higham-on-the-Hill.—A correspondent of the *Covestry Herald* states that the fever which prevails at Higham, where there have been sixty cases and six deaths in a population of 500, arises from nuisances on private property in that part of Higham where the fever broke out, and also from overcrowding. A medical report also speaks of bad drainage as one cause; this, however, the writer says, relates chiefly to the private property referred to. Private or not private, the nuisances will surely be abated. Of the cases of fever, it is said, thirty-five occurred within fifty yards of the nuisances.

ASYLUMS FOR THE INSANE POOR, LONDON.

On the 14th, the Metropolitan Asylum District Board, a body formed by the Poor Law Act of last Session, held a meeting at the Westminster Palace Hotel, for the purpose of considering the designs sent in, as we mentioned last week, by various architects for building an asylum for the insane poor, at Leavesden, Woodside, Herts. The designs were from,—

Messrs. Tolley & Dale (estimated cost), 65,000l.; Mr. Wm. Lee, 82,000l.; Mr. F. H. Pownall, 108,800l.; Mr. A. Wilson, 91,000l.; Mr. P. Gordon Smith, 78,800l.; Mr. F. Chambers, 96,350l.; Mr. John Giles (Giles & Biven), 66,700l.; Mr. Thomas Worthington, 94,300l.; Mr. Henry Jarvis, 78,000l.; Mr. M. P. Manning, 92,000l.; and Mr. J. E. Knightley, 125,000l.

The first premium of 250l. was awarded to Mr. Giles, whose design was estimated at 66,700l.; the second premium of 150l. to Mr. A. Wilson; and the third (100l.) to Mr. F. H. Pownall.

The designs for an asylum at Caterham were referred to the same committee, who have sent in their report. The competitors in this case are Messrs. Giles & Biven, Mr. Knightley, Mr. Andrew Wilson, Messrs. Tolley & Dale, Mr. F. H. Pownall, Mr. Thos. Worthington, Mr. Jarvis, Mr. F. Chambers, and Mr. M. P. Manning.

The committee have recommended to the Board the design submitted by Messrs. Giles & Biven, as in the first case, and it will probably be selected. We have no hesitation in saying, after examination, that the design selected is far superior in several important points to any of the others.

HASLINGDON WORKHOUSE TENDERS.

From the report to the local Guardians, of the Building Committee, it appears that there was but one tender for the whole work—that of Mr. J. Barry, of Scarborough; the others, which were very numerous, being from smaller contractors for portions of the work only. The tender of Mr. J. Barry, at the sum of 20,865l., was accepted by the guardians. Several of the guardians expressed surprise at the necessity for the original grant of 33,500l. being so largely exceeded; but the architects, Messrs. Lockwood & Mawson, who were both present, explained that all this was mainly due to the increased requirements of the Poor-law Board since the plans were originally decided upon, alterations and additions thereby being rendered compulsory which greatly enhanced the cost. Not long ago, 17l. a head on the number of inmates would have been ample to have paid for a well-built workhouse, but now, so stringent had the requirements of the Poor-law Board become, nearly double that amount was necessary if good material and satisfactory workmanship were to be used. A few years back 500 cubic

feet of space were allowed for each pauper, but now the Poor-law Board were satisfied with nothing less than 1,500 ft. per head. A large increase in the cost of internal arrangements was entailed by reason of extra staircases, passages, bath-rooms, &c. They also stated that before the plans were drawn they had not been shown the site, and had, therefore, not taken into consideration the cost of taking material thither. However, they were content to accept the 5 per cent. on the original estimate as their remuneration; although, in consequence of the alterations taking, it would be far from a profitable undertaking. It was decided that application be made to the Poor-law Board for permission to borrow 15,000l. additional. As to payment of the architects, it was resolved that these gentlemen be paid 300l. down, on account of expenses already incurred; 150l. more when the main building was ready for the roof; and the balance (200l.) on the completion of the work—making in all 650l., or 5 per cent. on the amount originally estimated.

COMPETITIONS.

Hereford Lunatic Asylum.—A meeting was held last week of the committee appointed at the last Quarter Sessions to select the plans for the new lunatic asylum for the county and city of Hereford, which it has been determined to erect on the Barton estate, near the city, consequent on the decision which has been arrived at to dissolve the present union between the counties of Hereford, Monmouth, Brecon, and Radnor, and the city of Hereford. Three architects had been invited to send in designs, viz., Mr. Kempson and Mr. Chick, of Hereford, and Mr. Griffiths, of Stafford. After investigation of the respective plans, and interviews with the architects, the committee selected those of Mr. Griffiths, and they have been forwarded to London for examination by the Commissioners in Lunacy. It is stated that there was not more than 1,000l. difference in the estimates of the architects, the highest being 39,000l.

Darlington Workhouse.—The second premium was awarded to Mr. G. Styan, not Stanger.

THE "EGYPTIAN HALL" IN THE CITY.

Your "Old Correspondent," who sent the interesting "Notes from York," in the number for Feb. 1st, writes in evident ignorance of the meaning of the expression "Egyptian Hall" as an architectural term. He is, however, by no means singular in this: indeed, I have scarcely ever met with any one, however familiar with the science of architecture generally, who could tell me why the "Egyptian Hall" at the "Mansion House" of the City of London has that designation. When the subject is referred to, either in printed descriptions of the building or in conversation, surprise is usually expressed that a building should be so called which is so entirely devoid of the characteristic features of the architecture of Egypt; and various wild suggestions are made to account for the name, which affords no difficulty whatever to a student who has read his Vitruvius,—evidently few enough at the present day.

Any one who will take the trouble to consult Vitruvius, "*De Architectura*," lib. vi., c. 5, § 31, will find two kinds of hall described, the *Corinthian* and the *Egyptian*. The former is stated to have a single row of columns, supporting an architrave and cornice, with a vaulted roof of elliptical form springing from them. The latter, or Egyptian hall, has a second row of columns, one-fourth part less, placed vertically above the lower row, with a decorated flat ceiling supported on the entablature of the upper order. I have never seen the Assembly Rooms at York, and it is at least thirty years since I looked at the engravings in the "*Vitruvius Britannicus*," so that I cannot say how far the room, in its present condition, corresponds to Vitruvius's description; but my impression is that, as there depicted, it possessed the double tier of columns which is the chief characteristic of an Egyptian hall. Your "Old Correspondent" will doubtless be able to tell us whether the design is still unaltered, or whether, like the Egyptian Hall at the Mansion House, it has lost its upper story, and with it all right to the designation it still bears. As everybody knows, the Mansion

House room corresponds exactly to the Corinthian Hall as described by Vitruvius, and few are aware that when originally built it was half as high again as it is now, and had a second tier of three-quarter Composite columns, with ohlong windows between, and a flat ceiling. The design, as erected by Dance, may be seen in Campbell's "*Vitruvius Britannicus*," 1767 (I must apologise for my inability to give a more exact reference, writing from old notes), and was evidently drawn in exact accordance with the description given by Vitruvius. I cannot say when this upper story was taken down (it appears in the external view given in Strype's "Stow," 1754), but when I first knew the hall in 1825, the alteration was not very recent. Probably some correspondent connected with the corporation may be able to supply the exact date.

The corresponding upper story which surmounted the Ball-room is fresh in the recollection of many of us. It was demolished somewhere about twenty years ago.

It may not be generally known that the architect of the Mansion House, forgetting the difference between an Italian and an English climate, constructed it originally with an open court in the centre, with colonnades, which had to be traversed by the guests when passing from the long parlour, or dining-room, to the drawing-room. I well remember a lady saying that on one occasion she was powdered with snow in going from one room to the other, on the occasion of a grand civic party.

EDMUND VENABLES.

FIRE-PROOF CONSTRUCTION OF DWELLING-HOUSES.

I was attracted by Mr. George Burchett's title to his letter on the fire-proof construction of dwelling-houses to read it reflectively. There is no doubt about it: fire-proof construction is of the greatest importance, not only for dwelling-houses, but for factories and agricultural buildings; nor would the expense in many cases be so much as the ordinary mode of building, and I think in none so high as Mr. Burchett puts it, 25 per cent.

Why do not the class of architects employed on ordinary dwelling-houses give attention to the subject? I believe they have time enough and to spare. Then something might be done to prevent the terrible accidents, loss of life and property, the agony of public feeling, and the call on the public purse as evinced by the heroic conduct, but sad case, of William Lyons recently.

Even when liberal and enlightened employers are found who would not only listen but discuss the question with the architect, and adopt any plan for the better security of their buildings, does the architect put himself out of the way or give himself any trouble to point out the actual cost and the great advantages of fire-proof construction? I fear very seldom.

I am acquainted with many such cases, but with one especially, where on an estate houses intended to let for 60l. per annum are being erected without the commonest precaution against fire. With the exception of the outside walls, all the interior divisions, both on the ground and chamber floors, are lath-and-plaster partitions, where even chimney-hars are omitted, and the outside arches, apparently of bricks laid as 9-in. headers, are in reality only half-bricks laid in that way which reveals for the box shutters to the hay windows are cut away after the brickwork is carried up and where the door linings have the rebates formed by nailing thin strips of wood to plain casings.

"But whom do I advise the fashion led,
Th' incorigibly wrong, the deaf, the dead."

In building brick arches for floors, lateral thrust should, of course, be avoided as much as possible, and iron ties sparingly used. Mr. Burchett is right in this respect to recommend bricks perforated vertically.

I am persuaded that we owe the existence of many old buildings in the Midland counties to the practice of forming the floors with gypsum (sulphate of lime), which is a native mineral and easily procured. Reeds instead of laths were used; and the plaster, as it is called, was thoroughly incorporated with them, and so as to be beaten and cover both sides; the upper side was smoothed and trowelled to a polished and smooth surface, almost indestructible. I was born in a large old house erected in 1692, where all the

floors were formed in this way; though, for warmth and modern notions of comfort, some of the floors had been covered with floor-boards. The polish and smoothness of the old plaster-floors remain perfect after a lapse of 176 years; not a crack or flaw is to be seen.

The material used for the Dennett arch is, I believe, gypsum; and spaces of 12 ft. in width may be covered on this plan without any intervening support. The upper surface can be made level and trowelled to a polish, as above described. Such arches are without any lateral thrust, are like a shell, solid and in one piece. When floor-boards are intended to be used, the top surface can be left rough, and the floor-joists are mere fillets, partly inserted and fixed in the fire-proof material. The cost of fire-proof floors on Dennett's plan would be about *4s.* per square.

When large openings have to be covered, rolled wrought-iron girders are available for dividing the space: these cost about *3s. 5s.* per ton, and they may be laid 8 ft. or 9 ft. apart, the intervening spaces being arched with the fire-proof material.

In the re-construction of Kelham Hall, Nottinghamshire, after the fire, floors of this kind were used throughout by Mr. Scott; and I believe he has employed the same material extensively in the new Government offices and other works.

The plan is preferable to hollow brick arches: is light in weight, exerts no lateral pressure on the walls, and is fire-proof. Provision should be made for the floors at the time of building the walls, and salient courses two bricks in thickness should be formed, the lower projecting three and the upper five inches from the inner surface of the walls.

The space in height required for the floor is little, if any, greater than where through joists are used, as in ordinary floors.

With respect to agricultural buildings, I made drawings which, accompanied by a model, were sent to the Dublin Exhibition, for a set of farm buildings for the late Mr. E. W. Wilmot, and carried out similar works for the same gentleman, in which all the roofs were formed of hollow brick arches, up to spans of 30 ft. The arches, when finished, were covered with asphalt to carry off the rain-water. The side-walls of the buildings were only 9-inch work. Efficient ventilation was provided by louvre boarding and frame-work along the centre of the arches, and the lateral thrust on the walls was counteracted by the insertion of three-quarter wrought-iron tie-rods (a chord of the arch, in fact), placed at intervals of 8 ft. or 9 ft., passing through wall plates at the springing, and secured with nuts and screws. The height or versed size adopted for the arches was one-quarter of the span.

This mode of construction was both durable and economical, and the buildings were cooler in summer and warmer in winter than those covered with ordinary slated or tiled roofs.

The importance of cheap and improved fire-proof construction for buildings of all kinds must be my apology for troubling you with this letter.

JOHN BLENKAIN.

THE DUTIES OF THE BURGH ENGINEER OF EDINBURGH.

SOME weeks ago a correspondent, writing from Edinburgh in the name of certain sufferers from the storms, asked us for some information respecting the duties of the burgh engineer. We are now able to refer him to an opportune publication of Messrs. Blackwood, which consists in fact, of a classification, or rather codification, of the relative clauses of the numerous Acts of Parliament under which the Edinburgh police is administered.*

From this he may learn all that he desires. He will find that it is not only the engineer's duties to see to the repairs of chimney-stalks, chimney-cans, &c., but that he has also most ample powers, as procurator fiscal, in the police court, to prosecute all offenders against the provisions of the several local Acts. This does not coincide with the statement of those duties which our correspondent pointed out in the *Scotsman*; and certainly the official responsi-

bility in the matter should not be allowed to rest on that unsatisfactory footing.

In connexion with this subject we may print the following letter of the Dean of Guild, with regard to the obstruction of masons' sheds on the public streets, regarding which many complaints are constantly made:—

"As Dean of Guild for the time being, I am often applied to about street nuisances, but especially on the vexed subject of masons' sheds. If the gentlemen who so favour me with their correspondence would only attach their names to their complaints, I would satisfy them without the least delay whether they remedy them for or against me within my limited powers or not. When I have nothing more specific than initials to deal with, I cannot answer; and therefore the writers remain for days, or even weeks, under the erroneous impression that I am guilty of a dereliction of public duty.

Masons' sheds are erected on the public streets by warrant and authority of the Paving Board, under their Order as obtained, sanguine hopes were cherished that the 81st section of that Act would put a spoke in the wheel of the Paving Board, and take the mason-shed question to a great extent out of their hands; but it was soon found that the powers and privileges of the Paving Board in regard to street nuisances was reserved to them in full force and effect by section 45 of the Provisional Act. Such being the present state of the law, neither the Town Council nor the Dean of Guild Court can do anything to mitigate the evils occasioned by these masons' sheds. Unless some joint measure can be devised between the Paving Board and the Town Council, so as to reduce the nuisance to a minimum of discomfort to the inhabitants, I can see no other way out of our present difficulties. It will never do for the powers that be to attempt an antagoistic policy. That would only add to all the evils frequently complained of; and as for the masons, they have no mercy,—room and time they will take in their own despotic way.

WILLIAM LAW, D. G."

Here, it would appear, are three different local boards concerned about a very simple matter, and between them the public interest is neglected. Indeed, conflicting jurisdiction seems to be the great bane of the Edinburgh local authorities.

THE VENTILATION OF A BALL-ROOM.

In the newly-acquired house of Mr. E. Ward Jackson, at Clifton, he has adopted a plan for ventilation, which, on a late occasion, when a large number of persons were gathered together, was found to be very efficacious in letting out all gas effluvia and vitiated air; in reducing very greatly the heat of the room; and in rendering the air both agreeable from its moderated temperature, and sanitary from its quality. It is a plan so practical that it ought to be made known.

The house was lately in the occupation of Bishop Anderson, and of the Bishop of Gloucester and Bristol, and it may be mentioned by the way, was by them considered as an extremely cold house. This, it may be cursorily said, has been by Mr. Jackson effectually remedied by appliances to the outside and inside of the house, to its windows, doors, and floors, and also, by the introduction into the hall of a large gas-stove, which is said to consume its own products, without the least smell, and to be perfectly innocuous. The heat from this stove is disseminated through the corridors, the rooms, and passages; and, during the very cold easterly gales, with frost and snow, which prevailed in December, the stove was kept slightly burning by night, as well as by day. The sitting-rooms, and all other rooms, preserved their warmth through the night, and were found in the morning exceedingly agreeable. They are all kept throughout at an agreeable temperature, in cold weather, at 56° Fahrenheit, as marked by fourteen thermometers distributed through the house. This temperature may be quickly brought, if desired, to a much higher point. In the bedrooms, where heat is required, it is obtained by a very small gas stove in the room, on the same principle; and each bedroom is provided with a covered opening into the passage, near the ceiling, 10 in. by 5 in., through which any extra heat is carried off. The passages themselves are provided with an air-tight wooden valve to the roof, which can be opened or closed at pleasure by a short wire.

Thus the whole of the house and bedrooms preserve the same even temperature, and in effecting it the consumption of gas is comparatively trifling; the consumption of coals is diminished, and dust is thereby avoided.

But what we chiefly desire to speak of is the ventilation of the drawing-rooms and other sitting-rooms, on the occasion of large numbers of people being assembled. This was effectually proved recently, when Mr. Jackson and his family gave a house-warming, and received about 130 persons.

The plan adopted for thoroughly ventilating these rooms, without any perceptible draught, seems

to have been based upon the fact, that while heated air always ascends, cold air descends, each offering to the other, at all times, a considerable resisting power, and may be very easily carried out, without much expense. The two drawing-rooms are each 26 ft. long, 16 ft. wide, and 15 ft. high; the dining-room is 29 ft. long, 18 ft. wide, and 15 ft. high. In the drawing-rooms were burning eighteen full gas-lights, and in the dining-room nine.

The plan adopted appears to have been as follows: the centre-piece in the ceiling of each of the drawing and dining rooms was broken through or removed sufficiently to receive a tube of zinc 14 in. long by 10 in. wide (the breadth of the joist), which was inserted at the opening. The two tubes of the drawing-room were then carried between the joists of the room above, to the adjoining wall, where they were united, and were run up along and by the side of the wall to the other room above it, till it reached the roof; not, however, through the roof, since a slate or tile roof above it generally contains sufficient apertures through which the heated air can pass. The same also with the dining-room. The zinc tubes in the bedrooms above being afterwards covered with the same room-paper presented no unsightly appearance.

Over the lower part of the tubes in the drawing-room ceiling was placed a *popier-mâché* covering, easily obtainable, five inches from the ceiling, to conceal the opening. In this manner a direct open communication is made from the drawing-room and dining-room through the side tubes to the roof.

To prevent the rush of a down blast of cold air from the roof through the tubes to the rooms below, three points must be attended to. First, a jet of gas, with a small glass door four inches square, must be placed in each bedroom, inside the tube, half an hour before the party assemble, so as to warm the tube and produce an upward current.

Secondly, a wooden valve must be formed upon the very top of the large zinc tube under the roof, worked by a wire in the room below it, to be opened and closed, or partially closed, at pleasure. And thirdly, the drawing-room door must be always open (or there must be some other means of admitting air) to allow of the admission of the ordinary atmosphere of the hall into the rooms, and to set the hot air in motion upwards.

A certain proof, beyond the experience of all, as to the agreeable temperature and the sanitary condition of the air in those rooms, was to be found by opening the small glass door in the tube near the roof; when a rush of gas and other fetid air took place of a strongly disagreeable kind.

The plan here described has completely answered the purpose. Several medical men were present, and bore full testimony to it. Something like this has been tried by many before, but seldom, perhaps, so efficiently; a very ample tube being adopted, and carried direct to the roof; remembering that hot air is a body of great dimension, and cannot be compressed within a small compass.

Where a similar arrangement has failed to produce satisfactory effects, it would probably be found that the tubes used were too small. In a new house, of course, the shaft could be formed without even the slight disquiet that Mr. Ward Jackson's tube presents in the upper rooms.

BRISTOL.

THE LOGIC OF THE "ARCHITECTURESQUE."

HAVING perused with considerable interest the report of Professor Kerr's lecture on the "Architecturesque," I am desirous of asking a few questions for the further elucidation of his theory.

His general proposition (he must correct me if I misapprehend) appears to be contained in the following extract. The italics are mine:—

"If this be so, let me next try to define what I call the architecturesque. It is an essence of form and disposition, which (speaking vaguely at first) may be said to make architecture what it is. . . . Architecture is the fine art of the beautiful in building; and as all architecture must therefore be based upon building, I think it plainly follows that there is something which is to be superadded to building, in order to convert building, if the expression be allowable, into architecturesque. This element it is that I am endeavouring to suggest to your minds." . . .

* Provisions of the several local Acts regulating the Police of the City of Edinburgh, classified and arranged, with comparative Table, Arrangement of Sections, explanatory Notes, and Index. By James D. Warwick, S.R.C., Town Clerk. Edinburgh, 8vo. pp. 211, William Blackwood & Sons, 1868.

Thus the "architecturesque" is the essence of architecture; and it follows naturally as the Professor explains further on, that painting and sculpture, to accord with architecture, must receive "architecturesque" treatment.

So far the theory is clear, but when I read further on, "all this brings me to the great fact, that Medieval architecture is all picturesque," I naturally become confused. Nor are my difficulties lessened when again he states, "I have been for years persisting in this proposition, that all Classic architecture forms one School of Art, and all Medieval architecture another School of Art,—the latter picturesque, and the former something not picturesque. I have called it Classical for want of a better term. But if I am now right, I should call it Architecture." If the essence of architecture is the "Architecturesque," in opposition to the Picturesque, and Gothic architecture is all picturesque, it follows that Gothic architecture, which does not contain the essence, is not architectural at all. If not, what is it? I have carefully gone over all Professor Korr's reasoning, and find it impossible to get out of this dilemma. It appears to me that he himself is rather confused on the subject. He feels something in architecture he cannot quite explain, at least he does not; something that differs from the picturesque, and of which the Parthenon is the present embodiment; but either he covers too much ground with his major proposition, or the minor one relating to Medieval architecture is too narrow.

Thinking it is better for those who propound theories to support and explain them, I refrain from offering any suggestion for making the "Architecturesque" hypothesis "bold water."

T. M. R.

"THE MAGNET AS A STOVE."

AN instance of the correlation of the physical forces, as existing between magnetism and heat,—more striking, perhaps, than the one you quote under the above heading in the *Builder* of February 29,—is to be found in Professor Tyndall's work, "Heat, a Mode of Motion." The experimenter I refer to also disposes of the doubt expressed at the end of the paragraph in your journal, as to whether heat would not be "generated in such a case, whether the apparatus had magnetic power or not."

The experiment may interest some of your readers, and, briefly described, is as follows:—A small copper cup is filled with an alloy, fusible at a low temperature, and is so arranged that it can be made to rotate with considerable rapidity between the poles of a powerful electro-magnet, without, however, touching either of them. As long as the magnet is not connected with the battery, and is in fact not a magnet, the heat developed by the rapid rotation of the cup is quite insufficient to melt the alloy; but, if the connexion with the battery be completed, whilst the cup is in rotation, the alloy soon melts and drops out of the cup.

Another experiment, equally remarkable, is decided in the same work.

A silver medal is suspended in a vertical position by means of a thread, between the poles of the electro-magnet. It is not, of course, attracted by either pole of the magnet, even when the latter is in connexion with the battery. If, the circuit being broken, the medal be caused to spin by twisting the thread, nothing more than the ordinary resistance of the air will be felt; but, when the current is passing, much more resistance will be experienced, as if,—to use Professor Tyndall's own metaphor,—the medal were rotating in some viscous fluid.

H. H. G.

A NUT FOR THE PROFESSION TO CRACK.

THE following extract from a letter addressed to myself by a client of mine, with my reply, may be found worth some consideration:—

"This county is building a lunatic asylum for 30,000. They had a limited competition among three or two local architects and one engineer from London. When I ask the committee, one by one, 'Why not have a local architect?' all give the same answer, 'Oh, those fellows run us into such expenses.' Is there not something amiss in the profession, as well as in the justices, for such notions to be so common?"

This is part of my reply:—
"I am sorry to hear the result of the lunatic asylum competition in your county. I myself some years ago sacrificed to the same notion

in another locality; for, although all the magistrates acknowledged that the plans submitted by myself and my late partner in a similar limited competition for X Asylum were by far the best, and though they were exceedingly plain and simple, they chose a most indifferent work by another competitor upon the ground of his not being a professional architect.

The cause, I fear, lies deep in the English mind, in the utter severance of art from the affairs of practical life. So complete is this, that men think that, because architecture has something to do with art, and its professors are to be avoided whenever it is possible to do without them, especially with buildings of this class; as if planning and scheming to supply the requirements in the best and cheapest manner were not the principal parts of the business of an architect, and as if this could be done better by a non-professional or what they are pleased to term a practical man. * * * * *

Certain it is that an architect who knows his business can save far more than he could spend, nor would he be allowed to spend, in art; and the architect that engineers can build cheaper than architects, is amusing.

Still, it is not to be denied that there may be faults on both sides; but then, while the public run after quacks and avoid architects, they saddle the profession afterwards with the blame due to the incompetence of the very men they themselves have helped to boist into it." J. P. S.

NORWAY STOVE.

Sir,—I shall feel obliged if any of your readers will inform me how to construct the self-cooking stove used by the peasantry of Sweden and Norway, and lately exhibited at the Paris Exhibition, by which a working man may cook a dinner and keep it hot all day. W. S.

LOW ESTIMATES AND HOW CARRIED OUT.

Sir,—Many of your readers, I doubt not, feel somewhat surprised at the great discrepancy in tenders for works which appear weekly in your journal, and any information which would tend to explain or throw some light upon the way in which they are carried out, and would, I feel assured, be acceptable. Some months since I, amongst others, tendered for the erection of a fire brigade station at St. John's Wood, for the Metropolitan Board of Works, the highest estimate being 2,400l., and the lowest a trifle under 1,600l.; the latter was accepted. I paid 10s. for plans and specifications, and went through them most carefully, and priced it out to do (as the specification certainly implied) a first-rate job. After providing that the ground should be excavated to a sufficient depth to insure should be composed of brick-bats in the proportion of one of the former to six of the latter, to be thrown in white-hot, and my business taking me past it very frequently, I was rather curious to see how these instructions would be complied with, when I confess not very greatly to my surprise) instead of clean-washed Thames ballast being used, a little dirty pit ballast with a great deal of unscreened burnt clay (or ballast if you will) was being carried up on this substitute for good concrete. Why, estate detected some speculating builders doing the same thing, when he ordered and insisted that it be taken out, and proper ballast substituted; and yet, in a public building, one that the whole of the metropolitan public have to pay for, it is allowed to remain. I would, in conclusion, ask what inducement can there be for respectable builders to enter into competition jobs with so little chance of success against the "cheap Jacks" of the present day? FAIRPLAY.

BUILDERS' CHARGES FOR TENDERS.

A CASE of considerable interest was tried in the County Court of Gloucester last week—Jones & Sons versus Rees. The plaintiffs are a firm of builders at Gloucester in a large way of business. The defendant is a leading promoter of a Welsh undertaking for the erection of English Congregational churches in South Wales. In June, 1866, a committee, of which Rees was chief acting member, having appointed Mr. Paull, of Manchester, to be architect for the new church to be erected at Swansea, directed him to obtain tenders in limited competition from the firms, including the plaintiffs. Quantities were supplied or either tender not being accepted. The tender of plaintiffs was the lowest, but being somewhat in excess of the architect's estimate he was authorised to communicate firm consequently with a view to reducing the work. One of the were arranged and fully reported upon by the architect to the committee, who, after some delay, wished to enter into a contract with the plaintiffs for the erection of the building. The amount of this having been settled upon and agreed to by plaintiffs, the committee found they had been too sanguine as to obtaining funds, and they desired superintendence of a clerk of works approved by the architect. Plaintiffs demurred to such a course, but on the desire the architect, consented to withhold claim for compensation, and accept a fair amount for their time and expenses in their journey to Manchester. The founda-

tions of the church having been completed up to the ground line, the works were suspended till the spring of last year, when the committee found themselves able to enter into a contract for the superstructure. The architect was then commissioned to re-open negotiations with the plaintiffs, and ascertain if they would take the work at the rates upon which their original tender was based.

They consented to do so with a few modifications which the architect arranged, and terms of contract were prepared. Plaintiffs were called upon to provide responsible sureties, which they did, and an appointment was made with the architect to meet and settle all details for a contract. This appointment was set aside by a telegram from the committee, followed by a letter, stating that "for many reasons" they had decided not to enter into a contract with plaintiffs, and directing the architect to arrange for the work to be carried out by Messrs. Thomas & Co., of Swansea, whose original tender was next in amount above that of the plaintiffs. Whereupon plaintiffs sent in a claim of 33l. 14s. 9d., consisting of the following items:—8s. per cent. on the amount of original tender, 14l. 4s. 9d.; expenses to Swansea in 1867, for further local information, journey to Swansea in 1867, for further local information, 10l. 10s.; journey to Manchester, 10l. 10s.; second tender, 5l. 5s.; journey to Swansea in 1867, for further local information, 10l. 10s.; and for the action of plaintiffs, Mr. Paull gave evidence as to the above, and Mr. Neville, of Aberystwyth, and Mr. Jacques and Mr. James, of Gloucester, gave evidence as to fairness of plaintiffs' charges and demands, under similar circumstances, had been paid to builders for estimates. On behalf of defendant, Mr. Watkins and Mr. Rees, of Swansea, two well-known competitors of plaintiffs in the limited competition, were called to prove that under no circumstances were builders' tenders ever paid; Mr. Watkins admitted he should consider he had a claim for compensation in competition with the plaintiffs, but used, in one or two instances, in his own experience, if he had known he could recover.

Defendant admitted the item of 10l. 10s. in plaintiffs' bill, and plaintiffs withdrew the last item of 5l. 5s. The judge decided for the plaintiffs in the other three items, with costs.

NEW RACE-COURSE FOR MANCHESTER

THE following are lists of the tenders delivered for the grand stand, second-class stands, stabling for eighty horses, fencing, approaches, &c., for the Manchester Race-course Company (Limited). Messrs. Thomas Bird & Son are the architects. Quantities were supplied:—

Grand Stand.

Cochrane, Parker, & Co.	46,967 0 0
Terras	6,828 0 0
Greenup & Co.	6,300 0 0
Thompson	6,234 0 0
Yell & Son	5,915 0 0
Warburton, Brothers	5,850 0 0
Johnson (accepted)	6,189 0 0

Second-class Stands.

Cochrane, Parker, & Co.	6,073 0 0
Terras	4,856 0 0
Thompson	3,780 0 0
Greenup & Co.	3,700 0 0
Nevil & Sons	3,594 0 0
Yell & Son, Brothers	3,321 0 0
Johnson (accepted)	3,653 0 0

Stabling, Fencing, &c.

Cochrane, Parker, & Co.	5,150 0 0
Terras	5,084 0 0
Warburton, Brothers	5,020 0 0
Thompson	5,000 0 0
Greenup & Co.	4,960 0 0
Johnson (accepted)	4,930 0 0

THE EMBANKMENT WORKS.

MR. BAZALGETTE, the chief engineer, presented a report as to the progress of the Embankment works at a recent meeting of the Metropolitan Board of Works. We give some extracts from it:—

North Side of the Thames.—Thames Embankment between Westminster and Waterloo Bridges.—The whole of the dams have been completed and removed. The Westminster steamboat pier and 670 ft. of the adjoining river-wall are complete, and a further length of 50 ft. of the latter is constructed to a height of 33 ft. above the Trinity high-water mark; 100 ft. of the York-gate substructure, and 380 ft. of the wall adjoining, are also constructed to that height, and a further length of 393 ft. of the latter is complete. The Charing cross steamboat pier has been brought to levels varying from 5 ft. 4 in. to below 3 ft. above Trinity high-water mark, and of the adjoining wall 220 ft. are constructed to 3 ft. above high-water mark, and a further length of 193 ft. is complete. The Adelphi landing-stairs are constructed to a height of 34 ft. above Trinity datum: 50 ft. of the outer capping are fixed, a length of 154 ft. of the river-wall adjoining is constructed to heights varying from 5 ft. to 5 1/2 ft. above datum, and a further length of 244 ft. of the wall is complete. In the Waterloo steamboat pier the works have been carried up to levels varying from 1 ft. below to 3 1/2 ft. above Trinity high-water mark, and the junction with the No. 2 contract has been made. Filling in earth, &c., behind the embankment walls, and in the works generally, has been carried on for the purpose of the Waterloo and Whitehall Railway the lower portion of the Victoria Road, and Regent-street sewers from Scotland-yard to the Thames have been diverted, and a part of the railway tube has also been formed. The approximate cost of the whole of the works, including 18,000l. for the materials of the ground, is 443,000l., of which the sum of 5,000l. represents the past month's progress.

Contract No. 2, between Waterloo Bridge and Temple Gardens.—The works on this contract, to the extent of 2,000 ft. of the river wall, sewer, and subways contained in this contract, is now complete, and the only works remaining to be executed to finish the contract are the laying of about 1,900 ft. super.

of York landings, and the levelling of the surface of the intended roadway. The approximate value of the whole of the works completed is £20,000, of which the sum of £6,000 is due to the past month's progress.

Admiralty Pumping Station.—The buildings and works of this station are actively progressing. The iron work is fixed in its place for a height of 12 ft. The two chimney shafts are, with the exception of the lighting conductors in connection therewith, complete in every respect. The superintendent's house and the workmen's cottages are all roofed in and slated. The reservoirs for the water supply are near completion; and the tunnel under the northern outfall, for the passage of the water thenceforth to the boilers, is steadily proceeding. The approximate value of the whole of the completed works is 171,700*l.*, of which the sum of 3,950*l.* is due to the progress made in the past month.

South Side of the River; Thames Embankment.—Of the 2,370 ft. of dam and staging that had been constructed between Westminster and Lambeth Bridges, a length of 1,100 ft. has been removed, and about 750 ft. of the single pile dam and staging have been constructed above the latter bridge. Within the completed dams a length of about 2,800 ft. of the river wall has been brought to heights varying from 7 1/2 ft. above to 17 1/2 ft. below Trinity high-water mark. The approximate value of the whole of the completed works, including 20,500*l.* for materials upon the ground, is 156,000*l.*, of which the sum of 3,000*l.* is due to the progress made therewith in the past month.

THE DRAINAGE OF GIBRALTAR.

The new system of drainage works to be carried out by the Sanitary Commissioners of Gibraltar was inaugurated by a public ceremonial on the 20th February; the first stone of the new works having been then laid by Lady Airey, the wife of Sir Richard Airey, the Governor and Commander-in-Chief of the City and Fortress. The cost of the new system is estimated at 35,000*l.* The old town drainage, it is said, was spelt to improve the defences, the breakwater having led to a great nuisance in connexion with the old drainage. The new system, however, has not been gone into by the Government, nor is it to be entirely at Government cost, the inhabitants having been rated to the extent of 25,000*l.*; but the Imperial Government aid by a subvention.

The *Gibraltar Chronicle*, in reporting the ceremonial, says:—

"There is one statement made in the address of the Sanitary Commissioners to Lady Airey, and referred to in her ladyship's reply, which we would gladly see the subject of further investigation. It is said that the annual death-rate amongst the resident population in Gibraltar is 32 in the 1,000. This, compared with the mortality in England, is certainly a high rate, being equal to that of Liverpool, the worst town, as regards sanitary conditions, of any in England. At the same time, those who have lived many years on the Rock do not share the opinion that the place is unhealthy, nor have we heard that typhus fever or the other forms of illness springing from bad drainage and want of ventilation, are common in Gibraltar.

Doubtless, as in other towns, there is in the poorer quarters overcrowding, inevitable amongst those who have very large families and very small means. It seems, too, that Gibraltar is very deficient in properly constructed dwellings for the poor. In coming to a conclusion as to the healthiness or unhealthiness of the town, the rate of mortality should, we think, be compared rather with the towns of Southern Europe than of England."

The drainage and water-supply works were designed by Mr. Edward Roberts, assistant surveyor of the War Department, under the direction of Major-general Edward Frome, Commanding Royal Engineer. The contractors for their execution are Messrs. A. Kyan & Co., of London.

COURT OF COMMON COUNCIL: BLACK-FRIARS BRIDGE, HOLBORN VIADUCT, SMITHFIELD MARKET, &c.

At a recent Court of Common Council a report was brought up from Mr. Gabbit, the engineer of the new bridge in course of erection at Blackfriars, detailing the progress of the works during the last two months. The works were going on satisfactorily, but the matters relating to the diversion of the Fleet sewer, the connexion with the Thames embankment, and the railway, are in the same state as last year. No coins were found in the old bridge foundations. The new bridge, it is expected, will be opened by the beginning of next year. A report was brought up from Mr. Haywood on the works of the Holborn valley. So far as the carriage thoroughfare is concerned, it is believed that portion of the work will be completed by the end of this year or the beginning of next. The western approach to the viaduct is nearly completed.

A report was brought up from Mr. Horace Jones, the City architect, giving a detailed account of the state of the work at the new market in Smithfield. It appeared that 220 men were at present employed upon the works, and the erection of the different portions of the

market was proceeding rapidly. The market would be ready for business to be commenced in it before next Christmas. The following resolution as to markets was agreed to:—

"That to meet the urgent wants of the increasing population, it is expedient that the whole question of market accommodation be at once entered into, more particularly as to vegetable markets, seeing that Covent-garden, the Borough, and Spitalfields are almost inadequate to meet the demands now made upon them, and that it be referred to the Markets Committee to inquire into and report whether additional accommodation is not needed, and whether daily vegetable, meat, and fish markets should not be established for the benefit of the public."

The fish market, it is believed, will ere long be removed from Billingsgate to Smithfield. The Markets Committee have under consideration the question of the enlargement of Farringdon market and the removal of the fish-market.

NOTES IN HOUSE OF COMMONS.

The New Works at Burlington House.—Mr. Layard asked the First Commissioner of Works whether the works to be undertaken on the Piccadilly side of the Burlington House site had been stopped on account of an alleged interference with the rights, or, rather, he should say "lights" of the Albany; and whether, if this were the case, the Royal Academy would be able to complete the building which they have commenced, so as to hold their annual exhibition in it next year.—In reply, Lord J. Manners said that the works had not commenced in consequence of unforeseen difficulties. These difficulties, however, were on the point of being removed.

The Irish Academy.—Mr. Gregory asked the Chief Secretary for Ireland if his attention had been called to the recent operations of the Irish Board of Works at the Royal Irish Academy, and if it were true that the new heating apparatus put into the Academy by the same Board of Works was so dangerous and defective that the two insurance offices in which the structure was previously insured had refused to continue the insurance as before.—The Earl of Mayo said, in reply, that the Irish Government was not responsible for the Irish Board of Works, which was directly under the control of the Treasury. The heating apparatus at the Academy was not new, but it had recently been altered, and the insurance companies objected to the mode of water supply. He believed that the attention of the Chancellor of the Exchequer had been called to the proceedings of the Irish Board of Works generally, and that a careful inquiry would be made.

AMUSEMENTS.

Haymarket Theatre.—The new version of M. Octave Feuillet's "Roman d'un Jeune Homme Pauvre," which has been produced under the supervision of Dr. Westland Marston, and is entitled "A Hero of Romance," is a very interesting play, pointedly written, well put upon the stage, and capably acted. Mr. Sothorn as the Hero, Mr. Buckstone as an old army doctor, Mr. Compton as a dandy man of the world, and Miss Robertson, bear the burden of the piece with ease and finish; and Miss Ione Burke, Mrs. E. Fitzwilliam, and others, materially contribute to the success of the *ensemble*. The former lady, Miss Burke, has a part which, by a little more study and effort, might be rendered even more prominent than it is. We must give Mr. John O'Connor great praise for the scenery. The scene of the second tableau,—the Park of the Château Dumont (Brittany), with the terrace-walls, and the chateau in the distance; and that of the third,—Ruins of the Tower of Elfen,—are very clever and effective; and the last scene, a *salon*, is furnished with elegance. The piece is a complete success.

Mr. Henry Leslie's Concerts.—The concert on the 12th consisted of songs and glees, set forth by a large number of operants, including Madame Sainton-Dolby, Madame Rudersdorf, Mr. Cummings, and others equally well known. It was a popular evening, and very successful. On the 19th the concert was orchestral and choral, Mendelssohn being in the ascendant.

The Polytechnic.—The attention given by the audience, night after night, to Professor Pepper's excellent lecture on Astronomy, illustrated by spectral analysis, speaks well, both for the ability of the lecturer in rendering even abstruse subjects clear and interesting, and for the advanced intelligence of Polytechnic visitors.

THE RATE-PAYING CLAUSE OF THE REFORM ACT AND THE POOREE CLASSES.

GREAT ignorance of the means and habits of the poorer class of tenant householders is manifested in the clause relative to compound householders; otherwise, if not ignorance, there has been reckless indifference, and hundreds of thousands have been wilfully and unjustly punished, as it were, because some scores of thousands of the working classes have received a voice in the legislature of the country. No less than 6,000 poor creatures, women no less than men, who can hardly hold body and soul together, in themselves and their children, or a roof above their heads, by sharing it with a crowd of others, were summoned in one day for poor-rates in Hackney parish alone, and by the same rule the poor in every parish in the metropolis must suffer; and not in the metropolis alone, but throughout the whole country. Thus in Salford, a sort of Southwark to Manchester, no fewer than 3,500 summonses for poor-rates were in one week issued, and it is stated that for some time to come the parish overseers will require to have at least 800 issued every week, even after exhausting all possible means for arranging for the payment of the rates by instalments, so low, in many cases, as 6d. a week. It is a fine opportunity for law pickings, and also for the landlords of the poor people who, after paying their rates through these landlords in the form of rent, are now called upon to pay over again to the parish; and, in multitudes of cases, no doubt, for others who had formerly tenanted the houses they now occupy. Such wholesale iniquity and want of consideration for or knowledge of the poor have been the cause of revolutions and of awful bloodshed ere now; and the Government and the Legislature may depend on it that the feeling they are exciting amongst the people is a dangerous one, as the writer of this has himself some cause to know.

DISSENTING CHURCH-BUILDING NEWS.

Bradford.—The chief stone of the new Unitarian Chapel, in Chapel-lane, has been laid on the site of the fabric recently removed. The style of the architecture is Gothic, the accommodation for 500 persons, and the estimated cost, 5,000*l.* Messrs. Andrews, Son, & Pepper are the architects.

Walker (Newcastle-on-Tyne).—The chief stone of a building, intended to be used as a Primitive Methodist Chapel and school, has been laid in close proximity to Walker Colliery. The new edifice is to be erected from a plan by Mr. James Robinson, of Gateshead, on ground leased for seventy-five years from the corporation of Newcastle, and is intended to have a classic front with a Grecian pediment. The chapel, with the addition of a rising gallery, will be sufficient to accommodate 300 persons, while the school, under the same roof, is adapted for 150. The whole of the work is contracted for by Mr. Thos. Smith, of Walker, and will be completed for somewhere about 700*l.*

OPENING OF THE MILLWALL DOCKS, ISLE OF DOGS.

THESE new docks have been formally opened for business by the Millwall Docks Company. A large area of marshy ground has been converted to useful purpose by the formation of these docks. The extent of land purchased in the first instance by the Millwall Company was some 204 acres, of which they proposed to appropriate 52 acres to dock accommodation, and 152 acres to wharfs and warehouse accommodation. At present, however, there are only about 33 acres of water. The lock is said to be the largest in London, being 450 ft. long and 80 ft. wide. Its depth of water is 28 ft. in the centre. The sides of the lock vary in section at different points. They are faced with Staffordshire blue bricks to 24 ft. below the top, and have stone copings 1 ft. 6 in. deep, formed of blocks not less than 4 ft. long, well united by stone joggles. For a depth of 6 ft. below the top of the coping the brickwork is 3 ft. thick; then its thickness is increased to 3 ft. 4 in. for a depth of 10 ft.; and then for a further depth of 10 ft. the thickness is made 3 ft. 9 in. Below this the brickwork is thickened to 13 ft., a culvert being

formed in it. The upper part of the wall is backed with concrete, courses of brickwork running back into this concrete to bind the whole together. The lock-gates, which are each 43 ft. wide by 31 ft. high, are box-gates; but the river side of each gate is perforated, so that the water flows freely in or out of the box. The other side of the gate next the dock is, of course, made water-tight. The wet-dock is an extensive basin, which has been constructed in the most modern fashion. The depth of water is 28 ft. on the sill, which will enable vessels of very large tonnage to enter and discharge their cargoes. Around, on the wharfs, there are nine warehouses, and cranes have been erected capable of lifting from 35 cwt. to 15 tons, worked by hydraulic power. Sheer-legs, worked by steam, and of a capacity of 80 tons, are being erected for masting and dismanting, and the shipment and discharge of machinery and other heavy goods. Inside the wet-dock is a dry-dock 413 ft. long, 65 ft. wide at the entrance, and 80 ft. wide in the centre, having a depth of 25 ft. of water on the sill at Trinity high water. Engines and hydraulic machinery have been erected all round the docks, and will be employed in opening the lock-gates, sluices, road-bridges, and cranes. The water by which the vast hydraulic machinery will be worked will be supplied at a pressure of 700 lb. per square inch, by a pair of horizontal engines placed in a suitable building near the graving-dock. The Customs offices, contracted for by Messrs. Mills & Son, are completed. The engines and machinery have been supplied by Messrs. Armstrong & Co.; and the contractors for the whole have been Messrs. Kelk & Aird; the joint engineers being Messrs. Fowler & Wilson.

TRADES UNION FUNDS NOT BEYOND PROTECTION OF THE LAW.

At the Manchester Assizes, Mr. Justice Lush has delivered a decision of the greatest importance to trade societies. A man named Dodd, the treasurer of the Manchester Operative House Painters' Association, was charged with having embezzled about 800l.; nearly the whole of the available funds of the society. The defence set up was, that the association was an illegal one, and that the charge of embezzlement could not therefore be sustained. Mr. Justice Lush decided against this impudent plea; and, in sentencing the prisoner to five years' penal servitude, said that no greater mischief could be caused than by the notion getting abroad that, because a society was a trades' union, it could therefore be plundered with impunity. "Although it had been held that trade societies were not within the protection of the Friendly Societies Act, and, therefore, could not avail themselves of the special remedies given by that Act, they were in no sense illegal societies, and their property, as well as their persons, were as much protected as the property and the persons of any other society."

CHURCH-BUILDING NEWS.

Wentworth.—The rebuilding of the tower, nave, and porch of the church here is now advancing to completion. A considerable amount of work was found desirable to be carried out, more than was originally intended. All the windows had to be replaced by new stone windows. The late Dean Pascock commenced the restoration of the chancel, and such parts left undone are now also being restored; an east window has been fixed, the gift of a gentleman, a friend of the rector. The whole of the works throughout are being carried out by Messrs. Freeman, of Ely.

Carlisle.—At a recent meeting of the St. Mary's New Church Building Committee, the plans of Mr. Christian, the architect, were received, and, with only a trifling alteration, adopted. The style is Decorated, though early. The area of the church will be spacious; and a lofty aisle with seven lights forms the east end. The clearstory is lofty, and calculated to throw light well into the side-aisles. The principal entrance is by a porch on the north side, facing Castle-street, while a western door admits from the abbey. It is intended to throw open the whole of the space around the church into the abbey grounds. The general effect of the different religious buildings, mutually supporting each other, will, in the opinion of the architect, be very good.

York.—The Church of St. Mary, Castlegate, has for some years past been in a dilapidated condition, both externally and internally. Its dampness, also, is a considerable drawback to comfort, as are the large box pews, which will only accommodate 260 persons, instead of upwards of 400, as now seating would. The edifice internally will have to undergo a thorough renovation, the outer walls will have to be partially rebuilt, and the top of the spire, which has rather given way, will have to undergo reparation. The expenditure which will be created by all these necessary works, it is thought, will amount to at least 2,000l. A meeting of the parishioners has been held in the church to take into consideration the propriety of restoring it. At his own cost, the dean had instructed Mr. Butterfield, of London, to examine the church and prepare plans for its restoration. That had been done, and the plans were before the meeting. The parishioners gave their consent to the proposed restoration, on the understanding that there would be no call upon the rates.

Puddletinton (Dorset).—The church of this parish has been restored, at an estimated cost of 1,050l., from designs by Mr. Ewan Christian, of London, architect. The whole of the works were carried out by Mr. G. I. G. Gregory, of Dorchester, builder.

Kettering.—Warkton Church, which has recently undergone a restoration, has been reopened for Divine service. A new chancel arch has been inserted; the western gallery has been entirely removed, together with all the fittings in the nave, and oak benches have been substituted. The work has been executed under the direction of Mr. Stephen Brown, of Kettering, builder, from the designs of Mr. Slater, architect.

St. Pancras, London.—Mr. George Moore, of the firm of Copstock, Moore, & Co., of Chesham, has undertaken to build, at his own cost, a church, parsonage, and schools for a destitute district in the parish of St. Pancras. A site has been obtained near Clarendon-square, Somers-town, and it is expected that the cost will reach at least 12,000l.

St. Austell.—At a public meeting it has been resolved that the restoration and re-seating of the parish church be forthwith proceeded with, in accordance with plans and specifications which had been prepared by Mr. H. M. St. Aubyn, architect, and approved of at previous meetings of the Diocesan Society. It has further been resolved that the necessary funds be raised by subscription and other means. About 2,000l. will be needed to carry out what is contemplated, of which 1,000l. have already been subscribed.

Bathaston.—The parish church of Bathaston has been opened after restoration. A new aisle has been built, the south gallery over the west of the nave has been removed, the tower arch has been thrown open, the church has been re-seated throughout with open benches, and it will be warmed by an apparatus by Mr. Skinner, of Bristol. Gas has been introduced, the standards being supplied by Mr. Singer, of Frome. Mr. F. Freedy, of London, was the architect, and the contractors were Mr. Newman, of Bathford, and Mr. Silver, of Maidenhead.

Newcastle-upon-Tyne.—The church of St. Stephen's, in Scotswood-road, Newcastle, has been consecrated by the Bishop of Durham. The foundation-stone was laid by Sir William Armstrong towards the end of 1866. The church is in the Early Geometrical style of fourteenth century. The church will accommodate 650 persons; 500 in free sittings. The architect was Mr. R. J. Johnston.

Englefield Green (Windsor).—The dedication of the north transept, which has been added to St. Jude's Church, Englefield-green, has taken place. The transept has been erected in architectural unity with the edifice. It has a lofty open timber roof, and it is constructed of stone and brick, red, black, white, and orange tinted. At the extreme northern end of the transept is a five-light stained window, which formerly occupied a position nearer the nave. In the western wall is a large circular window, filled with trifoliations in stained glass. The cost of the had been promised or paid prior to the dedication, leaving a balance of 205l. required.

Frampton.—A new reredos has lately been placed in Frampton Church. The design comprises three gables, carved in Caen stone, over the altar, the central one being a little the highest, flanked by an ornamental arcade on each side. Under the latter is an inlaid diaper formed of bands of white alabaster, incised with

black lines and green marble eyes, the ground being a brown mottled alabaster. The portion of the reredos over the altar is lined with Maltese alabaster from Gozo, the central panel having a floriated cross, composed principally of a yellow marble, also from Malta, and resembling gold in colour. The shafts and spandrels of the arcade on each side of the altar are composed of marbles of various tints. The greater part of the inlaid marble and alabaster work was selected by Mr. R. B. Sheridan, M.P., of Frampton Court, when on a recent visit to Malta, and was prepared there. Mr. Earp, of London, carved the ornamental Caen stone work, and also the arcade and diaper work underneath it, and fixed the reredos in its position. The design was prepared by Mr. Forry, architect. The reredos is intended as a memorial of a relative of Mr. Sheridan, who has borne the entire expense.

Burn Moor.—The church of St. Barnabas, at Burn Moor, near Fence Houses, has been consecrated by the Bishop of Durham. The foundation-stone of the new church was laid on the 3rd of May, 1867, by the Countess of Durham, the cost of the whole edifice being defrayed by the Earl of Durham. The building is erected at the meeting of four roads from Fence Houses, Sunderland, Chester-le-Street, and Bowes House, and is built in the Early Geometric style, from designs provided by Mr. R. J. Johnson, of the firm of Austin & Johnson, Newcastle. The material used for the walls is variegated bricks, and the same scheme of colours is observed in the roofing.

STAINED GLASS.

York Guildhall.—Another stained-glass window has been added to those already in this Guildhall, representing pictorially the history of the city. The two first, that given by Alderman Meek and that by Mr. Farrer, represent respectively the Roman and Saxon periods, and the present one represents the Plantagenet period, the Norman period, not yet being completed, but in progress. The event commemorated is the confirmation of the great Charter in a Parliament held at York, on January 15th, 1298, in the reign of King Edward I. On the left is John de Hulton, Bishop of Carlisle, who holds in his hands the Charter, and looks to the representative of the king for his public assent to what has been done. Behind the bishop are Humphrey de Bohun, Earl of Hereford, the Constable, and Roger Bigod, Earl of Norfolk, the Marshal of England. In the centre is John de Warenne, Earl of Surrey, guardian of Scotland, and lieutenant in the North, who, in the king's name, ratifies the confirmation of the Charters. To the right are the Earls of Gloucester and Arundel, with Henry de Percy representing the Barons. Behind them stand a serjeant-at-law, and a serjeant-at-arms with his mace. This window, as were several of the others in the Guildhall, was designed by Mr. Jas. E. Doyle, author of the "Chronicles of England," and executed by Mr. Wallis, of Newcastle-upon-Tyne. In placing the new window, it is to be hoped it will not be forgotten to restore to its place in the Guildhall the old window which is described by Drake, the historian and antiquarian of York, and in the "History and Description of the Ancient City of York," by William Hargrove, 1818, p. 434, vol. iii. It was the window over the Crown or Lord Mayor's Court, and exhibits some stained glass representing the royal arms in the centre; and on the two sides of them the figures of Justice and Mercy; and underneath, the arms of the city, the sword and mace, with the date 1682; executed by Edmund Gyles, an artist resident in York.

SCHOOL-BUILDING NEWS.

Prittlewell.—New schools are in course of erection in this rising place. The building is of Kentish rag-stone, with Bath stone dressings, and there is hardly any work of a merely ornamental nature about it. The architect is Mr. Blake, of Westminster, and the contractor, Mr. Carter, of Rochford. The school-room, which will be divided by a moveable partition, separating the boys' department from that of the girls, is about 50 ft. long by 20 ft. wide, and the class-room is about 18 ft. square. The dwelling-house contains living-room, kitchen, and scullery on the ground-floor, with four bed-rooms above. An under-ground tank receives all the rain-water

from the roof, and is of sufficient size to render any failure in its supplies improbable. The total cost of the building is estimated at 1,500l.

Tannorth.—The new Grammar-school building, designed by Messrs. Spragg & Joyce, of Stafford, architects, and now in course of erection, by Mr. C. Clarkson, approaches completion.

Bangor.—The chief stone of a new building for the Bangor National Schools has been laid on one of the most desirable sites in the town for the purpose. The spot in question is a triangular piece of land, sloping to the south on its principal frontage, just above the road leading to the Garth Ferry, and below the road leading to Upper Bangor, running on the east side of the Palace grounds. A spot to place the required buildings being thus provided, instructions were given to Messrs. Kennedy & O'Donoghue, of Bangor and London, architects, to prepare the necessary plans and specification, which, after receiving the approval of the Committee of Council, were submitted for tenders by advertisement. The amounts of the tenders received were as follows:—David Roberts, Aher, 2,988s.; John Roberts, Chester, 2,950l.; John Thomas & Sons, Bangor, 2,863s.; W. T. Rogers, Beaumaris, 2,716l. 9s. 9d.; Hugh Rowlands, Carnarvon, 2,654l.; Joseph Hughes, Llansantffraid, 2,596l.; William Williams, Bangor, 2,579l.; Richard Parry, Menai Bridge, 2,546l. Mr. Richard Parry's being the lowest tender was consequently accepted by the committee, the architects' estimate being 2,500l. The schools will comprise, first, a school-room for 190 boys, 85 ft. 9 in. long by 18 ft. wide, and 16 ft. 6 in. high to the collar beam, with detached class-room 15 ft. by 14 ft., approached by a porch, at the end of which is a lavatory. Second, a school for 190 girls, 64 ft. 9 in. long by 18 ft. wide, and 16 ft. 6 in. to the collar beam, with class-room, porch, and lavatory. Third, a school for 100 infants, 30 ft. long by 20 ft. wide, and 15 ft. 6 in. high to the collar beam, similarly approached, and having the same conveniences as the two school-rooms before described. Fourth, a master's residence, comprising a parlour, kitchen, back kitchen, and three bed-rooms, of the sizes required by Government. There are also playgrounds to each division, a kitchen-yard to the residence, together with a small garden. The front elevation, which faces the city, is a gabled composition, having lancet triplets and other windows, the roof line being broken by smaller gables and dormers over the entrances, windows, &c., and a bell-turret, set off into several stages, forming a central feature. The dressings in front will be of a kind to harmonise with the rubble-work walls, and of brick at the back and less prominent parts. The ventilation is to be on Boyd's principle, and the whole of the desks are to be arranged in groups, divided by curtains. The roofs will be of dressed American timber, lightly stained, the principals being supported on stone corbels.

Books Received.

UNDER the title "Practical Remarks on the Drainage of Land," Mr. W. H. Wheeler, C.E., has issued in a pamphlet form the papers recently published in our pages with his initials. Many may be glad to have them in this more handy shape. — In the sixteenth volume of the "Collectanea Antiqua," Mr. C. Roach Smith has given an interesting and appreciative biographical notice of the late Frederick W. Fairholt, and announces his intention of publishing hereafter in a separate shape Mr. Fairholt's own journal, and completing the biography. — "A Yorkshireman's Trip to Rome in 1866," by W. Smith, jun. (London: Longmans & Co.), is a pleasantly written little record of a pleasant trip, but does not pretend to afford any special information or comment. — "Second-grade Freehand Drawings," designed and adapted by Alfred Copham, of St. John's School, Ladywood, Birmingham (Simpkin & Marshall), comprises fifty graduated outline drawings calculated to exercise the eye and hand. — Mr. Eugene Rimmel has issued, as a pretty little book, "Recollections of the Paris Exhibition of 1867" (Chapman & Hall). It pretends to be nothing more than a surface view; but being illustrated by a number of engravings (principally borrowed from Mr. S. C. Hall's fine catalogue, now in course of publication), it forms an agreeable drawing-room souvenir of a great event.

Miscellaneous.

FREE LIBRARIES IN LEEDS.—A public meeting has been held in the Leeds townhall, the mayor in the chair, to consider the advisability of adopting the Free Libraries Act in the borough. There was a very determined opposition, principally on the grounds that free libraries were not used by working men, but by a superior class; that the rates in Leeds now amounted to 7s. 7d. in the pound; and that the present time, with the distress now existing in the town, was inopportune. When the vote was taken, however, the mayor ruled it was in favour of the adoption of the scheme.

THE REGULATION OF RAILWAYS BILL.—The Bill introduced into the House of Lords by the Duke of Richmond is one essentially for the regulation of the conduct of the affairs of railway companies, and will, if adopted by Parliament, establish a supervision calculated to improve railway interests and to protect the public. Companies will be required to publish before each half-yearly meeting uniform accounts, and to give an estimate of the proposed expenditure out of capital for the ensuing half-year. There is a penalty of 50l. for falsification of accounts, recoverable against the auditor or other signatory of the company. The Board of Trade is to have power to appoint inspectors to examine into the affairs of a company, and the condition of its undertaking. The Government propose measures to secure the safety of the travelling public. On the other hand, companies are to be protected from extortion in compensation for accidents.

THE CONTRACT SYSTEM IN CALCUTTA.—The Governor-General remarks in connexion with the failure of the new Custow-house sheds in Calcutta, that "the experience of the last few years clearly shows that the system of contracts for large works, as in force in Calcutta, has entirely failed, and there has been a large waste of public money." As regards new buildings, the system adopted is scarcely a contract system at all: the work is of course superintended by Government engineers, and the materials are all supplied by Government, and it is only the labour that is let by contract. The consequence is that nearly all these contracts are taken by native mistresses, as Europeans cannot compete with natives for labour only. In spite of extra supervision the work of native contractors, as compared with that of respectable European firms, is dilatory and unsatisfactory in the extreme, as any one acquainted with the history of buildings in Calcutta for the last few years can testify. The writer advises the appointment of a committee to inquire into the working of the contract system in Calcutta.

WORCESTER CATHEDRAL RESTORATION: THE NEW REVEDOS.—The new revedos, which has been given by the Dean, is nearly completed. The principal portion of the work is in the finest alabaster, varied with marbles and granites of the most choice and rare descriptions, and decorated with gold. In the central portion of the revedos, there is first a height of plain highly-polished alabaster, upon which rest moulded plinths and bases of the same material. These are surmounted by columns of Languedoc and verd antique marbles, and of granite, crowned by capitals of carved foliage, forming five niches, the centre and largest of which contains a sculptured figure of our Lord, in alabaster of the purest tint, representing him in the act of giving benediction. The figure stands beneath a canopy of inlaid mosaic marbles, Sienna, grayot, and emperor's red. The canopy is completed by a finial in white alabaster, relieved by blue, red, and green marbles. In the niches which support the central shrine on each side are the figures of the four evangelists, Matthew and Mark on the right hand of our Saviour, and John and Luke upon His left. Over the canopies, or rather between the gables in which they terminate, are the heads of the apostles Peter, Paul, James, and Thomas, and over these again is a tier of angels. The gables are completed by carved finials, and the whole is surmounted by an elaborate cresting, above which is a second tier of angels. In the gables on the left are the heads of Moses and David, and on the right the heads of Samuel and Isaias. The sculpture has been executed from the designs of Mr. Gilbert Scott by Messrs. Farmer & Brindley, of London; and the erection of the revedos has been under the superintendence of Mr. Farrow.

CHARGE FOR TAKING OUT QUANTITIES.—Messrs. André & Hornblower prepared the quantities for the Sefton Park contract, and guaranteed them to the Improvement Committee of the Liverpool town council. Their charge is 1,000l. On a motion in the town council for the adoption of the recommendation of the committee, that the council should pay Messrs. André & Hornblower, an amendment was carried, by 34 to 15, that the recommendation should be postponed till the recommendation [of the committee] to confirm the contract with Mr. Campbell was considered.

MEANS OF TECHNICAL INSTRUCTION.—A correspondent writes to the *Manchester Guardian*:—"The rumor is, I believe, perfectly well founded that a munificent friend to popular improvement has offered to give a sum of 100,000l. to be devoted to the purpose of promoting technical education. For the present the donor refuses to have any announcement made of his name; but he has taken counsel of some of the persons best qualified to advise him as to the most useful mode of allocating his splendid gift among the communities that are, by their numbers and activity, most likely to turn it to good account."

VERIFIED CAOUTCHOUC.—In a recent number of the *Moniteur de la Photographie*, it is stated that M. Marion is putting forth a new invention, destined, perhaps, to be of importance to photographers. The new product appears to occupy a position halfway between glass, which is too fragile, and paper, which is too opaque. Its description seems to correspond with one of the forms of the English invention called parkesine. According to M. Lecan, the so-called verified caoutchouc has the suppleness of paper and the transparency of glass, without its brittleness. The use to which this transparent film of india-rubber is destined is to receive from the glass negative the film of collodion bearing the photographic image. It can then be put away in a portfolio or box, until it is required to print from it as a negative; so that the most valuable subjects can thus be preserved, packed, or travel without the slightest fear of breakage.

COAGULINE.—This is a new transparent cement, it appears, the production of operative chemists in Stockport. Its adhesiveness and tonacity are said to be extraordinary. Glass, leather, wood, stone, ivory, bone, or minerals can be pieced or joined by it; and so tenacious is it that, when thus used, it will resist a strain of 224lb. or more. Heat and cold, fire and water, are successfully resisted by it. In piecing glass or crystal with it, its transparency renders the junction imperceptible, and its adhesiveness, in fact, makes the broken glass or crystal as good as new. Its usefulness has led to the introduction of a leather line for window cords, the splice of the cord being joined by the cement, and thus an endless, smooth, and regular hand is produced. Its uses are described as being innumerable. The producers (and discoverers, we presume) of this new cement are said to be Messrs. Kay, Brothers, of Stockport, operative chemists.

BRITISH ARCHEOLOGICAL ASSOCIATION.—At the meeting of the British Archeological Association on Wednesday evening, the 11th, Mr. T. Wright, V.P., in the chair, a number of forgeries were exhibited by Mr. Cuming, who remarked that two small bronze figures then before the meeting were copies of genuine figures in the possession of two gentlemen present. It was interesting to notice that the fabricators of copies of Indian hills had stolen them in the Roman fashion; and there was a small copy of a Greek bronze vessel, with three feet, such as the Greeks had never put under them. Mr. Roberts said that a remark of Mr. Planché's on the subject of these forgeries was worth repeating. He had said that the ready sale for these things was an evidence that there was a widely extended interest felt in such matters, and should make us hopeful of the future of archaeology. Mr. Gunston exhibited a series of knives which had been dug up in Clerkenwell, manufactured in the sixteenth century, some of them of the time of Henry VIII., and ranging on to the close of the century. He also showed a very pretty little urn of Samian ware which had been dug up in Cannon-street about two years since. The discussion on the bronze urn, said to be that of Tanagra, was resumed, and further evidence was brought forward, but not sufficient to satisfy some gentlemen present, that the bronze was a genuine antique.

THE DRAWING OF THE THRONE, HOUSE OF LORDS.—We have received a letter from Mr. E. W. Pugin, denying the truth of Mr. Talbot Bury's assertion in our last. We are forced to decline inserting it.

CARBONIZED PAPER.—Mr. J. E. Hoyer, of Philadelphia, remarks the *New York Tribune*, has invented a new kind of writing and printing paper. The improvement consists in charging the paper with an earthy carbonate. Common writing-ink, of the palest description, when applied to it, becomes intensely black. The mineral surface given to the paper prevents "greasiness," and allows the ink to flow freely. It also takes printing-ink more readily, and produces a black and smooth impression.

LECTURES ON ART BEFORE THE ROYAL DUBLIN SOCIETY.—Professor Macmannan recently lectured on "Sculpture," in the theatre of the Royal Dublin Society House. There was a full attendance. The lecture was illustrated with a collection of plaster casts, placed so as to correspond as nearly as possible to the several epochs in the history of the art of sculpture. Mr. Macmannan commenced by deploring that there is in Dublin no sculpture gallery adequate to the representation of the several stages of development through which sculpture has passed, from its infancy in remote Greek antiquity down to the present day.

ENCROACHMENT ON OPEN SPACES.—Earl Spencer, it is said, has been exciting the ire of the people of Wandsworth by leasing an ornamental lake, of nearly three acres, to an architect or builder, who is about to drain it and build over the site.—It is believed that the negotiations as to the purchase of Sir T. Wilson's rights to Hampstead Heath are *in statu quo*, owing to the price, \$,000, per acre, which had been demanded by Sir Thomas. Further inquiry is to be made on the part of the Marylebone vestry.—It is intended by the owner of Sobu Pool, says the *Birmingham Gazette*, to drain the pool, fill it up, and let it out for building purposes. Our authority shares the regret of the people in the vicinity that the only considerable sheet of water in the town should be thus disposed of. The only alternative, he adds, is a public subscription, or a limited company.

DISTRICT EXHIBITION OF ARTS AND MANUFACTURES IN ABERDEEN.—Arrangements are now far advanced for an Arts and Manufactures Exhibition. It is intended that the whole collection exhibited shall be drawn from the northern counties of Scotland, except in respect to the works of native artists and the products of native workmen's skill or ingenuity, which will be sought for wherever they can be procured. Some branches of industry, such as granite cutting and polishing, are almost peculiar to the district, whilst in others, such as shipbuilding, special excellence has been attained. In respect to art, however, and for comparison, works of art and art manufacture not native to the district, or even to the country, will be received. The Queen has consented to patronize the undertaking. The Prince of Wales allows himself to be named president, and the list of its supporters already includes nearly all the nobility and prominent men of all classes in the north of Scotland. It is contemplated that the exhibition will take place in the months of July, August, and September, 1869.

THE METROPOLIS GAS BILL.—The draft of the Bill brought in by Mr. Morrison, Mr. Locke, and Mr. Gorst, to amend the Metropolis Gas Act of 1860, and to make further provision for regulating the supply of gas to the metropolis, and for other purposes connected therewith, has been published. The Bill contains a hundred clauses. By this Bill it is proposed that the Metropolitan Board of Works, or the Commissioners of Sewers, shall have compulsory power to purchase the undertaking of any company (if notice of such intention be given within six months after the passing of the Act), and in case of inability to agree to terms, that question shall be determined by an arbitrator, to be appointed by the Board of Trade, on the application of either party. The price to be charged by the several companies for gas, from the present time to January, 1870, is to be 4s. per 1,000 cubic feet up to the standard of sixteen candles, except in the case of the Independent and the South Metropolitan Companies, which are to charge 3s. 4d.; but after that date the price charged by any company is not to exceed 3s. 9d. The companies may in 1871 appeal for a revision of the scale.

PROPOSED LIVERPOOL FINE-ART GALLERY.—We regret to hear that in consequence of their heavy pecuniary liabilities, the Liverpool town council have resolved to postpone the erection, at a cost of 18,000*l.*, of a Fine-Art Gallery, to which good intent we have before referred.

CHARTER HOUSE SCHOOLS.—The *Guardian* states that the erection of the new buildings for the Charter House School at Godalming has been entrusted to the hands of Mr. Hardwick, architect, and that a governors' meeting will be held immediately to consider his designs.

SAFETY APPARATUS FOR ENTERING POUL AIR.—M. Galibert's apparatus consists of an air-reservoir, with two tubes attached, the one for the exhaled air extending just within the top of the bag, the other for the air to be inhaled to near the bottom. The outer ends of the tubes are connected with a single mouthpiece, and the person using it secures all the advantages of valves (without the danger which might arise from valves being used and getting out of order), by simply placing his tongue alternately on one or other of the orifices within. Goggles are employed to protect the eyes from irritation, and the nostrils are closed by a small spring clip. M. Galibert's apparatus has been adopted in France by the Ministry of Marine, the Paris Fire Brigade, and by numerous other public bodies and private firms, and it has just been exhibited and tried in London, under the direction of Mr. T. Brown, C.E.

EDUCATION WANTED TO INFLUENCE TRADES UNIONS, AND TO MEET FOREIGN COMPETITION.—Two working men have just delivered public addresses in Birmingham, according to *Arist's Gazette*. One was Mr. Robert Applegarth, the able secretary to the Amalgamated Society of Operative Carpenters and Joiners; the other, Mr. Hibbs, one of the artisans who went in a representative character to the Paris Exhibition. The former treated on Trades Unions; the latter on Foreign Competition with English Trade. Different as these topics may appear, they led the two speakers to one and the same conclusion. Mr. Applegarth wound up his speech with saying that the great want of the working classes was an efficient system of non-sectarian education; while Mr. Hibbs said, what they had to do was to throw themselves with all their might into that new movement for education, not committing themselves to any scheme until they had well pondered over it. Let them at least resolve that their children—the future artisans of England—should be better educated than themselves.

TENDERS.

For alteration and addition to Mr. Cardland's premises, Roman-road, Old Ford. Mr. Iron, architect.—Dean (accepted) £280 0 0

For the renovation and repair of the Parish Church of Avelon Gifford, Devon. Mr. Henry Elliott, architect.—
 Matcham £3,700 0 0
 Stevenson & Croker 3,150 0 0
 Call & Pethick 2,654 0 0
 Condy, Brothers 2,440 0 0
 Elliott 2,307 0 0
 Bone & Son 2,280 0 0
 Ruth & Sons, and Chas. Ruth, Junr. 2,341 0 0
 Steer 2,241 18 8
 Hannaford & Luckraft 2,170 0 0
 Willocks 1,987 0 0

For hand-room and training kitchen at the St. Mary-lebone Parochial Schools, Southall. Mr. H. Saxon Snell, architect.—
 Harding £285 0 0
 Tull 817 0 0
 Eustace 795 0 0
 Keys 798 0 0
 Eustace 795 0 0
 Manley & Rogers 790 0 0
 Wards & Baker 770 0 0
 Gibson, Brothers 745 0 0
 Brown (accepted) 732 15 0

For new wing and stable buildings to Urmaton Lodge, Wimbledon, for Mr. Frederick Thompson. Mr. J. H. Good, architect. Quantities supplied by Mr. L. C. Riddett.—
 Nicholson £2,670 0 0
 Barton & Moreland 2,626 0 0
 Colls & Sons 2,342 0 0
 Ariss & Son 2,316 0 0
 Webb & Son 2,300 0 0
 Adamson & Son 2,270 0 0

For the erection of Wesleyan Sunday School premises, George-yard, Hill. Mr. W. Botterill, architect. Quantities not supplied:—
 Steels & Darneley £1,225 0 0
 Halls 1,190 0 0
 Barrett 1,173 12 0
 Raynard 1,158 8 0
 Waller 1,130 0 0
 Marshall 1,108 15 0
 Brown 1,061 0 0
 Habbershaw 1,064 8 0
 Hutchinson 1,009 0 0
 Jackson (accepted) 993 5 0

For John's-place School (St. Philip's), Stepey, for Mr. E. Denison. Mr. Iron, architect.—
 Goddard £390 0 0
 Larkle 370 0 0
 Smith 365 0 0
 Paine 355 0 0
 Brown 354 0 0
 A. & J. Smith 335 0 0
 Johnstone (accepted) 307 0 0

For new shop-fronts for Longbays & Co., Commercial-road. Mr. W. Smith, architect.—
 Including Plate-glass.
 Crabb & Vaughan £848 0 0
 Excluding Plate-glass.
 Sabej £510 0 0
 Eaton & Chapman 475 0 0
 Ennor 467 0 0
 Earle 425 0 0

For alterations and additions at 223, Upper-street, Islington. Mr. W. Smith, architect.—
 Parrah & Vaughan £360 0 0
 Bradly 383 0 0
 Pask 355 0 0
 Sabej 350 0 0
 Eaton & Chapman 393 0 0

For erecting dwelling-house and rebuilding stables at Buck-street, Camden-town, for Mr. Barrow. Mr. R. W. Hart, architect.—
 Langmead & Way £650 0 0
 Tanner 650 0 0
 Stephens & Batagh 645 0 0
 Catepool & Cooper 50 0 0
 Kelly, Brothers 547 0 0

For Congregational Church, Exeter. Mr. John Tarring, architect. Quantities supplied:—
 General Estimate. Spike in Bath Stone.
 Inch £9,998 19 0
 Per-ram 6,681 12 8
 Call & Pethick 5,514 0 0
 Mous & Sons 5,541 0 0
 Kenushaw & Co. 5,259 0 0
 Force 5,452 0 0
 Luscombe 5,150 0 0
 Tozer 5,085 0 0
 Stephens & Son 4,493 13 2
 Pollard & Son 4,400 0 0
 Hragg & Dyer* 4,278 5 0
 *Accepted.

[This is an interesting specimen of estimating certainly; remembering especially that the difference are produced by the prices alone, the "quantities" having been supplied.]

For alterations and additions to the Sussex County Prison, Lewes. Mr. Henry Card, county surveyor. Quantities supplied by Mr. B. H. Nunn:—
 Perigo £16,154 8 6
 Nutt & Co. 14,400 0 0
 Williams 13,378 6 2
 Fatman & Fotheringham 13,285 0 0
 Henshaw 12,778 0 0
 Hughes 12,590 0 0
 Nightingale 12,352 0 0
 Berry 12,110 0 0
 Kirk 11,990 0 0
 Howell 11,715 0 0
 Hall 11,445 0 0
 Cheeseman & Co. 10,990 0 0
 Chappell 10,693 0 0
 Perry, Junr. 10,444 0 0

[We understand that the quantities named by the top seven contractors were provided by one surveyor, and those used by the following seven were furnished by another.]

For the enlargement of the Port of Hull Society's Sailors' Orphan Home, Park-street, Hill. Mr. W. Botterill, architect. Quantities not supplied:—
 Hutchison £3,495 0 0
 Barrist 3,317 8 0
 Clarkson 3,291 0 0
 Jackson 3,230 0 0
 Habbershaw 3,220 0 0
 Sergeant 3,177 0 0
 Marshall 3,146 0 0
 Halls (accepted) 3,081 0 0

For the erection of five pairs of semi-detached residences at New Malden, Surrey. Mr. W. Sim, architect.—
 Kelly £5,850 0 0

For a pullio-house, with cottage and shop adjoining, at Clever, Harks. With power to use certain old materials on the grounds. Mr. W. Sim, architect.—
 Gray £690 0 0

For additions to Bull's Cross National Schools, Enfield. Mr. Thomas J. Hill, architect:—
 Brett £263 0 0
 Hayes 520 0 0
 Field & Sons 512 0 0
 Fatman, Brothers 5 8 0

For the erection of warehouse, Whitecross-street. Mr. T. C. Clarke, architect:—
 Kilby £1,783 0 0
 Turner & Sons 1,772 0 0
 Conder 1,750 0 0
 King & Sons 1,680 0 0
 Abraham 1,635 0 0
 Mortar 1,627 0 0
 Webb & Sons 1,596 0 0
 Kelley 1,572 0 0
 Screnener & White 1,476 0 0
 Henshaw 1,439 0 0

For alterations and additions to No. 23, Pembridge-gardens, Notting-hill, for Mr. P. P. Gordon. Mr. John Taylor, architect:—
 Corry £498 10 0
 Higgs 473 0 0
 Clement 419 0 0
 Lathley, Brothers 418 0 0
 Stoner 388 0 0
 Kilby 389 0 0

The Builder.

VOL. XXVI.—No. 1312.

Architects and the Volcano.

SOUTHERN Italy should be the paradise of architects. No country in the world can show nobler, more romantic, more lovely sites for palatial buildings. None can show worthier occupation of such sites. None possesses a greater variety and abundance of building materials. The traces of Roman grandeur still mark the buildings of to-day, for they, like the structures of Rome herself, must be built so as to resist the shock of an earthquake. For this reason, building south of the Alps is a serious occupation. No little pestilent rows of brick huts,

like those that attend on the industry of our great manufacturing centres, spring up in the purlieus of Florence, of Turin, or of Naples. The duration of such houses as are now swelling the circumference of London would be at once certain and uncertain in Italy. It would be the latter, because no law has been discovered as to the periodicity of earthquakes. It would be the former, because they would exist only till the moment of the first shock. Such a wave as howled the towers and bellries of Naples in 1858, causing in that city great terror though little damage, but overwhelming thirty thousand sufferers in Calabria, would, if it occurred in London, leave hardly a single building to be shaken by the replica, or dreaded return shock, always the most severe.

With the necessity of erecting substantial buildings arises the necessity for the employment of architects. The profession comes into daily requisition. The solid palaces which form the main buildings of the cities, and, to a great extent, of the country at large, are too important in the eyes of their owners to be left to the mere chance. They often need the eye of the expert. Built with the intention that they shall endure for at least a century without any very material repairs, it is yet certain that numerous works of a slight nature will be required within that term in order to maintain that durability. Hardly a single palace is to be seen without cracks, or the significant autographs of the earthquake. The massive and noble palace of Caserta itself shows, in several places, a narrow vertical rent from roof to foundation. Immediate attention must be paid to each signal of danger, and this attention must be given under the direction of the family architect. No wonder that these gentlemen abound.

Again is Italy the home of the architect, because there he has the field to himself. He is not jostled unpleasantly by the engineer. The civil branch of that youthful and vigorous profession is unrepresented in that part of Europe. The only engineers there are those of the *Ponti e Strade*, the *Ponti et Chaussées*, the military officers answering to our own Corps of Royal Engineers. Their numbers are limited, and they very rarely interfere with the archi-

tect. It was to the latter that the construction of railways, when not carried on by foreign energy, was committed under the old regime. What a loss to the profession has been the result of the different course adopted in England! If the four hundred and ninety millions which the men of the school of Stephenson and of Brunel have laid out on our iron roads had only passed through the hands of English architects, what might not have been the result.

The Italian architects, then, constitute a numerous body of men, including members of high and cultivated talent, and exercising no slight influence on their contemporaries. In a sense unknown to ourselves, they are expected to exercise a constant vigilance, to care for the health of the buildings under their charge, as a family physician will attend to the health of his patients—not waiting for formal summons, or for positive malady to declare itself, but looking in over and anon to suggest the timely one stitch that always saves the nine.

As they are thus expected to maintain that which is old, they are not unnaturally consulted as to that which is new, or which is to be in the future. In all cases in which the surplus capital of this country has been invited to fructify under the genial influence of the Italian climate it is the architect who has offered to the foreigner the rare and exceptional privilege of thus enriching himself. Plans of all kinds,—railways,—the progress of which nothing but the subtle and persistent treachery of successive Governments could have arrested,—ports and basins, roads through thickly populated but pathless districts, boulevards and arcades in the plethoric capitals, mines and factories, all these means of investment have been pressed upon the attention of Englishmen, who were supposed to have money to lay out under the authority of Italian architects. In most of these cases a simple division of labour was proposed: the English engineer or architect was to find the money, or to find the men who should find the money; the Italian would answer for the spending of it. From the canalisation of the Po to the restoration of the ancient port of Brindisi, as the land terminus of the Indian mail route, the same arrangement has been contemplated by the adroit *savoir faire* of our Italian friends.

Again, the Italian architect is eminently happy in the materials at his command. The people are born masons. If you are about to build, you have, in nine cases out of ten, only to sink down a few feet below the surface of the vineyard or garden in which you intend to erect your abode, to find an ample supply of tufa for your walls. This volcanic product, the agglomeration of the fallen products of long extinct volcanoes, resembles in its building properties the chalk of this country very closely indeed. It has not the purity of colour of white chalk, being of a grey, or drab, or violet tint when first exposed to the air; but it cuts very much after the manner of chalk, and it shares with that mineral the characteristic of forming reliable masonry, if protected from frost, or from soaking wet. We could point to many instances of obalk walling in this country, faced with brick, and thus forming economical and durable work.

Frost is a rare phenomenon in the south of Europe. Rarely more than two or three times in the course of the year is a slight scale thrown off from the surface of the tufa walls of the vineyards and gardens by its silent but irresistible agency. In buildings of any pretension to architectural importance, the tufa, which forms the mass of the structure, is protected from the injuries of the weather by brick or stone facing, or by the use of plaster or stucco. The Italian masons have peculiar facilities in the use of lime. As has been previously noticed in the pages of the *Builder*, the establishment of a lime-pit is always the first practical step taken towards the erection of a building. The unmixed

but well-slacked lime remains for years under a slight film of water; and the readiness with which it yields its aid to the mason, the plasterer, the maker of *scagliola*, the beautiful artificial marble so common in the churches, or to the noisy services of the men who form the heated floors, is perfect.

Not only the tufa, which thus forms the main substance of Italian masonry, but every other requisite of the mason, is readily to be met with in the districts to which we refer. Vesuvius himself, and many silent outlets of former volcanic fury, supply a hard and readily-worked stone, admirably suited to form the coigns, lintels, and jamba of domestic buildings, as well as to serve for a solid pavement to the streets. The *scala* limestones of the Apennines afford a finer, and not less durable, material, as well as sending chips and rough blocks to the lime-kiln. Volcanic sand is not rare, associated at times with the *lapilli*, or beds of small volcanic pebbles, that form a concrete capable of a finish so exquisite as to make a ready substratum for the art of the fresco painter. The most usual, and, with the sole exception of marble, the finest, floors for a mansion of importance, are of this material, which is beaten into place for a fortnight without intermission, and then carefully painted in figures. Marble itself is a native product, and, in the severe heat of the summer, the luxury which results from the introduction of a marble floor, or even of a marble staircase, is so great that a house supplied with these expensive fittings seems to be situated in a distinct and much cooler climate than the adjoining mansions, with staircases of lava, and heated floors. Thus the architect, in these favoured regions, while his skill is constantly in request, has close under his hand an abundance of the finest materials fitted for the exercise of his ability.

Vesuvius, the symbol and concentrated expression of that force which shows its terrible energy in earthquakes, is thus a great friend, if not of architecture, yet at least of the architect. The best of friends, however, have their failings, and in this respect the fiery crater does not possess greater immunity from dangerous caprice than is common to human patrons. Very recently a disaster has occurred in the very heart of the city of Naples which people have not been slow to attribute to the activity of the volcano. If they are right in this opinion, it is far from improbable that very unpleasant proofs of the correctness of their views will be hereafter furnished from the same source.

Among the most striking and peculiar features of the neighbourhood of Naples, are the large buildings which, in several different directions crown the summit of lofty hills, often looking down a precipitous bluff on the water, or on the shore beneath their battlements. The old Angevin palace at *Vico Egnense*, built by the brother of King Saint Louis of France, is a well-known instance. So is a monastery not very distant from that same palace, where the walls of the chapel seem so far to overhang the face of the lofty rock on which they stand, as to impress the passer-by with an instinctive dread; so very little seems necessary to cause chud and cliff together to topple over into the blue waters of the bay. In the city of Naples, a hill some 250 ft. high, shuts out the "west end" from the centre of the town. This hill, precipitous towards the sea, is covered with buildings. One noble palace, recently restored on its crest, has its upper apartments, which are usually the principal rooms, ascended to by a series of marble staircases, containing 170 steps, and the view from this elevation is one of the wonders of the place. Nearer to the sea, and commanding a steep zig-zag ascent up the seaward bluff, stood a large monastery, now converted into a barrack. The face of the hill was covered with a revetment of masonry, at the foot of

which burrowed a small row of shops and dwelling-houses of a humble description.

It is now stated that it has been long matter of remark that this mountain was in an unsafe condition. Large fissures are said to have been visible in it from top to bottom. A year ago (but we must take the statement with the usual caution as to Italian *viva voce* evidence) the delegate of the quarter reported his opinion of the danger to the city architects, but investigation was deferred till "*domani mattina*," which, in that part of the world, generally falls on the Greek kalends. The attention of these gentlemen received a terrible call on the 28th of January, when the whole face of the hill came down without any further warning, hurrying the houses at its foot, and—it is even yet unknown how many—inmates and passengers. The alarm and excitement were naturally intense. By daylight the crowd on the spot was so dense that the troops were required to preserve order. The architects of the city were, of course, on the spot, and the expedient was adopted of appointing a commission to examine the mountain. That an immense deal of theory was ventilated on an occasion so favourable for the Italian love of speculating, there can be little doubt. What rather shocked our less material minds is the fact that for *thirty-six hours*, while the impression was general that many wounded sufferers might yet be living under the *débris*, *nothing was done* to rescue them. A Venetian military engineer, whose name deserves record—Signor Zampari—endeavoured immediately on the occurrence of the catastrophe to commence a tunnel through the *débris*, in order to reach the site of the houses. His proceedings were suspended by authority. When this precious time had been lost, he was allowed to proceed, and worked incessantly for seventy hours, the city architects, of course, opposing so unprecedented a step. Another tunnel was driven towards the same spot beneath the level of the street itself, but with the lapse of time the human interest in the case vanished, and the spot gradually came to present only the usual features of work carried on for the Government in Italy—"sleepy men and half-grown *gamins* being engaged in carrying off the rubbish in small baskets." The entire want of energy and resource in a people that are far from being callous or unkindly, and through whom a sudden excitement runs like a shock of earthquake itself, is a mournful characteristic of the scene.

Whatever be our own national short-comings, and it must be confessed that the history of our public works has not been free from the occurrence of fatal accidents provoked by incredible carelessness or foolishness, there is one feature of our character of which we may be justly proud, and that is the manner in which every Englishman, by a common instinct, pulls off his coat in an emergency. Let him hear that life or limb is in peril, and he never doubts to share that peril if he can in any way hope to bring aid to the sufferers, or even to gain certain intelligence of their fate. By land and sea, in the coal-mine and in the life-boat, this unselfish and noble promptitude never fails at the call of danger. It is a characteristic that may even console us for the fact that our houses are not so habitually looked after by properly educated architects as is the case in the Italian cities.

The chief interest that now attaches to the scene of this calamity depends on the question whether we have had the last word of Vesuvius in the matter or not. The cause of the accident has been attributed either to the percolation and accumulation of rain behind the revetment, or to the gradual loosening of the face of the hill by the vibration attending that prolonged and splendid eruption of the volcano which has scarcely ceased. If the account given of the vertical fissures in the hill be true, there can have been no accumulation of water capable of producing the fall by hydrostatic pressure. The vibration from the Vesuvian shocks, though of the nature of earthquake, is far lighter than have been many of the actual earth-waves that from time to time pass over the whole country. In 1858, for instance, the whole shore for miles in circuit appeared to be permanently elevated some eight inches, as shown by the level of the waters in the bay. As it is the last straw that breaks the camel's back, so the last of a series of vibrations may have concluded an operation that had long been silently in progress. But it must be borne in mind that, in all cases, sharp high mark centres or nodes of geological action. A sudden break of continuity, a contrast of elevating and of depressing forces, must have occurred beneath

this exact spot at the distant time when the hill of Monte di Dio rose, or when the shores of Santa Lucia sank down. And just at the base of the mountain, giving certain indication of connexion of some kind with antihorrean fire and energy, bubble warm and sulphureous springs. It is thus quite possible that what has been called a land-slip is, in fact, an indication of a direction of the volcanic force towards Naples itself. The city lies, as it were, between two fires,—Vesuvius to the south-east and Solfaterra to the north-west. Its position recalls forcibly to the traveller the aspect of Lisbon. The Tags now rolls over the spot where, in the Great Earthquake of 1755, the quay, covered with human beings, sank suddenly to a fathomless depth. For a volcano to open in the Santa Lucia, close to that famous Castello d'Uovo, under the foundations whereof, according to the legendary derivation of the name, lies the egg on the security of which depends the salvation of Naples, would be a calamity neither without precedent nor without warning. It will be an immense relief to the Neapolitans if they can persuade themselves to cast the blame of their impotence on the supineness of the city architects rather than on the activity of Vesuvius.

Not foreign to the question of probable geological change in Italy is the intelligence recently received of a gradual but steady depression of the shore of the Lago di Garda. The physical state of Italy seems almost as feverish as its political condition.

ON THE UTILIZATION OF SEWAGE BY IRRIGATION.*

3. Flat Flooding or Submersion.

FLAT-FLOODING may be considered as a very modified form of catch-work irrigation. The land upon which it is used requires no other external conditions than those of being tolerably level and free from irregular depressions or elevations, and of just sufficient inclination to prevent the accumulation of sewage to any great extent. This is, perhaps, the cheapest form of irrigation practised, and where the object is rather to utilise the grosser impurities of sewage than to render it perfectly clear, it may be tried with moderate success. Great care is necessitated in the selection of the soil, which must be well drained, as this system has perhaps a greater tendency to stagnation than any other,—an evil which destroys vegetation, ruins the land, and is very detrimental to the surrounding atmosphere, rendering its locality, indeed, neither more nor less than a noisome swamp. The sewage enters on one side the inclosure by an overflowing conduit, and, after moving slowly over a very considerable extent of ground, is passed out at the other. There is no doubt that occasions may arise in which this method may be pursued with advantage, from its economy of cost and slight trouble; yet it must be understood that, to extract the utmost possible advantage from sewage irrigation, greater perfection of means must be used.

The mode of irrigation by submersion, as practised in Northern Italy and other countries bordering the Mediterranean, materially differs from the foregoing, which, as has been said, is simply catch-work in its most modified form. In the rice cultivation of these countries, the inclosure is completely circumscribed by light banks, with provision for admitting the sewage or manuring liquid, which is allowed to entirely submerge the land to a depth of several inches, where it is left to be wrought upon by evaporation and the absorbing properties of the soil. There is little doubt that the benefit to the crop derived from this method of utilisation is great, yet this benefit is almost counterbalanced by the prejudicial effect of the thick, unwholesome vapours exhaled by such stagnant and watery surfaces upon the health of the vicinity. Much might be done to mitigate this evil by good drainage, yet it must always exist more or less. Under our dull, watery sky, unfavourable to evaporation, and in the midst of our teeming population, this system would not be tolerated, even if it could be adapted to a suitable crop; whereas in the West of England the former method has been attended by good results.

4. Sub-irrigation.

By sub-irrigation, which is said to be limited extent in some parts of the Continent, is under-

stood that mode of applying the sewage, not from the surface or from above the roots of the plant, but from below the surface, whence the liquid is drawn upwards by the capillary attraction of the soil particles.

Perforated or very porous drains are laid down, which from time to time are completely filled from the source of supply, and are stopped up, so that their contents shall have no other means of escape, save by the capillary action of the surrounding particles of soil, which are supposed to exercise this property chiefly in an upward direction. The construction of these drains is special, being laid very near the surface, inasmuch as the superior depth of ordinary drains would render them almost wholly useless for this purpose. But the very avoidance of this evil, by the construction of shallow drains, induces an alternative evil of scarcely less gravity—that of stagnation. To understand this clearly, it will be simply necessary to briefly remind the reader of the principles of common land drainage.

Drains, which are laid down for the purpose of ridding certain uppermost stratum of soil of its superabundant water, and rendering it dry, light, and porous, do not receive these waters in their downward descent from the surface: on the contrary, it is only after passing below them and having thoroughly saturated the subsoil up to their level, that the water, rising upwards flows into them, and is carried off. In all ordinary soils, therefore,—that is, in soils which are not excessively absorptive—the horizontal plane defined by the position of the drains constitutes a distinct boundary between two conditions of soil; namely, soil in a productive state, free from superfluous moisture, and accessible to air; and soil in an unproductive state, crude, stagnant, and permeated with water. This indesirable result of drains is not, however, productive of harm in the case of those of ordinary depth; but when the shallow system of drainage required by sub-irrigation is used, a degree of permanent coldness and stagnation is induced near the surface, very injurious to the productive power of the soil. Nor is it attached to the double system of drains usually adopted in surface irrigation, since in this method both systems of drains are free outlets by which the drainage is speedily carried off, admirably adapted to keep the soil in its normal condition. Again, in very light porous, and sandy soils,—perhaps the only soil upon which it would be possible to avoid the insuperable evil of stagnation,—the capillary attraction of the particles of earth above is not sufficient to counteract the gravitating tendency of sewage away from the roots of the plant, a result which would effectually destroy the chief end of sewage utilization, namely, profit. Further, it is well known that no manure can convey hence to a crude, unworked soil, and the soil in immediate contact with any underground pipes, must necessarily partake of this crude nature; therefore under these conditions the application of sewage must be fruitless.*

Fourthly, sewage matter gravitating through an unworked soil, such as subsoils invariably are, cannot be so effectually cleansed of its organic or inorganic impurities as sewage passed through a quickened soil.

Lastly, the periodical choking up of the pipes used in sub-irrigation is a defect which could hardly be avoided; even ordinary drains may be rendered useless by the accumulation of foreign substances entering through very minute interstices; and it will be scarcely thought that sub-irrigation will not be infinitely more liable to this annoyance. It may, therefore, be held, so far as our present experience of this method has proved, that as a means of utilising the sewage of towns, the system of subterranean irrigation is essentially wrong in principle and practically useless. As a means, however, of purifying sewage from much of the organic matter it contains by turning a large area into a vast natural filter-bed, this mode is worthy the attention of those who are sceptical as to the practicability of profitable utilisation under certain circumstances.

Sundry small experiments have been tried in sub-irrigation, but the author is not aware of a single instance in which in this country any practical benefit has accrued from it.

* The difference between the subsoil and the arable surface soil, or the crude and the cultivated soil, supposing that both contain the same amount of nutritive substances, can only be founded upon this, that the cultivated ground contains the nutritive substances of plants, not only in a more uniform mixture, but also in a finer form.—Liebig's "Natural Laws of Husbandry," p. 61.

* See pp. 146, 168, and 202, *ante*.

Dr. Thudichum's Plan.

The necessity for the separation of the liquid from the solid portions of the human excreta, and these again from the ordinary house and street refuse, which goes to form what is now universally understood as sewage, has been long and powerfully advocated by men whose opinion claims some degree of consideration, although hitherto no satisfactory plan has been evolved with this end. By the most of these advocates, there is one thing which appears to be too often lost sight of, to wit, the need of some means of dealing with the more dilute portion, after some other fashion than the collapsed methods of precipitation. It cannot be disputed that the collected voidings of human beings may, without extraordinary difficulty, be rendered into an excellent manure; but if it be proposed, as we have invariably seen it to be the case, practically to utilise this portion only, by what means is the crying nuisance of polluted streams and water-supply to be abated? It has already been explained that, independently of the contents of the water-closet, town sewage comprehends matter which, few will pretend to deny, ought not to be passed into running streams.* A thousand other ingredients of filth combine to swell the contents of the common sewer, which, under the present condition of things is discharged into the nearest stream. To effect the thorough cleansing of our water-courses is the main central object of all the vast agitation which has arisen in this regard of late years; and this—the all-important question—the method of separating the urine and feces of human beings from the contents of the sewers, leaves, so far as can be gathered from the various schemes of the projectors, entirely undisturbed. Are we required then, while utilising this small portion, which may be regarded as a drop to the ocean of sewage, to abandon the great aim of utilisation? It avails little to assert that after the closest refuse is abstracted from the sewer, the fouling of rivers will not go on as before. As well might it be said that the abstraction of the sewage of Woolwich and Greenwich from the Thames, would effect the purification of that vast volume into which the combined filth of the metropolis and a hundred other towns is being poured night and day. It has, indeed, been proposed to treat the remainder with lime with a view to precipitation; but after the experience which has been so dearly bought on this score, such a proposal can receive little credit. Another objectionable feature is the great cost necessitated by a two-fold system of drainage which at the same time does not effect the separation of the rainfall from the ordinary sewage.

Dr. Thudichum's proposition to the Metropolitan Board of Works for dealing with the London sewage is, to use his own words, "founded upon the discovery of a process by which a most valuable portable manure can, without difficulty, and at comparatively small expense, be procured from urine," and is in outline as follows:—Urines are to be attached to water-closets, which ensure the urine and feces being conducted separate and distinct, the one from the other. By this means the urine is to be brought to the sewers, through which it is proposed to conduct it by a system of pipes contained within the drains and sewers, main and intercepting, to the outfall at Barking Creek, there to be dealt with, and converted into a portable manure. In addition to the manure, the other component parts of the urine would, at a trifling additional expense, yield most valuable products; amongst others, purpurate of ammonia, or murexide, a magnificent purple dye, estimated by Dr. Thudichum to be worth 1,000l. per ton. In this way the product of the urine only would amount to the gross sum of 1,365,000l. per annum, or 10s. per head of the population.

The remaining portion of the sewage of the metropolis, consisting of surface water, street lavois, local and other matters, is, by this plan, to be conducted, as at present, through the sewers to Barking Creek, to be treated by the lime process, with a view to the utilisation of the product as manure.

Another proposition for dealing with the sewage of towns generally, from the same projector, was to dispose of the liquid voidings by products,

laid in main sewers, to be combined at suitable stations, or at the outfall, in tanks, and thence carried by road and rail. In conjunction with this mode of treating the urine, a system of deodorization by dry earth and paper bags was to be adopted for the feces. The manifold advantages of the foregoing methods of dealing with this important question are enumerated with considerable force by their author, who is very severe upon those who assume "sewage" to be an "unalterable entity," and terms the water-closet "the most stupid of all inventions that ever interfered between man and his first duties." The author has, with the singular aid of his knowledge of the structure of the human form, built up a theory, which, however, has the disadvantage of being unillustrated from the practical basis of experimental proof.

When, therefore, Dr. Thudichum's theory is opposed to the experience of the past, and we are told, in the face of the most undoubted testimony to the contrary, that sewage contains nothing that is valuable for agriculture, or any other human purpose, beyond the excretions of men and animals, we may, without great violence to justice, suspect that he who tells us this speaks not as an impartial judge, but as a strongly-biassed advocate, who, with his own commodity in the market, lustily decries all other wares.

Separation of House Drainage from Rainfall.

By those who see in the extreme dilution of sewage in its present state, the chief objection to the economic utilization of its fertilising ingredients, it has been proposed to avoid such dilution by the construction of two separate and distinct systems of drainage. By one of these it is proposed to convey the rainfall alone, and by the other the household refuse, including fecal matter. As, in the event of sewage irrigation becoming a chief means of utilization, this will be one of the most important and difficult questions affecting it, it may be expedient to enter into a short examination of the arguments for and against the adoption of this system of separation.

In designing a scheme of works for the utilization of sewage, under the combined system of rainfall and sewage, there is this indispensable feature, namely, the necessity for making provision in the construction of such works for the maximum rainfall of the district, in addition to the maximum flow of sewage proper. To effect this, there are three alternatives,—firstly, the undue flooding of the lands under irrigation; secondly, the construction of a hy-wash, or storm overflow, by which the surplus waters shall pass into their natural outlet; and thirdly, the construction of a reservoir capable of storing the surplus. On the other hand, in laying out a scheme under the separation system, the flow of sewage is steady and unvarying, and the works may be constructed in accordance with the maximum consumption of water alone.

The arguments in favour of a separate and distinct set of sewers for the reception of the sewage proper are chiefly as follow:—First, the liquid being more concentrated in form is more easily manageable. When it is intended to pump sewage this is unquestionably an advantage, as it tends to lessen the cost of lifting. Instead of laying down pumping apparatus to correspond with the maximum rainfall and flow of sewage, or constructing huge storage reservoirs, the requisite power need only calculate upon the basis of water-supply.

Secondly.—Regularity of flow. No district, however favoured by nature, can at all times provide for the uniform distribution of storm-water, by the ordinary methods of irrigation, without heavy flooding. To avoid this, the construction of storm overflows becomes necessary, which must unavoidably cause a certain waste of the fertilising material, and in some measure affect the purity of the outlet stream.

Thirdly.—It has been stated that the extreme dilution of sewage caused by the rainfall materially diminishes the commercial value of the manurial ingredients it contains; that these may be more profitably applied in a stronger solution.

In favour of the combined system these arguments are met on almost equal terms. To the first, in respect of the cost of pumping, it is allowed that where no outlet by gravitation alone can be provided for the surpluses or storm-waters, such cost must perforce be greater; but that there are few cases in which the well of the pump is placed so low as not to admit of an outlet. The power, therefore, need only be calculated on the basis of the ordinary rainfall and water supply. To the second, it is replied

that the providing of the hye-wash aforesaid will obviate heavy flooding, and produce a degree of regularity in flow not inconsistent with profitable management; that such hye-wash, in sending storm-water down the water-course, does not send them in the form of sewage, but simply in that turbid condition which pertains to every stream during a period of heavy rain. That these joining a similar current, are borne rapidly away without the slightest ill effect. That if it be asked what becomes of those rich contents which a freshet is supposed to bring down a sewer, it is answered that the scourgings of the sewer are the first results of the storm, and are retained by the grating at the outfall. To the third argument it is said, that as yet it is by no means definitely settled that the manurial elements of sewage would be productive of greater results in a less diluted form, in so far that, although there is a limit to dilution, the actual experience of sewage irrigation renders it doubtful whether such limit has been reached; and it is well known that water alone, judiciously applied all the year round, has a most beneficial effect upon the land. In fine, it is asserted, when the pith of those objections is extracted, they are found to amount to an allegation that, under the combined system of main drainage, perfection in utilization is not attained,—to which its advocates are prepared to submit.

In return, manifold objections are alleged against the adoption of the separation system.

In the first place, it is argued, our chief aim is to render our water supply as pure as possible. To do this, we must not only refrain from polluting it with house refuse and fecal matter, but it is absolutely necessary that all the matters heretofore described shall be withheld. The thick, muddy impurities of the streets and courts of a large city, full of the dung of beasts and other animal matter, cannot be poured into a stream without injury to the water for all drinking and culinary purposes; and these constitute but a minor portion of the filth which, besides household drainage, sewage contains. Again, instead of forthwith easing the rates of communities, a double system of drains would add enormously to their already weighty burden; perhaps 50 per cent. on the original cost of severing. In the third place, drains into which the watercloset refuse enters, but from which rain-waters are excluded, would require frequent flushing by artificial means; otherwise sediment would be deposited and silted up to the prejudice of the drainage flow. Lastly, gradients which are perfectly practicable where the rainfall goes to swell the volume of the sewage, would not suffice under this method; which, in a flat district, with slight fall, like Hull, would prove a formidable objection; and there are few towns without certain localities wherein all the skill and energies of the civil engineer are not taxed to maintain the sewers in a wholesome and efficient condition. On the whole then, it is said, it will be found that, whereas the advantages to be derived from this method are slight, its defects, on the contrary, are numerous and weighty enough to render the change inexpedient.

To decide upon this, the critical point in sewage irrigation is at present no easy task. The question at issue lies within a very small compass: is it expedient for the sake of certain contingent advantages, which have not as yet been sufficiently demonstrated by experience, to double, or nearly double, the entire system of main drainage in a town? A satisfactory solution cannot be derived until a just comparison of the net results in two parallel cases shall be within our power; one illustrating the combined system, and the other the separation system. There can be no doubt that circumstances may exist in which two distinct systems, communicating with each other, are advisable, and there are already instances in which some of our eminent engineers have proposed to adopt it.

Captain Liernur's Method.

The removal of human voidings and their attendant gases by means of the pressure of air, or pneumatic force, has recently attracted some attention on the Continent, more especially in the Netherlands, where it is, to some extent, in present operation. The chief exponent of this principle, Captain Liernur, whose views have been especially advocated in a late publication by a Dutch engineer, proposes to dispose of the closet refuse of households by forcing it through pneumatic agency along certain subsidiary and

* "The Sewage Question." By Frederick Charles Knepp. London, 1867.

* Dr. Hawkesley stated at the Leamington Congress, 1856, "That the dry-earth system effectually relieves the towns of the necessity for sewers, but not of drains and conduits to carry off the rain-water and the water used for domestic purposes;" but he did not state by what means he proposed to deal with the contents of these.—*Leamington Congress Papers*, pp. 69, 60.
† Rep. Met. Sewage, 1864: App. 288, et seq.

main pipes into central tanks, fixed underground at the crossings of streets. These tanks, or, to speak plainly, cesspools, are of cast-iron, purporting to be so put together that all escape of gas or odour is prevented, as well as loss of percolation downwards, and are from time to time cleansed by the removal of their contents in carts or boxes to their final destination for agricultural purposes. What the advantages of this system may be over many others involving the cesspool principle, which have been rejected as impracticable, does not very plainly appear. Mr. Krepp, in the work above alluded to, expends much energy in denouncing cesspools as deadly and dangerous, and straightway proceeds to plead frankly for the construction of these iron "reservoirs" at the busiest points of public resort: in fine, to dot the town or district with cesspools on a grand scale. It is idle to talk of hermetically sealing these tanks; the gases invariably find egress at the joints, and rising to the outer air, whether palpably to the senses or not, are subtly absorbed into human lungs. Before the question of sewage utilization can be solved, this fallacious principle of hoarding up and concentrating in our very midst the pernicious exhalations of sewage must be utterly discarded. No time should be allowed for fermentation and putrefaction, but the source of danger should be hurried out of reach without delay, and dealt with by a form of deodorisation at once simple and beneficial.

The Land and the Crops.

The Land.—In the selection of the site for the utilization of sewage, much of the success which may attach to the enterprise depends upon the nature and condition of the soil to be treated. There is no doubt that in cases where it is stated to have been tried and failed, the want of success is due to want of judgment in this regard, coupled with that stiff, unyielding, impervious soil, should make such a grateful return by this means of tillage as soils naturally dry, light, and porous, well-worked and pulverised, so as to render it greedy of the liquid manure. But, as what is necessary to complete the process of utilization is not only the absorption of the water by the soil, but the extraction by chemical affinity of the manurial properties contained therein, it would be a mistake to insist, as has often been done, that very loose gravelly, or pure sandy soils alone are adapted. Mr. Latham says,—"The purification of sewage is due to a very beautiful property possessed by all soils to a greater or less extent, and that is, the affinity the soils have of separating the fertilising matter from the sewage, and holding it until required by the plant. *Clay soils* have a much greater affinity for fertilising matter than pure sandy soils." Therefore, although less absorbent of moisture than sandy or gravelly soils, light, well-opened clays purify as effectually. Mr. Latham even goes so far as to say that "clay soils excel in production any other when treated with sewage."

Nevertheless, it is considered by agriculturalists generally that sandy soils surpass all others in the proportionate benefit which they derive from the application of every kind of manure. Liebig says† that, "in comparing a fruitful sandy soil, with an equally fruitful loam or marl, as regards the nutritive substances contained in them, we are surprised to find that the sand, with one-half, or even one-fourth of the total substances contained in the loam, will furnish an equally rich harvest. To understand this circumstance properly, we must remember that the nutrition of a plant depends less upon the quantity than upon the form of the nutriment in the soil, just in the same way as, for example, half an ounce of animal charcoal presents as large an acting surface as half a pound of wood charcoal. If the small quantity of nutritive substances in the sandy soil presents as large a surface for absorption as the larger quantity of those substances in the loam, the plants must thrive as well upon the former as upon the latter."

We must also recollect that the most prolonged and successful experiments in sewage irrigation have been conducted upon sandy soils, with results proportioned to the purity of the sand. The celebrated Craigentiny meadows at Edinburgh were originally of this nature, being, in fact, neither more nor less than sea-sand blown into dunes or billocks by the wind.

The experiment which is now being tried at Aldershot, with hopeful results, is upon the drifted white sand of Aldershot Heath—the most barren of soils. At Croydon the land consists of sand, with a subsoil of gravel, on the porous chalk formation; and very recently excellent results have been reported from the poor gravelly soil at Barking. On the other hand, the success of the application of sewage to the heavy clay at Norwood cannot be doubted; and at Rugby—where, however, the result has not been so decidedly favourable,—the land is on the lia formation. Mr. Lawes states that the soil most suitable for the application of sewage is the lightest that can be procured—a porous, sandy land.* Professor Way, before the select committee, said that he would select a pure sandy soil in preference to any approaching a clay, and that such a soil would become a light friable loam by the deposit of the suspended matters in sewage; at the same time endorsing Mr. Latham's theory, by adding that sand is inferior to clay in its retention of the materials of manure.†

It would appear, therefore, that experience has conclusively demonstrated that two totally different soils—clay and sand—are alike highly favourable to the utilization of sewage; the chief condition of success being a light, dry, workable state of the soil, whatever it may be. This being the case, we are justified in the opinion that sewage irrigation is adapted to every quality of soil.‡

M. P.

"THE HEALTH AND HAPPINESS QUESTION"

An address, of which the following is an outline, was delivered in the Town-hall, Brighton, on Friday evening, the 20th instant, by Mr. George Godwin. The chair was occupied by Mr. Douglas Fox, and the hall was filled with an attentive audience:—

When I was invited by a committee of gentlemen to say something to you about "Town Swamps and Social Bridges," the title of a little book, one of a series written by me several years ago, to set forth the condition of the metropolis and our large towns, I was at first strongly disposed to decline. My ordinary occupations are heavy, and, moreover, I feared that, after talking and writing of the subject for many years, I could say little that was fresh and would interest you. Learning more, however, of the views of the gentlemen who have organized these lectures, and being led to believe that some good might be done by even a weak word in season, I have willingly come to you, though at personal inconvenience, and I ask your kind and serious attention on the ground that the subject of my talk is of the utmost importance to every man, woman, and child in the kingdom, let their position in the social scale be what it may. The public health is a public question, and a matter of the deepest public interest. The well-being of the whole must depend on the well-being of the individual. When we call down Happiness on the head of our friend or benefactor, we put Health before it,—Health and Happiness to you," is the cry,—and well we may do so. The rich man without health has little, the poor man has nothing.

As with the separate members so with the state as a whole. The state that is not healthy decays, and weakens, and perishes.

"It fares the land to hastening ills a prey,
Where wealth accumulates, and men decay."

And how have we shown our appreciation of this fact? By careful teaching and careful tending? By removing all adverse influences and guarding each bud of promise till it had reached an age of strength? On the contrary, by the most culpable indifference and neglect, the most profligate waste of energies and life. Men, women, and children are exposed, and expose themselves, to circumstances under which healthful life is impossible; under which decency and virtue are little less so. Much has been done of late years to render widely-known the simple fact that people cannot exist without air, and moreover that the air must be renewed; must be pure. It has been written and printed, and shouted, that air which has been breathed is no longer fitted to sustain life. Dip a lighted taper into a bottle and it will burn for some

time, but fill the bottle with your breath and the taper when put in will be extinguished. The same gas that is needed to keep the taper alight is needed for respiration. Without oxygen the lamp of life also expires. You all know this every one, we might suppose, knows this. Nevertheless, thousands and hundreds of thousands do constantly in direct violation of the requirement. An examination of the way in which human beings are herded together in towns shocks and startles.

"Overcrowding" means want of pure air, and want of pure air means debility, continued fever, death, widowhood, orphanage, pauperism, and money-loss to the living. It ought to be unnecessary now to give proof of its deadly doings: still, it may be well to recall the facts of the incident in the military hospital at Versailles, where for several years, in a certain month, being about a week after the arrival of the king at St. Cloud, there regularly occurred a fatal epidemic of typhoid fever among the soldiers. It never attacked the civil population, nor the officers. The cause was simply overcrowding. The garrison ordinarily consisted of about 500 men; but when the king came the number was increased to 1,200. The inmates were in consequence closely packed in small rooms, and fever and death came at once amongst them. The non-commissioned officers, better fed and never sleeping more than two in one room, escaped.

I have recently revisited a court in Drury-lane described by me several years ago. It is now nearly as bad as it was then. Every room is thickly occupied. The inhabitants are of the dangerous classes. Haggard and drunken women, with every trace of womanhood gone, are in the pathway; and there are swarms of children, some trained to begging, and others, it may be feared, to worse. In the majority of the houses the rooms are small, and the staircases are narrow and without ventilation. In two of the houses, 37 persons, I was told, lived in each, but it would probably be nearer truth to say that each house of 8 rooms contains on an average, including children, 40 persons; and as there are 21 houses, we have here 840 persons of the worst class pent up to their own destruction and the danger of the public. I will not distress you with any description of the condition of the inmates.

In a decent-looking house in Islington, occupied by workmen and others, I found that 9 persons slept in one of the rooms (12 ft. by 14 ft.), a father, mother, and 7 children. If shoemakers worked in the attic; and in each of the other five rooms there was a separate family. I could quote scores of such cases of overcrowding in what would seem to be decent houses, but the repetition might tire. No words, even aided by the pencil, can give a full idea of some of the dens which are occupied by a lower and different class: many born to evil, and without the power to rise; others the victims of more recent misfortunes or their own conduct. The world has still an interest in improving their condition: children as yet innocent cry aloud to be rescued from the otherwise inevitable gulf. In some places in the eastern districts quite recently visited I have found 11, and in three cases 14 persons occupying a single room. By the Sanitary Act of 1866 power is given to authorities to interfere and prevent such cases of overcrowding, but the difficulties in the way are found to be great and comparatively little has yet been done.

700 cubic feet is shown to be the smallest space, under ordinary arrangements, that will afford one person healthful sleeping-room. In apartments such as I have described, the occupants have not one-sixth of the required space. In hundreds of rooms that I have seen, each occupant had not more than 80 cubic feet! The drawings I now show you will give you some idea of these places.

Some of you may perhaps fail to see the connexion between overcrowding, evil structural arrangements, and disease. When, however, you find that in one part of a certain parish, for example, where the conditions are good, twelve die annually out of 1,000 living, while in another division of the same parish, where the conditions are such as I have described, twenty-eight die each year in 1,000, the connexion must surely be obvious. Some dwellings furnish a regular supply of fever-cases, which supply stops when structural improvements are made. It may be affirmed that there are thousands of houses where health, decency, or virtue is scarcely possible.

* Paper read before Society of Engineers, April 9, 1866.

† Natural Laws of Husbandry, p. 138.

* Rep. Met. Sewage, 1861: 4540.

† Rep. Met. Sewage, 1861: 4739, 4933-36.

‡ To be continued.

When the difference effected in death-rate per thousand living is mentioned, it may not convey to all my hearers its full meaning. A few words will serve to make it more obvious. The annual death-rate to 1,000 persons living in London in 1867 was 23; in Manchester it was 31 to 1,000. If we call the population of Manchester 250,000, it will be seen that had the same rate prevailed as in London 2,000 fewer persons, under Providence, would have died there in the year. The fact that the death-rate of the small towns and country parishes was only 17 per 1,000 during the year, and that even there many conditions not favourable to health are allowed to exist, shows how much sanitary work remains to be done in the large towns. Lessening the death-rate of the metropolis by 1 in the 1,000 only, means saving about 3,000 lives *per annum*,—a very serious matter surely. The Act for regulating common lodging-houses has worked very well: fevers have ceased to infest them; and the manners, even, of those frequenting them, especially with reference to the provinces, are much improved. Similar good results will follow the exercise of proper supervision over other houses let to various families. The Act that gives the power was greatly opposed on the ground of interference with private rights and the inability of the poor to afford better lodgings; but as I ventured to urge in various directions at the time, a man is not permitted to knock on the head those who are dependent on him because he is poor; neither should he be allowed on that ground to kill them with bad air, and set up a fever-still for the benefit of his neighbours. "An Englishman's house is his castle," is a good saying; but, surely, it should not protect the ill-doer.

Typhoid fevers continue to be destructive of life, and that, too, not so much in the dwellings of the poor as in those of a higher class. It is clear to all who have well considered the subject, that these diseases result from the neglect of sanitary laws. The parish inspector, the medical officer of health, and the sanitary police have been at work in the courts and alleys, crowded back-slums, and common lodging-houses, and have effected great improvements in many quarters,—lessening the prevalence of disease. It is not too much to say that the inspection by competent persons (armed with certain powers) of the town and suburban dwellings, of all classes, indeed of dwellings in the country too, will be productive of the greatest advantage.

I should be glad to say something of the workplaces in which many thousands of young girls pass their lives and are destroyed; milliners, artificial-flower makers, feather-dressers, and others; but time will not permit.

To discover the cause of preventible illness in many cases is difficult; it needs technical knowledge in the observer. The close proximity of the cesspool and water-supply is the unsuspected cause of an immense amount of illness and death. Years ago I brought forward cases in proof of this, and the belief has been terribly confirmed more recently. The history of the Broad-street pump, Soho, afforded striking examples; as did the outbreak of fever at Terling, not yet stopped. [The speaker then gave some particulars of this disaster, and the lessons to be drawn from it.]

Some matters in our own houses call for notice from the Health point of view. As, for example, bad foundations, permitting dampness; thin and porous walls,—contributing to the same evil, and increasing the cost of firing; defective drains and traps; want of ventilation—supply of pure air and removal of bad; insufficient height of rooms; want of pure water; wasteful means of heating; smoky chimneys; want of light (dark rooms give a larger amount of sickness than light ones); and the defective paving of yards and areas. Never allow a trap to be open. Never close a fire-place. Evil is often produced by the damp site on which buildings are placed; and yet, at the present time, new streets may be seen where the scavengers are depositing liquid sweepings, masses of decomposing animal and vegetable refuse, and other abominations; and upon these, presently, the walls of houses will be raised, without the slightest arrangement to keep down the moisture, or prevent dangerous exhalations.

[At this point of his address, Mr. Godwin said he had seen some things that day in Brighton which had greatly shocked him; not because they were worse than might be found elsewhere, but because one expected to find in Brighton all the arrangements for perfect health: one expected to find in a place situated geographically

and geologically like Brighton all that which would bring about a good state of things. One would not, he said, expect to find in such a town as this any health-destroying back-slums, or any small rooms filled with people without the possibility of air getting access to them. He then described the condition in which he had found Dorset-street, Thomas's-street, Derby-place, Pimlico, Claremont-street, Carlton-street, and Orange-row: in some cases badly drained, and in others ill supplied with water, although there was a good supply of the latter in other parts of the town. Improvements were most seriously wanted in these smaller districts of Brighton: the houses had no opening, no windows at the back; and the rooms were so small that persons were living where it was impossible to retain health; without which happiness was quite out of the question. He was glad to hear of the existence of the Brighton Sanitary Association, and the good it had done; and of the appointment of a medical officer of health. ("We haven't one.") "Then the sooner you get one the better," said the speaker; and he proceeded to state that what had been done had lessened the death-rate in Brighton from 25.8 in 1865 to 21.7, which meant that 300 persons were saved during the year. But the notion of finding a death-rate of 21 in 1,000 in a place like Brighton was simply preposterous. He had no desire to reflect upon the authorities; he knew the difficulties they had to contend with. But it was desirable they should know the effect the state of parts of the town had upon a stranger.]

I have already alluded to the effect upon the inmates of such dens as have been described. An assertion that I ventured to make some years ago, "As the home, so the people," is beginning to fix itself in the popular mind. It has been made the text of essays and the motto of associations. Widely admitted, it would be certain to produce good fruit. I have tried to add to this another:—

To drain and pave,
Means raise and save.

The connexion, perhaps, is not at once obvious, but it is, nevertheless, undeniable. Drainage alone will not do everything, but it is an important first step. There is evidence from Salisbury, Ely, and other towns that hundreds of lives have been saved by the improved drainage introduced.

As the education and the training, so are the children; as the children, so are the men and women. If we would have the sons of the struggling classes grow into orderly, sensible, and striving citizens, we must give them a road out of the slough, show them the value of order, and furnish them with weapons for the strife. Moreover, in a limited island-space such as that of Great Britain, the true greatness of the nation and its ability to sustain its poor could not but be vastly increased, were the foundations of life well and securely laid by improved arrangements promotive of health and vigor, so as to raise the samina of its manhood to a high pitch. And it is not the improved condition of the matured man alone that would thus be realized: the fact that vigorous parents lead to a vigorous progeny is no less obvious; and thus the nation would improve, physically speaking, in an accelerated ratio, were more care and attention given to the rearing of infants. The condition in which thousands are now brought up is fearful to contemplate. The result is what might be expected. Beneath the feet of society exists an army of ruff and desperate men and women, unsuspected and unheeded for. They are to be counted in thousands. An execution or a local riot sometimes brings them into daylight and the streets; but at ordinary times they are to be found only where they live massed together, and under such conditions that improvement is impossible. From the vice-producing quarters to which I have referred, the prisons are supplied, and in these places the convict, when liberated and in prison, finds his ease of operations in continuing what he considers the business of his life.

Whatever is spent on education is saved twice over, and more, in prisons and police; to say nothing of the mighty saving of misery and life. This is pretty generally admitted. But we are very slow to act upon it. Some of the hinderances are found where one would scarcely expect to discover them. When all things are ripe for a large extension of the blessings of education, even Religion and Conscience step forward, and, with a resist-to-the-death expression, bar the way. Not that they are opposed to education; they have got beyond that after long reflection; they

desire that education should be given, but it must be their own sort of education, and mixed up with their own menstrem.

And so neglected weeds grow apace, and instead of corn we get deadly-nightshade: instead of men and women with honest hearts and clear minds, we get "roughs"; and from roughs come burglars, garotters, and murderers.

The cost of crime is enormous; in fact, it cannot be counted. It operates in a hundred ways. The expense of the machinery towards punishment of crime alone amounted in 1866, according to judicial returns, to three millions.

Three millions sterling *per annum*, and this is not all. Another million, at least, should be added for the interest of money expended on buildings, the salaries of various officials, and items. And each year it becomes greater!

Convicts in England, according to returns, cost 34l. 7s. a head per annum. What do they cost the country when they are free? The number of the criminal population in England and Wales was computed in the year 1864-5 to be 145,000, and I believe this to be enormously under the mark. Including beggars and persons subsisting by other disgraceful means, the number has been calculated at 250,000. Let us, however, take the first to be the number, and say there are 145,000 persons, 117,000 of whom are at large, destroying instead of producing, living upon the industry of others,—taking from the community instead of giving to it. World 60l. per annum a-piece be too much to put down as the loss caused by them to the community? No, nor enough, and yet at that sum we get nearly six millions to be added to the other four millions; or ten millions sterling a year, the cost of crime. If part of the cost of pauperism were added to this, as it might fairly be, the amount would be raised some millions more.

It is from such homes as we have contemplated that the ranks of the dangerous classes are recruited day by day. It is a disgrace to us that we should have such a class as "roughs";—it means short-sighted parsimony and criminal neglect. The thousands of children running the streets of London and other places may be very nearly what we choose to make them. Humanity, Christianity, economy, self-interest, are all in favour of rendering them decent members of a society. See that every child be awakened to a perception of the difference between good and evil, and receive the elements of knowledge. As the education and the training, so, I venture to repeat, are the children; as the children, so are the men and women. Improve the homes, raise the standard of health, and teach the children, and we shall soon cease to have "roughs";—we shall soon lessen the numbers of the dangerous classes.

It would be a saving in money, a saving in misery beyond calculations, if the unheeded-for Arabs of our streets were gathered up and sent, at the country's cost, to the best schools in Brighton. Children have been called the poetry of the earth; beams of light; and "living jewels dropp'd unstrain'd from heaven!"

"Childhood is the bough where slumber'd
Birds and blossoms many number'd."

If society get but a deformed and hurtful stamp instead of a flowering, gladdening, good-giving tree, the blame and crime are society's own. Every child is a white page on which may be written good things; an impossible mass which waits to receive beautiful forms. The blame be on those who permit the page to be blurred, and the forms to be made repulsive. Children are the sacred trust of the State. The neglect of this trust—a great sin—brings its own great punishment. There is danger to the State in the increase of large masses of neglected poor; and these masses are supplied from the heaps of neglected children who survive the dangers they are exposed to.

It is of the utmost consequence that a knowledge of the laws which govern human life should be given to women. A frightful loss of infant life occurs through their want of this knowledge. The difference in the proportion of deaths amongst infants in various localities shows that this loss is unnecessary. Thousands of preventible deaths which occur, both in London and the provinces, from other than sanitary imperfections, are clearly to be traced to the ignorance of the mothers of the simplest principles of healthful management. In the schools in which the future mothers of the next race of English workmen are being educated, attention should be given to the instruction of the young, not only in sanitary matters, but as to the structure and

functions of the body. To the mothers we have to look for the education of the world. "When shall I begin the education of my child," said a young woman once to a wise man; "it is now four years old?" "Madam," he replied, "you have lost three years already. From the first smile that gleams over an infant's cheek, your opportunity begins."

Our workhouses, hospitals, manufactories, all need improvement. There are fairly-arranged hospitals on very bad sites: there are bad hospitals on comparatively good sites; but there is hardly an instance, in this country at least, of both hospital and site fully embodying those sanitary principles which are essentially necessary for the rapid recovery of the sick and maimed. Air of sufficient purity is not to be obtained in towns. Every existing town hospital ought, therefore, to be removed into the country, if it be possible to do so. At a moderate distance from towns land is much cheaper than in close-built places; and there are many large hospital establishments covering considerable areas of ground in crowded and valuable parts of towns and cities, which might be removed to the country not only with incalculable advantage to the sick, but with great pecuniary gain to the hospital establishment. Even in so vast a place as the metropolis, a few casualty wards, where accidents might temporarily be seen, rooms for the examination and the reception of cases, and suitable vehicles for transferring them to the country, would be all that would be necessary to effect the reform. A great mistake has been committed, as it seems to me, in the choice of a site for the new St. Thomas's Hospital.

The fundamental idea of all hospital plans ought to be this,—to have pure fresh air in every part of the building. Fresh air is the *sine quâ non*.

Unless a building be so planned that the sick shall breathe air as fresh within its walls as they could do externally, they will suffer in a ratio corresponding to the degree of impurity. The infirmaries of many of the workhouses are in a most, discreditable condition, and call for immediate improvement.

Do not be impatient of taxation for sanitary improvement. Illness paperizes and demoralizes. Better sanitary arrangements would lessen poor-rates immensely.

A Bill is now before the House of Commons, brought in by Mr. McCullagh Torrion, which would give power to authorities to enforce the removal of houses dangerous to health and life, and enable them to afford facilities to societies willing to rebuild or re-arrange them in a fitting manner. It is to be hoped that it will become law.

Repeating an observation I have made elsewhere, I would say, in conclusion, that it is scarcely possible to estimate the amount of misery, remorse, and crime produced by unhealthy houses. Apart, however, from the avoidance of extreme evils—sickness and death—a home should be a place of repose, cheerfulness, and comfort, where the worker may gain fresh strength and energy for the daily struggle. Dulness, gloom, apathy, ill-temper, will not produce this. We all know what trifling matters will change a career, and that the misery of a life may be born of a chance observation. The connexion of these remarks with our subject will be seen at once. Amidst had domestic influences the spirits flag, the temper changes. Breathing bad air, suffering from the effect of damp, the world looks dark, the heart is heavy; cheerful effort is out of the question; kindly companionship is withered; and jangle and anarchy take the place of mutual encouragement and healthful converse, which develop the affections and powers. The occupants of such houses as we are contemplating do not live; they only pass their time—and a very bad time it not seldom is. Life, which should be a blessing, is often made a curse by an unhealthy house and its consequence—an ill-ordered home. Besides remedies of evils referred to, we want also more colour in our houses, pictures, flowers, and a garden; the effect of these on the spirits, and so on the health, the thoughts, and the habits, is greater than some imagine; and the same argument will apply in calling for the well-ordering and proper adornment of towns.

To ensure the largest amount of general happiness, let us do our best to promote the general health. And this, after all, is not wholly unselfish; for happiness, it has been said, is a perfume that you cannot shed over another without a few drops falling on yourself.

At the close of the address the chairman (Mr.

Fox), Mr. Thorncroft (assistant overseer), Dr. Füssel, and others, in very interesting speeches expressed their entire concurrence in the remarks of the speaker. Mr. Councillor Davey, chairman of the Sanitary Committee, stated the healthy in every respect. A vote of thanks, moved by Mr. Henry Willett (who in the course of an able address, said he had hoped to see more of the clergy present), was given to Mr. Godwin, who thanked his audience, and moved a vote of thanks to the chairman, which terminated the proceedings.

EXCAVATIONS ON THE PALATINE.

AFTER the preamble on the earlier undertakings in the search for antiquities on the Palatine, we may take a brief review of what has hitherto been achieved within the Farnese grounds by the works ordered by the French emperor, and under the direction of Signor Rosa. We cannot attempt to support all the theories advanced by that learned gentleman, as the inscriptions on posts, like sign-boards, indicate according to his conclusions respecting every ruin and every site. In most instances there is little or nothing in the ruins extant to announce their character, save in respect to the magnificent fragments of cornices, friezes, pavement, and glances, in an extent of low structures, interspersed with a few loftier piles of brickwork, a column, and great variety of such marble debris as manifest the former splendours of halls and imposing ruin-masses stand in the gardens not comprised within the French property, where the totality of hitherto excavated remains has rather, indeed, the appearance of a vast ground-plan, traced in lines of brickwork, and more or less occupied in every part by the remnants saved from past grandeur, than that of an excavation presenting any unity of design or architectonic effect. It is evident that the Cæsars, one after another, successively destroyed, or at least disregarded, the erections of their predecessors; the buildings of one being contradicted by or sacrificed to those of another, without regard to the symmetric character of the whole; and in many instances, more ancient—some, indeed, very richly-adorned—structures being reduced to mere foundation-works for the support of the imperial chambers raised above. Thus the vaulted halls, to which we descended at some depth, and which were long erroneously designated "Baths of Livia" (see *Corinne*), attest by the beautiful decoration of their ceilings, in fresco-painting and gilt stucco-relief, a manifestly palatial in these interiors, left for ages inaccessible, since their sacrifice to more important buildings raised above them, but now the art-works of the past, may be referred to and are now, though unattractive, seen by daylight; their decorations having much suffered, evidently belong to a suite, the entrances and other parts of which are recognizable; and the deep vertical channels along the walls, for wood-work, as apparent, gave rise to the popular error respecting the imaginary "Baths." We may begin, however, from the approach to the terrace in front of the villa built by Pope Paul III., a pleasant residence looking east and westward. An extent of lofty halls still retaining their roofs, divided into parallel aisles, of irregular in scale and plan, are entered from the lower level, southwards, below the elevated site of that villa: nothing could be more dismal than those interiors, the inner range of which can never have received natural light save through the doorways communicating with the outer. It is probable they are the buildings of Caligula, or the structures forming a new front above the Via Sacra, raised by Vespasian after he had destroyed the greatest portion of the vast Neronian palace. Farther to the south opens a wide which ascends a steep road, with its massive ancient pavement, and recognised as the *Via Nova*; the ascent at this point, as the *Summa Porta Magonia*, one of the three (or, according to some writers, four) gateways in the walls

of the city ascribed to Romulus. To our right, as we follow this road, rises from the hollow an enormous mass of concrete, or rubble work, propped up in the lower part by brick and hewn stone work, manifestly of very ancient date, and which Signor Rosa identifies with the terraced-substructure that supported the temple of Jupiter Stator, vowed by Romulus before the battle with Latius (Liv. i. 12), and rebuilt in fulfilment of another vow by Attillus Regulus, Consul, according to his engagement, self-imposed, before the Samnite war (Liv. x. 36-7), this restored temple having stood from A.U.C. 458 to A.D. 65, in which year it was destroyed by the fire under Nero. Arrived at the summit of the ancient way, past the site of the Porta Magonia, we reach a vast extent of roofless buildings extending to the western ridge of the hill, and supposed the palace of the Flavian emperors, begun by Vespasian, continued by Titus and Domitian, with the character of which period in art the rich decorations, here found in marble fragments, well accords. Among these quadrangular buildings is a peristyle, once surrounded with columns, and evidently rich in decorative details, supposed the *Comatio Sicilia*, where Pertinax was surprised by the Praetorian guards on the day of his death. Another is styled (we quote from the sign-boards) *Jovis Comatio*; another, *Tablinum*; another, *Atrium Publicum*, as the edifice thrown open to the citizens by Nerva (Pliny, *Pomegry, Trajan*), and one of the smaller interiors is recognised as the *Lararium* by its altar still erect, with reliefs of religious ministers. Rich and varied are the decorations in the larger halls, the friezes, cornices, graceful candelabra of white marble, and intarsio pavements in geometric patterns, filled up with porphyry, serpentine, giallo antico, &c. Here and there we see portions of incrustation, showing a correspondent surface of coloured marbles, particularly the Numidian *giallo*, on the now reduced walls. Some mutilated husks of good style are seen, among other such relics, on plasters thrown up for their display. At the western ridge of the hill extends a series of terraces, which appear to have been reached by steps, leading probably to a portico, that may have served for contemplating the spectacles in the Circus Maximus, that lies below.

The character of one interior, as a basilica, with its semicircular recess for the tribune, remnants of a marble screen in front, and also of the columns that divided its area into three aisles, is sufficiently evident, and justifies the conclusion that this may be the Basilica Jovia mentioned in the Acts of two martyrs, Silvester and Lawrence, who suffered A.D. 264; and further westward we enter a roofless court, designated *Nymphorum*, with an ample elliptical structure for a fountain, in two stories, the higher surrounded by niches, once adorned (we may suppose) with sculpture, the lower with a broad channel; some portions of massive fluted columns, of giallo antico, remaining here to attest the richness of architectural details at the pleasant spot where Cæsars and their empresses may have whiled away the hours of summer-heat. Beyond this range of hills, westward, rises a restored colonnade, Corinthian, with shafts, in Caryatian marble monoliths, on bases here found, immediately below which, on the further side, we look down into an *stys*, where a monument of imposing character, and evidently high antiquity, meets the astonished gazer,—two lofty interiors, divided by a rectilinear wall, built in square-hewn blocks of lithoid tufa, the masonry like that of the *Tamliarium* in the capitol, and supposed referable to about the same date, within the century before our era, or about the period of Sylla (138-78 B.C.), the origin and purpose of this solid structure being now pure matter of conjecture, though we must certainly assume some edifice for public reduced to a mere cellar, or foundation, for the support of later buildings. Beyond extends an area with fine intarsio pavement, supposed a library; and further, immediately at the brow of the hill, another roofless interior, surrounded with a ruinous circle of terraces rising stepwise, which Rosa designates as an academy or hall for declamations, where classic poets may have recited their verse to imperial and courtier audiences. North-eastward from this point we descry another ample terrace, the site, no doubt, of some conspicuous building that stood in the centre, on a lofty basement of concrete, supported by buttress walls of peperina stone, with several portions of fluted shafts, in the same stone, and other architectural fragments, ar-

anged for view upon the spacious level, here being recognisable the stylobate of a temple, which Rosa identifies with that to Jupiter Victor, vowed by Fabius Maximus during the third Punic war (Liv., x., 29), and which stood from the year of Rome 439 till at least as late as the close of the fourth century, being mentioned by the Regionaries. The festival of Jupiter Victor, held on the Ides of April, is described by Ovid in the "Fasti," l. iv. We must turn back in the direction whence we started, to visit, at a point nearly central, a long walled corridor, evidently subterranean from the first, now, indeed, almost totally deprived of its ceiling, which we see was covered with coloured mosaics, representing birds and other ornamental designs in compartments,—a building supposed to be of the time of Tiberius, and to have served for private communication between different wings of the palatial residence; some noticeable detail here—the restoration, in coarse, careless work, of the original black and white mosaic pavement—leading us to infer a comparatively late appropriation of this corridor. It is apparent, and especially at this point, that the Palatino was divided by a wall into two portions; the height to the south called *Summa Velia*; that to the north, *Germalis*; the imperial building having long concealed this natural formation; and Tiberius's covered way serves to unite the two, or rather the edifices overlooking that valley from opposite terraces. Here, too, was found a plain massive altar, circular, with a shell-like cavity at the summit, and dedication, inscribed in large letters by the pontifex, Cneius Domitius Calvinus, a personage conspicuous in the wars between Caesar and Pompey. Further northwards we reach the *Aguradorium*, assumed site of the Augustan College, which was restored by Hadrian, now reduced, in fact, to little else than an apparently natural mound, with terraces-summit shaded by ilex trees. An epigraph, relating to that college, was found near this spot (see Gruter's series) confirmatory of its local claims. And from this point we overlook a long extent of low vaulted chambers, all on the same plan, and with the rudest species of black and white mosaic for pavement, referred to the buildings of Tiberius,—perhaps the ground-floor story inhabited by slaves in that emperor's addition to the Augustan Palace. As we skirt the hill side, westward and northward, our attention may be distracted from things near to the beauty of nature and of the distant city views, the Jovianic height, the winding Tiber, the Trastevere quarter, the Capitol, and the Forum, with many of the monuments that attract all Europe to those historic sites; but the most striking group of imperial ruins is that which suddenly spreads before us on our arrival at the north-eastern angle of the Palatine, overlooking the Forum, or, rather, its southern portion. Here we find ourselves in the upper story of two vast systems of building, divided into lofty vaulted halls ranged parallel, and only lighted from the entirely open side by which each is entered, the two stories being utterly without accordance in plan and symmetry in design, even the partition walls falling to coincide; the higher and more recent having been built without regard to the lower story—and here, as so often observable elsewhere among the Palatine ruins, one emperor's work precisely answering to the purpose of spoiling, in effect at least, that of another. It is the great wing added by Cneius Calpurnia, who first extended the imperial buildings to this side above the Forum, that we recognise in the lower structure; that of Nero, raised above and absorbing his predecessor's works, in the upper. Some remains of painting, two groups of figures, and stucco reliefs, in panels on the vaulting (the latter, in the lower halls, particularly graceful), remind us of Pompeian art, and may well be ascribed to the Neronian period.

These gloomy halls seem to penetrate into the heart of the hill, range within range, the innermost, in some instances, lighted by orifices at the roof, but for the most part in darkness only dispelled by the faint light struggling for entrance through doorways from outer chambers. In those where daylight prevails have been erected the few sculptures, busts, and other fragments here found, on antique pilasters. Portions of a marble grating have been placed along the edge of a terrace that traverses the higher story, and which, we are told, is no other than the bridge ordered by the insane Caligula to communicate between his palace and the Temple of Jupiter in the Capitol. The ominous gloom of these imperial halls, now rather like cavernous excavations than the abodes of,

sovereign grandeur, accords well with the darkest memories and most horror-striking deeds that cast their shadows over the story of guilty despotism in Rome. Along the ground-floor, near the north-eastern angle of the hill, extends for some distance the ancient pavement of the *Clivus Victorine* that passed through a gateway, *Porta Romana*, one of those in the primitive Romulean walls, now represented by a restoration in brickwork of the imperial period. Returning to the villa of Paul III., we observe on the platform before its western part the lower part of a round chamber, called *balneum*, and probably one of the bath-rooms in Caligula's palace. Not far off is a pile of brick ruins, quite isolated, long supposed the sole remnant of Augustus's Palatine library, as seems confirmed by the discovery, in digging beneath that spot, of columns in precious marble and fragments of colossal statues in basalt (see Burgess's notice of these made in 1720); and, farther to the south, near the limits of the Farnese estate, Rosa places the Temple of Palatine Apollo, some portion of the stairs before whose front he has seen (as he tells us), beneath the road that ascends towards the Convent of S. Bonaventura, from the arch of Tivoli. We may be sceptical before such designations, on the placards put up by the learned director, as the "staircase of Cacus," the palace "where Tanquilla addressed the people from a window after the death of Tarquinius Priscus" (Liv., i., 41); the site of the house of Cicero, on the slopes overlooking the Via Sacra, may be admitted; but when we are required to believe that on a grassy platform, north-westward, stood the "Tugurium Faustuli," or cottage, where Romulus passed his childhood, we may ask whether modern Roman antiquarians can to this day persist in ignoring the school of Niebuhr, and all the attainments of thought and research due to the impulse given by that historian?

Before leaving we should visit the museum of sculptures and other antiques found in the course of these works, now occupying an out-house of the villa, most noticeable among its contents being the casts from originals already taken to Paris of a torso, one of the many replicas, from the celebrated Faun of Braxilles, and of another figure (little more than a torso) of a winged Cupid, with quiver and bow, the latter object inferrible, but no longer seen; also some expressive busts, and a graceful draped female figure, probably a Venus, still left in the marble original; besides columns, lamps, glasses, and every species of coloured marble, alabasters, &c., in the profusion found in so many similar Roman collections. We should advise the visitor to choose for Palatine rambles the hours near sunset of an autumn or spring evening, when the effects of light and shade among these labyrinth of ruins, and the solemn beauty imparted by the hour to monument and mountain, to city and landscape, seen from these grounds, cannot fail to impress and delight,—to remain in memory among the unforgettable things of Rome.

Roma.

THE MUNICIPAL OFFICES OF LIVERPOOL.

In our last volume* we published some descriptive particulars of the large building which has been erected by the Corporation of Liverpool with the object of concentrating all the various municipal establishments, which have hitherto been scattered over the town, to the serious inconvenience of the public. We now give an elevation of the building and the two principal plans.

We may repeat that the building is a quadrangle, comprising about 4,800 square yards. The style is Corinthianesque, treated freely, the capitals being composed from English forms instead of the acanthus. The height of the building to the upper cornice is about 60 ft., and to the roof of the pavilion between 80 ft. and 90 ft. A tower, about 200 ft. in height, rises from the centre of the front.

The cost of the building, without land or furniture, has been about 100,000l.

The contractors were, for the brick-work, Messrs. Holme & Nicol; stone-work, Messrs. Parker & Son; carpentry and joinery, Messrs. Haigh & Co.; plastering, Mr. Jones; plumbing, Mr. Credlin; warming and ventilating, Messrs. H. Price & Co.; bells, Messrs. Warner & Sons; clock, Messrs. Penlington & Hutton; &c.

The building was begun from the plans of Mr. John Weightman; but has been almost entirely carried out by his successor, Mr. E. R. Robson, the present architect to the Corporation.

The building is occupied; but the spire is not yet wholly completed.

The following references show the appropriation of the various apartments:—

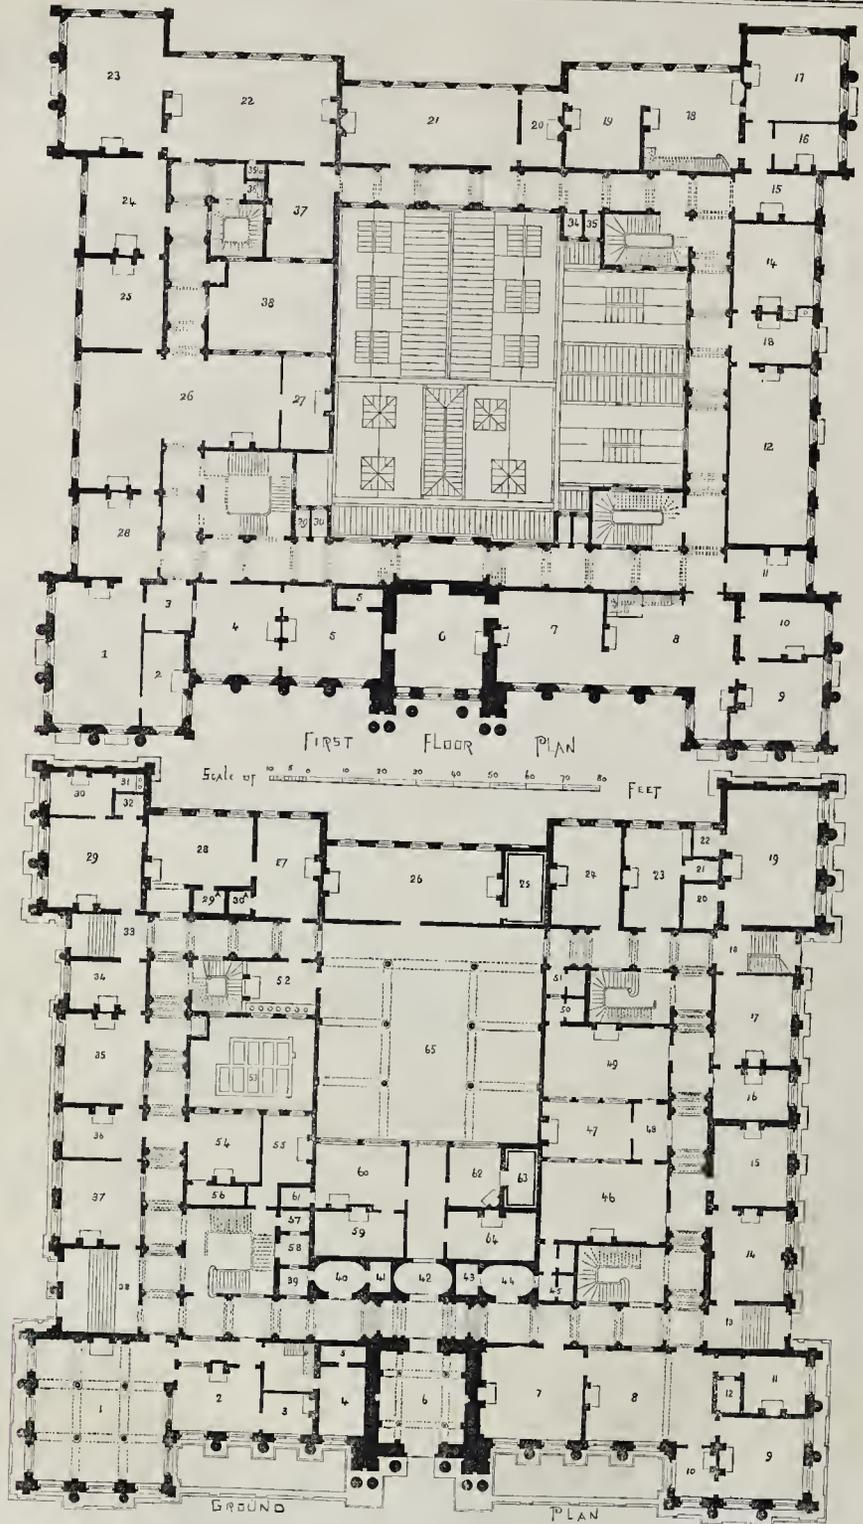

- Basement.**
Under rooms, ground floor, Nos. 1 to 5. Treasurer's store-rooms.
Under Nos. 7, 8. Joiners' shop.

THE MUNICIPAL OFFICES, LIVERPOOL.—MR. E. R. ROBSON, AND THE LATE MR. JOHN WEIGHTMAN, ARCHITECTS.

"SHARROW CHURCH."

THE architects of this handsome church are Messrs. Blackmoor & Mitchell-Withers. In connexion with the illustrations of it published in our last we gave the name of Mr. Mitchell-Withers alone.

THE STAGE.

Royal Princess's Theatre.—The revival of Mr. Boucicault's version of "Jeannie Deans," has proved quite successful. The trial scene is as effective as ever, the adapter appearing as the Counsel for the defence, and the firing of the Tolbooth at the close was so real, that some of the theatrical critics present on the first night expressed their belief that the intention was to burn down the house and get rid of them all at a blow, or rather a burn. Mrs. Boucicault as Jeannie Deans, touches the hearts of her audience more than once; and Mr. Leeson makes a quaint Dumbdiekes. Mr. J. G. Shore (*Arvyll*), Miss Litton (*Effie Deans*), and Mrs. Chas. Harcourt (*Mrs. Murdochson*) deserve a word of praise.

St. George's Opera-House.—Mr. German Reed's season terminates on (this) Saturday evening, March the 28th. We must congratulate Mr. Reed on the success of it. His endeavours will, we hope, lead to the permanent establishment of English opera under his spirited direction. Madlle. Liebhart's engagement was a capital move.

THE UNIVERSITIES AND ART-TEACHING, BY AN ARTIST.

ONE of the advantages of public discussion consists in obtaining individual experience and conviction, for where so many conflicting interests and opinions exist, education may be compared to a figure not only having many sides, but like one of those cut crystals which glitter at every angle, so lucid and imaginative that the mind's eye is dazzled by its contemplation.

As an artist, it is natural that I should look at the question in an artist's point of view, and I am fully aware that people are as easily apt to be led away by their pursuits as by their feelings.

Education is a work of the *mind*, mind in the abstract having no material existence visible to the human eye. A substance must be given to thought—an image (so to speak) to the intellect—before it can be made transferable, just as a Bank of England note which, in itself, possesses no intrinsic worth, is the representative of solid metal.

There are only two ways of doing this, viz., by the language of *form and words*. A thing speaks for itself—is a recognised fact—the surest record of its own integrity—an acknowledged testimony of a truth—a mirror to the mind.

On the other hand, "a man may possess all the tongues which Babel cleft, but if he have not a knowledge of the *solid things* contained in them, as well as the words or lexicons, he is no more to be esteemed a learned man than a yeoman or tradesman completely wise in his own mother dialect."

Why education should be so exclusively conducted as an affair of books, no reasonable cause can be assigned; for words, in themselves, either in their structure or likeness, convey no idea of things; and to attempt to educate people only through books is like trying to squeeze a kilderkin into a half-pint measure. Books cannot alone contain education; and it is a question, more especially in the exercise of the industrial arts, worthy of consideration, how much the world has gained by the invention of printing, in so far as the *solid things* are concerned.

If the ancients were worshippers of wood and stone, in the present day we are idolators of words. Ancient mind is revealed in form as well as letters. Phidias and Socrates, the two greatest men of almost any age, were by profession both sculptors, as well as priests and philosophers. Each died in prison, a martyr to his mission—the elevation of mankind.

In the language of form, Wisdom was represented springing, fully armed, out of the head of Jove, and placed on the Acropolis, as the presiding Deity of Athens. In words, "Wisdom," says Solomon, "is the image of God"—each an example in its own way, an expression of mind. Taking, however, still higher, the highest ground, for revealing the most sublime and

sacred truths, God himself hears testimony of Himself in like manner; for "as words are the image of our intellect," even so was Christ "the express image of God. He was begotten of the Father, even as our words are the children of our intellect." "The word was made flesh."—"This is my body," &c., &c.

And yet, with all this clear evidence, both Divine and human, of a great necessity, the language of form is not even recognized, or its most simple and elementary principles taught in our schools or universities, otherwise than as a mere accomplishment; whereas, on the Continent, large provision for education in art, as an essential accompaniment to all intellectual cultivation, is made, not only in the more professional schools, but in every school, and of every grade, each in proportion to its grade and object. In the elementary school, the purely people's school, elementary drawing fitted for the people's purposes is taught. In the district provincial secondary school this preliminary instruction is further developed. In the college and university, whilst opportunity is given for its manual cultivation, a higher object is aimed at—the philosophy on which it rests, and by which it is regulated, both intrinsically and in its relations to the other departments of human thought and action, is pursued. There is scarcely a university without its regular chair of aesthetics, its gallery of casts, drawings, and engravings, as well as library, to which the student can refer from the pages of his author for illustration whenever he needs. It is something to study antiquity in this double mirror,—one day dwelling on the fatal fortunes of Læocœon and his sons, in the impassioned lines of Virgil, and the next pursuing and completing the poem in the still more powerful production of the statuary. Our classical education is not a knowledge of its antiquity; it is scarcely a knowledge of its classics: they know the language of words, but they do not know the language of form; they leave out one-half of ancient mind. It is not by mere mechanisms of versification the solid things can be appreciated, or as a philosophic graphic expression of the general intellectual and moral elements of the age and country.

Without such accompanying inquiries, no one can understand Homer or Virgil as Homer or Virgil ought to be understood; it is not merely to understand, but to appreciate, both through philology and art. The spirit is not less written in the Venus, Læocœon, Apollo, the Elgin and Egina marbles, than in the pages of Hesiod, Homer, or Horace.

Æschylus, and Sophocles, and Euripides have no nobler—nay, truer—commentary, more steeped in their own spirit, more thoroughly, more accurately themselves, than the myths of those splendid vases, which are the admiration of mankind, and without their aid it is vain to hope to reach, through the language, the literature, much less the general mind, of a country.

Science undoubtedly has accomplished great things to redeem other shortcomings; but it must be remembered that the greatest work of eminence has been self-educated. Their school has been the universe, their Creator the guide; they found "tongues in trees, hooks in the running brooks, sermons in stones, and good in everything." They derived their knowledge from observation and the exercise of those faculties (as well as by the use of those senses as instruments) in acquiring knowledge which are not recognized in our curriculum.

Gonius is the gift of God; it is an affair of great moment in what manner its growth is sustained, and any mistake on this point is fatal. I have seen a child of four years old draw a Bantam cock flapping its wings without difficulty, and a full-grown man unable to imitate a pill-box without suffering as much agony in the attempt as though he had swallowed the contents.

"There is a vigilance of observation, and an accuracy of distinction, which neither rules nor precepts teach." By the exercise of this faculty, the first link in that long chain of discovery was the fact (which to many minds would seem trifling and unimportant) of Galvani's discovery of the convulsion of a dead frog, which chanced to lie near an electrical machine while a spark passed from it, and he examined the precise circumstance under which the convulsion took place. One of the persons also concerned in modern electrical researches was a youth, my pupil, William Jenkins, whose discovery of a shock from a single voltaic pair of plates formed the occasion and subject of Faraday's ninth series of Experimental Researches; and this branch of modern discovery is not of mere theoretical

interest, but has culminated in such practical applications as the Atlantic Telegraph, which has influenced the intercourse of nations, affected the fate of empires, connected the Old World with the New, and been instrumental in giving happiness as well as employment to millions of people.

It is the office of genius to open ever fresh combinations and resources, for the exercise of national industry, whilst upholding the greatness of a country, equalising labour and capital, keeping pace with the times.

Surely, if university extension means anything, besides conferring degrees and the abolition of tests, it might recognise *mind* in art as well as literature, for, "like twin cherries, they grow on the same stem." It is not by attaching D.C.L. to a name, or ceremonial observances, and conventional ornaments, or picture-making (which is the business of an artist). This important movement can be effectually accomplished but by founding an art school, where the *language of form* can be initiated, and requiring the same degree of efficiency in the examinations as, at least, on a level with philosophy, Latin, and Greek; and no just reason can be given for a neglect which is a source of such grievous consequences, in every way, to the whole community.

The prosperity of the country is vested in our educational institutions. The university is the precedent, being the representative of mind and intellect. Education in these days means not only religion and virtue, but a right application of knowledge to the wants of the people.

WILLIAM RIVIERE.

GARTH STONE FOR LONDON.

EVERY ONE who has paid attention to the subject of building materials in the metropolis must have arrived at the knowledge of two broad facts; first, that stucco, as now used, is the standing reproach of London architecture; and, secondly, that the efforts to introduce stone into our public buildings have been attended with more signal failure and disappointment than any other great city in Europe can have experienced in that respect.

The inquiry would be long which would lead to a correct knowledge of the causes that operate to produce this state of things: they are, doubtless, to be traced partly to commercial, partly to natural influences. Meanwhile the difficulty remains; our public taste is impugned, and the durability of our edifices compromised.

Lately we have examined some specimens of a remarkably fine sandstone, from the millstone grit formation, near the mouth of the Vale of Llangollen, North Wales. This stone is not a new discovery, and it seems strange that attention having been once called to it, no efforts have been made to render it subservient to a requirement of the metropolis, which points precisely in its direction; and at a moment when so many large public works are either on hand, or just about to be commenced, it seems to be a matter of great importance that the claims of such a building material should be strongly tested.

In 1861 a committee was appointed by Government to inquire into the state of the Houses of Parliament, and to suggest a remedy for the decay of the stone in that structure. In the minutes of evidence attached to the report made by this committee, we find Mr. Burnell (himself a member of the committee) saying,—

"Perhaps, going a little beyond the immediate subject before us, I may mention that in the course of this week I was sent down purposely to examine the series of formations which are represented on that table,—the millstone grit,—and I may be allowed to express my regret that we in England do not with that class of material, which we have so easily at hand, employ, as the French engineers and architects do, those harder and more lasting materials." The millstone grits to which I refer are those of the North Wales formation, near Riehon, called the Garth stone, close to the canal and close by the railway."

Mr. Tite, M.P., the chairman of this committee, appears to have followed up the suggestion, for we remember that he produced at the Metropolitan Board of Works a specimen from one of the quarries referred to; and, after stating that the price per foot cube in London would be about 2s., gave his authority to the statement that it would be equal for all the purposes required for the Thames Embankment to the granite, which at the time was with difficulty obtained at more than double that price. Indeed, as to the qualities of the stone they almost speak for themselves. It is one of the purest sandstones, in which the grains of quartz are cemented

together by a silicious cement almost as indestructible as the quartz itself, and if evidence were wanted to prove its power of resistance to atmospheric influences, the Abbey of Vale Crucis and the Bridge over the Dee at Llangollen, both built of this stone, present themselves to show how little effect has been produced upon it by many centuries of weathering in a mountain district.

We add part of a report by Mr. T. W. Keates, F.C.S., upon a sample of the stone sent to him for examination:—

"This stone is compact and uniform in texture. Its specific gravity is 2.120, consequently the weight per cubic foot is 132.4 lb.; the ton weight measuring 18.9 cubic feet.

The composition of the stone is as follows, per cent.—	
Silica	80.10
Carbonate of lime	4.30
Alumina	4.20
Oxide of iron	8.00
Moisture	.97
	98.77

The iron is partly in the form of carbonate which makes up for the loss."

Here is a material which we are quite disposed to think may be advantageously used in the metropolis,—a material which may help to make London a city of stone instead of stucco; and it seems to us that those who have the command of the carriage of this or the like material, from whatever part of the country it may be obtainable, have a great responsibility if, by excessive demands for freight, they deprive themselves of our London market and the public at large of the great benefit of a supply of this article of stone at a price that may compete with that of a less enduring and a less desirable material.

FARADAY AS A DISCOVERER.*

AN interesting and graceful memoir of Faraday as a discoverer has been written by his able successor and personal friend, Dr. Tyndall, whose knowledge of the philosopher and the man was complete, and enabled him to do full justice to his subject in every sense. We have all heard much of Faraday's gentleness, and sweetness, and tenderness, says Dr. Tyndall; and it is all true; but it is very incomplete: you cannot resolve a powerful nature into these elements; and Faraday's character would have been less admirable than it was had it not embraced forces and tendencies to which the silky adjectives "gentle" and "tender" would by no means apply. Underneath his sweetness and gentleness was the heat of a volcano. He was a man of excitable and fiery nature; but through high self-discipline he had converted the fire into a central glow and motive power of life, instead of permitting it to waste itself in useless passion. "He that is slow to anger," saith the sage, "is greater than the mighty; and he that ruleth his own spirit than he that taketh a city." Faraday was not slow to anger, but he completely ruled his own spirit; and thus, though he took no cities, he captivated all hearts.

Faraday, as his biographer elsewhere remarks, was more than a philosopher: he was a prophet; and often wrought by an inspiration to be understood by sympathy alone. The prophetic element in his character occasionally coloured, and even injured, the utterance of the man of science; but, subtracting that element, though you might have conferred on him intellectual symmetry, you would have destroyed his motive-force.

His experiments were always suggested and guided by his theoretic preconceptions. His mind was full of hopes and hypotheses, but he always brought them to an experimental test. The record of his planned and executed experiments would, Dr. Tyndall does not doubt, show a high ratio of hopes disappointed to hopes fulfilled; but every case of fulfilment abolished all memory of defeat: disappointment was swallowed up in victory. In dealing with his hypotheses he incessantly took them down, as an architect removes the scaffolding when the edifice is complete. "I cannot but doubt," he says, "that he who, as a mere philosopher, has most power of penetrating the secrets of nature, and guessing by hypothesis at her mode of working, will also be most careful, for his own safe progress and that of others, to distinguish the knowledge which consists of assumption,—by which I mean theory and hypothesis,—from that which is the knowledge of facts and laws." Faraday himself,

in fact, was always "guessing by hypothesis," and making theoretic divination the stepping-stone to his experimental results.

When, from an Alpine height, the eye of the climber ranges over the mountains, he finds that for the most part they resolve themselves into distinct groups, each consisting of a dominant mass surrounded by peaks of lesser elevation. The power which lifted the mightier eminences, in nearly all cases lifted others to an almost equal height. And so it is with the discoveries of Faraday. As a general rule, the dominant result does not stand alone, but forms the culminating point of a vast and varied mass of inquiry. In this way, round about his great discovery of Magneto-electric Induction, other weighty labours group themselves. His investigations on the Extra Current; on the Polar and other Conditions of Diamagnetic Bodies; on Lines of Magnetic Force, their definite character and distribution; on the employment of the Induced Magneto-electric Current as a measure and test of Magnetic Action; on the Reversive Phenomena of the magnetic field, are all, notwithstanding the diversity of title, researches in the domain of magneto-electric induction.

Faraday's second group of researches and discoveries embrace the chemical phenomena of the current. The dominant result here is the great law of definite Electro-chemical Decomposition, around which are massed various researches on Electro-chemical Conduction, and on Electrolysis, both with the Machine and with the Pile. To this group also belong his analysis of the Contact Theory, his inquiries as to the Source of Voltaic Electricity, and his final development of the Chemical Theory of the pile.

His third great discovery is the Magnetization of Light, which Dr. Tyndall likens to the Weisshorn among mountains,—high, beautiful, and alone.

The dominant result of his fourth group of researches is the discovery of Diamagnetism, announced in his memoir as the Magnetic Condition of all Matter, round which are grouped his inquiries on the Magnetism of Flame and Gases; on Magnecrystallic Action; and on Atmospheric Magnetism in its relations to the annual and diurnal variation of the needle, the full significance of which is still to be shown.

These are Faraday's most massive discoveries, and upon them his fame must mainly rest; but even without them sufficient would remain to secure for him a high and lasting scientific reputation. We should still have his researches on the Liquefaction of Gases; on Frictional Electricity; on the Electricity of the Gynnotus; on the source of Power in the Hydro-electric machine (the two last investigations being unmentioned in the foregoing memoir); on Electro-magnetic rotations; on Regulation; all his more purely Chemical Researches, including his discovery of Benzol. Besides these he published a multitude of minor papers, most of which, in some way or other, illustrate his genius.

"Taking him for all and all [concludes his biographer], I think it will be conceded that Michael Faraday was the greatest experimental philosopher the world has ever seen; and I will add the opinion, that the progress of future research will tend, not to dim or to diminish, but to enhance and glorify the labours of this mighty investigator."

The self-devotion of Faraday as a philosopher,—he disliked to be called a physicist, and always spoke of himself by preference as a philosopher,—was most disinterested and admirable. At a certain period of his career he was forced, as he said, definitely to ask himself, and finally to decide, whether he should make wealth or science the pursuit of his life, as he could not serve both masters, and was therefore compelled to choose between them. After the discovery of magneto-electricity his fame was so noised abroad that the commercial world would hardly have considered any remuneration too high for the aid of abilities like his. Even before he became so famous, he had done a little "professional business." This was the phrase he applied to his purely commercial work. His friend, Richard Phillips, for example, had induced him to undertake a number of analyses, which produced, in the year 1830, an addition to his income of more than 1,000*l.*; and in 1831, a still greater addition. He had only to will it to raise in 1832 his professional business income to 5,000*l.* a year. Indeed, this is a wholly insufficient estimate of what he might, with ease, have realized annually during the last thirty years of his life.

*While re-studying the Experimental Researches with reference to the present memoir [says Dr. Tyndall], I sought to ascertain the period when the question, 'wealth or science,' had presented itself with such emphasis to his

mind. I fixed upon the year 1831 or 1832, for it seemed beyond the range of human power to pursue science as he had done during the subsequent years, and still to pursue commercial work at the same time. To test this conclusion I asked permission to see his accounts, and on my own responsibility, I will state the result. In 1832, his professional business income, rising to 6,000*l.*, or more, fell from 1,600*l.* 4*s.* to 1,651*l.* 9*s.* From this it fell with slight oscillations to 621*l.* in 1837, and to zero in 1838. Between 1839 and 1845, it never, except in one instance, exceeded 921*l.*; being for the most part much under this. The exceptional year referred to was that in which he and Sir Charles Lyell were engaged by Government to write a report on the Haswell Colliery explosion, and then his business income rose to 1121*l.* From the end of 1845 to the day of his death, Faraday's annual professional business income was exactly zero."

Taking the duration of his life into account, this son of a blacksmith and apprentice to a bookbinder had to decide between a fortune of 150,000*l.* on the one side, and his undowered science on the other. He chose the latter, and died a poor man. But his was the glory of holding aloft among the nations the scientific name of England for a period of forty years.

The outward and visible signs of fame were also of less account to him than to most men. He had been loaded with scientific honours from all parts of the world. Without, probably, a dissentient voice, he was regarded as the prince of the physical investigators of the present age. The highest scientific position in this country he had, however, never filled. He declined to accept the chair of the Royal Society.

PROFESSOR LEVI ON "OUR WORKMEN."

A LECTURE has been delivered in the Temperance-hall, Townhead-street, Sheffield, in connection with the Sheffield Chamber of Industry, by Professor Leone Levi, F.S.A., London, on "Our Workmen, their Labour, Rewards, and Trials." The Mayor occupied the chair. The lecture was a very able one. In alluding to the national influence of the working classes, the lecturer said: Collectively, the working classes exercise considerable influence on the welfare of the nation. Their income on the aggregate is something enormous. I have estimated upon very good bases, though necessarily in a general manner, that the 12,000,000 persons at work annually earn 418,000,000*l.*, giving a proportional income per head of about 19*l.* per annum, or 85*l.* 10*s.* per family. The accumulation of capital among the working classes has been very great of late. In 1830 the number of depositors in savings-banks was 17 in 1,000 of the population, and the amount of deposits averaged 1*l.* 3*d.* per head. In 1848 the number of depositors was 39 in 1,000, and the amount of deposit 20*s.* per head. In 1856 the number of depositors was 47 in 1,000, exclusive of the depositors to the Post-office Savings Banks, and the amount of deposits 30*s.* per head, inclusive of the deposits in the Post-office Banks over and above the amount invested in friendly societies, building societies, and co-operative associations. These are cheering evidences of progress, though, indeed, the working classes might accomplish a great deal more, were they more careful and more saving, more persistent in labour, and more economical of their time and opportunities. There is one great source of absorption of the working man's earnings, and that is drink. It is a sad, very sad fact that in the United Kingdom as much as 80,000,000*l.* a year are spent in drink, upwards of 50,000,000*l.* of which, at least, are spent by the working classes! What a large proportion does that constitute of their earnings! Can it be that any one having 25*s.* to 30*s.* a week will expend upwards of 5*s.* a week in drink, and that mostly for the gratification of one individual member of the family, regardless of the limited resources, amounting almost to penury, of wife and children? To say nothing of the evil of drunkenness, that fruitful source of crime, riot, and sorrows without number, is there any comparison between the momentary sensual gratification of drinking to excess and the enduring happiness resulting from a comfortable home? Home! If any of our working men have not got it yet, resolve, and tell your wife of your good resolution. She will aid it all she can. Her step will be lighter, and her hand will be busier all day, expecting the comfortable evening at home when you return. The table will be ready at the fireside; the loaf will be one of that order which says by its appearance you may eat and come again; the cups and saucers will be waiting for supplies; the kettle will be singing; and the children, happy with fresh air and exercise, will be smiling in their glad anticipation of

* Faraday as a Discoverer. By John Tyndall. London: Longmans, Green, & Co.

that evening meal when father is at home, and of the pleasant reading afterwards.

When we speak of our working men, we cannot, indeed, help including our very selves in the great number. Labour is with us a second nature. To forego our duties, to neglect our calling, and to indulge in idleness, would be to accelerate the end of our existence. And we need not be ashamed of our calling, nor despair if it be a lowly one.

Work, work, be not afraid!
Look labour boldly in the face;
Take up the hammer or the spade,
And blanch not for your humble place,
There's glory in the shuttle's song;
There's triumph in the axill's stroke;
There's merit in the brave and strong,
Who dig the mine, or fell the oak.

SCIENTIFIC AND ART INSTRUCTION.

THE Department of Science and Art have issued an Explanatory Memorandum to accompany the Minutes of 21st December, 1867, already noticed in our columns. As respects scientific instruction, it is stated that the payments are only made for the instruction of students of the artisan or weekly wages class, and those whose incomes are less than 100*l.* per annum. The teacher, to be qualified to earn payments on results, must have taken a first or second class, unless he has obtained some University degree. Six royal exhibitions of the value of 50*l.* per annum, tenable for three years, are given in competition at the May examinations. Three of these are to the Royal School of Mines in London, and three to the Royal College of Science in Dublin. Free admissions are given to the courses at these institutions to all who take gold medals. To schools of art held in rooms devoted to art-instruction, the aid consists of the following payments, in addition to others similar to those awarded to night classes—20*l.* on account of every artisan satisfactorily instructed in art; 15*l.* or 30*l.* on account of art pupil-teachers; 5*l.* or 10*l.* on account of students trained for art-teachers or national scholars; 3*l.* on account of free studentships to artisans submitting advanced works; 10*l.* on account of expenses of annual report and examination. The night-class aid towards art-instruction of artisans in elementary schools in literary, mechanics', or similar institutions, consists of payments of 10*l.* or 15*l.* on account of artisans or their children above twelve years of age satisfactorily taught drawing of the second or third grades; of prizes to successful students; and of payments towards the local expenses of examination.

THE MANCHESTER TRADES' UNION OUTRAGES REPORT.

THE report of Mr. Pickering, Mr. Barstow, and Mr. Chance, has been issued as a Parliamentary paper. It is addressed to the chief commissioners now sitting in London.

The examiners commenced their inquiry at Manchester on the 4th of September last. They found that the members of several of the unions of brickmakers and bricklayers throughout the district had destroyed their books containing the accounts of their expenditure and the minutes of their proceedings. In one case five chests containing books were broken open by order of the commission, but all documents relevant to the inquiry had been removed.

They then proceed to give an account of the cases brought under their notice, commencing with the Stockport Operative Brickmakers' Union. Various accounts are given pointing to acts of intimidation, outrage, and wrong, promoted, encouraged, connived at, and committed by the unionists. These statements were publicly made and reported on at the time. Manchester, Oldham, and Bolton were the other places dealt with. The commissioners find that within the past ten years no masters' association has committed any intimidation or outrage in the district. All the outrages recorded were instigated and sanctioned by the several trades' unions. They were deliberately planned and executed, in furtherance of a system which had for its objects the subjection of both masters and men to the rules of the union, and the destruction of the freedom of labour. When a master had rendered himself obnoxious, a meeting of unionists was held, and if either a

resolution or a tacit understanding was come to that an outrage should be perpetrated, the measures for carrying it out were left to the officers, and the funds of the society were available for the purpose. The largest sum which the examiners found had been paid was 20*l.*, and the share which generally fell to the lot of each man engaged in the transaction was 1*l.*, though the amount varied, and in others the money paid for destroyed, but in others the money paid for outrages was frequently entered as "certain expenses," and in others a sum total was put down without any explanation whatever. These modes of making up the accounts seemed to be so well understood that the auditors never objected to them. The books were always open to the inspection of members of the union, and the examiners have no doubt that the expenditure of the money and its object were well known.

POVERTY, DISEASE, AND "JERRY" BUILDING IN LIVERPOOL.

A VERY interesting, though painful, discussion on this subject has taken place at the meeting of the Liverpool health committee. Dr. Trench, the medical officer of health, stated, that in spite of the efforts of the health committee, "jerry"-builders and others managed to evade the laws and erect buildings, hundreds of which were mere living tombs. He also pointed out as a curious fact, that while many of the streets through which the north-west breezes (prevalent at Liverpool) could blow direct from the sea were comparatively healthy, the streets nearest the mouth of the river had been, for the most part, built so as to exclude the westerly wind, and that in those districts fever and other diseases were rarely, if ever, absent. It was, he said, painful to think, that while the town council could vote thousands of pounds for parks, in which the working population could have but very moderate enjoyment, it seemed almost impossible, with the present legal enactments, to purify and cleanse quarters of the town where fresh air, light, and cleanliness were so necessary. He invited members of the committee to accompany him in his tours of local inspection, and if they found his observations warranted, support him in obtaining better sanitary laws. Mr. Robinson, a member of the committee, said it was a painful fact that in Liverpool, the richest port of the United Kingdom, one in every eleven of residents in the parish was in receipt of parochial relief—20,000 persons being out-door, and 5,000 in-door paupers. To return to "jerry"-building, we may add, that this week the Liverpool magistrates fined two builders of this class for building houses without mortar, street-sweepings having been employed as a substitute.

THE SEWAGE QUESTION.

Ipswich.—The sewage of Ipswich, as is the case with the sewage of Norwich and many other large towns, is likely to prove a nuisance to all those connected with the town. At a recent meeting of the Ipswich Dock Commission it was stated that the Harbour Master had reported to the committee that the town sewage sediment had been found in various parts of the New Cut. The basin in the Cliff Bight, which was made in 1865, so as to provide a depth of 11 ft. of water below ordinary low tides, had been reduced in depth to 3 ft. below the ordinary low tides, and had, in fact, become unfit for the purpose for which it was intended. The Town Clerk had been communicated with, and the matter was now reported to be under the consideration of the town surveyor.

Norwich.—A special meeting of the local board of health has been held for further consideration of the contemplated sewage scheme. Mr. Johnson explained that the Board had already sanctioned the expenditure of 21,000*l.* for the purchase of land for the pumping station and for contracts; and that the rest of the estimated cost of 60,000*l.* was made up in three contracts, two for sewers (16,000*l.* each), and the other for branch drains, amounting to 7,000*l.* He also mentioned that 10,000*l.* of the sum would be required for the completion of the northern drainage, and showed that this sum must be expended whether they went on with the scheme or not. He stated that by having it

done with the rest of the work about 25 per cent. might be saved, and that his conviction was that nothing but the sewage being taken from the river would satisfy the injunctionists, reminding the Board that not only had they to remove excrementitious matter from the river, but also the refuse and offscourings from the gas-works, manufactories, &c. It was important that the Board should come to a decision that day, because to-morrow they would have an unusually long list of competitors for these contracts, and he hoped the Board would now do its duty manfully. He concluded by moving—

"That this Board do authorize the Sewerage and Irrigation Committee to negotiate for the loans required for the construction of the sewage works, not exceeding 60,000*l.*"

The motion led to a long and warm discussion, an amendment being moved,—

"That before proceeding with this scheme, it is expedient that a full representation of the position in which the Board is now placed in reference to the sewerage be made to her Majesty's Government, with the view to obtain their assistance and advice; and that this be done by memorial, followed by deputation."

A large number of councillors took part in the debate, after which the original motion was carried by thirty-four votes to sixteen, so that the scheme will go on without further delay. At some parts of the proceedings the opponents of the irrigation scheme gave expression to their feelings in such a manner as to call for rebuke from the Mayor.

THE STUDY OF SCIENCE MORE THAN RECREATION.

IN reading over in your journal the report of the paper upon "Technical Education" read by Mr. Randall, F.G.S., before the Society of Arts, I was struck with a remark that emanated from him, and to which I must take exception. The paragraph runs as follows:—"He had been made a Fellow of the Geological Society in consequence of his studies in that science, which he looked upon merely as a recreation." I am of opinion, personally, that the study of geology and kindred sciences, or, in fact, any study, ought not to be looked upon as merely recreative; neither does it prove so, as I, and doubtless many others, know full well, who have devoted their leisure hours to it.

That it is a recreation I have no doubt, but it is combined with a good deal of downright hard study, which means work, more especially to those who have few or no opportunities of attending lectures and discourses, and whose progress and success depend entirely upon their own exertions. Neither do I think that any one about to commence, or having in view, the study of science, would do so for the sake of mere recreation: he would, I presume, have in view some higher, and, perhaps, more worthy object,—a desire to store his mind with facts, to increase his knowledge, to improve his abilities, and with the fair hope that he would hold his own amongst, and perhaps instruct, his fellows; and that it would prove in the course of life of no little benefit, from his superior attainments, if well applied.

Perhaps an illustration, out of many, from my experience may be of interest to some of my own class of your readers.

Some few years ago I was engaged abroad upon a line of railway, and where machinery of any kind was difficult to obtain, costly when obtained, and then only after months of waiting. The lines used upon this line of works were of an aluminous and slightly hydraulic nature, hard to burn and difficult to grind, especially with our imperfect appliances, would not slack like ordinary lines, took but a small proportion of sand, and the works proceeded but slowly. I had been present but a short time, when I one day observed to my superior, who was passing,—by the way, he was a retired officer of the army and of high rank,—it was a pity no limestone could be obtained in the neighbourhood; for it would be a large saving in expense and progress, and not take a much greater proportion of sand. His only reply was, "Ah! my dear fellow, you don't know this country yet: there is no limestone within a couple of hundred miles of here." I, however, thought differently, but said nothing. In a few days I rode to the base of a range of hills distant a few miles, and where I soon discovered a beautiful hard, white, compact crystalline limestone, of superior quality, and afterwards other descriptions of lime. I need

scarcely remark that these were afterwards used upon the works to the benefit of my employers, and therefore to my own. This was not all: the very stone had frequently been observed by my superior—the officer of rank,—as well as by others; but they had no knowledge of its nature, and if ever thought of, concluded it was quartz, as one of them afterwards said. A similar circumstance occurred when in Wales some time ago.

And now, sir, in conclusion, I think, should any such distinction as suggested by Mr. Randall be conferred upon men who devote their energies to the attainment of excellence in their several branches, these aspirants would surely not devote their energy, time, &c., for the mere recreation. Would they not rather do so for the supposed benefits that would accrue for their superior knowledge, skill, and ability which would result if properly applied? With all due respect for Mr. Randall, such is the opinion of a

CARPENTER.

GREAT LONDON.

From a central elevation Caractacus viewed his old domain. He was amazed at the vast expanse of roofs, the many thousand chimney-stacks, all sizes and shapes; pots vomiting smoke; factory shafts; church spires, towering structures; the net-work of railways (like a spider's web); and Old Thames suffering from congestion. He was informed that the population numbered millions! and that there were 4,000 miles of roads. A statistical account was given of our requirements; our progress in arts; *improvements* in war implements for slaying men miles off (science of slaughter); transmitting messages instantly to all nations on earth; that we have peopled new-found lands; conquered ancients, who now bow allegiance to us. "Extremes are here," said he, "riches and poverty, vice and virtue." Our fame is pre-eminent; but all our deeds will not stand analysing. We are mainly fed by foreigners,—steam-agents constantly rushing to and from all quarters of the globe with supplies. In the event of no aid from other climes we betide us, for then will London fall.

He was sad while speaking these words:—"Degenerated descendants! ye have indeed built a mighty Babel; but it is rushing, crushing, artificial life, with symptoms of decay. I see men perishing from want; others heaping up mountains of uncountable wealth, the fools or knaves! It was not so in my time here. Are there no green fields? Look beyond Streathamrise, over Stamford-hill from Essex towards Hendon. Enough!" he cried, "I am anxious to depart, and thankful I am out of it." His form was wafted through the smoke over (black) St. Pauls.

R. T.

THE DONJON OF COUCY.

SIR,—The account you publish of the Castle of Coucy would lead one to suppose the donjon still retained its vaulted floors and the conjectural ridge-like finish, and, indeed, had suffered nothing serious to its stability. When I saw it about five years ago, there was no vestige of any of its vaultings beyond their twelve carved springers; nor, indeed, could there be, since the mining ordered by Cardinal Mazarin in 1652, as two fissures, a foot wide at top, and descending to the base, would probably have been fatal to the monument ere this, but for the great iron bandages which M. Viollet-le-Duc says the wick the present weather-proof roof, and which encircle it below the great windowed parapet. This grandest of all castles was thus saved from the fate of our grandest English one, that of Corfe, whose superb donjon fell a year ago, in the gale of "the London." The magnificent cornice, moreover, of Coucy, though "overhanging both ways," and cut on both sides, as the account should have added, into two tiers of crumbling leaves, intelligible miles off, is not "about twice the thickness of the wall," the wall, or rather parapet, is about 5 ft. thick, and the top about 9 ft., perfectly flat when I walked round it, weather-worn, and without the least trace of having ever received another course. It is certainly not the case, therefore, that it "slopes upward into a ridge," nor do I see that this was at all necessary for the support of the *hourdes*. M. Viollet-le-Duc founds this imagined finish on an old engraving, and says fragments were found, in the fosse, both of this "glacis,"

and of the four strangely-placed, unmeaning pinnacles, which may have belonged elsewhere.

This monarch of castles has none of the picturesque charm for which British ones are chiefly valued, being, in fact, like the Pyramids, too grandly simple to acquire much picturesque interest, even in ruin; but every architect should study it who visits Reims, as he should also the most unique trigon of almost first-rate cathedrals, and their highly-interesting towns, Laon, Soissons, and Noyon, within which, and about equidistant from them, Concy stands.

E. L. G.

THE ARCHITECTURESQUE.

A CORRESPONDENT in your last number suggests a dilemma with reference to the theory which I ventured to offer in a recent lecture. In reply I need only say that the interpretation of my language upon which it is based is quite mistaken. There is one point raised, however, which is a fair question, and in the present condition of architectural opinion, ought to be fairly met,—namely, the effect of my theory upon the rivalry of Gothic and Classic. My notion is this: if the Architecturesque has a reality of art-essence, then, firstly, all good architecture must necessarily possess it; but, secondly, some architecture may possess something more; whilst, thirdly, other architecture may possess nothing more. Gothic architecture, for example, may owe its peculiar charms to its essential super-addition of the picturesque; whilst Classic architecture may owe its equally peculiar charms to its essential reliance upon the Architecturesque that I have advanced this as an illustration merely, not as a doctrine: I lay no stress upon it; it is no part of my theory. My proper thesis goes no further than the inquiry whether what I call the Architecturesque is a reality or not; if a reality, then I ask my brethren to turn it over in their minds and see whether it can be brought into the form of useful doctrine.

R. K.

A WORKING MAN ON EDUCATION.

SIR,—The *Builder* from its commencement has advocated the social, sanitary, and educational well-being of the industrial classes, and great benefit to them has resulted therefrom; and I feel sure that the various educational movements of the day will have the valued and able support of your journal. The great agitation which is a portion of the upper and middle classes from their spate on this important matter; and at last it is spate that all who are capable of appreciating the advantages which education confers upon the community, are in earnest to establish a thorough educational system. Nevertheless, some workmen are sceptical as to the reality of the movement, and are impatient at the neglect of this vital question by the governing classes. I confess that to me it does seem that the leading idea of many of them has been, that "ignorance is bliss," so far as the working classes are concerned, and therefore it would be folly to make them wise. And, judging from the debate on the East London Museum Bill, some hereditary legislators think so still. I think education has made some little advance since I went to school, for there neither grammar, history, nor geography was one of the essentials of workman's education. All I was taught of grammar was to pease at a come long enough to count one, and so on up to the period, or full stop. I do not remember hearing anything about art or science, and yet at that period an advanced education was taught the poorer classes in the French and German schools. Many intelligent workmen cry out most strongly against the present and past government. And even now much doubt is expressed as to their ability to comprehend the nature of the crisis, and the wants of the people. I think great blame is attached to all classes, and one is sorely at deep in the mud as the other is in the mire, as up to the present education has been a bone of contention between the so-called educating parties, and between them the masses have been horribly mutilated. And I am almost sure that our own professed interest in us, but few of them understand our wants, and our capabilities for learning.

The evils resulting from the neglect of a well-ordered educational system in the past is now bearing fruit. As the majority of workmen in this country take but little notice of passing events, whilst their limited wants of food and beer are supplied, they are content. That rude leaving the country is nothing to them. Technical and general education is with them a matter of perfect indifference; they follow the track their fathers walked in. The want of little or nothing has as yet been done to supply it. Many of them who can read indifferently will manage to spell through the police-news columns of *Lloyd's Newspaper* on a Sunday afternoon, and then content themselves with public questions ends. Their houses, as a rule, are in a deplorable condition; and in their most flourishing periods they are but one degree removed from pauperism.

The truth must sooner or later be told to the condition of a large portion of the people in towns and cities; of their ignorance and neglect of everything of an elevating and ennobling character. And I think when their condition is fairly known that it will be evident to the most obtuse and bigoted intolerant that compulsory education is needed, not only to teach the first elements of knowledge, but also to teach the duties and science of life, whereby they will be able to avoid the excesses which every intelligent man deprecates. The advantages of a system of

education which would give the working classes the means of knowing themselves, and of the improvement of their condition in their own hands, and by the influence of their respectability, are so raised the status of their class that the evils which now afflict them would soon be things of the past. Let then the State, for the present at least, provide for the rising generation the means to acquire the principles of knowledge and morality, and the opportunities for retaining that already acquired, and still further strengthening it on their errand at school; and then, people of ignorance, there will be a reading and a thinking that which will have become a necessity and form a part of their daily existence. The statesmen who are far-sighted enough to sow the seed will reap a rich harvest, and have an exceedingly great reward."

Already quacks and nostrum-mongers are at work, making capital out of this question. A few evenings ago I was at a meeting. On leaving, a bill was handed to me, headed, "The Technical Education of the People." After giving an extract from a speech of the chairman of the Society of Arts, in support of these views, it stated, "that the opening of the British Museum, National Gallery, &c., on the only day when they can be visited by daylight, and without fatigue, by the working classes, would be unjustly, and might be expected to fail in elevating the artistic and moral taste of the people." It is therefore proposed that all those who believe there is a great work to be done should at once turn their attention to the "opening of free libraries and museums on week-day evenings." An Act is already upon the statute-book for the establishment of them in every town, and it only awaits sufficient enlightenment to put it in force, and thus give the industrial classes opportunities to cultivate a taste for science and art. Reading for knowledge would soon form a part of their every-day duties; a higher and a better feeling would be created; the habit of encroaching upon the day of rest and forcing Sunday labour would be abandoned; and soon be scouted by those who now advocate the morals of the people would rise with their educational requirements, and which are so prominent would fall before the intellectual advancement of the people.

After writing the above I had some doubts as to whether it was interesting and suitable to the columns of the *Builder*; but I altered my mind, and attended a meeting at St. John College, on the opening of museums, &c., and I felt that, excepting three or four speakers, the others went away so weary of the mark, that I determined to send a working-man's thought in the hope that I should be able to show the working men's wants. JACK PLANT.

IMPROVEMENT OF GLASGOW.

GLASGOW ARCHITECTURAL SOCIETY.

At the last meeting of the Glasgow Architectural Society, the City Improvement scheme was under discussion, Mr. John Honeyman presiding.

Mr. Thomson read a paper on the subject, of which the following is a summary:—It is clear that, except in the great thoroughfares, the streets of Glasgow are cluttered with shops and warehouses occupies very much of the amount of population in a locality, and of course the value of property and the rent. In the most densely populated area in the plan, the superficial space of ground set down to each inhabitant is about 31 square yards. I have made a diagram showing an area of 352,440 square feet, including surrounding streets, upon which may be accommodated very considerably more than the requirements of the New Police Act, a population of 10,234—that is, nearly 343 square yards for each inhabitant—only a small fraction more than the present. I make it up thus:—There is space in the plan for 112 streets, and towards the surrounding streets contain 124 shops and 2,272 apartments, which in the lower localities mean and allowing 9 feet for the height of ceiling, gives over 100 cubic feet, which by the Police Act provides space for 3 adults, or taking the mean, about 4 individuals. It will be seen that the plan allows a block of ground 1,068 ft. by 339 ft., having streets for general traffic round it, and subdivided by narrow streets for local traffic only. Keeping in view the statement made by Mr. Stevenson, that the way to secure more of the ground, make the open spaces unequal, I have shown a leading street 60 ft. wide on one side, 60 ft. on the other, and two cross streets 50 ft. wide each, with the sub-divisions of streets are each 32 ft. wide in the middle and 16 ft. at each end. The main feature of the plan is that the spaces are all open at the ends upon. There is, instead of a continuous detached tenements of 48 ft. in length, with 16 ft. spaces between. These led alternately into streets covered overhead with glass, and lanes providing access to coal and amongst children. These covered streets are intended chiefly as play-grounds for the young, where they may run about under shelter and out of danger from carts and other vehicles. But the warmth which would result from this method of building would be conducive to the health and comfort of all. As to the expense, I propose to build the walls of the covered streets with brickwork, stone walls, the more than sufficient to provide for the glass carried up in the gutter behind the smoke flues, no harm could arise from the spread of contagious disease.

ST. PANCRAS SCHOOL COMPETITION.

The Guardians of St. Pancras have awarded the first premium of 150l. to Messrs. Giles & Biven for the best design for the parish schools at Levensden near Watford, and have resolved to carry out the plans with some modifications. The estimated cost is 31,300l.; and, in lieu of the premium and commission, the architects are to receive 1,000l. for superintending the erection of the building. The premium of 100l. for the second best design is awarded to Mr. Peck; and the third of 50l. to Mr. Manning.

COMPETITIONS.

St. Andrew's, Hereford.—A number of designs have been sent in and examined. Last week a meeting was held for the purpose of making choice of one of them. On a motion to receive a report recommending this, it was moved as an amendment that it be referred to a committee to consider the claim of Messrs. Smith, and to report to a meeting of the General Committee to be held on the 3rd of April. On the amendment being put to the vote, eight hands were held up for it and eight against it. The amendment was declared lost. The original resolution was then put to the vote, with the same result. Lord Cowper remarked that they had now come to a dead lock, and an adjournment having been suggested, it was agreed to adjourn until Friday.

FROM MELBOURNE.

BEFORE he left Australia, Prince Alfred laid the memorial stone of a new graving dock at Williamstown, Melbourne. This dock, now in course of construction, will, when completed, be 420 ft. in length over all, and 400 ft. long on the floor within the entrance. It will be 97 ft. in width on the top, and the entrance will be 80 ft. wide in the clear. At ordinary spring tides there will be a depth of water of 24 ft. 6 in. on the sill at low water, and 27 ft. at high water. The entrance will be closed by an iron caisson. The dock is built of the basaltic stone of the neighbourhood, known as limestone, and is estimated to cost, when complete, with pumping engines, &c., 185,000*l.* The dock-yard comprises an area of fifteen acres, and includes the present patent slip, which is capable of raising vessels of 2,000 tons; and within this dock-yard workshops for the several trades connected with ship-building will be erected. The works of the dock were commenced in November, 1864, and its completion is expected by the end of 1869. Engineer: Mr. W. W. Wardell, inspector-general of public works, assisted by Messrs. W. H. Steel and A. C. Todd. Contractor for works now in progress: Mr. J. Leggatt. Resident inspector: Mr. H. Woods. After laying the stone his Royal Highness embarked, and bade adieu to Victoria.

GAS.

At Wilton the price of gas is 7s. 6d. per 1,000; while at Salisbury it is 5s. In Devices it is 4s. 2d. per 1,000 ft., and at that price the works yield a profit of something like 700*l.* a year.

The Wolverhampton Gas Company have declared the usual dividend of 5 per cent. for the half-year (free of income-tax). The reduction in the price of gas to a uniform rate of 2s. 9d. per 1,000 cubic feet, announced in February, 1867, came into operation on the 1st of October last, but the full effect upon the reserve of the company could not be ascertained until the close of the present half-year, ending 30th June next.

The Richmond Gas Company have declared their usual dividend of 10 per cent., together with a bonus of 6s. 8d. per share, which would itself be about 1,000*l.*

Books Received.

A Treatise on Smoky Chimneys; their Cure and Prevention. By F. EDWARDS, Jun. Fifth Edition. London: Hardwicke. 1868.

The fact that five editions of this brochure have been already called for shows the extent of the evil it is intended to combat. Mr. Edwards wisely makes evident that the causes of smoky chimneys being very various, the remedies are so too, and must be applied intelligently and according to circumstances. The book contains numerous suggestions which may usefully be considered as well before building a house as after it has been found that the chimneys smoke.

The Waterworks of London; and on various other Waterworks. By ZERAH COUBURN and WILLIAM H. MAW. London: Spott.

The contents of this volume are articles reprinted from *Engineering*. It is divided into three parts. The first gives a detailed account

of each of the London waterworks; the second an account of proposed schemes for supplying the metropolis with water; and the third is on waterworks and water supply in other parts of the country and abroad. The whole forms an important volume on water supply, and is illustrated by numerous good engravings.

VARIORUM.

COUNTRY TOWNS, and the place they fill in modern civilization. By the author of "Three Months' Rest at Pau." London: Bell & Daldy. This is a thoughtful and useful volume on the advantages and disadvantages of country town life, and how to increase the advantages and diminish the disadvantages.

"If small towns," says the author, "surrounded by country aspects and elements, furnish so much healthy development for the body; if in this healthy physical development they contain the germ of much healthy development of character; if they are open to a sort of education which unites the advantages of school and home; if the very faults of their habits and manners are on the natural and healthy side; and if they give special opportunities for cultivating the charities of life on one hand, and public spirit on the other,—have we not a warrant for upholding them as the best field for the production of good, sound, human material to fulfil the highest purposes of civilization? We do not want country towns to supply us with very learned, or very scientific, or very accomplished men,—for these are the growth of special gifts and opportunities; but we want something more valuable, men of strong sense and high principle, who will put down evil, alay strife counsel wisely, and act faithfully in their own little spheres.

Let us add one more to the advantages country towns possess; their happy leisure, their freedom from the crush and turmoil or busier social life,—from its exciting stimulants, its grinding pressures, its dreadful wear and tear. . . . There is hardly a question which agitates the public,—education, strikes, the social evil, ritualism, relief of poor, &c.,—which does not press upon men in the shops, and vestries, and committees of a country town;—indeed, as abstract questions, but as a duty, or the neglect of it. Therefore we are inexcusable if we allow the mental inertness of country-town life to beset us. All have not special gifts of genius, but breadth of sympathy, and a spirit of intelligent interest in things around us, may be cultivated by all.

No with regard to other things. To keep ourselves young in the power of innocent enjoyment, to keep our selves true against vanity and all forms of faleness, to cultivate courtesy and real refinement, to practise the charities and amenities of life, to serve our neighbourhood and generation,—we can do all this; we can thus far shape and complete our character by resolute will and the aid of God's Spirit, and make ourselves wise and true, gentle and valiant Englishmen,—though we may be destitute of polished manners, polite accomplishments, and literary tastes."

Miscellaneous.

THE LYNN DOCKS.—The foundation-stone of the wet dock now in course of rapid construction at the northern end of the port of King's Lynn, has been laid. The stone formed part of the sea-wall of the dock. The contractor is Mr. W. F. Lawrence. The stone laid was a large mass of concrete, one of a number of blocks of a similar composition which will be used in the construction of the work.

PROPOSED LUNATIC ASYLUM FOR THE BOROUGH OF SOUTHAMPTON.—The County Asylum getting more crowded, pauper lunatics from Southampton and Portsmouth have been removed from it, and the lunatic commissioners have intimated to the town council of Southampton that they will require the borough to erect an asylum of its own, or conjointly with Portsmouth. The estimated cost of the new asylum is stated at 16,000*l.*

WINDOW FOR GUILDHALL, LONDON.—At the last meeting of the Lancashire Cotton Famine Fund, it was stated that a fine painted window, as a grateful memorial of the generosity of the citizens of London on the occasion of the calamitous famine, and the result of a penny subscription among the cotton operatives, will shortly be set up in the Guildhall. The history of its creation should be placed upon or below it in English, and in letters that could be read by all. Some of the inscriptions on modern windows convey no meaning whatever to nine out of ten of those who look upon them. The last meeting of the Cotton Famine Fund, when it was determined to divide the balance of the fund now in hand, amounting to about 9,800*l.*, among the principal towns in Lancashire, in aid of infirmaries and dispensaries *pro rata*, according to population, was presided over by Alderman Cotton. Such coincidences often occur: thus the morning papers the other day, mentioning the attendance of the Prince and Princess of Wales at the Obolop Royal, St. James's, showed that, while the service was performed by the Rev. A. Sitwell, the anthem was "Stand up and bless the Lord."

HORSHAM COTTAGE HOSPITAL.—At a meeting held in the Literary Institution, Horsbarn, Mr. W. E. Hubbard in the chair, it has been resolved to establish a Cottage Hospital in the neighbourhood; and a committee has been appointed to carry out this object, with Mr. Edward Bostock as hon. secretary.

BEADON'S PATENT DOOR-HANDLES AND OTHER FASTENINGS.—The object of this invention is to get rid of the annoyance and expense arising from defective methods of fixing door-handles. Those attached to the spindle by a screw in the neck of the knob cannot be nicely adjusted or secured. Others which are attached to the escutcheons soon get out of order, because the screws by which the escutcheons are fixed to the door draw out, especially when the wood has been thinned by the insertion of a mortice-lock. Beadon's patent plan adjusts the knob, and fixes it on the lock-spindle between screw-nuts, the escutcheons serving as bearings. They are simple, strong, and cheap, and certainly deserve a trial.

THE WEST LONDON HOUSE PAINTERS' AND DECORATORS' MUTUAL IMPROVEMENT ASSOCIATION.—We are glad to repeat that this association has been started with the idea of imparting to its members a more thorough knowledge of the principles and practice of ornamental decoration and colour. It is governed by a committee of seven members, also a chairman, secretary, and treasurer, and the members meet for the purpose of study on certain evenings. Members of the trade are admitted into the association on the payment of 1s. entrance fee, and a contribution of 1d. per week. The meetings are at present held on Friday evenings, at the St. John's Working Men's Club, Kirkman's-buildings, Tottenham-court-road. Mr. Cave Thomas was to lecture on Fresco on Wednesday evening last.

NEW USES FOR PAPER.—In America, pails, washing-basins, and pans of all sorts are being made out of paper. They are light, particularly cool, and may without injury be placed in an oven till the water in them boils. Greenhicks are not the only evidence of the advent of the paper age in America, therefore. There was lately a "paper ball," in which the dresses were made of paper. Paper collars, cuffs, &c., we suppose, are also to be had in America as well as here, and they are making Manila broad-brimmed hats of paper. Extremes meet, so do east and west—the Japanese and the Americans. Paper hats and cloaks and paper pocket-handkerchiefs are in common use in Japan, and all our American friends want to complete their paper age in the paper pocket-handkerchief; the paper spittoon they no doubt already have.

A MEETING-ROOM WANTED.—Charles Ashby, a plumber, applied to the Lord Mayor the other day, on the part of some working men, for leave to meet in the Guildhall. He said the recent meeting at St. James's Hall ascribed the existing want of employment to the effects of foreign competition and of free trade, but that line of argument was so manifestly repugnant to the views of many working men present, himself amongst the rest, and the result of the meeting was altogether so unsatisfactory, that they were desirous of having another convened for the discussion of the question, and under conditions calculated to secure a fair hearing on all sides. The difficulty was that all places for public meeting in London were to men like them so costly, and were besides inadequate in size. Mr. Ashby said that he was of opinion that strikes were driving trade from the country, and he was prepared to state the reasons for that opinion at a public meeting. He knew men who, under the existing state of things, worked under a feeling of terror. The Lord Mayor replied they were the more fools on that account. Let them, he said, emancipate themselves forthwith from such thralldom, and work for any master who might be willing to employ them, and at such wages as he might be able to afford. As a rule, no honest man need be under such apprehensions. In the end, the Lord Mayor told Mr. Ashby that he himself could not grant the use of the Guildhall. The privilege of affording the use of the hall for a public purpose lay with the Common Council, and Mr. Ashby left with the intention of applying to them. If he can show that there are a number of artisans desirous of testifying their opinion, and that they have amongst them men capable of conducting such a meeting properly, it is to be hoped that the Common Council will afford the opportunity desired.

NATIONAL PORTRAIT EXHIBITION.—The arrangement of the third and final collection is now making progress at South Kensington. There is no want of portraits; indeed the great difficulty is to find space for those already received. The exhibition will consist of portraits of eminent persons who have lived during the present century, and of many distinguished people who flourished prior to that time, forming a supplement to the whole series. In all there will be about 900 portraits, and efforts are being made to open the exhibition, which promises to be of greater popular interest than its predecessors, on Easter Monday.

FALL OF A WALL AT THE SOUTHERN EMBANKMENT.—Two men, with several others, were engaged in Fore-street, Lambeth, in pulling down several buildings, and carting away the materials, in order to clear away the space required for the Thames (Southern) Embankment, when suddenly a portion of brickwork, about 20 ft. long, was observed to bulge and totter; and, although an alarm was promptly given, enabling the majority to run away, before the two referred to could escape the wall fell, and they were buried beneath the ruins. It was found they were so seriously injured about the head, face, and other parts of the body, as to require their immediate removal to St. Thomas's Hospital, where they remain in a very precarious condition. Several other men were slightly injured by being struck with bricks, &c.

TEMPLE-BAR.—The City architect (Mr. Horace Jones), replying to a question in the Court of Common Council as to the rumours of the alleged insecurity of Temple-bar, said he had brought the matter before the City Lands Committee, and received their instructions to make a careful survey of the whole structure. Although he believed it had suffered a great deal from settlements of the fabric at various times, there was nothing of that kind that he could see of recent date. The joints from which mortar had fallen were now being filled in with fresh cement, and no further settlement of the structure had taken place. Mr. Fricker, however, amidst some cheering, gave notice of a motion for the next court, to the effect that the removal of the Bar would greatly facilitate the enormous traffic continually flowing into and from the City, and that the City Lands Committee be instructed to cause the fabric to be removed forthwith.

PANIC IN A THEATRE.—The Rev. R. Stanton, an Independent minister, recently delivered the 1st of a course of lectures to the working classes in the Sheffield Theatre Royal. The subject was the *Tomorrow tragedy*, and very nearly terminated tragically to a great number of persons. The place was crowded to excess. A cry of "fire" was raised, and a scene of the wildest confusion ensued. Two women precipitated themselves out of the boxes into the pit, falling on to the heads of those below them. Women and men scrambled out of the boxes to the stage, smashing the chairs and music-stands in the orchestra and the foot-lights on their way. Others broke through a skylight at the back of the stage, and dropped from thence into a yard. Some found their way underneath the stage, and, pushing their arms through the grating into the street, besought those outside to smash the grating and let them out, as the place was on fire. There was no loss of life. The alarm of fire was groundless.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—On Thursday last, Mr. W. Cave Thomas gave another of his series of lectures on painting, the subject on the present occasion being "An Attempt to Systematise the Methods of Oil Painting." Mr. Madox Brown was in the chair. The lecturer said that if the grand style ceased with the neglect of mural painting, on the other hand the revival or discovery of oil painting multiplied pictures; and he next drew attention to the different methods for obtaining transparency of colour and solidity, the former quality being seen to perfection in jewels and in painted glass, which afforded a clue to the painter; and he concluded a very able and scientific lecture with hints as to the employment of pigments, and other interesting particulars. Mr. H. Warren confirmed some remarks of the chairman as to the justness of the principles enunciated, the neglect of which had given rise to some curious pictorial effects, instancing a picture of a man in armour, by Vanduyke, over which the artist had painted a man in velvet, in which, however, in the course of time the original picture had re-appeared underneath.

NAVAL HOSPITAL FOR JAPAN.—We are glad to find, by the *Lancet*, that the usual estimates include the sum of 25,000l. for the erection of a naval hospital at Yokohama. Those who know the insalubrious condition of Hong Kong, the only naval station we possess in the Eastern seas, will appreciate this intention of Government, since Yokohama is an essentially salubrious climate as Hong Kong is the reverse.

WORKING MEN'S COLLEGE.—A deputation, consisting of the Rev. the Principal F. D. Maurice, Mr. Thomass Hughes, M.P., Mr. Lindlow, Mr. Lishfield, Mr. W. Cave Thomas, and Mr. Jennings, waited upon Lord Robert Montagu to solicit Government aid in carrying out the new buildings for the art classes, museum, &c., at 45, Great Ormond-street. We understand this assistance is likely to be granted.

THE NEWCASTLE CENTRAL EXCHANGE DOME.—This dome was recently destroyed by fire; and the proprietors being unwilling to re-erect it, a proposal to do so by subscription, as it was regarded as an ornament to the locality, has been made, and the town council have agreed to subscribe 120l., and others additional sums, amounting in all to 400l. It will be stipulated that the dome be insured; and, if again burnt, that the money be used in re-erecting it.

VALUE OF LAND IN LIVERPOOL.—The Liverpool Corporation offered for sale by auction twenty-nine plots of land suitable for building purposes in the principal thoroughfares of the town. The competition, however, was very slow, and only three of the lots were sold. Although the reserve price was not mentioned, it was understood that in several instances it amounted to 32l. per square yard. One of the plots sold was bought by the occupier, Mr. Rigby, publican, for 32l. per yard. The other lots were sold for 5l. and 7l. 10s. per yard respectively.

THE ISLINGTON WORKHOUSE.—Some of the parishioners do not feel quite easy about this matter, and express an opinion that scarcely sufficient care was exercised in making the selection. It is said that the buildings, according to the design chosen, will cover 7 acres 3 roods of land! It was stated at a meeting in the parish of St. Pancras the other day, that although the architect's estimate was 30,000l. (for 1,000 persons), the alterations made in the plans had brought the amount up to 70,000l. The Board should take advice upon the subject before it be too late.

OIL TESTER.—A patented machine for testing the lubricating qualities of various oils is being introduced by Messrs. John Bailey & Co., of the Albion Works, Salford, Lancashire. The apparatus consists of a bed-plate, two pedestals, fast and loose pulleys and strap, fork, two brass steps with weighted levers to produce friction, an indicator to show the revolutions, and a thermometer to indicate the temperature produced. The exact money value of oil may be arrived at as follows:—Suppose a certain quantity of No. 1 oil on the machine shows 200 deg. by being driven 10,000 revolutions; No. 2 oil shows 200 deg. and 7,500 revolutions, or 25 per cent. less value; in addition to this practical way of obtaining a result, the machine may be driven to a higher temperature, to see which oil produces the worst residuum.

FIRE IN THE CITY: SAFETY IN CLOSED DOORS. A fine old mansion in Devonshire-square, Bishopsgate, once inhabited by the late Bishop of London (Blomfield), took fire last week, it is believed in spirit cellars beneath it. The occupier, Mr. Hart, was roused in the middle of the night by his wife, who smelt fire, and having ascertained that the house was on fire, Mr. Hart caused his wife to arouse the female inmates, and himself awoke his wife's father, a man of seventy-two years of age, and conducted him to the outer door, and having left him in the street, carefully shut the door, and ascended to the upper floors, where he found the other inmates already on the roof, and assisted them to a place of safety. Other doors inside were shut, and by the aid of the fire brigade the fire was confined to the one house where it began. The furniture in the drawing-room, and a valuable library, as well as other property, were saved, and the firemen regarded the result as something like an unusual triumph over "the devouring element." It was observed that wherever the doors had been shut the fire had failed to penetrate, even although the doors were blackened and charred. The fine old staircase was completely destroyed.

STRIKE AND LOCK-OUT AT SALTAIRE.—The harmony of this celebrated model establishment has been disturbed by a strike of weavers, who urged their employers for an immediate advance of wages, on the ground that other employers in the district gave higher wages than Messrs. Salt's firm. The firm promised a rise, if on investigation they should find it to be the fact that others gave higher wages; but this reasonable proposal did not seem to suit the views of the weavers, who immediately struck work. Messrs. Salt being offended, and indeed not believing that there was any truth in the assertion of the weavers, shut up their whole establishment, which seems to have brought the weavers to better views, as they agreed forthwith to return to their work, pending the inquiry originally proposed by Messrs. Salt.

TENDERS.

For rebuilding house and shop, Commercial-road, E., for Mr. Colson. Mr. Iron, architect:—
Moyle (accepted).....£217 10 0

For the erection of warehouse, No. 154, Minories. Mr. N. S. Joseph, architect:—
Hight.....£3,948 0 0
Myers.....3,871 0 0
Newman & Mann.....3,858 0 0
Ashby & Sons.....3,729 0 0
Axford & Whittier.....3,709 0 0
Ashby & Horner.....3,685 0 0
Conder.....3,651 0 0
Piper & Wheeler.....3,618 0 0
Broome & Robinson.....3,624 0 0
King & Sons.....3,575 0 0
Hill & Keddell.....3,525 0 0
Henshaw.....3,498 0 0
Brass.....3,485 0 0

For alterations and additions to the Plymouth Work-house. Messrs. Dweley & Son, architects. Quantities supplied:—
Elliot.....£2,757 0 0
Jenkins.....2,629 0 0
Call & Perbick.....2,411 0 0
P. Marshall.....2,038 0 0
Price.....2,029 0 0
J. Marshall (accepted).....1,865 0 0

For building a sixty-quarters mulling at Preston, next Faversham, for Messrs. Shephard, Neame, & Co. Mr. Benjamin Adkins, architect. Quantities supplied by Mr. Thos. M. Rickman:—

Contract No. 1.—Builder's Work.
Stid.....£3,866 0 0
Austen.....3,230 0 0
Eppit.....1,150 0 0
Shrabole.....3,698 0 0
Creed.....3,055 0 0
Solih (accepted).....2,835 0 0
Gotham.....2,575 0 0

Contract No. 2.—Smith and Engineer's Work.
Smyth & Co.....£898 15 0
Drury & Biggleston.....865 0 0
Garrett & Co.....649 0 0
Weeks & Son.....639 10 0
Spencelayh & Archer (accepted) 618 0 0

For house at Coolhurst, near Horsham, Sussex, for Mr. C. Scrase Dickens. Mr. M. Dighty Wyatt, architect. Quantities supplied by John Young:—

	Local Stone.	Add Ransome's Stone.
Myers & Sons	£8,229 0 0	£ 210 0 0
Cheel	5,415 0 0	465 0 0
Abraham	5,174 0 0	491 0 0
S. Simpson	5,319 0 0	288 0 0
Simpson & Son	5,209 0 0	449 0 0

Wood.....4,389 0 0
Sharpton & Cole.....4,339 0 0
Foale.....4,035 0 0
Henshaw (accepted).....3,567 0 0

For an oratory, Kensal Green, for Baroness Wald. Mr. Pugin, architect:—
Hill & Son.....£350 0 0
Hodgson.....290 0 0

The Builder.

VOL. XXVI.—No. 1313.

The Old Crosses of Gloucestershire.

HERE and there, in the market-places on the waysides, and in or near the churchyards of Gloucestershire, stand the remains of about eighty crosses. We have to call to mind that the county contains three hundred and thirty-eight parishes, two cities, and twenty-six market towns before we can realize the proportion this number bears to its extent. Between thirty and forty of these crosses are now represented only by inconsiderable fragments: in some cases only by their steps, in others only by their sockets; but there are also included in the number some of the most interesting examples of these monuments in the kingdom. Mr. Pooley* has diligently collected measurements and drawings of all the known remains, including those reduced to such fragments as we have mentioned, and, aided by the somewhat meagre particulars afforded by the county history and traditions, has placed his survey in the hands of the public in the form of a pleasant unpretending volume. His collection includes illustrations of crosses that were once famous, but are not now to be found, as well as of some that have been removed and others that have been restored. Gloucester, for instance, once possessed a fine old cross which stood at the point of intersection,—the “cross”—of its principal streets. It is marked in Speed’s map of Gloucester, 1610, and an engraving of it is given in the *Vetusta Monumenta*; but not a stone of it has been preserved. Mr. Pooley reproduces this illustration of the lost treasure. The vicissitudes of some others are represented with like care. Bristol cross has likewise been removed; but it has been preserved, and a new one, carrying out its sentiment, placed on its site. Some half-dozen have been restored with more or less feeling. As in other parts of the country, some of them are built in close proximity to wells; and in one case antiquaries

find it difficult to decide whether the dwarfed pyramidal structure close to a spring was originally intended for a cross or a well-cover.

Of all the Gloucestershire crosses, perhaps that of Bristol was the finest. Mr. Pooley relates its vicissitudes with more detail than he is able to give in most cases. A town clerk in the reign of Edward IV., who must have been an archæologist in his day, has left a drawing, among the archives of the city, of what he considered was the aspect of Bristol in the Saxon era (?). He shows a four-sided walled city having an embattled gateway at each angle, from which four roads depart, all meeting in the centre of the town, thus forming a St. Andrew’s cross. At the point of intersection he places the High Cross. The first historical mention of the structure occurs in a MS. calendar, where the year 1247 is given as that of its erection, when Bristol and Redcliffe became one town and the two former markets were merged into one; “and both being made one were kept where now it is, and a faire cross there built, viz., the High Cross, which is beautiful, with the statues of several of our kings.” This account does not, however, quite tally with other evidence, which gives the exact date as 1373, and the occasion of its erection a desire to commemorate a charter granted by Edward III., in which the municipal difficulties of the burghesses were diminished. Hence, we may conclude that tradition handed down the existence of a cross upon the spot shown by the Medieval town clerk in his restoration, and that, as in these later days, it has in the course of centuries been more than once removed and replaced. It is pretty clear that the memorial of Edward III. is the cross that stood down to the year 1763, when it was given by Dean Barton to Sir R. C. Hoare, of Stourton, who removed it to his seat, and had it erected there at a cost of 300l. It was a building of three stages, surmounted by a spire, the whole being 39 ft. 6 in. high. The first stage was an open arcade; the second a series of four niches filled with the full-length statues of the kings who had been benefactors to the city; and the third another range of canopied niches, each having the figure of a monarch seated in it. It was built of a coarse grained oolite, the liability to injury from frost and rain, being guarded against by polychromatic decorations. The upper stage of statues appears to have been added in 1633, when it was placed in efficient repair, though somewhat marred by the curious design of its new pinnacle. Mr. Pooley finds evidence that it was re-painted and gilded in 1697 with such sumptuousness as to rival every structure of the kind in the kingdom; and in 1733 taken down at the request of a silversmith living close by, who feared that it would fall and kill him. It remained for a time in the Guildhall forgotten, when Alderman Price exerted himself in its favour, and got it erected in the centre of the College-green; but in 1763 it was again protested against and pulled down, and thrown into a corner of the cathedral, where it remained till the dean, mentioned above, gave it to the owner of Stourton. In 1851 a feeling of regard, or compunction, or regret, induced the burghesses to build a new cross, and place it on the site this interesting relic first occupied, which was done at a cost of 450l.

Cirencester Cross has shared a similar fate, so far as it is removed and rebuilt in private grounds. This was of a different form from those of Gloucester and Bristol, and not more than 20 ft. in height. It was a tall shaft standing on a solid base raised on steps, or on a calvary. The capital of the shaft possessed some sculptured decorations, and was surmounted by a cross. There were six crosses in the town about eighty years ago; but this is the only one that has been preserved. It was removed first to the neighbourhood of a fine avenue of firs in Oakley Park, the seat of Earl Bathurst, and thence to

another spot in the same park. The same form of cross exists at Clearwell, Ayltherton, and Sydney, diversified only by the number of the steps, the ornamentation of the pedestal, and the absence or presence of the shaft. That at Clearwell has a new shaft. The pedestals and steps of the two latter are the only remains.

A different form of cross exists at Iron Acton. It is called a preaching cross, and is built in the churchyard, on the north side of the church. This structure is raised upon three octagonal platforms, rising one above the other, and diminishing in size. It consists of four arches formed by four buttresses connected by groining ribs to the capital of a central shaft. Three of the arched spaces are divided by transoms with cusplings, while the fourth is quite open to admit of the entrance of the preacher. On the crown of the vault of this first stage is a four-sided shaft, having a niche on each face. The basement to this shaft is ornamented by eight shields clasped in the hands of winged figures. The surmounting cross no longer exists; but when present the structure probably measured about 30 ft. in height. Four of the shields are charged with the emblems of the Passion, two are incised with armorial bearings and two are left blank. The armorial bearings give our author the date of the cross (*circa* 1430). This is the only example of this form of the cross in the county.

Mr. Pooley was fortunate enough to discover the head of a remarkably fine cross at Amney Crucis. The base and shaft stood in the churchyard, but, as in so many other cases, the head was gone. This, which he found under a heap of rubbish in a recess on the south side of the church, has now been restored to its proper place, much to the intensification of the interest of the locality. More than this, it appears to be the only evidence extant that illustrates the title of the parish, Amney Holy-Rood. Raddes accounts for the name from the circumstance of a large cross being there; and Sir Robert Atkyns mentions that it is derived from the Holy-rood in the church. But the newly-found head of the cross suggests another version. In one of the four niches is a representation of the Virgin and Child, which Mr. Pooley considers is a testimony to the rights of Tewkesbury Abbey (likewise dedicated to the Virgin) over this church and parish. In the second niche is the complete Rood, to signify, as the image of the Virgin did with reference to the abbey of which she was patron, that this church was dedicated to it. In the two smaller niches, one at each end of the oblong block of stone forming the head, are two figures, one of which our author reads as Gyraldus, first abbot of Tewkesbury; and the other as Robert Fitz-Haimon, a Norman knight, who, at the suggestion of his wife and the pious Gyraldus in question, rebuilt Tewkesbury Abbey. Altogether, taking the costume and style of architecture into consideration; our author concludes that a subsequent abbot, Parker, erected the monument at the close of the fourteenth century as a testimony of the dependence of the church and parish upon the abbey; as an authentication of their title; and as a perpetuation of the memory of the abbot and knight who founded the establishment at Tewkesbury.

Among the mutilated remnants the cross at Westcote is remarkable for the suggestions it makes of its heauty before destruction. The base alone remains. This is 2 ft. 1 in. in height and 2 ft. 1 in. in diameter, of an octagonal form, each face of the octagon being recessed as a trefoil-headed niche, with a standing figure in it, having the appearance of thirteenth century workmanship. It is a mere wreck; but the fate of the village or church to which it is supposed to have belonged is still more melancholy. There was once a village called Coombe Baskerville in this parish, and this bit of the cross is the only memorial of the fact that has ever come to light within the memory of the oldest inhabitant.

* Notes on the Old Crosses of Gloucestershire. By Charles Pooley, F.S.A. With numerous illustrations on stone and wood. London: Longmans, Green, & Co. 1868.

Village and church have as completely disappeared as a Mediæval crop of hay.

The nearest approach to the type of the celebrated Yarnon cross in Oxfordshire is in Didmarion churchyard. Here it is called "the preaching stone," though when the present incumbent came to the parish only the top of the broken shaft was above ground, the octagonal socket being buried in accumulations of soil. On four of the faces of its base are four half figures sculptured in high relief, which are, probably, intended for the four evangelists. It is now raised on two stone steps, set diagonally; had these been circular, it would have resembled the Yarnon cross still closer. The Biskay cross differs from any other. This well-known object consists of a panelled hollow hexagon, surmounted by a hexagonal truncated spire, ornamented with cusped arches and recesses. Probably portions of the original base and summit are both missing, though a small modern cross finishes the structure at the present day. At the angles of the hexagonal pedestal are columns supporting cusped arches; and half-way up the pyramidal cover, at the angles, run thick fillets. Mr. Pooley tells us that the good villagers once kept their baptismal font upon the top of this cross, though, to their credit, they have now removed it into the interior of the church. This is the cross which some archaeologists say is, perhaps, an isolated campanile. The villagers call it "the bone-house," and it has been considered a well-cover. Our author says,—

"There is a traditional belief that some one was drowned in a well in the churchyard, and that the well was ordered to be closed, and this building erected over the spot. This is mere conjecture. The truth more probably is, that formerly a spring, since dried up, rose there, which, according to custom, was protected from pollution by the erection of this building over it, and at the same time consecrated by having a cross fixed on the top. The circumstance of the baptismal font having been placed there would lead to the supposition, that at one time it was used in that situation for baptismal purposes, and perhaps water was obtained from the clear spring below."

At King's Weston, in a garden in the rear of King's Weston House, is a cross which is said to be the Sailors' Cross, or one to which mariners paid their devotion as they sailed up and down the Severn. It is of a type very common in the county,—a tapering shaft squared at its foot by broaches, with a solid broached socket set upon three steps. Ivy has grown upon it up to its summit, which, however, is not more than 9 ft. from the ground. That this is ground not yet explored by the archaeologist we may assume from the discovery of the foundations of a chapel close by a few years ago, concerning which no information appears to be at hand. At Calmsden there is a tall tapering wayside cross, with a spring of clear water bubbling at the foot of it. It is placed on four steps, and is composed of a pedestal, a hexagonal monolith, and a cube, the four sides of which face the cardinal points. Placed there in the early part of the fourteenth century, or in the days when the Knights Hospitalers of Jerusalem were located at Quenington, close by, this structure has escaped the rough treatment that so many have experienced. The charm it gives to the elm-shaded nook in which it stands is great. Mr. Pooley's labours will doubtless secure the preservation of many fragments that might otherwise have been lost sight of; freshen many memories; and serve as an agreeable indication of what Gloucestershire possesses in this department of archaeology.

IMPERIAL ARCHITECTURE AND IMPERIAL FINANCE.

THE architect, whatever may be his political bias, must confess a weakness for the French empire. Whatever other claims the second ruler of the house of Buonaparte may have on the gratitude of France, he must at least be regarded as a great builder. We may criticise style, we may say it is easy to build at the cost of others, we may apprehend evil consequences from over-building; but, after all these and many other objections are exhausted, the architectural facts remain. The second Emperor of the French cannot be said to have found Paris brick and to have left it marble; but if he found it fit for the capital of France, he bids fair to leave it fit to be the capital of the civilized world. The completion of the Louvre alone would have reflected no slight glory on the reign of any monarch of the line of St. Louis. The name of the ferocious

Alva is borne by the busiest street in the world, the *Via di Toledo* of Naples, which was a long, straight, military road, pierced through city and suburb by that unsparring veteran, but which in width and grandeur is in no way comparable to the *Rue de Rivoli*, although incomparably more picturesque. For the painter, indeed, and for the antiquary, Paris is now to a great extent spoiled, no less than it is for that erratic and characteristic group of natives whose chief delight is in the building of barricades. The citadels of *Émeute* are overthrown; the centres of insurrection are brought under direct lines of fire. The new quarters for the garrison of Paris are no less admirable for their military convenience than for their architectural fitness for their object. Masked guns may at any moment enforce that supreme reason which is the logic of a man who holds an army in hand. In these piles of palatial buildings, miles of broad street and broader boulevard, careful and studied provision at once for the proper accommodation of metropolitan traffic (so much needed in London) and for the supply of possible political or military exigencies, it is impossible to ignore the genius of a great builder. As to the cost, we have a word to say; but it is so common to see money melted away without result, that in a case where the result is colossal we must be excused for lingering on that fact with the admiration which it demands.

But the building energy of the empire is not confined to Paris. Activity is normal in the France of our day. Lyons, long a stronghold in which discontent could entrench itself at the shortest notice, is no less transformed than the capital. Marseilles would be unrecognizable by the good bishop whose devoted life during the ravages of the plague has consecrated his memory by a more indisputable canonization than that against which the "Devil's Advocate" is called on to plead at Rome. Nearly two milliards and a quarter of francs—a sum equal to ninety millions sterling—have been "borrowed" since 1852 by the towns, departments, and communes of France, including Paris; so that the past fifteen years have been good times for all those who live by the click of the trowel or the blow of the mason's hammer in France; good times for most of those who live by the compass and drawing-pen.

It is evident that the question how far this extraordinary architectural activity has been over-stimulated and unnatural is one of immense importance. With us, where the architect still earns a living (to the envy just now of his sturdy but starving brother, the engineer), the lesson to be derived is one of no small importance. It chiefly concerns us to read it aright. Two main perils are likely to follow a forced activity in city building: the one is, that the consequent rise of rents may bring discomfort and distress on the population; the other is, that the accumulation of workmen is such as to make it a grave political danger to discontinue their occupation. We may add the great sacrifices often entailed on the poorer classes of citizens, or at least of city dwellers, by the "improving away" of their humble abodes. For the rent—its struggle between the owner of capital invested in expensive residences for due return on his outlay, and the inhabitant who, not discontented at the price of that which, *bon gré, mal gré*, has been substituted for it—will, no doubt, sooner or later, adjust itself. But the temper of the people will not be improved in the process, and spent to a considerable amount must fall upon some one; and the some one always ultimately means the public. The second danger is one which we can less realise in this country. Its magnitude is evident to those who are familiar with the genius of the French nation, or even with the facts of French history. The worst of it is, too, that, whatever may be its magnitude, it has been actually incurred, and that, even within the past few months, significant hints have been given that it is by no means imaginary.

The reconstruction of Imperial Paris, of an Augustan Lyons, a Julian Marseilles, the stimulus given to the labours of the architect and the engineer by the powers of the prefects of departments, is, however, but a small portion of the magnificent expenditure of the Second Empire. During its fifteen years of existence, it has spent, exclusive of the above-named departmental outlay, eleven milliards of francs more than the total expenditure incurred during the fifteen preceding years of parliamentary government. Of that sum about eight milliards

has been derived from increased taxation, and the remainder from the expeditious resource of loans.

The main evil of reckoning without one's host is the probability that the operation will have to be repeated, and that to the satisfaction of the latter. It is a long account, that has been running up for the last fifteen years, and although the veritable host, the French nation itself, has not yet called for the reckoning, a sort of programme of the Bill has just been sketched by M. Horn, and that in very formidable figures. Yet the whole case is far from being exhausted when we have grasped the summary of the *Bilan de l'Empire*.

There can be no doubt that the national expenditure, or rather the administrative expenditure, of the French empire has been on a scale of unprecedented magnitude. Not only so, but it may be said with perfect propriety that it has increased, is increasing, and ought to be diminished. It is something to disentangle the purposeful confusion of the French budgets. It appears that in these documents the most instructive point, the sum total, is generally so studiously veiled that it is only by a degree of clear-headed investigation, for which few men of adequate ability have time to spare, that it becomes evident what is actually expended from year to year. There are budgets ordinary and extraordinary, prospective budgets, rectifying budgets, supplemental budgets, and definitive budgets. The amounts of three or four years, in different stages of "rectification," are continually referred to together; and the habit prevails of stating all those various items rather in a relative than in a positive manner. The increase or diminution of an amount, as compared with the magnitude of the amount devoted to the same purpose in some other estimate, or in some former year, is the main feature visible in the reports of the finance ministers. To present actual facts and definite totals in a few intelligible lines seems to be repugnant to the genius of imperial finance.

It is, therefore, a service to those to whom the stability of political institutions is matter of concern, to bring clearly before their view the main and gigantic outline of the French revenue, and the far more colossal outline of the French expenditure. It is in the comparison of the two that the gist of the question lies. It is much to know that France has been living, financially, since 1852, at the rate of 30,000,000 sterling a year. It is more to know that the Imperial Government commenced by spending 12,000,000 sterling per annum more than its predecessor. It is even more to know that, after fifteen years of rule, that Government is now spending 12,000,000 sterling per annum more than it did at its commencement, or 24,000,000 more than its predecessor. But it might be the case that this great increase in expenditure was only an indication of the elastic and vigorous growth of the national prosperity. In itself, a large expenditure may be regarded as a sign of wealth. To say, then, that the France of 1868 is spending more than a third more than did the France of 1840, may be met by the rejoinder that the difference is the result of a healthy and robust development of the elements of national grandeur.

It is here that the importance of clear and distinct statement becomes apparent. The import of the facts thus far may possibly give rise to differences of opinion; but the actual facts are not matters of opinion, but of definite knowledge. As to the wisdom or the reverse of a liberal expenditure there may be room for discussion; there can be no room for doubt as to the result of a steady, unchecked, augmenting increase of debt. This certain test of progress or of decline cannot be altogether concealed. While raising revenues unknown to the earlier rulers of France, the financiers of the empire have more than doubled the national debt. Since the year 1854 eight loans have been authorized, amounting to a total sum of 125,480,000. The floating debt, which will only be partially reduced by means of the 18,480,000 loan of the present spring, amounts to 25,000,000 more. The same profusion of expenditure,—for to expend continually 10 or 12 per cent. above your income is profusion,—marks the proceedings of the minor administrations of the country no less than that of the ministry of finance. The cities and corporations of France, including Paris, have, as previously stated, raised loans to the amount of 90,000,000 sterling within the same time. Exclusive of this the State alone has steadily and systematically exceeded its income

large as that income has been, during the whole time of the Second Empire. The loans which have met and, as it were, veiled that excess, have been placed on the market in a manner unprecedented before the present reign. The ultimate source of revenue, the public, has been appealed to directly, and not, as in ordinary financial operations, through the agency of the larger capitalists. The readiness with which the country people of Franco have laid out their savings in the investments offered from time to time by the Government has increased the horrowing power of the latter, and removed that check which is imposed by the experience of men accustomed to operations of a monetary character. Confidence, no doubt, is thus to some extent shown in the Government, while, at the same time, the bonds of society may be drawn closer by interesting the poorer classes in the stability of existing institutions. But a facility in anticipating the resources of the future, which must be termed a fatal facility, has financial perils enough in its wake to counterbalance any such political advantages.

The loan of the present year has this special feature of evil promise. It does not even profess to be the last of a long series. On the contrary, on the very face of the application it is shown to be a mere loan on account; not providing for the floating debt, which is only reduced by about a third—not even providing for the expense of the re-organisation of the army—in fact, doing nothing but give temporary and partial relief. Temporary relief, at the cost of permanent and intolerable burden. So long as M. Fould was at the head of the finance department—so long, indeed, as his application to that able financier to take office on his own terms, in case of need, was possible—France was always in a state of hopeful expectancy as to her finance. If revenue did not meet income this year, it would do so, it was anticipated, next year; if not, certainly not later than the year after next the equilibrium would be established. For the first time this promise has now disappeared. Loan this year does not mean no loan next year. Quite the contrary. The revenue of this year being insufficient to pay the outgoings, including the interest on former loans, 18,480,000*l.* is borrowed to stop the gap, and to increase by the additional interest which the tax-payer has to provide to the burdens on the already insufficient revenue of next year.

There is one set-off to this gloomy picture—a picture which is by no means that of France alone, but which more or less accurately represents the state of affairs over the greater part of the European continent. The property of the French railways will ultimately revert to the State. In 1865 the net revenue derived from the railways was 12,500,000*l.* The augmentation of the gross revenue during the past year was a little over 2,000,000*l.* Thus, if the French national debt could be kept within the limits which it attained in 1865, there is reason to hope that by the year 1955 the whole burden of the *Rente* would be removed from the shoulders of the tax-payer and provided for by the self-collected revenue of the railways.

It is rather a long period to wait. There is that amount of hope in the distance; but what a distance! How does experience in other countries tell us that the expected benefit may be discounted before it arrives? As it is, if the present rate of increase of the French debt be maintained, a sum equal to the whole capital represented by shares and debentures will be added to the existing debt within thirty years. Within the ninety years at the expiration of which the French nation is to enter on the proprietary enjoyment of its railway revenue, three times the total amount of the entire railway capital will have been borrowed to make both ends meet. The hope and comfort of 1955 is therefore somewhat cold.

The inadequacy of godsend to restore the balance of national income and expenditure is being illustrated even as we write. The vast and hereditary property of the Church, in the former kingdom of the Two Sicilies, has just been cast into the seething oculo of Italian deficit. What is a network of railways in comparison to that long accumulating and fertile estate—the harvest reaped by the clergy, where their influence was most irresistible, in the very garden of Europe? Wherever you see a spot specially favoured by nature, rich in the heaviest growth of grapes, shaded by the loftiest stone vines, dark with arcades of orange-trees, or glittering with the silvery foliage of the olive, throughout Southern Italy, you may be sure it is

the property of the Church. Such a boon, or such a robbery, call it as we like, should have extinguished extreme poverty for the remainder of the century. How far will it go? The telegraph makes answer as we write:—"Comte Cambrey Digny demonstrated that not more than 574,000,000 lire of ecclesiastical property were available to remove the deficit of 1868 and the forced currency. He deemed it necessary, therefore, to meet the deficit of 1869 by new taxes." The actual amount of the Church property has never yet been clearly known. Eighty millions sterling was spoken of as a low estimate when the idea of seizure first assumed a definite form. The evaporation of this noble property into a miserable contribution towards the deficit of only a couple of years, is one of the most striking and appalling lessons of modern national finance.

We have been almost alone in the English press in calling, and repeatedly calling, the attention of our readers to that which, in our deliberate opinion, is the first European question of the day. Even war itself, uncertain in its outbreak, is now for the most part brief in its fury, and chiefly injurious, in its permanent effects, by the increase of debt which it involves. The steady, certain, and rapid increase of public debt menaces more unavoidable general distress, and probable internal convulsion, all over Europe. In Paris the minds of men are now becoming fixed on this feature of the political situation of the day. Four pamphlets have appeared within the month of March, grim satires upon the "inspired" and feeble "*Vives de la Dynastie Napoléonienne*." The last of these publications, an examination by M. Achille Mercier, of the *Grand Livre*, or record of the public debt, distributes the burden between the successive Governments of France in startling proportions. Eleven per cent. alone was incurred by the old régime, Three per cent. by the Parliamentary Government of the Restoration and the July Monarchy, Eleven per cent. by the First and Second Republics, and Seventy-five per cent. by the First and Second Empire!

The attempt is now being made to galvanize into artificial life the failing attractions of the foreign loan market, and the most unusual profit, upon paper, is promised to those who will take shares in a species of consolidated foreign loan company. It is, of course, possible that among a number of foreign indebted Governments some may continue to meet their engagements for a year or two longer than others. Any man who thinks it wise and safe to invest money so as to obtain a promised or even an incipient return of 15 or 20 per cent. can generally find the means of doing so. There is a west-end discount market in which such rates are current, no less than on the foreign hedging markets. But we cannot too distinctly repeat that, unless some vast revolution occur in European finance, the cessation of the payment of dividends on the national debt of Europe is, with few exceptions, a question of time alone. And when the crash comes in one State, it is not very likely that neighboring stocks will be permanently stable. We have called attention in these pages to the rapid growth of the metropolis of England—a fact unparalleled in the march of European civilization. London doubles her size in forty years. The debt of Imperial France laughs at the slow progress of the London builders. It has more than doubled itself in fifteen years. *Vive la dette!*

ON THE UTILIZATION OF SEWAGE BY IRRIGATION.*

The Crop.—From the principle and conditions of sewage irrigation, its peculiar fitness for the cultivation of grass lands has long since been definitively settled, and hitherto there has been discovered no other crop which so fully repays its application, or which, indeed, can receive beneficially the whole year round, the constant flow of the liquid. We find, therefore, in all those districts where the systematic utilization of sewage is being carried out, grass, in many varieties, is the staple product. Other crops must arrive at a mature growth ere they can be reaped with profit; but with grass it is not so; it may be cut with advantage in a green state, and so disposed of; or, again, it may be eaten on the ground at various stages of growth, and by these means several successive crops may be

obtained. This important quality of reproduciveness, the facility of its cultivation, and the readiness with which the ground may be turned to irrigation purposes, render the adoption of the grass crop by far the most profitable. Where a root is cultivated, the judicious application of sewage may be attended by immense benefit; but the crop cannot be repeated, nor can the liquid, which is at all times flowing, be regularly administered even during the one growth. Consequently; although arable lands may be made accessory to the utilization of sewage, and thus reap considerable advantage, grass lands alone can be relied upon to develop to the full extent its true commercial value.

Cereals are not adapted for beneficial cultivation by methodical or regular irrigation, as, generally speaking, the climate of England contains of itself too much humidity, without artificial addition. It is in fine dry climates, under an unclouded sky, that the soil gives forth the finest crops of wheat and other grains; whereas, on the contrary, universal experience has shown that the richest pasture-lands are found under a moist sky. Moisture in a cold country is indicative of a temperature comparatively mild and equable; and a mild temperature, with moisture, promotes the rapid growth of grasses; it is certain, moreover, that the grasses most rich in nutritive properties, especially in milk-producing, are those of rapid growth. In putting sewage-manure in regular quantities on corn lands, you are supplying proper ingredients in a too diluted form; in bestowing it, in like manner, upon grass lands, you are supplying these same ingredients in their most beneficial form.

Still, there are occasions when every crop may derive benefit from a timely application of sewage, as when in tender growth, after a protracted period of drought, it would have the same invigorating effect as a shower of rain, besides a certain manual power. The dressings in these cases must be very light, and carefully administered; and where the crop has attained any weight, and the use of the hose and jet rendered hurtful, special preparation of the ground will be required, an expense which may weigh so heavily as to take away the profit. If, however, by a very flat system of catch-work, at slight cost, sewage is thus brought into use upon cereal crops, undoubted benefit will accrue during a dry season.

The almost universal application of the sewage irrigation principle has been illustrated by a remarkable series of experiments at the works of the Metropolitan Sewage Company, at Lodge Farm, near Barking, which have been fulfilled upon so extensive a scale as to be deemed conclusive. The land is of the poorest kind, the gravelly sub-soil coming up to the surface in many places. Of this soil, about sixty acres was in 1866 prepared for irrigation, partly by the system of bed-work, and partly by catch-work,—no fertilising material of any description having been previously applied, with the exception of the harrowing in, here and there, of a thin and patchy coat of rye-grass of the past season. The results are described as being nothing less than wonderful.* On one piece, eight or ten tons per acre of rye-grass were cut early in April, ten or twelve tons were cut in the middle of May, and twelve tons again in the week ending June 22nd. This was sown in the August of the preceding year. Another small piece adjoining, which had been in potatoes, was sown in September, and did not yield the first cutting until early in May, when it produced not less than sixteen tons per acre; after which, in the week ending June 22nd, it produced a crop of fifteen tons to the acre. This is stated to have received 4,000 tons of sewage per acre. From a very poor gravelly slope, seven acres in extent, upon which was sown 2,400 tons of sewage to the acre, twenty-five tons of grass was taken in two cuttings. Mangel-wurzel, potatoes, lucerne, flax, and wheat were all remarkably luxuriant under certain applications of sewage. On two parts of a poor field of wheat the plant was strong and thick, with ears plentiful and large, the only explanation of the difference being that here during the early growth of the crop three or four slight dressings of sewage had been administered.

In this way Alderman Mechi has found sewage to be good for every kind of crop, and as a special preparation for subsequent crops.† For when the ingredients of fertility may not forthwith be utilised by the plant, the soil retains

* See pp. 146, 163, 202, and 222, ante.

* *Agricultural Gazette*, July, 1867.

† *Rep. Met. Sewage*, 1864: 3333, 3100.

them until required. A very clear illustration of the expediency of treating wheat crops with sewage in their earlier stages of growth was given in evidence by Mr. J. Dales. During seven years that gentleman applied nothing but sewage to a field of ten acres, which returned crops of wheat of unusual quality and quantity, yearly increasing, so that the last year's crop was the best. The application was regulated during two or three months every year.* We are also given to understand by Baron Liebig that in the *Commune of Oligheim*, near Rastadt, in Salzburg, sandy, unproductive soil was converted by the application of sewage into flourishing cornfields.† The Earl of Essex, experimenting upon sewage, marked out two adjoining acres in the centre of a field of wheat, to one of which he applied 270 tons of sewage, and to the other none. On being reaped, it was found that the first acre returned a value of wheat in excess of the second amounting to 3*l.* 1*s.* 6*d.*, or 2*d.* per ton of sewage applied.‡

The above cited examples of the successful utilisation of sewage in grain cultivation are too numerous and consistent to be considered as exceptions to the general rule; and, although the more important of them have not been subjected to the conclusive test of time, yet they afford a very good *prima facie* proof that few circumstances exist in which this manurial agent may not be utilised advantageously, either alone or as an accessory. It must be understood with reference to cereals, that no such quantities as have been instanced at Barking in the growth of ryegrass can be applied. It is generally held that a free and constant application of diluted manure tends more to the increase of straw than of the grain itself.

Maricic, or Italian ryegrass and clover, has been found by experience, both here and on the Continent, to be peculiarly adapted for irrigation, and it is therefore preferred to all other crops for this purpose. It is naturally of a rapid, luxuriant growth, and most readily avails itself of the fertilising properties of sewage. So extraordinary is this facility that it has been credibly asserted that as much as 100 tons of Italian ryegrass per acre has been reaped in a single year, while of ordinary grasses the quantity has reached 30 or 40 tons.§ With solid manure we have the authority of Mr. Lawes that 12 tons is the maximum quantity in ordinary grasses; but the most remarkable fact in connexion with this wonderful luxuriance of growth is that, according to the analysis of Professor Way, grasses irrigated with sewage contain 100 per cent more meat-making matter than grasses not so irrigated.¶ Experience, too, has shown that the milk from cattle fed on this grass produces far more and finer butter than usual, and is consequently in much greater demand. The old fallacy, therefore, that forced growths produce thinness and indelicacy in the article grown is thus once more signally refuted.

The fact that hitherto ryegrass alone has been found to possess this uncommon property of beneficially utilising sewage the whole year round, has been cited by the opponents of sewage irrigation as a fatal drawback to that system. It is asked,—Where is the market for such enormous quantities of a single product to be found, supposing that the whole of the town sewage of this country were to be applied to its growth? It is asserted that such a market does not exist. This assertion cannot be maintained. There has been of late years a charge laid against English agriculturalists of a tendency to curtail the cultivation of the wheat plant and extend the cultivation of pasture. Each year finds the extent of corn-lands decreasing through the high prices of manures and other causes, while the production of live stock increases. Every year the burthen of foreign importation grows heavier, as well in cattle as in corn; but far more seriously in the latter than in the former. Whatever tends to lessen this grievous burthen should be pursued with energy, and every discovery in agricultural science should be received as another step regained towards national solvency. The immense production of

food for live stock in the shape of sewage-grown ryegrass must inevitably lead to the stoppage of foreign importation, and ultimately to the restoration of corn-lands to their original purposes, manures of every kind being brought down in value. All the irrigation farms in the neighbourhood of large towns are stocked with cattle, which, as has already been said, are reared in fine condition, producing the richest milks and the finest flavoured buty.* It is possible also that the making of hay by artificial means may soon be introduced as an efficient auxiliary.

On the cultivation of ryegrass, the land must be broken up and sown every three years. If this be neglected, a steady diminution of crop may be anticipated.

In summing up the advantages derived by the crop from sewage irrigation, the exceeding value of the temperature it presents must not be omitted. It is a consideration of no mean importance, that in a country like England, whose climate is bleak and uncertain, we have at our disposal a vast supply of liquid manure, which, while it is rich in all the elements of vegetable food, comprehends also the quality of regular temperature, so that in winter as in summer, nay, even when the snow is on the ground, the process of vegetable growth may be uninterrupted. And in the colder weather, when its effect is enhanced in value, this temperature riss in proportion as it is needed,—a result, due no doubt to the more habitual use, at that season, of hot-water for household purposes. Conversely, when the temperature of the atmosphere passes a certain limit of heat, that of sewage has a grateful and cooling effect on the soil. In reference to this subject, Mr. Latham says,—“From an experiment made during the winter of 1864 upon the irrigated fields of South Norwood, and carried out during a period of severe frost, he was enabled to cultivate a crop of ryegrass which was only sown in the early part of the month of November, and when measured at Christmas in the same year the plant was found to be 6 in. in height, and was then growing luxuriantly; and during the following year that crop was cut six times, the last of which was within one week of Christmas-day, 1865. The first crop measured 35 in. in height; the second, 40 in.; the third, 42 in.; the fourth, 32 in.; the fifth, 34 in.; the sixth, 14 in.; the total length produced, 187 in., which realised 40*l.* per acre.”‡

Mr. Latham's tables referring to the temperature of sewage at Croydon and Norwood, show that during the months of February, March, and April, 1865, while the temperature of the atmosphere varied from 32° to 67°, the variation of the temperature of the sewage at the outfall was only between 43½° and 55°; giving in the former case a difference of 35°, and in the latter a difference of 61°.

Sanitary Effects of Sewage Irrigation.

As to the Purification of our Water Supply.—In treating of the question of the utilization of sewage, we must always recur to the pre-eminent consideration to which it has reference, namely, the restoration of our riverine waters to their normal purity. If we make, then, a brief inquiry into what has actually resulted in this respect, we shall thereby be enabled to arrive at a proper conclusion as to the purifying effect which irrigation has, or is supposed to have, upon the sewage of towns, and, correlatively, upon those currents which heretofore have been infected by the infusion of such sewage matters. If it be proved that, after sewage has been applied to the land, by a process harmless in itself and at no impracticable expense, the residue—that is, the great volume of water by which the ingredients of fertility are transported—goes to swell the

hulk of our water supply in a pure state, there is needed no further demonstration of the expediency of adopting such a process in all convenient situations. For by no other means has this been accomplished. So important is this point, that irrespective of commercial return, or, further, even if such process were conducted at a certain pecuniary loss, the laws of public health determine it to be our bounden duty to promote its universal adoption until better substitutes be found.

At Croydon, after a litigation costing 10,000*l.* and after every conceivable expedient had been resorted to, the Board was absolutely compelled to have recourse to irrigation; and the river Wandle—the fouling of which originated so many lawsuits with the conservators, and ultimately proved of immense benefit to the cause—now receives the sewage water in as pure a state as clear river water ordinarily is, so that the fish in the stream come close up to the outlet, and have been found within it.* The engineer states that the water after purification is purer than that supplied by many metropolitan companies, and gives the following figures:—

Water supplied to towns contains	
of solid matter	21 grains per gall.
Sewage contains	39 ” ”
Sewage after utilisation contains	25½ ” ”

From this it appears that the amount of solid matter in a gallon of purified sewage water is but two grains in excess of the solid matter contained in the same quantity of the ordinary water supplied for human consumption.

Against this, however, it must be stated that an analysis of the sewage of Edinburgh before and after irrigation, made for the late Mr. Smith, of Deanston, recorded very different results; that whereas, before irrigation the sewage contained in the gallon 324 grains in suspension, and 87 grains in solution, after being passed five successive times over the soil, it contained but two grains in suspension and 72 grains in solution; thus showing that while the abstraction of the suspended matters was almost complete, only 16 per cent. of the matter in solution was taken away.†

The apparent inconsistency between the results of Croydon and those at Edinburgh is capable of a very simple explanation. At Croydon the mode of application has been reduced to a comparatively perfect system, under the supervision of an engineer whose name has been justly identified with the progress of sewage irrigation. At Edinburgh there is no system. The sewage is in the hands of certain owners of land, by whom, or by whose tenants, it is applied by a very rough system of catchwork, with such prodigal profusion that in many cases it passes off in a flood without the slightest percolation into the soil, and in a perfectly discoloured state. Evidence to this effect was given by Mr. Lawes, who certainly can be supposed of no undue prejudice in favour of sewage irrigation.‡

The degree of purity which has been obtained at Croydon must, therefore, be admitted as a practical illustration, capable of further improvement, of what can be effected by sewage irrigation, when conducted in a careful and scientific manner. When this result is compared with the results of all other methods of purification hitherto tried, many of which have absorbed a serious proportion of the rates annually levied for sanitary purposes, it cannot be rejected as doubtful or in any way unsatisfactory, and may be reasonably accepted as a valuable solution of the most important item in the sewage difficulty. The endless variety of circumstances in which our populous districts are placed may no doubt prove a barrier to the universal adoption of irrigation as a remedy. Yet an impartial estimate of its merits and demerits cannot fail to leave a well-grounded impression that it is destined to take the foremost place in the progress of agricultural and sanitary reform.

The powerful chemical action of arable land in decomposing and absorbing the dissolved constituents of liquid manure has been long known to agriculturists, and such a thing as its draining off in a violently discoloured state after percolation through an arable stratum is unknown under proper management. Lichig says, “Diluted liquid manure, of deep brown colour and strong smell, filtered through arable soil, flows off colourless and inodorous; and not

* Rep. Met. Sewage, 1864: 3766-70. The first crop scarcely paid Mr. Dales, as it yielded only 33 quarters per acre; but at the seventh year he had six quarters and one sack.

† Rep. Met. Sewage, App. p. 318. It would appear, however (see Liebig's Natural Laws of Husbandry, p. 273), that the sewage here referred to was excrementitious matter alone.

§ *Rep. Met. Sewage*, 1864: 4,698.

nerely does it lose its smell and colour, but the ammonia, potash, and phosphoric acid which it holds in solution are also more or less completely withdrawn from it by the soil, and this to a far greater degree than by charcoal.* (Concerning the supposed direct action of the roots of living plants upon the dissolved organic matter in sewage, there has existed and still exists, no small confusion. We repeatedly see it stated that soil alone will not deprive water of substances thus held by it, but that the living organization of plants is needed to effect a chemical change in the sewage. A few words will dispose of this somewhat prevalent error. The soil alone is the medium by which the chemical transformation of manure is effected, and the plants themselves have no inherent power to chemically dissolve and imbibe their food-constituents. To again quote an eminent authority: "A plant is not, like an animal, endowed with special organs to dissolve the food, and make it ready for absorption. This preparation of the nutriment is assigned by another law to the fruitful earth itself, which in this respect discharges the function performed by the stomach and intestines of animals."†

We see, therefore, that the suckers or root-tubers of ordinary plants can only absorb their nutriment through the digestive medium of the earth,—a process than which nothing can be more natural. The reason why the roots of growing plants have a tendency to facilitate the purification of sewage does not then lie in its capacity to deal directly with the dissolved matter it contains, but in the fact that as rapidly as the particles of earth assimilate the manurial elements, the plant in turn assimilates them to herself in their transmitted form, and thus preserves the land from becoming physically overcharged. A very pointed fact illustrative of this property of soil is, that upon lands where sewage irrigation is carried on it is found that the first crop after the winter season is the heaviest, showing that during the non-period of growth of plants the soil retains the enriching elements of sewage.

At Norwood, the results have equalled those of Croydon; and at Aldershot Camp, where a sanitary injunction was procured against the polluting of the river by the precipitation process, water is more fit for drinking purposes. At Bagby, where the operations from beginning to end were grossly mismanaged, the ground being one time parched and at another drowned, Mr. Walker has stated that, with proper treatment, the water went off in a clear state, although, when drowned and reduced to the condition of a morass, the land of course allowed the sewage to waste.‡ The result of similar judicious treatment at Edinburgh has already been described, and to this cause are invariably traced parallel results elsewhere.

The fact, therefore, that land possesses the property of restoring impure waters to their former purity, by retention of the organic and inorganic matter they contain, may be said to be fully established; and in the present uncertain state of our water-supply, the accomplishment of this end cannot be held as of less than national benefit.

As to its Influence upon the Atmosphere.

Amongst the many attempts to prove the deficiency of sewage irrigation to meet its sanitary requirements, the opponents of this system have taken their stand upon the argument, that the constant presence of so large a volume of impure fluid, as in the case of the sewage of a large city must inevitably tend to corrupt the whole of the surrounding atmosphere, and engender the baneful effects of cholera and other swamp fevers. We are warned, in prophetic diction, that rinderpest, and new and portentous diseases in mankind, will be the unfalling concomitants of sewage irrigation, as well as aggravated forms of typhus and other maladies but too well known; and it is plainly pointed out that in every movement in this direction we are but blindly preparing a scourge for our own backs, in the shape of a pestilential swamp, fated, like the Campanian marshes of ancient Rome, to decimate the land. § To those who have anything like a just con-

ception of the perfectness to which scientific drainage may be carried, and of the quickened action of the soil under its influence, or who know from experience the effect of irrigation upon town sewage, such wild prognostications can only excite an emotion of unmixed wonder that men professing to be followers of science may be so blinded by prejudice as thus to proclaim their ignorance. But as there are many who, while taking a lively interest in this subject, are not enabled by their own scientific or professional knowledge to refute or estimate at its true worth the value of these statements, some little examination into this matter will not be amiss.

Sewage in a stagnant and putrid state, and sewage flowing freshly and rapidly on to the area of absorption, are two very different things. The former gives forth foul emanations; the latter is without perceptible smell, and is perfectly harmless. A handful of sewage-water, such as is delivered on the crop in irrigation farms, may be held to the nostrils without any appreciable inconvenience. As in every condition of water, sewage, if allowed to accumulate and stagnate in any quantity, either in reservoirs or in ill-conditioned sewers, turns to putridity, and becomes dangerously offensive; but in the case of irrigation it is not so. The liquid rapidly traverses evenly laid pipes or brick culverts, and is poured down to its destination in a perfectly fresh state.* It is then passed through the soil—a natural deodorizer of the most efficient kind; and under proper management, as soon as decomposition sets in, the offensive particles are assimilated to the soil and the plant. When this process has taken place, the special system of drainage before mentioned relieves the moistened soil from all superfluous water and danger of saturation. By this means, therefore, of incessant motion or circulation, the fluid is never brought to a stagnating condition; all concentration of offensive gases is effectually avoided; and the state of the atmosphere is such that hardly the faintest odour can be detected during the summer months. So, on the green slopes of high-lying pastures, the pure water falling from the clouds in great abundance enriches the soil and strengthens the herbage, passing off the land harmlessly; while the same water falling upon a flat, boggy, retentive soil, creates a swamp and endangers human life. Accordingly, the argument that the manipulation of town sewage under irrigation is likely to engender baneful effects is destitute of foundation. It is only when its impurities are found in drinking-water, or when the gases they exhale are dangerously exalted by fermentation, that the presence of sewage is to be feared.†

M. P.

TWELVE MONTHS AGO.

BRITISH ARCHITECTURE AT THE PARIS EXHIBITION.

We are reminded of the bustle and excitement of this time last year—of expectation disappointed, of hopes raised only to be dashed, of longings unfulfilled—which accompanied the opening of the Great Exhibition of 1867 at Paris, by the appearance of the Report of the Paris Exhibition Architectural Committee, which has now closed its labours, not without some gleams of sunshine to enliven its last hours.

And, indeed, it would be a pity to let the whole remembrance of this last great display pass away without some lesson drawn from the event, at a time not too remote to notice some of the details of the picture in a mere general retrospect, nor too near to prevent any comprehensive view by the close proximity of detail.

So we gladly recur to the document before us, or, rather, to the events to which it refers, especially as it shows most clearly and distinctly that in the art of architecture at least Great Britain was not behind in the exhibition of works of artistic and constructive building that indicate in a way no mere architectural studies can do the practical importance of the art, and the position which it occupies amongst us at the present day. Speaking now of group I alone (Fine Art—"Architectural Designs and Models"), we may say it was a wise resolution of this committee which limited the selection of drawings at first, when space was valuable, to such designs as

were intended for actual execution, or such restorations as might reasonably be expected to assume some practical form; for thus almost the whole of the exhibits in the British Architectural Court were of a character which showed that the every-day considerations of site, cost, materials, &c., had in a measure ruled the design.

Of an exactly opposite character were the exhibits, generally speaking, of France and the rest of the world,—a circumstance which we could not but greatly regret at the time. The scope thus afforded for magnificence and castle-building in the air, by ignoring all these practical considerations, was too wide, and offered a temptation too strong for the imagination of any artist to resist; and, consequently, an immense number of drawings in illustration of "projects" not likely ever to be realized were contributed by all these exhibitors. While no one would wish to restrain the grand ideas of an architect under such circumstances, no one would argue that designs so produced were calculated to show the real practicability or the real living value of the art so represented. Of course, in a still less degree, would mere academic studies, or fancied restorations of ancient tombs, or the ruined temples of Classic times, be likely to show the state of modern architecture. Yet this representation of modern art was surely the chief if not the sole object of the exhibition; except, perhaps, in the inner circle, devoted to the history of labour, where drawings of ancient buildings might not have been out of place.

In a table compiled by the hon. secretary, Mr. C. F. Hayward, it is seen that Great Britain alone exhibited more than twice the number of designs for actual execution exhibited by all the rest of the world put together; and, with this remarkable fact before us, we think we may fairly congratulate the committee on the result of their labours, and award them our thanks for their perseverance, without which we are assured individuals could not have contributed sufficiently to vindicate the position which we are arrogant enough to assume for Great Britain in the art of architecture.

Further, by comparative figures, it is seen that the Royal Academy and the Architectural Exhibition were not the less teeming with drawings, for all this drain on the resources of the profession; and it must be further remembered that three times as many drawings as were sent to Paris were of necessity rejected for want of space, and that the profession generally was too much occupied with several unusually great and important competitions to give any time to the preparation of special drawings for the Paris Exhibition.

We must refer our readers to the report itself for the how, and the why, and the wherefore, as to photography being added at the last moment, and eventually hung in out-of-the-way places amongst ironwork, tiles, and furniture; but, while lamenting the result, we must not forget the exigencies of the case, and how difficult it is for the executive of any exhibition to suit the various and often extravagant requirements of exhibitors to the dire necessities of limited time and space.

Forgetting, then, most of the little troubles now over, we may fix our minds upon the lesson before us, and draw from the result consolation for the disappointments of the commencement. Turning to the list of awards, we see no reason to complain of the want of appreciation on the part of the jury of the British Exhibition; for do we not see that the fortunate Mr. Waterhouse obtained a grand prize for his Manchester Assize Courts, consisting of a special bronze medal, with the substantial addition of 100 of those ordinary gold medals, called Napoleon; while besides, to Mr. W. H. Lynn, to the late Capt. Fowke, and to Mr. E. M. Barry, were awarded gold, silver, and bronze medals respectively? Thus we may fairly congratulate Architecture on obtaining a far greater proportion of the awards than were obtained by the sister arts in the adjoining galleries; and we understand no *honourable mentions* were permitted in connexion with the Fine Arts.

The Department at South Kensington also deserves the thanks of the profession for its care in forwarding and returning all the drawings, and for the offer of the loan of frames where required, as well as for the organization of the preliminary exhibition; although, to say the truth, some disappointment was naturally felt at the lateness of the arrangements of the drawings at Paris, notwithstanding that this preliminary exhibition was closed in January. The desire also to produce a catalogue on the 1st of

 § Throughout the Lexington Congress papers, there is to be found a multitude of vague assertions of this kind, none of which are supported by substantial evidence. A letter from Mr. Samuel Cousins, lessee of the farm at Norwood, plainly demonstrates the slight foundation of such statements.—See p. 145.

* "From the time of using the closet at any particular house in the town, the time occupied by the contents in passing through the drains, through the straining beds, and out again into the river, varies from a minimum of four hours to a maximum of six hours."—Mr. B. Latimer, *Locam. Congress Papers*, p. 151.
 † To be continued.

April, although most of the drawings not being hung were put away out of sight, lest the emperor should see the incompleteness of the Exhibition, led to some ludicrous mistakes in the list, calculated to keep up the due observance of All Fools' Day; but, upon the whole, the result may be deemed satisfactory, even if it lead to the resolve to do better next time. But it is not only architects' designs in the shape of drawings and models that seem to have gained awards; for in the Art Manufactures Court as many as fifteen prizes or honorable mentions seem to have been achieved; so that as the exhibitors numbered about thirty, every other one, at least, may congratulate himself on being recognised. It will not be expected from what we have said in our former criticisms on the objects exhibited in this court, that we agree entirely with the manner in which these awards have been distributed, nor consider the right "exhibits," to use the current phrase, always to have been chosen for this distinction; but, upon the whole, the committee are probably justified in assuming a congratulatory tone to their exhibitors.

Whether or not the whole result, however, in this particular branch of their labours was worthy of the extraordinary efforts required to be used, and the numerous chances of misunderstanding and risk of objectionable interference with tradesmen and manufacturers, we must leave the committee themselves, who surely must have felt the hurthen of them most, to judge; but we gather from the report that notwithstanding all drawbacks, they would at any similar future opportunity recommend a similar course to be pursued,—of course with hopes of greater success; but as the time is probably far distant when exhibiting art-manufacturers will have any opportunity of benefiting by the disinterested labours of a committee of British architects subscribing their money to guarantee them against any distinctive failure, we may safely leave the consideration of this subject for the present.

At the same time we may remark upon the progress made—in the exhibition at least of Architects' Art Design—since the '51 Exhibition, when Pugin's name alone stood prominently out in bold relief as the designer of art-furniture, though of course rather of an ecclesiastical, and entirely of a Mediæval, character.

In the '62 Exhibition, a long list of names connected with art-workmanship appear; and now, in this '67 display at Paris, almost every work of this special architectural art-manufacture owes its design to some well-known architect.

The fact is in itself a justification to the committee in stating that they have done their best to "vindicate the right of the architect to design, or control the design, of important adjuncts to his ordinary work."

Financially, it appears, that the chief portion of the heavy expenses of this Art Manufactures Court (Group III.)—expenses which, let us say, were most unduly increased by the want of system and arrangement on the part of the French authorities, have been partially met by *pro-rata* subscriptions from the exhibitors themselves, but not entirely so; and thus the dividend to be returned to the guarantors—thirty-four in number—though satisfactory in itself, leaves those gentlemen minus about three guineas each, as well as the time, trouble, and anxiety given to the conduct of the whole business.

ON ARCHITECTURAL SCULPTURE.*

IMMEDIATELY that man has satisfied the necessity for shelter, he seeks to relieve the sense of monotony produced by his rude dwelling, by effecting a contrast of some kind, which he does in one of three ways,—that of form, of light and shade, or of colour. At present our concern is with the first two, and chiefly the second. He is not, however, free to express his thought as to him shall seem good; he is limited by the material conditions of the kind of edifice to be decorated, the material he has at command, and the climate he works under. Hence different styles of architecture and systems of ornament,

* The following is an abstract of an address delivered by Mr. Cressy to the students of the Lambeth School of Art, on the occasion of the annual distribution of prizes, on the 17th ult. The principal illustrations were derived from the collection of casts formed by the lecturer's late father, and recently presented to the Lambeth School of Art, which is now rich in Roman art, but requires some additional specimens of Greek and Mediæval work.

varying greatly, yet each may be good in itself, have peculiar beauties, and be subject to certain definite principles of art.

The earliest architecture we have, Egyptian, is peculiarly instructive on all these points. The religion of Egypt led to a peculiar disposition in plan, combining the temple, the palace, and the tomb. Their climate compelled, above all things, shade. A cloudless sky, a sun approaching the vertical, rendered the hypothetical arrangements of the Greeks, and the bold fenestration of the Northerners, inapplicable. Their buildings had small openings for the direct admission of light immediately below their colossal architraves. Hence their illumination was chiefly by reflexion, consequently neither high nor low relief would have been adequately appreciated. Their contours were, therefore, extremely simple, and their decoration depended on gigantic intagli, relieved by colour, forming the richest, most harmonious, and for its place, most consistent decoration applicable under the circumstances. Again, the system of decoration by intagli protects the surface of the sculptured object, and ensures its durability, while the extreme hardness of the granites and syenites, of which so many Egyptian monuments are built, lends itself to the sunk decoration, and opposes itself to a free treatment of relief.

Turning for a moment to a partly contemporary class of monuments we find an opposite mode of treatment. The Assyrian edifices appear to have been abundantly lighted from above. Their purpose was chiefly civil; they were either temples nor tombs, but palaces; while the material, comparatively soft alabaster, readily yielded to the chisel: hence we find the walls covered with spirited scenes, in extremely low relief. The shadows projected would only tell as broad black lines defining the main outline of the subject, whilst the minor details were rendered more visible by means of colour.

The conditions of Greek art differ wholly from the preceding. The climate, though sunny enough, is not the rainless sky of Egypt. True, the chief monuments are temples; but the cheerful mythology of the Greeks developed itself in a very opposite direction to the African nature worship; while their material leaves nothing to be desired, either as regards facility in receiving or durability in preserving the impressions of the artist. Obviously, as well as historically, the Greek decorative architecture was based upon an imitation of constructive forms, which fortunately afforded the requisite contrasts both of form and shadow to relieve the sentiment of monotony. We can conceive, that to a Greek a brick-built tenement would have been weariness to the flesh; but he did not rest satisfied with the contrasts which his constructive lines afforded; he needed the bolder and more diversified, as well as more subtle, and by degrees slowly he arrived at that perfection which we find in the Parthenon. Here we have three separate modes of decoration:—First, the great group in the tympanum of the pediment. The space to be decorated is triangular, with a back-ground of deep shadow; hence the sculptor arranged a group of perfect statues entirely separate and detached from the back-ground, and telling as lights against it. The massive treatment and individuality of each personage insured the intelligibility and distinctness of the parts. The bounding line of the architecture, especially its triangular form, the absence of divisions, and the simplicity of the mouldings, gave unity to the whole group. The metopes have to fulfil other conditions. In lieu of a triangular pediment we have a long flank of many equal square spaces; instead of a deep black back-ground, a series of shallow recesses partly shaded by the cornice. A single composition would be out of place here; we therefore have a suite of independent groups. Detached statues would project beyond and interfere with the lines of the architecture; we therefore have alto-reliefs, strongly relieved against the back-ground, but attached thereto, and, instead of telling as lights against a dark ground, we have an infinite number of high lights, half-lights, and shadows projected on a ground mainly light. Again, in place of a triangular space, each metope is rectangular, bounded by the horizontal lines of the cornice and architrave, and the vertical lines of the triglyph: hence, in his disposition of the limbs of the several groups, the architect sought to give them as much as possible diagonal directions, or at least intermediate between the vertical and horizontal, while an additional contrast was obtained by the oppo-

sition of the composite form of the centaur to the individual form of the man. Still further and subtler contrasts are afforded between the lines of drapery and the nude as well as by the contrasted action of the limbs in each group, and their open action to avoid unnecessary complication, and throwing the shadows upon one another. The third mode of decoration, the Panathenian frieze, was designed to meet quite other conditions. Placed beneath a relatively narrow portico, no direct light could reach it; the illumination was consequently wholly by reflection from the pavement. High relief was, therefore, out of the question; the figures could neither be made to tell as in the pediment as light on a dark ground, nor as in the metopes as themselves casting shadows on the ground; but the generally diffused light enabled the sculptor, by means of a skillful conventionalism, abundantly to tell his story. To do this, the outline of the figures next the ground does not sink or die into it, but cuts it at right angles,—that is, stands up vertically from the ground, and is even in some places nuderent to get deeper shadow; so that the general composition next the ground is indicated by a narrow but deep line of shadow. On the other hand, all the details within the outline are subordinated, the limbs against the figures, the figures against the horses, the drapery and the accessories are much less relieved than nature, so as to produce no shadows broad enough or deep enough to interfere with the main outline. In all gold the basso-relievo parts nearest the spectator are least relieved; those nearest the ground most relieved. In mezzo-relievo, on the other hand—especially small objects like coins, vases, and decorations to be viewed closely,—greater relief is given to the hair, the ear, and generally to the parts nearest the eye, and less relief to the features and other parts nearest the ground. In coins this treatment has condoned greatly to their preservation, as we often see the hair and relieved parts have, by their projection, protected the features and more delicate portions.

With the Greeks, although in the triple temple of Athens, Paandrous, and Erechthens, the Ionic, and in other buildings the Corinthian order, attained great perfection, as is seen from these casts of the capitals and mouldings, yet the Doric undoubtedly attained the highest perfection. With the Romans it was otherwise: that eminently practical people cared more for the building itself, for its destination and suitability to their wants, than for its ideal perfection. Nor were they such good sculptors as the Greeks: hence they sought to relieve the monotony of their surfaces by giving greater force and enrichment to the strictly architectural members, which these casts from Roman buildings abundantly exemplify. Even in these Greek feeling, or, at least, the principles of Greek art, are discoverable. Contrast the acanthus-leaf of the Temple at Tivoli with those of Jupiter Stator; the one is bladdery, swollen, innane,—in fact, my father believed them to be rather cores than finished leaves, and that sharpness was given by a stucco coat,—the other is sharp, bold, clear; the lobes separated by deep shadows; the veinage of the leaf indicated by clear, sharp, fine lines. Compare again the endless diversity of the Greek with the tendency to mechanical repetition of the Roman, beautiful as are some of the decorations of the friezes—Antoninus and Faustina, for example,—their repetition produces on our minds a sense of the very monotony they were intended to relieve. The egg and tongue, in the contrast between the exquisitely rounded elliptical contour of the egg and the sharply edged and pointed tongue, leaves nothing for the eye to desire; but how it wearies by its incessant repetition! Several of the Roman examples of enriched head and torso are in themselves absolute perfection for their place and purpose; but all repetitive architectural ornament tends to produce a sense of weariness and monotony, which the vitality of Greek and Mediæval sculpture entirely destroys. Not that the Romans had no sculptors, and very skilful ones, too; but their tastelessness was the death of their art. There never were two more wonderful monuments of man's skill and ingenuity entirely misplaced than the Trajan and Antonine columns. Their archaeological value is above all prices; their artistic, nil. To design such a series of bas-reliefs and wind them spirally round a tall column, so that no human eye could possibly read them, argues a perversion of right reason almost incredible. That the French should have repeated the greatest mistake a Roman architect ever made, is still more incredible in so clear-sighted and artistic a people.

The merit of some of the bas-reliefs themselves is very high, and a good opportunity is now afforded at South Kensington of observing their design and execution.

The long night which, so far as art is concerned, followed the ansversion of the Roman empire, is broken by the gleam which we derive from the growth of Byzantine art broadening into full sunshine, as it gradually communicates its influence to the West, and by that somewhat neglected, but, for our present purpose, very illustrative derivative from it, viz., Saracenic. Here we have the same climate, the same materials, in Asia, Egypt, North Africa, and Spain; and yet all is changed. The prophet's prohibition against the direct imitation of nature prevails through the wide extent of the empire of his successors; yet, in the hands of the skillful artists employed by them, so far from becoming a hindrance or impediment, a new style of decoration, perfectly suitable to the faith, the climate, and the purpose of the Mussulman, is wrought out. No more instructive lesson can be given to the young artist than is afforded by the successful struggle with the limitations imposed on art by Mahomedanism. The limits imposed by Protestantism are often lamented by those confined within them; but surely, if ours be the purer faith, it ought to lead to greater results. Starting from the data bequeathed by the decaying Roman civilization, see how the Northman worked out the problem how best to relieve the monotony of his buildings. His materials, his purpose, and his climate differ alike from Egyptian, Assyrian, or Greek. His materials are smaller, compelling the use of the arch; his climate leads him to look from within outwards. He has not yet the skill for representative sculpture, though his imagination is ever fertile and active. Hence his boldly-projecting corbel tables, supported by the admirably grotesque inventions of his imagination, his deep and elaborately enriched doorways, the great feature of early Norman work,—both divisions of his architecture procuring the broad masses of shadow requisite to relieve the monotony which would otherwise result from his flat unbroken wall, or broken only by shallow buttresses. See then how he enlarges upon his shadows, how he surrounds his buildings with arcades, more or less deeply recessed, to get more and more shade, less and less unbroken wall; and how his entrance door recedes till we get the deep cavernous openings of Notre Dame, at Paris, literally overflowing with the wealth of its decoration; and then observe how the architect has subordinated the parts to the whole. Nearest the eye the treatment is very low relief; shadow is not needed there; and as in the Parthenon frieze, the low relief is better read. As we mount towards the tympana of the porches, the relief holds us until in the range called the Galerie des Rois, far above the spectator's eye, the sculptor displays his skill in separate detached figures—individual statues, in fact; while above these, again, nothing interferes with the severe simplicity of the constructive lines. Compared with the sculptures of the Parthenon, doubtless, thirteenth century art leaves much to be desired, but there is also in its teachings many of the lessons which the great works of the great age so emphatically demonstrate. The modes in which the contrasts we have so constantly insisted on are worked out, widely vary. For instance, the alto-relievos which surround the choir at Notre Dame, and which may be advantageously studied in the casts from them at the Crystal Palace, doubtless depart widely enough from the classical canons, and their naive simplicity is calculated to provoke a smile in those unused to the study of that particular school of art. Yet see as compositions how dramatic they are. Compare, for example, "Christ disputing with the Doctors" with Hunt's celebrated picture, where every detail is elaborated with the conscientious care which characterises that great painter. Yet, I confess, the *naïveté* of the thirteenth-century sculptor speaks home more forcibly than the elaboration of the nineteenth century painter. The doctors are, in his version, ordinary grave old men of the period, on an elevated bench or judgment-seat. Christ is not the attenuated Syrian youth of the ascetic turn prematurely self-conscious of his mission. He is a little child, contrasting forcibly with the age and gravity of the surrounding personages; but mark His dramatic action! His little arms are raised to the height of the knees of the doctors

to snatch the book of the law from their grasp. The sculptor could not with the resources of his art indicate the questions heard and asked. What he can give is: the contrast between the new and the old,—the innovating action of the one, the conservative tendency of the other,—the suppression of the book of the law by that which this Child shall teach, is all here. Can we read the story as plainly in the picture?

Fully to treat on the merits and beauties of the architectural sculpture of the Christian period would require, not one, but many lectures. The object of the present address will have been answered if it stimulates the students of the Lambeth School of Art to a more careful and earnest study of those principles which are common to the best art of all periods, and to the manner in which they are worked out in the examples which we are so fortunate as to possess.

PICTURES FOR GUY'S HOSPITAL.

MR. JOHN ABSALON has done a good act, and done it well. He has reproduced in distemper, and of large size, ten of his best-known pictures, and has presented them to the governors of Guy's Hospital for the decoration of one of the sick wards of that institution. They are bright, pleasant pictures, suggestive of genial acts and smelling of new-mown hay. For many a year, we may expect, they will tend to amuse and cheer suffering occupants of the ward. It is a noble gift, and Mr. Absalon deserves warm thanks for it. Our impulse is to express a hope that the example may be followed by other artists, but reflexion puts the wish into another shape. Why make such adornments of our public buildings—such solace of suffering poor—contingent on the munificent willingness of an artist to sacrifice? We would rather therefore express a hope that corporations, directors, boards of guardians, and others, may be led, by what Mr. Absalon has done, to consider with what good effect artists might often be called in by them to cheer and elevate. The "distemper" Mr. Absalon has introduced would be welcomed in every hospital.

RIVER EMBANKMENT AND PLANTATION.

At this critical juncture of the season a few remarks from an old *habitué* of the Temple, as to the desolate appearance of the wide range of reclamation so long rescued from the slime of the Thames, may not be inopportune.

The *Builder* has long since argued for the quay-wall and the plantation, and now that the walls are nearly finished we look with shame at the wide expanse of levelled plateau, extending a mile from Westminster Bridge to the Temple Gardens, and containing over 200 acres, left in waste,—the weeds and grass germinating from the old border terraces to the magnificent walls of granite; and houlders, piles, snags, and waste being scattered fitfully throughout! How long is this to last? or are we to be treated with a repetition of the Victoria-street and Farringdon-street oases?

However good the architectural finish of the quay-walls and landings may be, in this especial position the ornate of plantation is indispensable: the aspect is most favourable for the growth and the telling effect of noble forest trees. The plane, beyond all others, is most suitable to the position, as being the freest of growth, the most unobtrusive, and ornamental. No more stiff and formal poplars; of them we have had lately too much, as in the Horticultural Gardens and Exhibition-road; and although the elm thrives at Buckingham-stairs, and other nooks of the old river banks, it is dingy at best, and lacks the fresh freedom of the lime, which graces the Parisian boulevards, and lends refreshing shade to *gilttons* and indulgent loungers upon chairs beneath.

The display of a double line of plantation, alternately ranged, on either side of a route, 100 ft. wide, would be gorgeous; from above as on the river bank; from below, as contrasting with grand architectural creations as yet in embryo, and, perhaps, in the artist's studio.

There is ample time yet this season to plant out forest trees, especially limes, which are nearly a month later; and these would strike at once, and flourish upon the loose rich soil of the embankment, and might be of ten, twenty, or

even more years' growth; but these at ten or twelve years' would soon luxuriate and spread, thus gaining a year if planted in April, or even in May. The planes of Park-lane, of over thirty years' growth, were moved inwards late in May, and have stood it; but that was a case of urgency, and done at a heavy expense.

Taking the length of embankment at a mile, or 1,760 yards, then each line would consist of 176 trees, at a distance of 30 feet apart, making a total of 352, in alternate ranges, and giving shade throughout the whole length; as the branches would spread across, at least to the centre, at every length of five yards, thus affording to us professionals and to all pedestrians a continuous cool shade from the Temple to the Halls of Westminster.

Any nurseryman would supply and plant these 352 trees at a small cost. They could be had from Hounslow, but Messrs. G. Gibbs & Co. would furnish them and respond for the rich issue of shade and splendour. Surely the Commissioners of Woods, or even the Board of Works, could bestow upon the metropolis, out of their stores of nursery saplings, two or three wagon-loads to form a belt richer than that of Saturn, at least, in sunshine. There are now in the parks transplanted limes, awaiting in their crowded beds open and permanent situations, more than would furnish and headify the melancholy and hungry range which festers in desolation in the arterial centre of the metropolis. It is now the 31st of March: there is a month or more to do it properly and effectively. The Board has but to mark out the two lines; and if the subways or alignments of sewage require change or removal, that could not much injure the young nurselings, which would acquire fresh strength every season from the passing stream alongside, and might, if requisite, be transplanted.

We may and probably shall have to wait a long time for the completion of streets of access to the Embankment; and longer still for the temples and terraces which have been foreshadowed in the speculative architect's studio. So far as the vicinage is concerned it is worse than ever, for whole ranges are kept untenant awaiting speculative changes and improvements: witness the Adelphi and other riverino terraces and approaches; no houseowner knows how to value his tenement *in transitu*. We have no Baron Hausman, and but little public spirit or authority for great municipal improvements, even in the most important and vital portions of the metropolis; twenty-five years of desolation in Victoria-street and Farringdon-street are evidences of dread defaults in this respect. The improvement now sought for is, however, a small item as to the expense, although great and invaluable as to its effect and utility for popular intercommunication; and that, too, upon a central line, which would be a relief to general traffic, and a solace to professional men connected with the Houses of Parliament and all the Inns of Court.

QUONDAM.

SIDMOUTH, DEVON.

POLWHELE, in his "History of Devonshire," says that "the valley of Sidmouth is one of the prettiest spots of enclosed land, and most cheerful to the eye, in Devonshire;" indeed, there is no place on the Devonshire coast, not even famed Torquay itself, that can vie with or exceed it for beautiful scenery. The valley averages two miles in width by six miles in length, and runs from north to south. It is bounded on its east and west sides, and at the north end, by richly wooded and brightly verdant hills, which rise to 500 ft. and 700 ft. above the level of the sea.

The views from these hills of the valley and the surrounding country, on the one hand, and of the lofty deep-red cliffs and the wide blue sea, glowing and sparkling in the sunshine, on the other, are very delightful. In spring and summer the valley is like a well-kept garden. Leafy lanes and woods, sunk deep in the rich red soil, and high hedgerow banks, covered with luxuriant ferns and beautiful flowers, interspersed with elms and oaks of richest foliage, divide and intersect the valley; while numerous apple orchards, just hursting into blossom, and their floors glittering with daffodils, are scattered in all directions.

The town of Sidmouth faces the sea, in the opening of the valley, to the south. It has a noble esplanade, more than one-third of a mile in length, commanding fine views of the expanded sea; and the bold headlands of the new

red sandstone formation stretching far away on either side. The town is a favourite health resort, and was formerly the most fashionable watering place on the coast. It is Thackeray's Bournemouth, in "Pendennis;" and Ottery St. Mary, six miles distant, with its picturesque church, is his Clavering St. Mary in the same tale.

The drainage of this beautiful watering-place is being greatly improved from the plans and under the direction of Mr. John Phillips. The sewage of the town, until recently, discharged into into the little river Sid, near its mouth, which is nearly always closed by a shingle bar thrown up by the sea. A long stagnant pool was thus formed, the emanations from which were very unpleasant, especially in dry warm weather. This objectionable feature, however, no longer exists, the sewage having been diverted from the river, and carried direct into the sea by large cast-iron socket-pipes, firmly bolted to each other, and to wrought-iron piles driven alongside them. The pipes are laid under the beach, at the east end of the esplanade, and are continued to low-water mark, where the sewage discharges imperceptibly and inoffensively at all times of the tide. The bathing-place, which is near the west end of the esplanade, one-third of a mile distant from the outlet-pipe, is not affected thereby. A connection made from a bell-mouth near the outlet with the river, enables the surplus water of the river, during heavy rains, to pass down the sewer into the sea, instead of inundating the marsh fields, and the haemements of the adjacent houses, as it used to do on such occasions.

The new outlet has been laid several feet below the level of the old one; and a new main sewer has been put down from it through the lower part of the town, where the drainage was very defective. A further length of 1,000 ft. is about to be continued to Woolbrook Glen, at the west end of the esplanade, and thence up Clifton-place. Woolbrook Glen is a retired but pretty spot, looking out upon the sea. It was some time the residence of the late Duke of Kent, her Majesty's father, and the scene of his death. Here a crystal brook, flowing between bright green lawns, falls into the sea. It is intended to connect this brook with the sewer, so that a portion of the water may always pass into it, and keep it well flushed and clean. Branch sewers will also be laid from the main sewer along the principal streets, at lower levels than the present drains. These sewers will thoroughly drain the subsoil, and afford improved drainage from the houses.

The sewer is rather of novel construction, owing to a sufficient quantity of bricks for the work not being obtainable within a reasonable distance of the town. The invert consists of three courses of stoneware blocks; that is, a centre course, and a smaller one on each side of it, with bird's-mouth joints; all properly bonded, and laid solidly in concrete. The sides and crown are formed of well-mixed concrete, made of five parts of clean sharp shingle of various sizes collected on the beach, and one part of best tested Portland cement. The sewer executed is like a stone throughout. It is also even and smooth inside, perfectly hard, and as strong and durable as brickwork. Under ordinary circumstances, the cost of constructing a sewer as described would be about two-thirds that of brickwork, but in this case the expense will be nearly the same as brickwork, owing to the necessity of sending the cement, and of employing skilled labour, from London. In all places where clean sharp shingle or gravel is obtainable, there is no reason why sewers should not be constructed of it and Portland cement. Great care, however, must be observed in mixing the materials, and also in well and solidly placing the concrete in the work.

The town is supplied with water from the Cotman Spring, which is distinguished for its brightness and purity, but is limited in quantity. Another spring, equally good and more plentiful, oozes out of the rocks at Muttermoor, about 150 ft. above the level of the town. It is the origin of the Woolbrook. It is proposed to impound this stream at a suitable elevation, and to lay pipes from the reservoir into the town. The two streams combined will give an abundant and constant supply of pure water not only for domestic purposes, but for flushing the drains or watering the streets.

Besides the beauty of its scenery, Sidmouth is a very healthy place. Its death-rate is as low as 16 in 1,000 of the population; and, as good drainage tends to lower the death-rate of towns, it is thought that the drainage-works

here will in time cause the death-rate to be less even than it is now. The temperature of the air is also remarkably equable. In winter the mean temperature is nearly 4° warmer, and in summer it is slightly cooler, than London. The air acquires this equability of temperature from the mild influence of the Gulf stream, which, by constantly supplying the British seas with its tepid waters, imparts warmth to the passing breeze in winter, and cools it in summer. The mild climate which Sidmouth enjoys is due partly to this cause, and partly to its sheltered situation. Its mildness is also indicated by the numerous exotics and other plants which flourish in the open air, even through the winter months, with surprising luxuriance and splendour. The air also contrasts most favourably with that of other watering-places on the coast, both in regard to equability and humidity. With these advantages there is no reason why Sidmouth should not be as much frequented as it was during the first half of the century.

THE TRADES MOVEMENT.

Councils of Arbitration and Conciliation.—A conference between employers and workmen has been held in the Grand Jury Room, Townhall, Derby, to make preliminary arrangements for the establishment of a Council of Arbitration and Conciliation in this town and neighbourhood. The mayor presided. A provisional committee, consisting of ten workmen and ten employers, was appointed to draw up a code of rules, to be submitted for the approval of a future meeting.

Arbitration in the Potteries District.—Mr. J. E. Davis, stipendiary magistrate, having, at the request of the arbitrators, agreed to act as umpire in the arrangement of a dispute which has arisen between the builders and the carpenters and joiners of the district, met the arbitrators, comprising six employers and six operatives, at Longton, for the discussion of the difference. The only point at issue is the hour of leaving off work. Last year, Mr. J. S. Forhes, acting as umpire in a dispute involving the hour of finishing the day's work among other things, laid down half-past five p.m. as the time of leaving off; but this arrangement the employers state to have proved very inconvenient, and in December last, acting upon one of the rules, they sent notice to the men of their desire to revert to the old hour of leaving off work at six o'clock. The operatives objected to this course, and hence the reference to arbitration. The arbitrators failing, after a long discussion, to adjust the difference, an appeal to an umpire became necessary, and Mr. Davis was unanimously agreed upon for that office by the arbitrators. The case on each side was laid before the learned stipendiary with the utmost fairness, good temper, and courtesy, and the difference was very fully and frankly discussed. Mr. Davis promised to communicate the result in a few days.

The General Builders' Association and the Trade Unions.—A memorial has been presented by the various branches of the General Builders' Association to the Royal Commission on Trade Unions. In relation to trades unions, the memorial suggests—

"That the Secretary of State should appoint a registrar of voluntary associations, with power to certify that the rules of such associations were not contrary to law and public policy—law and public policy being reconsidered as suggested.

That all associations whose rules were so certified should have a quasi corporate character, and be empowered to hold property end to sue and be sued.

That the accounts of all such associations should be publicly audited, in a manner similar to that adopted under the Poor Law administration. The expense of such audit could be met by charging registration fees. And the misappropriation of funds should be punished by heavy fines, as the mere disallowance of certain items of account would act as no bar to misappropriation."

Legislation embracing these points in connexion with voluntary associations generally, would, they believe, fully and satisfactorily remedy all evils, now matter of complaint on the part of trade unions particularly. In the second place, in relation to the general question of the present unsatisfactory condition of the intercourse between masters and workmen, as so amply evidenced, they remark, by the prevalence of strikes and lock-outs, they think that condition could be best improved by the establishment of courts of conciliation and arbitration. The registration of masters and workmen entitled to vote in the election of their respective representatives might, the memorialists remark, furnish a means of de-

fraying the expenses of these courts. In the building trade the payment of a penny per month by each workman, and a penny per month on each one of the average number of men he employs by each master, would produce about 100,000*l.* per annum. This might readily be collected through the masters, power being given to them to deduct the men's proportion from their wages.

Intimidations by Masons' Labourers at Bury.—At the Bury petty sessions, John Rostron, labourer, was charged with having, together with Edward Egan, threatened to take away the life of Charles Crawshaw, for the purpose of inducing him to cease being employed by Messrs. John & Thomas Dewhurst, builders, Heywood. The labourers in the employ of the Messrs. Dewhurst had solicited an advance of wages; and as their request for 22*s.* per week had not been complied with, they struck work. Other workmen had taken their places, but in almost all instances they left off work because they were in bodily fear from the violence threatened by the workmen on strike. The magistrates, after hearing evidence in the case, said it was one of the worst ever brought before the bench at Bury, and they would mark their sense of it by visiting it with the heaviest penalty in their power,—viz., three months' imprisonment with hard labour.

Amalgamated Society of Carpenters.—It is only on special occasions that the pleasure is afforded of recording so sociable and enjoyable an evening as that recently passed at the Freemasons' Tavern by the members of the Amalgamated Society of Carpenters and Joiners. The new ball-room at half-past seven was filled with long tables, at which from 400 to 500 persons, members of the society, with their wives and daughters, sat, to enjoy a substantial tea. At nine o'clock, Professor E. S. Beesly took the chair, supported by Mr. T. Hughes, M.P. for Lanbeth, and various other gentlemen, including the secretary of the society. The chairman, in commencing the proceedings of the evening, said he must admit that some trade societies had acted in a most shameful manner, by enforcing rules which might be of benefit to their own trade but were injurious to society at large. But he could safely say that this society had not one such rule. He hoped that ere long all trade societies would come to see the necessity of only adopting such rules as should be not only beneficial to themselves but calculated to promote the welfare of society at large. Mr. Applegarth, the secretary, made a statement with reference to the society, which was, he said, now eight years old. They had started in June, 1860, with 11 branches and 350 members, and very little funds. They had now 205 branches, above 8,000 members, and more than 15,000*l.* in band. During their eight years of life they had spent more than 30,000*l.*; and during the past year alone they had paid to members 5,271*l.*, which was equivalent to saying that they had supported during the ten weeks of hardship 8,800 members. Mr. T. Hughes addressed the society, especially dwelling upon the benefits of co-operation, which he hoped to see extensively carried out. The meeting was enlivened with music and dancing.

Discussion on Trades Unions.—At the Wootton Bassett Reading-room Society's meeting recently, a paper was read by Mr. R. T. Hawkins, "On Trades Unions," and was followed by a discussion on the subject. The paper treated of the operation of trades unions and their effect on prices and wages, their relationship to labour, and maintained that unionism sets up the terror of the few over the weakness of the many.

Strike of the Building Trades in Geneva.—The building trades workmen at Geneva have struck work, it would appear, by order of the International Workmen's Association, which extends its branches in every part of Europe, and of which the committee and head-office reside in London. Last summer, it will be remembered, a general assembly, composed of delegates from all parts of the world, met at Lausanne a few days before the opening of the Congress of Peace, which sat at Geneva; the committee acting in obedience to orders transmitted from London. This committee, it is said, has been acting at Geneva, and from thence last week issued instructions that a proclamation should be posted on the walls of that city con- voking a meeting of workmen for the purpose of deliberating on what measures should be adopted to obtain an increase of wages, in default of obtaining which a general strike would be decreed. The places of rendezvous

were scolded upon, and the workmen ordered to meet in various parts of the fanhours, preceded by drummers. The only men who responded to this call were masons and carpenters, and these not men working at Geneva alone, but at Lansanne and other towns on the lake; they mustered to the number of 1,200, and, after marching round the city, assembled at the Stand, where proceedings commenced. On the motion of a working mason a general strike was decreed. On the following morning a great proportion of those who had taken part in the procession struck, but not all. The rest, however, obeyed under the pressure of organized companies, who went from one factory to another, insisting on the men at work obeying the injunctions they had received. Having accomplished this part of their mission, these delegates, who were chiefly strangers, not only to the canton, but even to the Swiss Confederation, proceeded to every manufactory in the town, and, addressing the journeymen—tinsmiths, founder, and mechanic—at work, commanded them to lay down their tools and join the strike: those who were unwilling were threatened with violence if they presumed to disobey. These mandates were imposed on all workmen, not only at Geneva, but at Lansanne and all the neighbouring cities. The utmost consternation prevails in Geneva, where the result of the strike on the trade of the city, it is believed, will be disastrous.

The *Journal de Genève*, of March 24, contains a long article complaining of foreign intervention in the relations between the Geneva master builders and their workmen. It says the masters did not refuse to listen to the demands of the workmen. "They confined themselves," it says, "to rejecting the intervention of a foreign society, whose head-quarters are in London, and which has no legitimate place in our republican institutions."

CONGRESS OF GERMAN ARCHITECTS.

We have been requested by the president of the Architectural Society of Hamburg, Dr. F. G. Stannmann, to state that the fifteenth meeting of German architects (held annually, but in different cities) will take place in that city from the 1st to the 4th of September next. We need not remind our readers that Hamburg is reached in forty-eight hours from London, and we are sure that English visitors will be much welcomed.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

At the meeting of the British Archæological Association last week, Mr. Holt exhibited the iron lock of the *desecrated* of the parish church of St. Michel, Beauvais—a beautiful example of fourteenth-century ironwork. A letter from Mr. Roberts, who was unable to be present, detailed the result of inquiries made in Florence on the subject of the bronze urn said to be that of Tanaquilla, which, it appeared, was but doubtfully considered in Florence. Mr. S. Cuning said he had from the first considered the bronze a forgery, and one made by persons who did not mind their unities. One of the ornaments was a vessel of about 500 B.C., another was of about 150 B.C., and there was a representation of a bough pot of very recent character, which seemed to have been copied from printed books of the last century. Mr. Bailey exhibited a Roman remains dug up in Lombard-street, and bearing undoubted marks of having passed through fire—confirming the history of the fire in the days of Boadicea.

BELGRAVIA AND SOUTH KENSINGTON NEW ROAD.

ALTHOUGH the act for this great public improvement received the Royal assent in August, 1866, no progress has yet been made, as it was obtained at a time of great monetary difficulty. The matter is now, however, in the hands of some of our capitalists; but as the amount required for the purchase of the house property to form the road from Westbourne-place across Sloane-street on to the Pavilion-land, and from the other end of the Land into the Grange at Brompton, involves an amount of 326,944l., the company applied to the Metropolitan Board of Works to contribute one-half that amount to-

wards one of the grandest improvements ever made in the west-end of London, connecting those important districts by a grand boulevard. The Board did not find themselves able to comply. The company then applied to the vestry of Chelsea for an allocation of the improved rates that might accrue during a period of twenty-one years. A deputation from the company had an interview with a committee of the vestry on Friday last week, and after a long conference it was resolved: "That this committee recommend that the improved rates to be created by the company be allocated to them for a period of fifteen years." The vestry took the matter into consideration on Tuesday last, and on the motion of Mr. E. O. Symons, the recommendation of the committee was carried by a considerable majority.

THE LEIPZIG THEATRE.

On the Augustus Platz, at Leipzig, where the world-known yearly fair is held, opposite the museum, a new theatre has been erected, which is reckoned amongst the finest in Germany. The promenade commencing on the east side leads to the new Temple of the Muses, a picturesque background, to which the agreeable ornamental water hard by the building forms a beautiful foreground.

The fulfilment of the paintings, the hall, and the decorations, was given to Government Architect Laughaus. To connect the *magasins* to the main building and to use them, steep sloping ground was made on the Promenade, whereby a terrace, in two flights leading to the ornamental water, was formed. The sculpture on the front was finished in the factory of Mr. Czarnikow, of Berlin.

The sculpture and paintings inside were executed by the best obtainable artists, and unite simplicity and beauty.

The ornaments which decorate the new theatre were executed after designs of Architect Laughaus, in an artificial stone, and cast zinc, by Czarnikow.

The modelling of the cast work was undertaken by the artists, Professors Hagen, Wittig, Luerssen, and Schiele.

The artificial material is well spoken of, and has overcome all the prejudices which at first were against it, since the ornaments executed in it (also by Czarnikow) at the Corporation House and town theatre of Riga have stood well.

The most prominent object in the external decoration, is the large frontispiece in the central tympanum, 56 ft. long, modelled in high relief by Professor Hagen, representing Poetry inspiring the other arts. In the centre of the surface stands the figure of Poetry, with a crown of glory upon its brow, distributing with both hands crowns towards heaven. On each side are two winged spirits, also distributing wreaths and laurel branches; to the left kneels Music, a fine female figure, leaning on her lyre, listening to the inspiration. To the right Painting; then follow Architecture and Sculpture, also embodied as female figures, recognisable in the attributes. Technical skill, which is necessary to art, is represented by a bearded man, who is explaining machinery to a boy; the mural crown and Lipsia, leaning on the town arms, conclude the representation to the right; whilst on the left a beautiful dancing couple, with Love and the three Graces, form the end. The grouping of the whole is good. An acrotorium, 14 ft. high, also by Hagen, terminates the principal pediment of the building. It includes the god of art, Apollo, in flowing garments, with lyre and double pipe; at his feet sits Calliope, the muse of song; and Clio, the muse of history.

The theatre consists of a centre and two side-wings, or pavilions, each of which is decorated with reliefs in artificial stone, the modelling of which Wittig has executed admirably. The relief on the right side represents the Triumph of Bacchus. The god of refined enjoyment and of youthful beauty, provided with his necessary attributes, stands in the centre; close to him are the love-disappointed Ariadne, and Amor, the god of love; to the right a Bacchanalian is blowing the double pipe, and a young Satyr is walking by the side of the skipping goat, whilst another Bacchanalian is playing with a panther, the allegory of phantasy and ferocity; to the left another Bacchanalian is dancing grotesquely with a boy, to the sounds of bells and tambourine. A little apart from this group sleeps an intoxicated Pan, contrasting

gross sensuality with a young Bacchanalian crowned with vine-leaves.

The relief on the left side, perhaps in consideration for the use of this part of the building, which contains the *Foyer*, represents the Triumph of Ceres. This goddess, the tamer and benefiter of mankind, is handing some ears of corn to a rough soldier and his little boy, whilst with the other hand she is giving a basket of fruit; at her feet kneels a woman engaged in planting a vine. Right and left are the indispensable forerunners of all husbandry, working in metals, working in stone, pottery, and ploughing, all represented by male figures.

Luerssen had some difficult work to perform. The five groups, each 7 ft. high, on the end wall of the pillared hall of the centre are executed by him in the composition. Each of these contains, as centre and chief figure, one of the Muses between two winged spirits in the form of children;—Terpsichora, the Muse of Dancing; Erato, of Love; Polyhymnia, of Declaration; Euterpe, of Joy; and Urania, of Astronomy. The various mythological figures are so naturally represented by their form and attributes that even a visitor unlearned in classical antiquities easily guesses their meaning. The smaller figures for filling the corners above the bow-windows of the main building—namely, three pairs of Victory, partly sitting and partly leaning, are also by Luerssen, who by their completion has overcome a technical difficulty. Both the pinnacles of the pavilion, ornamented with swans, which, as is well known, represent Music, are also by him.

The terminals for the four angles of the upper story of the theatre, as well as the rest which are to adorn the various corners and pediments, are modelled by Schiele, who has executed this part of the work beautifully. Particularly worthy of note are the heads of the Muses ornamented with shells, the singing swan on the five-stringed harp, and the candelabra guarded by couples of winged griffins.

Within the theatre a piece of machinery for raising the curtain in its full extension is worthy of note, and is said to answer well. The auditorium is arranged for 1,800 persons. The whole of the building has been carried out at the cost of 500,000 thalers.*

Plan No. 1.

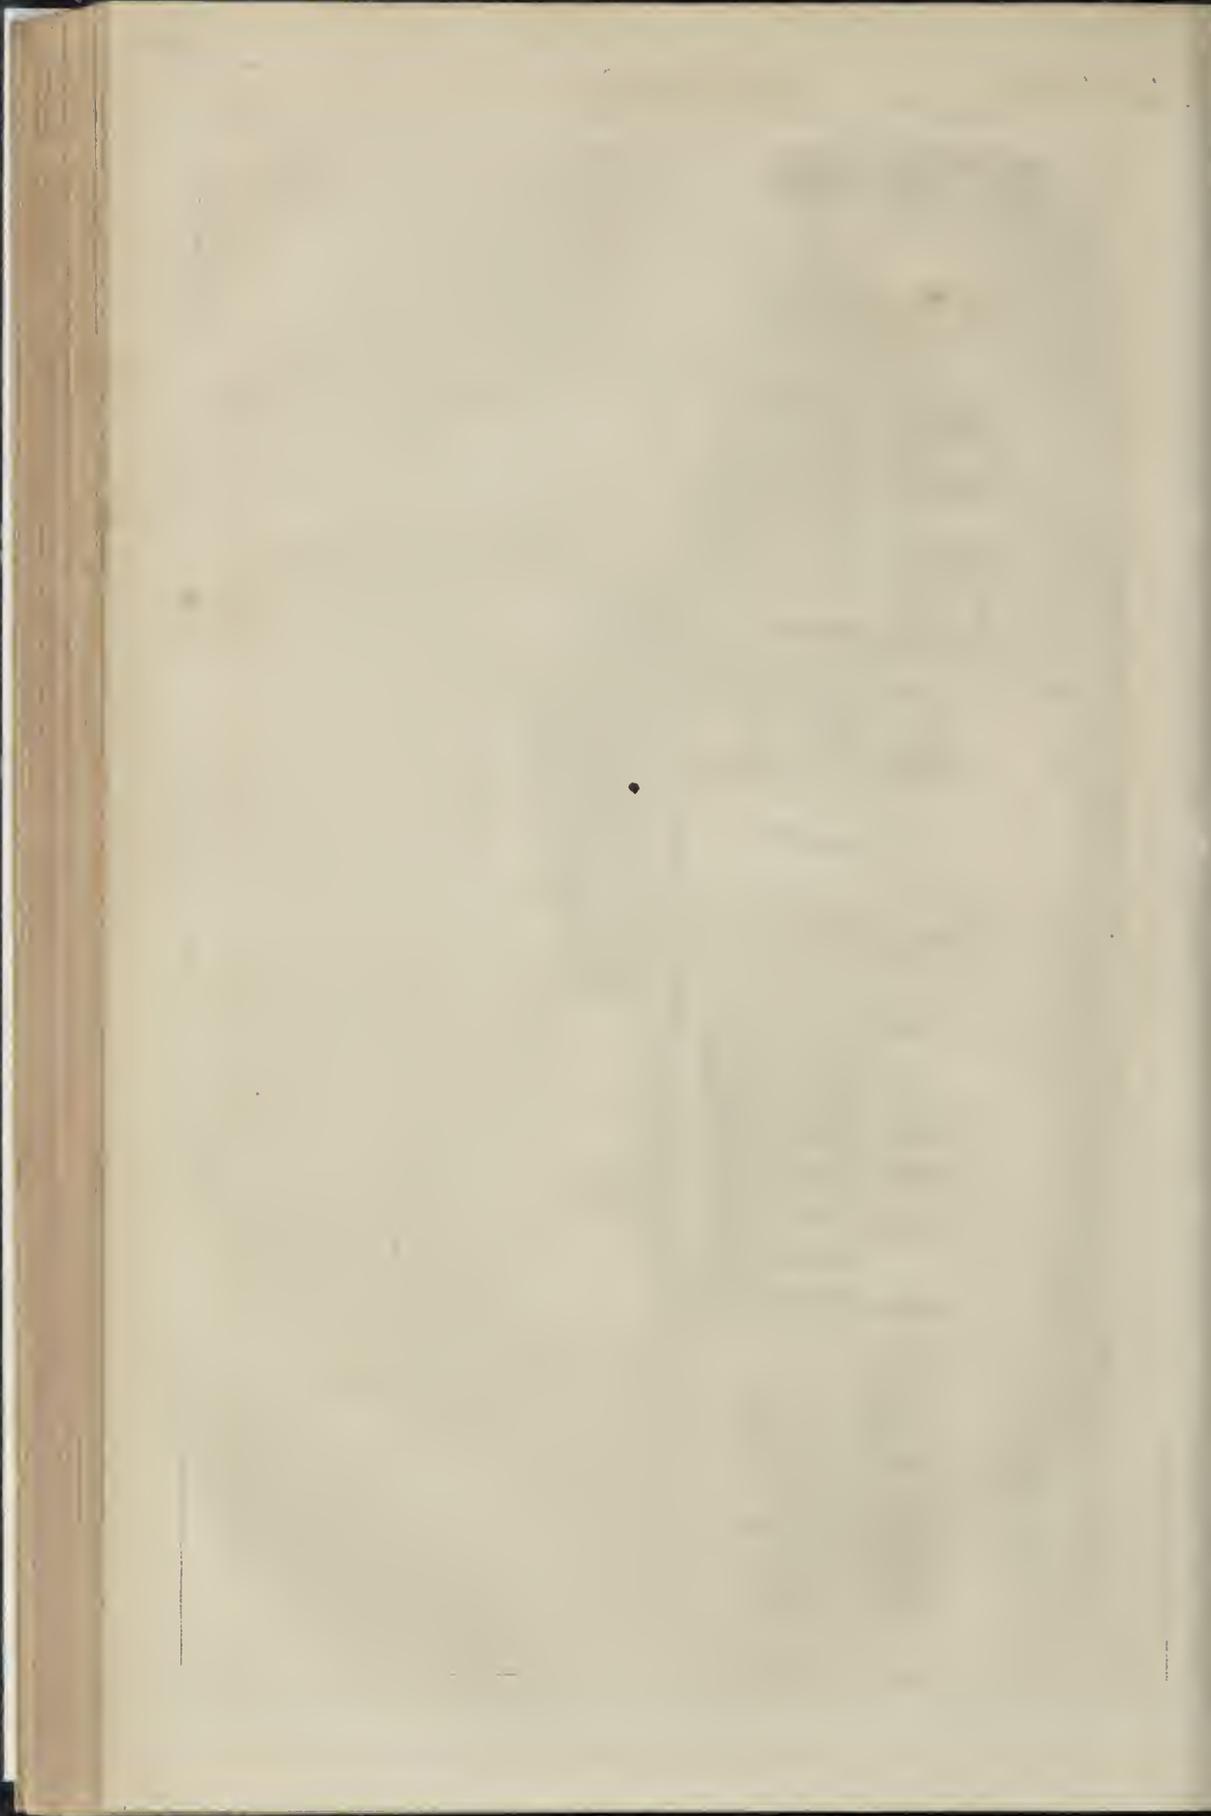

THE LEIPZIG NEW THEATRE.

Plan No. 2.

THE LEIPZIG THEATRE

THE AERONAUTICAL SOCIETY OF GREAT BRITAIN.

At a general meeting of this new society held in the theatre of the Society of Arts, the Duke of Argyll in the chair, the proceedings commenced by the reading of a paper by Mr. Heath "On the Control of Balloons by Pressure," and the paper was illustrated by models. The peculiarity claimed for the system is that the prime agent is nature, the simple apparatus used having in effect a mere resistance to the ordinary action of natural laws governing fluids. Another paper was read by Mr. Brown, who showed that in ballooning the chief thing was not the amount of force at the disposal of the aeronaut, so much as its proper application. The chairman quite agreed with this, but thought that science must be much more advanced before (as the reader of the paper had suggested) a machine like a steam-engine would have wing power to move itself. At the same time, there could be no doubt that science would by and by discover a lighter moving power than steam. The next paper, contrived by Mr. Alexander, C.E., was upon power in relation to weight in aerial navigation; and a gentleman who commented upon it said that some very important evidence upon this point had recently been given in the fact that Mr. Spencer had actually flown 100 ft. by his muscular strength alone, not merely by leaping down from an eminence, which was no flying at all, but by flying horizontally. At the coming exhibition of the society this gentleman had promised to fly every day, probably the whole length of the Crystal Palace. The subject of human flight was continued by the reading of a paper sent by Mr. Artinshall, of Manchester, accompanying it being a sketch of wings and machinery, the total weight of which was only 15 oz. The chairman, in conclusion, said the next meeting would be on the 25th of June at the Crystal Palace, when there would be an exhibition of models and some ballooning.

A mechanic of Glasgow, we may here add, has designed a machine which is intended to move through the air by flapping wings, which are to be driven in such a manner as to imitate the motion of a bird's wings. The motion of the wings is produced by a steam cylinder, fitted with a piston, the piston-rod carrying a cross-head, which is coupled by links directly to the wing; beams, which are fitted to shafts, running about three-fourths of the length of the machine.

Aeronautics is a subject which we have for many years regarded as a hopeless one, and have occasionally helped to keep before the public; and we are glad to find an Aeronautical Society making it up under influential auspices.

MANCHESTER TOWN HALL COMPETITION.

In consequence of Messrs. Donaldson and Street having placed the design attributed to Messrs. Speakman & Charlesworth first, as regards architectural merit, and second, as regards plan; while the design by Mr. Waterhouse was placed first as regards plan, and fourth as regards (external) architectural merit; they were requested to make a second report as to their reasons.

Mr. Heron, the town clerk, in his letter to them, said,—

"Considerable difference of opinion exists in the sub-committee as to the meaning intended to be conveyed by your report, and especially upon the points referred to in this communication; and it is, therefore, very desirable that you should be as explicit as possible in replying to the questions now asked, and generally in giving any additional information which you may, under the circumstances, consider will be valuable and useful to the corporation. I have respectfully to ask for information on the following points, to be understood that in all cases it is in relation only to the plans of 'St. Valentine,' 'Double Triangle,' 'Spandam,' and 'True to the Line,' that further information is desired. In considering your report, it was stated by the sub-committee that there was an apparent inconsistency in placing 'Double Triangle' first in point of merit in relation to architectural design, &c., No. 1, and second in point of general arrangements, &c., No. 2, and yet recommending the adoption of the plan sent in by 'Saint Valentine,' which are placed by you fourth in point of merit as regards No. 1, and first in regard to general arrangements and other matters referred to in Nos. 2, 3, 4, and 6. The sub-committee desire to have any explanation or further information which may appear to you to be desirable in relation to this part of your report. The sub-committee are also anxious to have the best opinion which, from the information afforded by the plans and descriptions, you may be able to give as to the acoustic properties (No. 5) of the large hall and of the council chamber in the four sets of plans before referred to, as this question is deemed to be of great importance. The sub-committee also desire to know in what order of merit you would place such four

designs upon the important matter of construction, and also shortly your reasons for any opinion given. They also desire to know whether, in your opinion, the plans of 'Double Triangle' and 'Spandam' could be carried out for the amount named by the authors, viz., in the first case 235,250*l.*, and the second 261,775*l.* It is also stated by some members of the sub-committee that defects in the plans of 'St. Valentine' are pointed out in your report, and various improvements and alterations suggested, whilst no similar observations are made in relation to the other three plans; and it is therefore assumed that they were not in your opinion open to any similar objections."

On Monday a second report from the referees was accordingly brought by the committee to the City Council, and the following note from Professor Donaldson accompanying it was read:—

"Mr. Street and myself herewith forward our second report upon the drawings sent in competition for the proposed new town-hall of Manchester. We trust that the sub-committee will be pleased to consider that we have been induced to submit to them our unreserved opinions as a confidential communication in the discharge of our duty, undertaken at their express desire. At the same time that we shrink from no responsibility, still we desire to respect the susceptibilities of our professional brethren, and hope that the sub-committee will not publish this second report, as we desire to avoid any steps that might be supposed to detract from the professional character of any of those gentlemen who have so honourably entered upon this competition, and displayed so much talent. We feel assured that the mayor and corporation will feel that no step should be taken which could tend to lower the competitors in the public estimation, or to interfere with the high position they so justly occupy."

A long discussion ensued as to the propriety of reading the report to the meeting. Ultimately, however, this was done; but it was determined that it should be regarded as confidential. We need scarcely say to those who know anything of public assemblies that this means nothing, and that the contents of the report will be made public.

Referees may always make up their minds to this, that anything that is written ceases to be private.

The result of the meeting was that the designs of Mr. Waterhouse for the new town-hall, sent in under the signatures of "St. Valentine," were selected.

COMPETITIONS.

St. Andrew's, Hereford.—On the 27th ult. the committee proceeded to select a design. On the first ballot, "Well considered," the design with a device, "All things considered," and that marked "3,000*l.*," were selected from the fifteen designs exhibited. On the second ballot "3,000*l.*" was left out; on the third, "All things considered;" and on the fourth, "Well considered" was unanimously chosen.

The envelope accompanying the successful design having been opened, it was found to contain a card with the name of "Mr. John Johnson, 35, Moorgate-street, E.C."

It was then agreed to appoint a committee for the purpose of communicating with the architect, going into the estimates, and other purposes specified.

The design selected is in the style of the thirteenth century. The estimate of 3,000*l.* does not include the warming apparatus, the tower, painted windows, encaustic tiles, or elaborate ornamentation of any kind. The old walls are to be used, and the sound portion of the old materials.

PROPOSED NEW STREETS AND ROADS AT BRISTOL.

Mr. Rawlinson, C.E., from the Local Government Office, London, has held an inquiry at the Bristol Guildhall, in reference to land proposed to be taken by the Board of Health for the forming of new streets in various parts of the city. The proceedings lasted several hours, and the question of the new roads at Clifton excited attention and argument *pro* and *con*. The inspector said there would be a special inquiry by a Bural Acts Inspector as to the churchyard. In other two cases the questions raised would be dealt with by the arbitrator. The inspector proceeded to consider the Clifton road, proposed to be carried from Victoria-square, through Boyce's-buildings, to Rodney-place. Two alternative roads were proposed by the opposition; one took the church of St. Valentine's, and went through Carter's stables; and the other passed near the memorial church, and came out at Saville-place. Both these schemes, but principally the first, were pressed on the inspector as more desirable than the Board of Health plan; while some gentlemen urged that there should be two routes—one through Boyce's-buildings, and the other

through Carter's stables. The inspector said Parliament would not allow the Board of Health to propose an alternative road and schedule the property thereof. If two roads had been petitioned for he could have recommended the abandonment of one of them, but he could not, under the existing circumstances, introduce a second. It was out of his power to recommend two roads, though he was rather inclined to think that two would be a great advantage. They had power to make roads by consent out of the current rate, and he should imagine, in such a place as Bristol, a 2d. or 3d. rate would make the Merchants'-road. It was arranged that Mr. Ashmead, the city engineer, and Mr. Ashmead, sen., on behalf of the opposi-on, should accompany the inspector when he went to view the proposed roads.

CHURCH OF ST. BARTHOLOMEW THE GREAT, SMITHFIELD.

This remarkably interesting church, the most valuable relic of the twelfth century possessed by London, was re-opened for service on Sunday last, after having been closed for some time for works of restoration, under a committee who have liberally subscribed, gathered, and spent upon it something like 6,000*l.* The announcement by the newspapers that the building has been restored will lead many to feel much disappointed when they visit the church; for its present aspect is to our eyes sufficiently miserable, and only those who know how much money an old building can absorb will believe that 6,000*l.* have already been spent upon it. At the east end there is a wretchedly ugly arrangement of iron girders and columns to carry the upper part of the wall. This, with lowering the accumulated ground within, and the drainage, don'tless ran away with a good deal of money. Truth to say, however, we are disappointed with the show made for the expenditure. The tomb of the founder, Rabere, on the north side of the chancel, has been repaired and decorated. We cannot praise the painting of the figure.

CONSTRUCTION OF FIREPROOF DWELLING HOUSES.

This subject being one in which most of your readers are much interested, it is desirable to circulate any practical information upon the matter that your numerous readers can contribute: I therefore venture to state a few facts that have come under my own observation for whatever they may be worth. Most of the buildings that are erected under my superintendence I make practically fireproof; and with this object in view, I have tried the "Dennett arch," Philipp's patent concrete floor; brick and tile arches, &c.

The "Dennett arch" requires 1-inch rise to the foot span, and about 7 ft. spans may be considered the average; the crown of the arch will be 5 in. thick; the ceiling joists may be either notched to hold on to the flange of the girder, and embedded in the material of the arch, or spiked to a plate bolted to the underside of the girder, occupying in vertical section from 1½ in. to 4½ in., to which add 1 in. for the plaster, and 2 in. for the wood floor above, will give a total vertical section of from 16 in. to 18½ in., as against an ordinary floor, with 9 in. by 2 in. joists, and 1½ in. floor boards, 11½ in. In my practice I omit the ceiling and the wood floor; the former I set to the curve, finishing with paint or distemper, and with the addition of a few lines and stencil decorations on the ceiling, and the flange of the girders. In rooms over 12 ft. high, I add a cornice or string of small projection a short distance down the wall, and so contrive a tolerably decent effect.

Ceilings so formed may be elaborated to a considerable extent, as circumstances may indicate.

Most floors are covered with carpets, kamptulicon, or floorcloth. If carpets are to be used, a fillet let in the floor all round gives good nail hold, and a Brussels carpet over a layer of thick brown paper is quite as comfortable in result as if laid on a board floor; kamptulicon is cemented down to the finished surface of the "Dennett arch," which, from its even surface, is better for that or floorcloth than boards.

It is common to over-sail to receive the "Dennett arch," producing a very awkward core

for a cornice. I get, however, the same result by setting my walls in from the general face about a quarter brick, the height of the haunch of the arch, and three or four courses above for convenience in working, to be filled in afterwards.

In the execution of floors constructed with the "Dennett arch," as with all concretes, expansion fillets must be used without fail, even in the smallest spans, or the walls will be disturbed or fractured more or less; and, although an architect may see that there is no structural danger, it is regarded as something very dreadful by a client, and may damage the architect's reputation.

Phillip's patent girder and fireproof floor is a combination of their patent girders placed about 5 ft. apart, with slotted flooring bars or laths, and concrete filling in; the ceiling is floated to the underside, the slotted bars forming a key as ordinary laths. The surface of the floor may be either boarded on 4½-in. joists, bridging from girder to girder, or finished with tiles or cement. The construction is very simple, involving no special contrivances; the girders are built in as the walls rise, and the floor may be formed when most convenient, or the floor may be finished off as a roof—the lower portion of the building occupied, and the execution of the remainder deferred.

Never using quarter or trussed partitions, I have the floor girders calculated to carry the half brick partition walls, which are executed with perforated bricks with a view to carrying out the fireproof system, and forming a more substantial and permanent class of work.

Comparative Cost, Thickness, and Weight, say of a Floor for a Room 22 ft. by 17 ft.

Ground Floor (exclusive of sleeper walls).—4-in. by 4½-in. oak sleepers (4 ft. by 2 in. centre to centre), 4½-in. by 2-in. joists, 1½-in. ploughed and tongued clean yellow batten floor, &c., 70s. per square	£13 6 2
Half-brick arches, 5 ft. 6 in. centre to centre, spandrels filled in and surfaced for carpet, 88s. 2d. per square	17 9 4
First Floor (same area).—Two 12-in. by 10-in. fir girders sawn down and bolted, 7-in. by 2-in. joists, 1½-in. yellow batten straight joint floor, 3½-in. by 2-in. ceiling joists and ceiling, say 17½ in. finished thickness, 120s. 4d. per square	22 11 7
"Dennett's Arch," with ceiling and wood floor as before described, 16 in. finished thickness, 216s. 4d. per square	42 8 10
"Dennett's Arch," without under-draw ceiling, surfaced for carpet as described, average thickness say 10½ in., 165s. per square	30 18 10
Phillip's patent floor with ceiling and wood floor 8½ in. finished thickness, 137s. 1d. per square	35 1 9
Phillip's floor finished with plaster surface for carpet, 8 in. thick, 175s. 6d. per square	32 18 0

I do not quote these data as evidence of the best thing that can be done, but as a contribution towards the general fund of information on the important problem of how to construct dwelling-houses or offices fireproof at an economical rate.

THOS. CHAS. SOBRY.

SOMETHING LIKE A CHURCH.

SIR,—Is church architecture keeping pace with the general development of the age? Churches of the present day, instead of out-rivaling those of past times, rather fall short, in size and execution, of the works of our forefathers, as displayed in old cathedrals. Now, really, considering the power, intelligence, resources, wealth, and influence of the present time, and of this, the greatest empire of the earth, something handsome might be accomplished to transmit as a memorial to future generations. However good any new church may be in itself, any one congregation is not capable of erecting such a memorial church as is now spoken of. But, sir, unity is strength; and on this sound truism allow me to propound a scheme which, if carried out, will effect the object.

Over no very large area of London, I dare say, will be found eight churches; and were these eight churches brought together into one central place, they would be equally serviceable for the congregations. Well, suppose a space of several acres set apart for a memorial church: we might have, clustered together, in one imposing group, eight different churches, of one style of architecture (say the truly British, second period of Pointed), with a common tower in the centre, and spire 600 ft. high. The spire would be the highest building in the world. The tower and spire might have towards their base galleries for statues, &c., and farther up balconies for views, to a height, say, of 500 ft.,

with at the same time immense bells, and an illuminated clock of eight dials, visible in clear weather all over London. Of course, all the improved constructive science of the present day would be brought to bear upon the work, both as regards durability and elegance. The building, standing apart by itself, as in the centre of a square, and accessible on all sides, would be known by some appropriate, short, distinctive, national name.

Eight congregations (they might be of different denominations) could easily carry out the scheme: besides, there is no doubt the Government and City would aid the national part of the undertaking.

I trust to see the matter taken up by some of our influential and patriotic gentlemen and architects.

PROGRESS.

"THE DRAINAGE OF LAND."

HAVING perused with considerable interest the paper on the above subject by "W. H. W.," as published in your issues of the 18th and 25th, of January, and the 8th and 15th ult., I think you may perhaps give publicity to a few notes confirmatory of the views advanced by the writer. The particulars I have to submit comprise practical observations by a land-agent and agriculturist, who, in the course of conversation some little time ago, on the subject of drainage and the beneficial results arising from the use of large-sized pipes in drainage operations, narrated substantially what I am about to submit to your readers. On reading the first part of the paper published on the 18th of January, I was so forcibly impressed with the coincidence of ideas, particularly on that part which treats on "Air and Warmth," that I was induced to write to Mr. Milner, the gentleman referred to, to favour me briefly with his experience on the point, as illustrated by using large drain-pipes, who replies as follows:—

"The first time my attention was directed to using large pipes was a remark made by one of our tenants. Having been engaged in draining a portion of extra wet or damp land, he used 3-in. and 4-in. pipes; ever since he has always had an unusual increase of crop, which I attribute to the large amount of air admitted through the unoccupied spaces in the pipe not required in running off the water. The air is heated and permeates the subsoil, communicating nourishment to the roots of the plants, and causes vegetation to act very rapidly. I have on different occasions drained partially patches of land with large pipes, and have always found the same results. I am of decided opinion, that by using not less than 3-in. and 3½-in. pipes, the result would be large returns. I may mention, that wherever a stiff retentive subsoil is drained, such as we have in this locality, I would not recommend drains to be cut deeper (using the size of pipes as described) than 2½ ft., and not more than 16 ft. apart. This depth and this distance apart I have found to be remunerative; but deeper and more apart I have found to be the reverse."

With these observations before me, and the tabulated statements of the beneficial results of "air drainage," as contained in the first part of the paper adverted to, I had expected the writer would have recommended a larger size of pipe than 2 in. diameter for the small or feed drains. I can, however, perceive that in the case of a feed-drain of considerable length a 2-in. pipe, with the "air-drain," as experimented upon by Mr. Hutchinson, might admit as much air as a feed-drain of similar length with a 3-in. pipe without the air-drain at the upper end. In reference to the air-drain, would a pipe continued from the last horizontal pipe, at the head of the drain, and communicating with the surface, not answer all the purposes of a cross drain at the upper end, connecting all the feed-drains? I can imagine this would even be better, as in the case of an air-drain constructed by connecting the upper ends of five drains, the air-drain being open at each end. In this case the air-drain would only give two air-outlets to five drains, whereas the simple introducing of a pipe from the upper end or terminus of each feed-drain communicating with the surface would give five air-inlets. An objection might be taken to the liability of ordinary 2-in. or 3-in. drain-pipes, placed vertically or at an angle, communicating with the surface, getting disarranged. This might be obviated by using a vitrified socket-pipe, with a proper bend, in one length, suited to the particular depth of the drain. The item of cost in drainage is no doubt an important consideration; and when the writer, under this head, states the average price at the maker's yard in the counties to which his paper has special reference, "is 2½s. per 1,000 for 2-in. pipes, and 42s. for 3-in. pipes," I can readily see a material reason for recommending a 2-in. pipe as suitable for the ordinary small feed-drains.

If, however, a 3-in. pipe would give generally the same extra increase of crop as stated in Mr. Milner's experience; or if similar beneficial results generally attended the adoption of air-drainage, as given in the experiments of Mr. Hutchinson, any extra cost incurred by using a 3-in. pipe instead of a 2-in. pipe, or by adopting air-drainage, would be repaid in the first year's crop—a circumstance which carries with it strong recommendations for using 3-in. pipes, and which might be supplemented by air-drainage at a comparatively trifling cost, by adopting the plan suggested of using vitrified earthenware pipes, communicating between the drains and the surface. This mode of air-drainage possesses the additional recommendation of not being necessarily confined to the head of the drains, but may be used wherever and as often as the drainage surveyor deemed advantageous. In this district of Lincolnshire the question of cost between a 2-in. pipe and a 3-in. pipe is not so material, as the current price of 2-in. pipes at the yard is 17s. 6d. per 1,000, and for 3-in. pipes 26s., each pipe being 14 in. long; while pipes of similar length in Surrey or Lincoln would be 2½s. 6d. for 2-in. and 49s. for 3-in. As a manufacturer, I am aware a considerable diversity of opinion has existed, and still exists, as to the size and shape of pipes best adapted for drainage purposes; but I believe opinion in this district is generally settling in favour of a 3-in. pipe for the small or feed drains, and the main drains in proportion.

The original paper and foregoing observations have special reference to arable land. Another aspect of the drainage question might be discussed with interest to numbers of your readers, and one which proprietors and occupiers must shortly come to some proper understanding upon, namely, the drainage of hill pasture, moorland, or the sheep-walks of England and Scotland. While arable land, efficiently drained and economically carried out, will admit of a consequent rent-charge, comprehending a good interest for capital expended, and repayment of principal in twenty-one years, and at the same time remunerating the occupier, instances, so far as I am aware, are not so general of experiments on the description of land to which I allude, proving they have been equally remunerative, or would bear a similar rent-charge; on the contrary, there is a feeling amongst occupiers that the drainage operations cannot be carried out to their remuneratively on the terms on which capital is obtainable from public companies or drainage associations, a circumstance which would suggest to proprietors the consideration whether they ought not to meet this difficulty by advancing capital on easier terms, or giving to enterprising tenants leases of such extent as would enable them to drain their respective holdings, receive a fair interest, and be repaid their capital during the currency of the lease. I forbear to enter further upon this question, trusting the hint incidentally thrown out may lead some of your correspondents to take up the subject, and furnish a paper as interesting as that you have recently published, by "W. H. W." W. H.

DRY EARTH SYSTEM OF SEWAGE UTILIZATION.

SIR,—Will you kindly allow me space for a few remarks on that portion of "M. P.'s" paper in your number of the 7th ult. which is headed "The Dry Earth System of Sewage Utilization"?

1. The earth to be used in closets need not be black, as "M. P." states; any surface-earth will answer the purpose, only, the less of chalk there is, and the less sand in it, the better. That which I have used now for ten years is the earth lying on a chalk substratum; and more than that, most clays will answer the purpose. When, some six years ago, Major Nugent, R.E., under orders from the War Office, experimented on the use of the system at Portland, he told me that the blue Oxford clay, though more difficult to break up and sift, appeared to him to possess greater deodorizing power than the rich Portland earth. This is a point which, with reference both to a given supply of earth and to the manufacture of manure for light soils, is well worthy of observation. Again, this dry earth or clay for use in closets ought not to be pulverized. That the manure manufactured may have its full effect, the mixed soil and earth should be pulverized; but for use in closets all that is required is to sift it.

2. In attempting to relieve "M. P.'s" misapp-

prohension on the subject of the supply of earth to a given town, I omit all reference to the metropolis; for however feasible the introduction of the system may be in certain districts, until smaller towns have tried it, the advocacy of its general introduction is futile.

I will take in preference a town with 7,000 inhabitants, situated in an agricultural neighbourhood, and I think I shall satisfy "M. P." that a sufficient supply of dry earth to the town shall not only be without prejudice to that neighbourhood, but with vast advantage to both town and country. In the first place, it is no mere supposition, but a fact fully established by the continually increasing experience of ten years, that as soon as the excretions have been deodorized and absorbed, and the mixed mass dried, that mixed mass may be used in a closet or urinal with the same efficacy and the same safety as the unmixt earth. For such immediate use, however, I do not plead. In the town of which I speak there is a school of eighty boys, in which now for three years the system has been adopted. The contents of the closets fall into a vault, which also serves as a urinal. This vault does not require emptying oftener than once in three months; so that a sufficient quantity being provided for six months, and this being used four times, there may be an interval of four months and a half between these several uses of any portion of it. I may here observe that the removal every three months is made in open day in the High-street of the town without offence to any one. Well, sir, on the estimate of 38 lb. per head per week, the population of 7,000 persons would require, if the earth should be used four times, from 1,500 to 1,600 tons a year; or if the coal ashes of the town should be mixed with the earth in the proportion of one-third to two-thirds, only about 1,000 tons would be required. At present, for cleansing the water-closets and flushing the sewers of this town, there are pumped 1,000 tons of water a day! Now, supposing the town to depend for its supply entirely on the surface earth of the neighbourhood, there would be no need of the excavation of a single foot of soil, much less of five acres 13 ft. deep, or sixty-five acres at 1 ft. All that is taken in this way is only borrowed to be repaid with interest from the 4,000 or 5,000 acres within two miles of the town; a quarter of a ton an acre, or less than a quarter of an ounce a square foot, would be a sufficient loan for the year, and each ton so employed in the closets during the year, ought at the close to be worth at least 5s. But then if the supply of manure should be more than the neighbourhood would require, there are clay pits and clay hills at no great distance from many such towns. And besides this, great use may be made of street sweepings and of local ashes, used in certain proportions.

If the contents of a closet be removed into a vault or chamber of suitable size, there is no need of the frequent removal of which "M. P." speaks, "every day or every week." From a vault within the walls of a parsonage-house near me, the practice for three years has been to remove them once in a month. From that of my day-school with ninety-boys, once in six weeks; from the school before mentioned, once in three months. Two vaults on my own premises, for a family averaging twelve persons, require to be emptied only once in six months. By removal at such intervals the addition to street traffic could not be great.

4. If the value of the manure be such as is now assigned to it by the united testimony of farmers, gardeners, and one manure dealer (3s. and upwards, according to the number of times the earth is used), the cost of drying either on a large or small scale is, in comparison with that value, a very trifling consideration.

5. The idea of putting any charge on the earth supplied to the poor has never, so far as I am aware, been entertained, unless they should retain the manure for themselves. In this latter case I know them to require very little inspection.

6. "M. P." does not seem to be aware that dry earth is just as available in "slaughter-houses and knackers' yards" as in closets. Some of my first and most trying experiments were on the horrible refuse of a slaughter-house. The butcher from whom I obtained it has told me that by what I taught him I saved him more than ten shillings a week,—such, at least, he reckons the value of this stuff mixed with a load of earth. In the case both of "the slaughter-house and the knackers' yard" the refuse mixed with earth should be removed to a large fly-yard. For hospitals the system appears to me

to be in every respect unexceptionable and perfect; stables may be cleansed by the same means; and, lastly, the removal and utilization of sink-water and slops by sub-irrigation or otherwise (Prospectus of E. C. Company) renders certain the prevention of the pollution of rivers.

7. "M. P." in his statement respecting the marketable value of night-soil, forgets how that value must be affected both by the necessity of its removal, and by the offensiveness of the operation. The earth, after it has absorbed the excretions, is so perfectly inoffensive, that I have known some that had been mechanically mixed taken the same day to London in a box in his carpet-bag by a chemist; and by two engineer's clerks it was taken wrapped in brown paper in their side-pockets.

The difficulties in the disposal of night-soil afford no illustration, then, of the removal of mixed earth. To any one who knows those iron troughs at Aldershot, it can be no wonder that the War Office has to pay 500l. or 600l. a year for the removal of the contents, besides a vast sum for various disinfectants. The wonder to me is that, when for some such sum they could not only annihilate all smell, but with the manure saved turn scores of acres of that sandy desert into a rich sward, they can hesitate to change the system. Our barracks generally, and our public schools of every description are, in their uncleanliness and the indecency of their latrines, a disgrace to civilized society.

HENRY MOULE.

ARCHITECTURE IN THE BIRMINGHAM SPRING EXHIBITION.

SIR,—Being on a visit to Birmingham, I have more than once visited the Architectural Room, making notes respecting the various drawings as I went through. As an architect of some position, I feel convinced you will not refuse to allow me a little space in your paper for their insertion.

The Gothic style appears to preponderate over Italian, and the examples of both styles are on the whole good. The designs of Mr. J. G. Bland may be mentioned as very thoughtful studies in Gothic architecture, the views of Strond and Acock's-green churches being worthy of remark. This gentleman has, I believe, distinguished himself by structures, in which polychromy is used extensively, chiefly in brick-work. Mr. J. A. Chatwin's designs for St. Augustine's Church, Edgbaston, and St. Lawrence's Church, Birmingham, show a knowledge of Gothic, and a considerable amount of aesthetic feeling. Mr. G. Holmes's designs are also worthy of remark. Mr. John Davis, jun., sends three elaborate drawings. Assuming that he is a young man, the drawings do him credit. The coloured drawing is not so satisfactory, being somewhat crude and approaching to tawdriness. The drawing by Mr. F. Barlow Osborn is a successful attempt to adapt Gothic to commercial requirements. It has a solid substantial appearance. The drawing of Norwich Cathedral, by Mr. Bakewell, is an interesting and faithful representation of the interior of that noble edifice. Among the other Gothic works must be mentioned those of Messrs. Nicholls, Ingall, Veall, &c., many of whose designs are satisfactory. Among the classic contributors are Messrs. Chatwin, Yeoville Thomason, Holmes, Bateman & Corser, Phipson, Plevius, most of whose designs are good.

A LONDON ARCHITECT.

THE BED OF BUILDING STONE.

It was my misfortune that I was not present at the reading of Professor Ansted's paper "On Building Stones." And now, using the almost solemn words which commence every section of the Building Act, St. Vict., what is the result of the discussion? Do we know which is the proper bed of a stone when taken from the quarry? I say, emphatically, we do not. I never found a mason with the stone on his banker that could tell me more than this, namely, the vertical and horizontal bed. We know this well enough, but we want to know more than this. We really do not know now which is the natural bed of the stone.

This is the point that I wish to direct the Professor's attention to,—Which is the zenith and which is the nadir of a stone? It was taken for granted that we knew all about it, and there-

fore it was not alluded to. I do not believe this problem has been solved; yet I think it is one well worthy of investigation. The delamination of the stone surely has something to do, I think, with the placement of it in a building, according to its natural growth or formation. Reverse the order of nature, fight against it, and you have a difficult battle; but study nature, follow her laws, and you will discover cause and effect.

I wish, therefore, to direct attention to this question. Which is the zenith and the nadir of a stone?

I believe the microscope would probably tell us this. We know the molecules of stone assume particular figures well known to the geologist.

The inference drawn is, that until you can place a stone in its natural bed you have not fully tested the durability of the stone. Turn a skin inside out, and your shoemaker will show you that it will resist water penetrating; but how about stone reversed?

A. J. HISCOCKS.

A PLAGUE STONE?

A STONE has been turned up in the market-place of Stockport, 24 in. long, 14 in. wide, and 15 in. deep, hollowed into a cup on the top about 4 in. deep. It is a sandstone grit from the old quarry behind the "Wizard," at Alderley Edge. It is supposed to be the old "plague stone," which was common at the time of the Great Plague, at market times, containing vinegar, to pass money through or fumigate all articles from an infected district. The stone has the peculiar appearance of bird-foot marks running through the sandstone, not impressions, but appearances—white streaks.

Can one of your correspondents give me any information about "plague stones?" I can only say that the stone is exactly the same as that old stone base of a modern pillar at Mottram St. Andrew, which marks the spot at which the market was held during the plague; at least, this is the tradition of the neighbourhood.

T. K.

THE ARCHITECTURESQUE.

WITHOUT staying to ask whether "all Picturesque," "primarily and radically Picturesque," and the "essential superaddition of the Picturesque," are convertible phrases, meaning precisely the same thing, now that we have Professor Kerr's explanation that his "proper thesis" goes no further than an inquiry whether what he calls the Architecturesque is a reality or not, we can deal with his views under another and simpler aspect.

It is, however, only by weighing his words and testing his illustrations, that we are enabled to arrive at the meaning he attaches to the term Architecturesque; and it is impossible for any one but himself to disconnect it from the meaning imputed to it by his own language. What we wish to know is, if there be such a thing or essence as the Architecturesque in the sense in which he puts it forth—not if there be a quality in architecture which might aptly be expressed by such a word.

The general impression conveyed by the lecture is, that the Architecturesque is the essence of beauty in architecture, founded upon regularity, symmetry, and system, and is a species of beauty directly opposite to the Picturesque. This principle he more fully brings out when he draws the contrast between the Gothic and Classic schools, the one being founded upon the Architecturesque, the other not upon architectural but the Picturesque principles. We can only examine his theory by the light he himself throws upon it; and if the specific meaning attaching to the word leads up to fallacious conclusions, either it is not founded in reality and architectural truth, or he fails to convey his meaning to us.

Possibly some subtle fallacy underlies his theory, also why does the explanation of it involve a change of position? We are not now told that Gothic architecture is founded upon the picturesque, but that the picturesque is an "essential super-addition," which, if I interpret rightly, means that Gothic architecture cannot exist as such without extraneous aid, and that it is necessary to introduce a new principle more architectural in its nature and origin.

Throughout the lecture Mr. Kerr hardly appears conscious that in coining his word by a

process he thinks parallel he is really inverting the order in which the term Picturesque arose. The Picturesque is not a beauty founded upon pictures on the principles of painting, but is a convenient and appropriate name for classifying a peculiar beauty widely distributed in nature, and the parallel word in nature to the Architectures would be the *Naturalæque*. On the one hand, the Picturesque is not a name for the "symmetry of irregularity" found in nature, and is a specific natural beauty that all see, feel, and acknowledge; while architectural beauty is variable, and being nearly all conventional in the Classic, and conventional and natural in the Gothic, it is difficult to arrive at the essence of its beauty and fix it in a word.

Like flowers, it may possess several essences; but while flowers do not cease to be flowers because of this, architecture will not the less cease to be architecture because the essence of its beauty is different in the Gothic to what it is in the Classic. If we use a term to signify a beauty peculiar to architecture in opposition to beauties not architectural, we must invent a word that will apply to all styles and periods; and I cannot at present see why the picturesque is not as legitimately an architectural beauty as symmetrical rigidity. As a mode of conveying an idea of the treatment necessary for architectural accessories, I am inclined to think it may have its use, though in the enlarged sense shadowed forth by Mr. Kerr,—in which it is placed in a parallel position with an all-prevailing natural beauty. It will hardly be admitted into our vocabulary. If it be admitted, the long perspective of "esques" with which we are likely to be inundated, cannot be anticipated without alarm. Potters, upholsterers, and other art-workmen, will be wanting terms to describe the essential beauties of their arts; and though, in the sense of importance, their claims for such a distinction may not be so great as ours, yet in principle we could not avoid admitting them, for doubtless each art possesses its own peculiar principles of beauty.

For starting an interesting subject containing plenty of "nuts to crack," Mr. Kerr deserves our thanks; but it would be cruel for him to leave us to clear up all the difficulties ourselves.

T. M. R.

THE GREAT BELL OF ST. PAUL'S CATHEDRAL.

In giving a brief history of the great bell of St. Paul's, in the *Builder* of the 14th of December, 1867, I stated, on what was considered the best authority, which I now produce, that the bell was made in 1709. The following is an extract from a letter written by Messrs. Mears, of Whitechapel, in March, 1855, with a view to decide this among other questions:—

"St. Paul's great bell was made at this foundry by our predecessor, Richard Phelps, in 1709."

Moreover, Sir Henry Ellis, in his edition of Dugdale's "History of St. Paul's Cathedral," 1818, p. 184, says:—

"Sir Christopher Wren, in his Answer to the tract entitled 'Frauds and Abuses at St. Paul's,' gives us the history of the present bell."

And here it is worthy of remark that Sir Christopher's "Answer" was published in 1713: so that it could not possibly give the history of any bell cast at a later period.

A few weeks ago, however, I found from a "rubbing" of the inscription that the present bell is dated 1716, which would seem to indicate that it was recast in that year. But to set this point at rest, I sought for some further evidence. Accordingly, by the kind offices of Mr. F. C. Penrose, architect, I ascended the south tower and made a careful examination of the bell. Subsequently the Rev. W. Sparrow Simpson, librarian of the cathedral, permitted me to have access to the "Folio Accounts," and very kindly assisted me in my researches.

The result appears to be that Richard Phelps recast his former bell, dated 1709, in the year 1716.

A word in conclusion, by way of throwing out a hint for the consideration of the authorities at some future period. Believing that the present great bell is quite sound, and satisfactory in certain other respects, I venture to say that it is possible so to alter its form and relative thickness,—without recasting,—as to render it capable of producing a fine tone.

THOMAS WALESBY.

FOOTWAYS ON THE THAMES EMBANKMENT.

A REPORT was presented at the last meeting of the Metropolitan Board of Works from the Works and General Purposes Committee, stating that they had issued an advertisement for tenders for footways and fences on the Thames Embankment (North), contracts Nos. 1 and 2, submitting specification for the works. In reference to this subject the following report from Mr. Bazalgette, the chief engineer to the Board, was presented:—

"Thames Embankment Footway and Temporary Approaches.

"Pursuant to the reference of the Board of the 13th ult. to the Works Committee, to make arrangements for opening the Thames Embankment and for footways during the ensuing summer, I beg to report that,—

To form the carriage-way along the face of the Embankment would not at present be prudent, because it would have to be taken up for the construction of the Metropolitan District Railway underneath it.

The specification and drawings now submitted by the committee for the approval of the Board provide for the formation of a paved footway, 20 ft. wide, along the face of the Embankment, from Westminster Bridge to the west end of the Temple-gardens.

Two approaches will be connected with Westminster Bridge, one down the steps to and along the new Westminster steam-boat pier, and the other at the back of the pier by a gradual incline from the level of the bridge down to that of the Embankment. A subway for foot-passengers is to be formed from the Houses of Parliament, underneath Bridge street, to the station of the Metropolitan District Railway; and I am now in communication with Mr. Barry with a view to submitting for the consideration of the Board a design for the continuation of the subway to give access to the Westminster steam-boat pier, and for allowing foot-passengers to cross the footpaths on the Thames Embankment to any part of Westminster without encountering the carriage traffic in the locality.

A temporary paved foot-approach is proposed to be formed from Villiers-street, Strand, to the Embankment roadway and Charing-cross steam-boat pier. Some arrangement will have to be made with the South-Eastern Railway Company in order to maintain the full width of this approach at the upper end; and it would be to the public advantage and their own interest that they should also form an approach by steps from the footway at the side of the Charing-cross Railway bridge down to the Embankment footway.

A third temporary paved foot-approach would be formed from the steps at the side of Waterloo Bridge, giving access between Wellington-street and the Waterloo steam-boat pier.

The fourth temporary paved footway approach would be formed from the steps at the end of Essex-street, Strand, to the Temple steam-boat pier, which, for the present, would be the eastern end of the Thames Embankment promenade. A communication may also be made to the Strand, Temple-gardens if desired by the representatives of that property.

The whole of these footways will be fenced off by temporary wooden fencing, and may be opened to the public in the course of the coming summer.

J. W. BAZALGETTE, Engineer."

The report of the committee and that of the engineer were adopted.

The District Railway Company stand in the way of a completion of the carriage-way on the Embankment.

THE EDUCATION OF THE PEOPLE.

THE NATIONAL SUNDAY LEAGUE.

Sir,—In the generally sensible and well-reasoned letter of "Jack Plane," in the *Builder* of Saturday last, a most unwarrantable allusion is made to a body of working men united for what they conceive to be for the enlightenment and elevation of their class by obtaining facilities for visiting our national museums and art treasures on the Sunday afternoon; and whom your correspondent calls *quacks* and *nostrum-mongers*, insinuating that the education question has been unfairly pressed into the programme of the National Sunday League, as a means of raising capital. Now, sir, some of the council of the League are subscribers to, and readers of, the *Builder*, and on their expressed desire I ask you to allow a vindication. "Jack Plane" and a prospect of the bills which have aified. I enclose a copy of the National Sunday League, as published twelve years since, which shows that the elevation of the people in art taste was then a primary element of the movement and a national necessity, now so generally recognised.

As he has given extracts to suit his purpose from the *Builder* in question, permits me to put it fairly before your readers by the introductory paragraph.

"All parties in the State now admit that the people can no longer be debarred from the educational advantages which are enjoyed by other civilised nations, and the late Exhibition in Paris has demonstrated that England will fail to maintain her pre-eminence in the markets of the world without increased facilities for the technical and artistic culture of her artisans.

The superiority of the French workman in matters involving taste, is almost unanimously attributed to the fact that they are, from infancy, enabled on the Sunday afternoon to visit the national collections of art treasures."

And, further, let me add the quotation from the chairman of the Society of Arts:—

"Our artisans nearly all desire that museums, &c., &c., should be open on Sundays; not only to assimilate the English to the French Sunday in other respects. Nearly all feel that it is the familiarity with the beautiful in nature and art from childhood that has given to the French nation as a whole that knowledge of artistic skill and feeling for the beautiful which threaten to make them the most successful workmen in the world, to the serious injury of our country."

These words being identical with those put forth by us through so many years, it was, I contend, legitimate in us to use them in support.

What, however, are we to say of "Jack Plane" when,

having denounced the advocates of the Sunday opening of museums as "quacks and nostrum-mongers," he forthwith proposes, on a Monday evening, the evening opening of such institutions? We of the League are in favour of such openings for those who could visit them; but we maintain, from our practical knowledge, that the great bulk of the working class would not be able to do this with any profitable advantage if open.

The miserable plea of rest for the attendants is raised as a barrier to the people obtaining knowledge and elevating their minds, as though there were not sufficient persons partially employed to recruit a special staff for Sunday duty (as shown by the Report of the Parliamentary Committee, 1857), or as it is well understood by the British Museum trustees, there is a reserve of police on Sunday duty from whom the duty could be obtained without the additional employment of a single person; and until your correspondent can show that injury to the individual or to the society is produced by working on Sunday for the bringing out of the Monday morning newspapers, the printers and compositors taking the Saturday for holiday; and, in fact, can tell us how all society is to be at perfect rest on the one day; we cannot give such as "Jack Plane" credit for consistency. Besides,—what sort of a friend to the attendants is this who would add some four hours nightly to their duties as necessitated by the evening opening? or his nostrum, like ours, must be supplied by relays.

When it can be demonstrated that by a vast majority the working classes of London are in favour of the Sunday opening, and that it is not the executive for these are we not justified in issuing a bill calling attention to the necessity of organisation? I trust, sir, that "Jack Plane" will not be so ready to apply his pen as he does to apply such offensive epithets, and not call for so much of your valuable space in refutation.

R. M. MORRELL, Hon. Sec.

BILLS OF QUANTITIES IN LIVERPOOL.

A CORRESPONDENT writes,—

A really good bill of quantities is an exception in Liverpool (unless when London architects bring down London quantities), on account of certain irregularities which unfortunately exist. In London the architect never supplies the quantities; it is not the etiquette of the profession, the assumption being that he is more profitably employed. But the chief reason is that he finds himself in a more independent position by keeping clear of the quantities, placed as he is an umpire between two parties. If he receives pay from the contractor for them he is responsible for their accuracy, and this is not a desirable position for him to occupy. He will therefore have nothing to do with them. But in Liverpool, with one or two honourable exceptions, the architect invariably takes out the quantities either directly or indirectly. Perhaps in no case does he actually take them out with his own hands. He employs a confidential clerk, who is a draughtsman, and not a qualified surveyor. He may place his own name to the quantities, or leave his clerk to place his name to them really one. But if he attaches his own name he generally states, as bold as brass, the interesting fact that he has taken all possible pains with them, he is not prepared to say that they are correct, and that he will not be responsible for their accuracy. In short, he employs himself, without consulting either his client or the contractor, fixes his own rate of charge, pockets the money, and refuses to be responsible for his work. If the name of his clerk is attached, the responsibility is supposed to be shifted on to his shoulders, but it is a responsibility which is never recognised, and which the clerk, of course, not in a position to meet. Now, it is a notorious fact that these quantities so supplied are often grossly inaccurate and inefficient, and even when correct, as to their general character they do not give the detailed information nor represent anything like the time and patience a good London surveyor brings to the same work. For doing this 2 per cent. are commonly charged, and in some cases 2½ per cent. Duly qualified surveyors are discontinued in Liverpool, the work being given out, not to the most efficient, but, in the interest of the architect. How much goes to show that, as now matters stand, we have no means of knowing, but it is always surmised that the fees are divided. There is one consolation for the unfortunate client, out of whose pocket the extra rate of course comes. He pays through the architect, and he pays in blissful ignorance. Such a state of things is a blot upon the profession.

THE ROYAL ACADEMY AND THE ARCHITECTURAL EXHIBITIONS.

Sir,—A short time back a suggestion was made to me, that the time for receiving drawings for the Architectural Exhibition should be postponed until after the Royal Academy judges had decided as to the drawings to be hung there. Architects prefer their drawings to be hung at the Royal Academy, and I know that a great number of drawings are prepared by the best architectural artists for that exhibition. Only a few of these drawings are hung, simply because there is not wall-space; and thus, after the expenditure of much time and money upon their production, they return to the architect's office without the public ever having a peep at them. Could not the Architectural Exhibition be made a success, if it could be so arranged that these rejected drawings should be included in the Conduit-street show?

I hope that this suggestion will receive a corner in your journal, and, if practicable, be acted upon by the Exhibition committee. I cannot deny that it seems anything but right that the representation of modern architecture should be almost entirely left in the hands of the junior members of the profession. We have reason to expect that men who have been blessed with success, and who must have ample means, will do all in their power for the honour of the profession; but how is our expectation met?

I fear that if the present utter lifelessness,—except where gold glitters,—goes on much longer, architecture will be erased from the list of professions, and put down as a dead letter. Sir Edwin Lutyens will be pictures without sending them to the R.A. Does he? No; he is an artist. How is it architects have lost all enthusiasm?

ADALPHI.

* This is not strictly correct.—Ed.

THE EAST LONDON MUSEUM.

SIR,—Thanks to well-directed efforts, a Museum of Science and Industrial Art will very shortly be established for the teeming populations of the great East London suburbs. The obstacles which impeded the progress of the enterprise have now been removed, and the site has been finally ascertained in the House of Lords; and it remains, therefore, with the public to subscribe the cost of the ground, in order that the Government may, in pursuance of their undertaking, commence building. I learn with some regret that some hundreds of pounds are still wanting to complete the sum; yet I shall rejoice if this circumstance be the means of eliciting from the people themselves an unostentatious expression of practical goodwill. Much might be done through an appeal to the loyalty of the East-end artisans to rally them to the support of their museum. Surely they owe it to the Government, the trustees, and the wealthy donors of money, that they should exhibit their interest by sharing, according to their means, the comparatively small burden which is the only condition attached to the wise and liberal concession of those who govern us, for the instruction and recreation of the masses.

In the East-end are 100,000 persons who have no pounds to spare, but can give pence. Let, then, a general contribution be made,—in workshops and factories, in offices and on tradespeople's counters, from house to house, and by the post,—of pence and postage-stamps. I am sure that Mr. H. Mansard, as the Rectory, Bethnal-green, N.E.; and Mr. Antonio Brady, Maryland Point, Stratford, E.; and I am permitted to add, the Council of the Public Museums and Free Libraries Association, 150, Strand, W.G., will be very glad of the help of your working class readers; and the body just named will cordially avail themselves of any opportunities offered them of addressing briefly, or for an evening, the meetings of literary, trades, temperance, mental improvement, friendly, and any other societies, in furtherance of so enormous a benefit to the toiling million of the East.

J. T. DEXTER.

HERNE BAY.

SIR,—My attention has been drawn to a communication from "One of the Piles" of our pier, which found a place in your columns. In the Bay will heartily rejoice, and many will be willing to lend a helping hand, should there at last really be a prospect of doing something towards restoring the last prestige of Herne Bay! And what more likely to effect such an object as re-opening the pier, and making it not only a point of call for passing steamers, but also a promenade for visitors? To attempt anything short of this would certainly be absurd.

I cannot, however, allow that the Herne Bay inhabitants have been reticent in this matter. Alive to their own interests, they more than once subscribed money, and offered to repair the pier; but then, as now, "difficulties piled in their way" by the proprietors of the pier rendered all efforts null.

Let but the owners of the pier meet fairly those who are now attempting a like object, stating upon what terms they will either cede their rights entire, or otherwise permit the rebuilding of the pier, and all the rest will speedily be arranged.

It is, indeed, a thousand pities that Herne Bay, possessing as it does the combined advantages of pure, bracing atmosphere, excellent bathing, charming country walks, and proximity to the chief cathedral city, should be so neglected, when a little public spirit would, if properly directed, soon cause it to take rank as a favourite watering-place.

ONE OF THE RESIDENTS.

RIGHT TO PLACE FOOTINGS ON ADJOINING GROUND.

SIR,—Will any of your readers kindly give me a correct reply to the following question:—

Providing two men purchase or lease two adjoining plots of land of R. frontage each plot, the one intends building, the other does not, can the one who builds legally encroach on his neighbour's plot for the purpose of putting in his footings, or can any part of them be built on the part of the man (his neighbour) who does not intend to build, should such non-building party object?

Parties to whom I have spoken are divided in opinion.

A SUBSCRIBER.

THE ARTISANS' AND LABOURERS' DWELLINGS BILL.

A REPORT on this Bill, now passing through the House of Commons, has been presented to the General Purposes Committee of the Manchester City Council by the Town-clerk, and by the Committee to the Council. In the outset the report says:—

"The Artisans' and Labourers' Dwellings Bill (against which the Corporation presented a petition last Session) has, with considerable alteration, and as the Town-clerk is glad to say, with much improvement in its provisions, been again introduced and read the second time in the House of Commons."

After reciting and commenting on the various clauses of the Bill, the report thus continues:—

"For the main object sought to be attained by the Bill, viz., an improvement in the dwellings of the working classes, the Corporation have always expressed their sympathy and approval; and the Town-clerk ventures to express the opinion that, if to the reasonable objections urged by the Corporation to some of the provisions more consideration had been shown, greater willingness to accept the amendments proposed by Mr. Goldney and others had been manifested by those who had charge of the Bill, very different progress would have been made, and in all probability a Bill to accomplish an object of which every member in the House approved, would, during the last session have received the willing sanction of the Legislature. In the Bill now before the House the whole of the amend-

ments referred to in the report of the town-clerk have been embodied. . . . The responsibility of making the alterations required to improve the sanitary condition of dwelling houses is, as the council has always contended it ought to be, cast upon the owner of the property; and in all cases where such owner either declines or neglects to make the alterations required, the council may, at their option, either close the dwelling until rendered fit for habitation, or they may purchase the property at such price as shall be fixed by two independent valuers, who are to value the property 'at the true market value as unfit for human habitation,' and use 'to add nothing for compulsory purchase.' As now framed, and subject to unimportant alterations which will no doubt be made in committee in the House of Commons, the powers proposed to be given will, in the opinion of the town-clerk, be found most valuable to the local authorities, and enable them by their exercise largely to improve the sanitary condition of the dwellings of the working classes."

PROPOSED WORKHOUSE FOR ISLINGTON.

THE architect of the selected design, Mr. Bardon, writing with reference to a paragraph in our last, says,—

"The amount stated in the original instructions issued by the trustees was 35,000*l.*, which, with the 10 per cent. margin, may be taken in round numbers as 40,000*l.* The amount of the accepted Tender, on the other hand, is under 22,000*l.* Since the selection and adoption of my design, the compulsory requirements of the Poor-law Board have considerably increased the necessary cost. Instead of a cubical space of 500 ft., as originally asked, for each inmate of the infirmary (a large building, to accommodate 400), my amended plan (on the pavilion principle) provide just upon 800 cubic feet per inmate in the infirmary, and 1,300 cubic feet in the 'separation wards' with additional kitchen, scullery, and other internal arrangements. Fireplaces also in the centre of the wards have been preferred, instead of ordinary fireplaces in the side-walls, as planned in the first instance. The cubical space of the casual wards has also been increased. The Guardians, moreover, were pleased to adopt several improvements which study of workhouse arrangements induced me to suggest for their consideration, and which were not included in their original instructions."

PARISH CONTRACTS.

THE tenders accepted by the vestry of St. Pancras for the supply of granites, road materials, &c., for twelve months, are as under-mentioned, the prices at this time last year being those named second, from which it appears that prices are lower, and this reduction is attributed to the cessation of numerous large works in the metropolis, and the lessened demand for men and horses.—Granite, in quarry lumps, at per ton, Messrs. Mowlem, 11*s.* 6*d.* (15*s.*); Mount Sorrell, 10*s.* 6*d.* (12*s.*). Mr. Culverhouse, Groby, 10*s.* 4*d.* (10*s.* 8*d.*). Sewell & Son, Markfield and Bardol-hill, 10*s.* 8*d.* (10*s.* 10*d.*). Kentish rag, broken, Mr. Culverhouse, 8*s.* (8*s.* 5*d.*) per yard. Road materials, per cubic yard.—Smith & Son, hard core, 1*s.* 6*d.* (2*s.* 10*d.*); Mr. Studd, loamy gravel, 5*s.* 8*d.* (6*s.* 4*d.*), and clean rough gravel, 6*s.* (6*s.* 6*d.*); Mr. Anderson, surface hand-picked flints, 8*s.* (11*s.* 10*d.*), and pit flints, 7*s.* 6*d.* (8*s.* 4*d.*). Carriage-way pavings:—Messrs. Sewell & Son, Aberdeen laid-in gravel, per yard super, cubes 9 in. by 3 in., 15*s.* (17*s.* 7*d.*); half coverings, 7 in. by 3 in., 11*s.* 10*d.* (13*s.*); pitchings, 6 in. by 3 in., 10*s.* 10*d.* (11*s.* 10*d.*); Mount Sorrell squares, 3 in. by 3 in., 5*s.* 2*d.* (6*s.* 4*d.*); channelling on macadamized roads, 9*s.* 6*d.* (10*s.* 10*d.*). Footways:—York stone, 3 in., per 100 ft. super, 2*l.* 12*s.* 6*d.* (3*l.*); York, 3 in., laid, per yard super, 5*s.* 10*d.* (6*s.* 6*d.*); kerb, 12 in. by 8 in., per foot lineal, 1*s.* 9*d.* (2*s.* 1*d.*); York channelling, 4 in. by 12 in., per foot lineal, 6*d.* (8*d.*); spnr stones, 2*s.* 8*d.* (4*s.* 9*d.*).

MONUMENTAL.

Proposed Statue of Faraday.—A meeting has been held in the library of the Royal Society with a view of memorialising Government to erect a statue of Faraday, in Westminster Abbey, at the national expense.

The Lincoln Statue.—The model of the statue of President Lincoln, which is to form a portion of the "Lincoln Monument," to be erected by the United States War Fund Committee, has arrived in New York from the studio of Mr. H. K. Brown, and been inspected by the committee. The statue, which will be of bronze, will be 9 ft. in height, representing Mr. Lincoln in a standing position, holding in his left hand a copy of the Emancipation Proclamation, with the right hand pointing to the words, "Shall he for ever Free," engraved thereon. The statue will rest upon a pedestal 15 ft. in height, ornamented with appropriate devices. The total cost of the monument will be 15,000 dols., which amount has been fully subscribed in 1 dol. subscriptions. The

monument will be placed in the Park, near the great fountain.

Monument to the Poet Tannahill.—For nearly sixty years after the death of Robert Tannahill, the poet, no public memorial of him existed in Paisley, his native town. Some time ago, it was proposed that a committee should be appointed for the purpose of organising an subscription for the erection of a monumental tombstone over his grave. The proposal was gone into, and soon sufficient funds were obtained for the purpose. The memorial was not intended to be more than a neat erection to mark the spot where the poet's ashes reposed. Tannahill was buried in the West Relief Churchyard, and there the memorial has been built. It was designed and executed by Messrs. Gordon & Barclay, sculptors, Paisley. It is composed of grey granite, and the style is Roman. Its general character is a pedestal, about 4 ft. square at the base, and 10 ft. in height. On the shaft is a polished subscription-plate with the following words:—"Tannahill, Born 3d June, 1774; died 17th May, 1810. Erected over the remains of the poet, 1867." The work was completed a few months ago, and the committee have been celebrating its erection.

CHURCH-BUILDING NEWS.

Tamworth.—A meeting has been held in the town-hall to promote the restoration of the parish church by carrying out the plans for increased accommodation, at a cost of about 2,000*l.*, prepared, some time ago, by Mr. G. G. Scott. Subscriptions to the amount of 1,850*l.* were announced at the meeting, and there was no intention of raising any rate. The "Bishop of Lichfield and New Zealand" presided, and the meeting was disturbed throughout by such "discordant noises" as the bishop said reminded him of the South Sea Islands; and indeed it looked as if his lordship had imported some of his New Zealand fock into the diocese of Lichfield.

Lichfield.—A vestry meeting of the ratepayers of the parish of St. Mary has been held to receive the report of the committee appointed to select a design for rebuilding the body of the church, as a memorial to the late bishop, and to determine whether an application should be made for a faculty for such rebuilding. There was a very numerous attendance. It appeared from the minutes of the committee that having advertised for designs for rebuilding the church in unison with the present spire and tower, nine architects sent in plans, and the committee, after examination, selected those of Mr. Griffiths, of Stafford, the county surveyor, and Mr. Fowler, of Louth, Lincolnshire, a native of Lichfield. Both plans were sent to the family of the late bishop, and the result was the adoption of Mr. Fowler's. The new church, according to Mr. Fowler's designs, will seat 1,000 persons, and the cost will be about 6,000*l.*, towards which the family and friends of the late bishop promise subscriptions of 4,000*l.* The report of the committee stated that the designs of Mr. Fowler had been accepted subject to certain modifications, to which that gentleman had assented. Until a formal tender had been made by a competent builder it was not possible to state the exact cost, but it might be estimated that the sum of 6,300*l.* would be required, towards which 4,500*l.* had been promised by the vicar's family, they allowing 500*l.* for the old materials; and sums amounting to 545*l.* had also been promised by other persons. The report of the committee was all but unanimously adopted, and it was resolved that as soon as the funds necessary for the rebuilding of the church had been guaranteed the churchwardens be empowered to apply for a faculty for such rebuilding according to the plans of Mr. Fowler. A committee was appointed to provide funds for the rebuilding and generally to carry out the object in view.

Wednesbury.—The cemetery here has been consecrated by the Bishop of Lichfield. When the formation of the new cemetery was resolved upon, an eligible piece of land, situated on the Walsall-road, at a short distance from the town, and measuring upwards of 12 acres, was secured at a price of 5,400*l.*; and a loan of 10,000*l.*, repayable in thirty years, was obtained from the Public Loan Commissioners. Plans and designs, prepared by Messrs. W. & S. Horton, of Wednesbury and Walsall, were accepted; and contracts were entered into for the building of the chapels and lodge, the levelling, and laying out of the ground, and the erection of the boundary

walls and palisading. The former was given to Messrs. Trow & Son, of Wednesbury, at the contract price of 2,220*l.* The remaining part of the 10,000*l.* has been expended in the levelling of the ground (at a cost of 540*l.*), the laying-out of the cemetery (a work which has been done under the immediate supervision of the Board's surveyor, Mr. Fereday), and the erection of the entrance gates, boundary walls, and palisading. The design of the chapels is Early English, modified to suit the requirements of the case. The chapels are situated on each side of an enclosed entrance porch, above which rises a stone spire, furnished with a bell, and springing in octagonal shape from a square base, to the height of 56 ft. The chapel to the right, entering from the Walsall road, is for the use of Episcopalians, and that on the left for the use of Nonconformists. Each is 30 ft. by 16 ft., and to each is attached a receiving place, 18 ft. by 13 ft., and a small vestry at the extreme end of the building.

Strood.—The committee interested in the erection of a new church for the inhabitants of Strood have finally decided on the site for the proposed church, which will be near the Marsh, at the rear of North-street, in the parish of Frindsbury, on land belonging to the Dean and Chapter given by the Ecclesiastical Commissioners. The erection of the church will, we understand, be proceeded with forthwith.

Mistley.—The preliminary operations for the erection of the new church are now in progress. Mr. Capon and his assistants have been staking out the site, which is in a meadow of Mistley Park. It appears that the dimensions of the new edifice, including the spire, will be about 110 ft. by 60 ft. The committee have engaged the architectural services of Messrs. Wadmore & Baker, of London. The existing building, which is regarded as a curiosity in ecclesiastical architecture, has so many friends among the parishioners that its ultimate fate still remains undecided.

Books Received.

Our Schools and Colleges. By HERBERT FRY. London: Hardwicke, 1868.

INFORMATION is given in this useful volume as to nearly 2,000 schools of all sorts, preparing for various public examinations, and also as to the universities. The present issue is the second annual edition, in which the whole has been revised up to the end of 1867, after direct communication with the principals of each institution, and the author has added considerably to the information given in the first edition. The chief object in view is to provide information to parents in the selection of schools for their children. An account is given of our ancient endowed schools as they now exist. This is a very important subject, which in past years was considered worthy of Government investigation; and that renewed inquiry and adjustment are necessary seems evident. Mr. Fearon, one of her Majesty's inspectors of schools, speaks of a little English grammar school which he visited where the schoolmasters, according to the Parliamentary returns, had 100*l.* a year, and he found two masters teaching one scholar! One of the most comical things ever witnessed in the county, says Mr. Fearon, was the examination of that solitary scholar by the venerable and learned head-master, the usher, and assistant master! He was a sickly boy and very ignorant. Such a mockery of education ought not to be possible in England, nor should such means be wasted.

An Inquiry into the Difference of Style observable in Ancient Glass Painting, with Hints on Glass Painting. By the late CHAS. WINSTON. Second edition. Oxford and London: Jas. Parker & Co. 1867.

PENDING further notice we mention the publication, in two handsome volumes, of a new edition of the late Mr. Winston's valuable work. Some few additions have been made from an interleaved copy, in which he had occasionally made notes; but these are not very numerous. His opinions remained very much the same as first expressed.

Some of our readers may be glad to be reminded that Mr. Winston's drawings from ancient glass paintings—a large and valuable collection, exhibited in 1865 by the Archaeological Institute,—have been presented by his widow, in pursuance of a wish expressed by

himself, to the British Museum, where, we suppose, they may be consulted. These drawings would have been more appropriately deposited if sent to South Kensington.

Haddon Hall. Illustrated by Drawings from Sketches made on the spot, by GEORGE CATERMOLLE; with an Account of its History. Derby: Bemrose & Sons. 1867.

WE have here twenty views of Haddon Hall, beloved of artists and lovers of the picturesque; but they are for the most part so badly lithographed, that we can recommend the book only on the score of its being a remembrance. The well-known flight of steps to the upper garden is "conspicuous by its absence."

VARIORUM.

"ENGINEERING Facts and Figures for 1867: an Annual Register of Progress in Mechanical Engineering and Construction." Fullarton & Co., London and Edinburgh. 1868. This annual contains a good deal of useful matter, which seems to be chiefly compiled from various journals named only in the preface in a general way. It is illustrated by plates and woodcuts, and contains notes on the various departments of the Paris Exhibition of 1867.—"A Treatise on the Petroleum Zones of Italy." By E. St. John Fairman, F.G.S., &c. London: Spon. According to this author, and, indeed, on ancient authority as well, there are distinct indications of the existence of petroleum in various places throughout Italy, more especially in the provinces of Modena and Reggio. These indications were observed by the author in a geological tour through a large district of rich mineral country in Italy, and he says, they appeared to him to be identical with those of the American petroleum districts, and in some places even more favourable.—"On the Purification of the river Clyde." By Michael Scott, C.E., London. Maclehoose, Glasgow. Mr. Scott here publishes his views in the form of a letter addressed to the Lord Provost of Glasgow. He proposes, intercepting sewers being constructed, that the Glasgow sewage should be raised by pumping, carried along near the line of the Glasgow and South Western Railway as far as Dalry, then from Dalry to Fairlie Head, where it would be discharged into the sea. This, however, would be a very costly system. The line of conduit would only be about thirty miles long, but for seven miles or more it would pass through a hilly country. Mr. Scott himself admits that the lift would be great, and the annual expense of pumping very large. Nevertheless, should it be found that this is on the whole the best or most effectual way of disposing of sewage which has become as great a nuisance in the Clyde as was that of London in the Thames, cost ought to be a secondary consideration. An alternative system is also proposed, however, by Mr. Scott, which consists essentially in diluting the sewage by help of a canal and basin, so as to restore it to the comparatively innocuous state in which it passed into the river in years bygone; and then twice in twenty-four hours to allow it to pass out to sea through the Clyde so as not to return, or not to remain in the river.

The illustrations of the Paris Exhibition in the current *Art-Journal* include a view and details of the exquisite ebony and ivory cabinet by Alessandri now in the South Kensington Museum; also one of Durenne's elaborate cast-iron fountains.—In the *Broadway* Mr. Holingshead gives a frightful picture of Theatrical Management, which notice, however it may be overdone, is not without its value, and may lead to some useful inquiries.—*London Society* continues to provide interesting particulars of "King Theodore's country." The April number is, in other respects also, fully up to its mark.—The "Easter Annual" is distinguished by a strikingly original story called "The Soul-Trap," by Mr. James Greenwood.

Miscellaneous.

NEWSPAPER PRESS FUND ANNUAL DINNER.—The Duke of Cambridge has consented to preside at the annual dinner of the Newspaper Press Fund on Saturday, the 6th of June, at Willis's Rooms, St. James's.

ARCHITECTURAL LIBRARY.—The Library of the Institute of Architects has received an accession by the gift of Miss Leicester, of Bishop's-road, Baywater, of numerous works on architecture, &c., which formed part of the library of her late brother, Mr. G. O. Leicester, who, up to the time of his decease, was a Fellow of the Institute.

SOCIETY OF BRITISH ARTISTS.—The forty-fifth annual exhibition by this society, now open in the Suffolk-street Galleries, consists of 650 oil paintings, 427 pictures in water-colours, and 11 pieces of sculpture,—1,097 works in all. The number of exhibitors is 600. The collection includes a number of very interesting pictures, and is better as a whole than has been seen here lately.

TELEGRAPHY.—The value of the telegraphic wire and apparatus exported from the United Kingdom last year was 209,688*l.*, as compared with 312,288*l.* in 1866, and 143,679*l.* in 1865. In the ten years ending 1867 inclusive, the value of this branch of our exports will be seen to have been very considerable—viz., in 1858, 234,708*l.*; in 1859, 742,306*l.*; in 1860, 251,712*l.*; in 1861, 214,411*l.*; in 1862, 320,897*l.*; in 1863, 317,314*l.*; in 1864, 218,464*l.*; in 1865, 148,679*l.*; in 1866, 312,288*l.*; and in 1867, 209,688*l.*

DRINKING FOUNTAINS.—We regret to observe, from the *Sheffield Independent*, that the various local drinking-fountains have been almost entirely abandoned, and that several of them have disappeared. A committee of the Town Council, it is said, have ordered the fountain at the Town Hall to be removed. Has the experiment of drinking-fountains proved a failure at Sheffield? Our authority thinks the subject has not yet been fully considered, and trusts that a structure intended to be both useful and ornamental, and that was erected at a cost of 50*l.*, will not be destroyed without due deliberation.

THE MANUFACTURE OF STEEL FROM CLEVELAND IRON.—At a recent meeting of the Cleveland Society of Engineers, held in the draughting-loft of Head, Wrightson, & Co.'s Works, South Stockton, a paper was read by Mr. Hargreaves, of Darlington, on his new process of manufacturing steel from Cleveland iron. About forty gentlemen were present, and a large amount of interest was evinced in the subject, which has of late occupied much attention throughout the district. Mr. Hargreaves's process is said to produce first-rate steel, securing, according to the *Darlington and Stockton Times*, the maximum of results at the minimum of cost.

THE CONDITION OF AGRICULTURAL LABOURERS. A conference of noblemen and gentlemen has been held at Willis's Rooms, to consider the present condition of the agricultural labourers of England. Resolutions were passed to the effect that the subject demanded serious attention; that district protection unions should be encouraged and aided; that such unions should be strictly defensive, and limited to securing a fair day's wages for a fair day's work; that a committee be appointed to initiate the formation of such unions, and otherwise promote the physical and social improvement of the agricultural labourer; and that those interested in this be requested at once to provide a fund to enable this object to be carried out.

NEW SYNAGOGUE.—The consecration of a synagogue was performed on Sunday, with all the accustomed rites, at Thornhill-road, Barnsbury, where one of these places of worship has been erected for the North London districts. The building is in the modern Italian style. The niche where the "ark" stands is approached by a flight of marble steps, which were decorated with flowers, and the arches, which are formed of decorative figuring, are supported by columns of rare coloured marbles. Immediately over the niche of the sanctuary, in Hebrew characters, is the sentence, "Know before whom thou standest," and on the second arch, in like characters, the sentence, "Let the fear of the Lord be constantly before thee." Below are two windows with the initial words of each of the Ten Commandments, and the door of the ark (or sanctuary) itself is covered with a crimson velvet curtain, on which a wreathed crown and characters representing the words "The crown of the law" are embroidered in gold. There are galleries to the body of the synagogue. The architect of the building is Mr. H. H. Collins, and the builder Mr. Henshaw. It is intended to build schools adjoining the synagogue.

VENTILATION IN STOCK-SHEDS.—Mr. Mechi says on this subject:—"When farmers see my twenty blocks in one covered and enclosed shed, they frequently exclaim, 'Can they be healthy there?' That is a proper remark, for unless the ventilation were perfect, they could not be healthy, so closely packed in a limited space. As my system of ventilation appears to keep my animals (although closely packed) in perfect health, I will describe it: a portion of the centre of the roof is raised above the rest, with louvre boards on each side, but the wind is not allowed to blow through from one side to the other, but a board, a yard or more in depth, is dependent from the roof, so that the current of air coming through the louvre boards is deflected and passes downwards, driving out the foul air through the opposite side or louvre boards, or through the holes in the top of the walls under the wall plate, the circulation is thus constant and perfect." He was able, he says, by the medium of steam, to see the circulation which could otherwise have only been surmised. In one of his sheds, where the animals are on sparsed floors, and very closely packed, say two bullocks in a space 2 ft. by 8 ft., for twenty years there has not been the loss of an animal, although many lots have been fattened there, some remaining from calves until two years old.

THE SUZ CANAL.—A letter by the Duke of Devonshire in the *Times* takes a favourable view of the prospects of the Suez Canal. The Duke says, in reference to the great or salt water canal, to which the smaller or fresh-water canal is merely subsidiary,—"The first point of interest after leaving Suez is at Great Shalouf. This is the most important cutting next to El Cuair. It is four miles in length, through clay, stone, and sand, and is dry at present. Three thousand European and Arab workmen are kept here. It was more struck here than anywhere else on the canal works. The canal is cut to its extreme depth, and the water will stand 26 ft. deep at low water in the Red Sea. You look down into an enormous dry channel, with its busy hive of workmen scooping away the ground and filling the trucks which stationary engines draw up and replace by others; and while looking down on this magnificent work you almost persuade yourself to believe in large steamers passing to and fro here between the West and the East, in the coffers of the company being filled with their shares, and in delighted shareholders drawing large dividends. At the Serpinn, some distance further inland, you come on another piece of the canal finished, and it is here you meet the waters of the Mediterranean, which have been brought over half the whole distance of the Maritime Canal, and are kept back from the other portion of the works by an embankment of earth."

BUILDING UP THE PEOPLE.—A M. Jules Borie says he has received the sanction of the Emperor of the French to the building of what he calls "Aérodromes." These structures are to be not less than ten stories high, access to the upper parts being afforded by lifts, as is already the case in many hotels, both in England and France. Iron is to constitute the framework of these vast edifices, which are to rise to altitudes from 100 ft. to 120 ft. "Let us suppose," says *Galignani*, "the building to occupy a large rectangle; the fifth story will be partially supported by a terrace, say 10 ft. broad. Above this rises what may be called a second set of gables, narrower than the basement part just described, and constituting the aérodome proper, no five stories high, making ten in all. The basement flats would serve for shops, banking, &c. other offices, &c.; those above the terrace could be inhabited by the clerks and other people generally connected with the establishments below. Let us now imagine a series of these rectangular constructions, separated from each other by wide avenues; the inhabitants of the aérodomes may communicate with each other by means of bridges thrown across from terrace to terrace, and in this way we get in fact two towns, one above the other. A large amount of traffic will be carried on without descending into the streets at all, provisions, fuel, &c. being obtained by means of the lifts. Each aérodome will be inhabited by 1,000 people or more, all enjoying commodious apartments, a pure atmosphere, and abundance of light, while the streets now will be wide and airy." We are by no means sure that this pure atmosphere would be enjoyed, and are not at all disposed to aid in arguing about this enormous collocation of man beings on a given area.

"PLANING AND TRYING MACHINE."—Mr. Chas. Powis dozes that the machine said by Messrs. Worssam & Co. to be "the only machine which has ever been brought out that will set a piece of twisted timber true, and at the same time give it a planed face fit for gluing up without requiring to be touched by a hand-plane," is so. We must leave him to settle this matter with Messrs. Worssam.

FALL OF A WALL IN THE CITY.—An accident has occurred in Bucklersbury, by which a man has lost his life. The deceased was one of several workmen employed in removing houses on the site of the new street from the Thames Embankment to the Mansion House. While engaged in undermining a wall between the houses Nos. 13 and 14, Bucklersbury, he was told that if he continued where he was the wall would certainly fall upon him; but he disregarded this warning, and continued to dig under the brickwork. He was again cautioned, but without any effect. The wall fell in with a crash, and he was completely buried beneath it. When he was got out he was found to be quite dead.

THE RATING OF CHARITIES.—A very large deputation of gentlemen from the principal cities and towns in the kingdom, headed by the Duke of Cambridge and the Earl of Harrowby, has waited upon the Premier, who was accompanied by the Chancellor of the Exchequer, to lay before him the hardship inflicted upon all institutions of an eleemosynary character, such as hospitals and schools, by the departure from the ancient principle that all such places should be exempted from parochial taxation—a principle which has been upset by a recent judicial decision. The cities of Bristol, Birmingham, Derby, Gloucester, Liverpool, Leeds, Manchester, Northampton, Newcastle, Sheffield, Southampton, Wolverhampton, and Worcester were all largely represented. After hearing various members of the deputation, Mr. Disraeli said the statements which had been made would be considered in a spirit adequate to the occasion and to the importance of the deputation.

THE MONT CENIS TUNNEL.—This remarkable work makes steady progress. Of the total length, 12,220 metres, 5,049 metres are completed. The following is the advancement and expenditure for each year since the commencement of this undertaking to the end of 1867. The expenditure for 1867 has not yet been published:—

Length of Tunnel completed.

Date.	Total during year.		Amount.
	Mètres.	Mètres.	
1857	497-00	497-00	3,299,248
1858	369-10	866-70	1,639,753
1860	343-30	1,210-00	2,500,000
1861	363-00	1,573-00	3,000,000
1862	623-00	2,196-00	2,000,000
1863	822-00	2,998-00	3,500,000
1864	1,068-00	4,068-00	6,532,254
1865	1,223-70	5,309-70	5,327,338
1866	1,024-99	6,334-69	5,644,932
1867	1,511-96	7,846-65	—

The probable cost of the work was estimated at 70,000,000 francs (2,800,000*l.*); of this amount 33,699,973 francs were expended up to the end of 1866, justifying the estimate very remarkably.

WHAT WE HAVE AND WHAT WE PAY.—A return, moved for in the House of Commons, has lately been published, which includes particulars as to the annual value of property in England and Wales charged under the different schedules, the Property and Income Tax. From this it appears that the annual value of property and profits charged to income-tax in England and Wales, amounted to 273,404,918*l.* in the year 1863, to 276,520,647*l.* in 1864, and to 296,031,791*l.* in 1865. The rateable value of property in England and Wales subject to local taxation was 76,357,145*l.* in 1863, 87,618,867*l.* in 1864, and 90,137,365*l.* in 1865. The amount raised by poor-rates, highway-rates, church-rates, police and prisons, drainage, &c. and local boards, amounted to 14,462,442*l.* in 1863, to 14,543,307*l.* in 1864, and to 14,966,751*l.* in 1865. The sums given as annual grants from the public revenue in aid of local taxation in England and Wales, amounted to 1,316,073*l.* in 1863, to 1,384,952*l.* in 1864, and to 1,398,000*l.* in 1865. The largest items in these grants are for prison and convict establishments at home, for the maintenance of prisoners in county gaols, for the removal and transportation of convicts, and for law charges and criminal prosecutions.

"LIVERPOOL MUNICIPAL BUILDINGS."—For the "late Mr. Weightman," under the view in our last, read the late architect to the corporation, Mr. Weightman.

THE AMERICAN STEAM MAN.—We were inclined to regard the account of the steam man as a Yankee joke, but it is now said that he is exhibiting in New York, and preparing for a promenade, at the rate of 30 miles an hour, down Broadway. A citizen of New Jersey invented him, but a speculator in New York is said to be "bringing him out." The inventor, it is said, offers to manufacture him by the score for 60*l.* a head. This is not a great sum to pay for a man who is as strong as three or four horses, who can be fed at a cost of 6*s.* a week, and can earn a hundred-fold that amount. Yankee jokes, however, are sometimes rather elaborate affairs, and the human form seems absurd as a one for any attempt to make steam useful as a locomotive, that we are not even yet caught.

ART INSTITUTION FOR DUBLIN.—A numerously-attended deputation, consisting principally of Irish noblemen and Irish members of Parliament, recently waited on the Chancellor of the Exchequer, at his official residence, Downing-street, to ask the Government to establish in Dublin a department of science and art, similar to the institution at South Kensington. The Chancellor said that the matter had already received the consideration of his colleagues and himself, and that they were prepared to give effect to the views represented by the deputation. A scheme had already been under their consideration, but it was not as yet fully matured. He hoped when the estimates were being prepared next year to be in a position to know what the desired institution would cost, and to insert a vote for that purpose.

EQUALIZATION OF THE POOR-RATES.—The question of the equalization of the poor-rates is daily extending. The ratepayers of Holborn Union have held a meeting, to take the subject into consideration. There was a large attendance of ratepayers. The meeting resolved,—That the Poor-law Board be requested to introduce a Bill into Parliament for the purpose of effecting an equalization of the poor-rates in the metropolis, and thus put an end to the present unequal and admittedly unfair mode of taxation for the support of the poor." Mr. Bullen showed the great inequalities existing. Paddington was assessed at 646,256*l.*, and contributed 16,504*l.* for the relief of the poor; while St. George's, Southwark, which was assessed at only 139,706*l.*, contributed 22,907*l.* A general equalization of rates would reduce the rates of the Holborn Union by 8*d.* in the pound. It was also resolved that a petition should be signed by the chairman on behalf of the meeting, and be presented to Parliament by the borough members.

OPENING OF CLERKS' DINING-ROOMS.—The first establishment erected by the Clerks' Dining Company (Limited), for providing clerks with dinners at moderate prices, has been opened at 36, Wallbrook. It is the first of ten proposed to be established by a capital of 20,000*l.*, raised in 20,000 shares of 1*l.* each. The premises opened are entirely new, and replete with all modern and convenient arrangements. The building is fireproof, being composed of stone and iron girders, and the floors of rubble and concrete. There are two stories underground. In the lower one are cold, well-ventilated vaults for keeping the meat, wines, and ales. Over these are the usual cooking kitchens, fitted with first-class ranges, and so constructed that, by means of air-shafts, the varied smells of the savoury meats under process are carried to the outside, and thus are prevented from rising into the upper rooms of the establishment. On the basement floor is a luncheon-bar and large room, and on the first floor a room capable of dining about 150. Above are coffee, chess, reading, and smoking rooms, and also a private Board-room for the directors. The interior walls are done in a lavender colour distemper picked in with stone and chocolate. There are about 1,200 members, holding among them 2,000 shares. Two 5*s.* calls having been made, the company has started with a capital in hand of 1,000*l.* An extra advantage held by the members is that they may be supplied with meat at 5 per cent. over cost price. Mr. Finch Hill is the company's architect, and the adaptation and fittings were by Messrs. Hill & Son, builders. Messrs. Waller & Son supplied the ranges, and Messrs. Buckley & Beech the beer-machines.

FEMALE SURVEYOR OF HIGHWAYS.—The Aylesbury bench of magistrates, at their annual session for the appointment of parish officers for the several parishes in their division, appointed Mrs. Sarah Wooster to the offices of overseer of the poor and surveyor of highways for the parish of Ilmire, there being no other "person" resident there so well qualified to perform the duties. Last year the same magistrates appointed not fewer than four women to similar posts, in parishes within the Aylesbury petty sessional division.

ROYAL ITALIAN OPERA, COVENT GARDEN.—The season was opened on Tuesday night last with an admirable performance of "Norma," Madlle. Frizzi filling the grand part grandly. We are disposed to say this lady is now the best *Norma* on our stage. Madlle. Lemmens-Sherington was an excellent *Adalgisa*, and Signor Naudin an equally good *Pollio*. Mr. Gye's programme contains an account of the recent negotiation entered into with the view of bringing about the union of the two opera managements, and shows, as it seems to us, that Mr. Gye was played by a so-called Financial Company. Had he been a man of less experience and providence than he is, the success of his season might have been perilled. On Thursday night "Don Carlos" was successfully presented.

ENGLISH PORCELAIN AT BOW.—In reply to questions in the Commons, put by Mr. Schreiber, Lord R. Montagu (vice-president of the Committee of Council on Education) said that some fragments of porcelain, dug up at Stratford-le-Bow, were sent to the Museum of Practical Geology, and Mr. Trenham Reeks wrote concerning them as follows:—"I immediately identified in these fragments patterns which exist on some perfect specimens in our collections, but of hitherto unknown manufacture. I subsequently visited the locality, and found that many very interesting specimens had been collected by the engineer of Messrs. Bell & Black's new patent safety match manufactory. . . . On Monday I called on Mr. Bell, who most liberally offered to open out the 'diggings' again, if any good is likely to result to the history of British Art." Directions had been given to enter into communications with Messrs. Bell & Black.

COINCIDENCES.—A correspondent writes,—"Coincidences such as you pointed out in your last do occur more often than might be expected, but they are overlooked: people do not look with their minds. The English excursionists who have been visiting Jerusalem lately were led by Captain Gaze, not a had courier for people who came to look about them. Notice how oddly names and trades sometimes agree. In the Hampstead-road, Cowdary, cow-keeper and dairyman, used to live, and may still do so; Waterfall, umbrella-maker, lived at Newton-cum-cuseway; Bacchus, publican, might be seen in Brompton not long ago; Sugar, confectioner, at Mitcham; and Kilham, undertaker, at Kennington. I have notes of many others.—H. Hamper, basket-maker; J. Tippler, publican; T. Unite, rope-maker (Notting-hill); J. Saddler, harness-maker; J. Pets, bird-seller; Veal, cow-keeper and dairyman; Miller, corn dealer; Eg-ham, poultryer; and Birch, schoolmaster; but will not ask for more space.

PROPOSED NEW WORKS AT CHATHAM DOCKYARD.—In the naval estimates for 1868-9, just laid on the table of the House of Commons, the sum of 229,705*l.* is taken for the works, &c., proposed to be carried out at this dockyard during the ensuing year. The total estimate for the extension of the dockyard by the formation of new docks, three large basins, factories, and building slips is 1,250,000*l.*, of which amount 437,564*l.* had been expended to the 31st December last. The original estimate for the extension of the yard appears to have been dependent upon the number of convicts available for the work, but there is little doubt this will have to be increased, the number of convicts engaged on the extension works having hitherto fallen far short of that upon which the estimate was originally based. The sum required to be voted for 1868-9 is 195,000*l.*, being 150,000*l.* for contract work, and 45,000*l.* for convict work, the further estimate for completing the whole of the works being 570,000*l.* Among miscellaneous works proposed to be carried out during the year, are a new iron roof over No. 2 dock, and at the angle iron smithery, at an expense of 20,000*l.*, new iron caisson for No. 4 dock, 4,000*l.*; foundations for new machinery, 900*l.*; erection of a new master station, and other works.

MANUFACTURE OF STEEL.—We read in a French contemporary that M. Galy Casalat has invented an ingenious process for compressing molten steel, intended for guns, so effectually as to save all the labour of hammering. In the upper part of the mould into which the metal is run is an apparatus containing a small quantity of highly inflammable powder, which, in burning, generates gas in such quantity as to produce thereby in a very short time a pressure of ten atmospheres. This pressure expels the gases contained in the steel, and forces the metallic molecules into the closest union.

EARLY CRYPT, ANGERS.—In digging for the proposed new theatre in Angers, M. Armand Parrot, secretary to the Société Académique of the department of the Maine-et-Loire, and intrusted with the superintendence of the excavations, has had the good fortune to discover the Gallo-Roman chapel in which the first bishops of Anjou used to officiate and preach to the Pagans who had recently embraced the Christian religion. This little temple was, therefore, the cradle of Christianity in that province. Two other crypts of different periods have likewise been found, which present some curious architectural details. One of them, called after St. René, contains a large number of very fine sarcophagi of various shapes. Some of them belong to the Mérovingian period, and consist of magnificent monoliths, in the interior of which skeletons, in a perfect state of preservation, have been discovered.

TENDERS.

For the erection of four cottages, for Mrs. Mulliner. Messrs. H. Davies & Son, architects:—
Rogers.....£550 0 0
Gwen.....780 0 0
Davies.....850 0 0
Samuels (accepted).....600 0 0

For altering and enlarging Paddington Chapel. Messrs. E. Hatherston, Brock, & Webb, architects. Quantities supplied by Mr. H. T. Northcroft:—
Henson, Brothers.....£3,530 0 0
Simpson & Son.....3,493 0 0
Ehiss & Son.....3,443 0 0
Simpson.....3,447 0 0
Manley & Rogers.....2,028 0 0
Sriviever & White.....2,900 0 0

For alterations, additions, and decorative works to house and stables, Stratford-place, exclusive of gas or hot water work. Mr. H. H. Collins, architect:—
Gillow.....£9,700 0 0
Henshaw.....8,600 0 0
Foxley.....7,733 0 0

For villa residence, Horney-lane, for Mr. T. E. Blax-hall. Messrs. Lander & Bedells, architects:—
Axford.....£1,450 0 0
Batman & Potheringham.....1,458 0 0
Saunders.....1,455 0 0
Grover.....1,394 0 0
Manley & Rogers.....1,375 0 0
Mann.....1,345 0 0
Sale.....1,170 0 0

For house and stabling at Silechester, for Capt. Lloyd. Mr. Smith, architect:—
Woodward.....£5,280 0 0
Lovatt.....4,857 0 0
Lockyer.....4,611 0 0
Dover.....4,530 0 0
Grover.....4,415 0 0
Wilcox & Spurgeon.....3,913 0 0
Hallaway.....3,470 0 0
Pither.....3,201 0 0

For rebuilding market-house at Hemel Hempstead, Herts. Mr. George Low, architect. Quantities not supplied:—
Sear.....£3,300 0 0
Watkins.....3,250 0 0
Humphrey.....2,565 0 0
Webb.....2,534 0 0
Cook (accepted).....2,140 0 0

For a detached villa residence at Beckenham, Kent. Mr. George Low, architect. Quantities supplied by Mr. Frederick Johnstone:—
Horse. Stabling. Total.
Browne & Robinson.....318.....318.....636
Colls & Son.....1,654.....318.....2,000
Marland & Sons.....1,635.....355.....1,990
* Accepted, for house only.

For additions, &c. to Loxley House, Warwickshire, for Mr. James Cove Jones. Mr. Thomas T. Allen, architect. Quantities supplied:—
J. & E. Callaway.....£3,600 0 0
Clark.....3,590 0 0
Clark & Smallwood.....3,520 0 0
Kibler (accepted).....3,140 0 0
Green.....2,986 0 0

For alterations to Edmonthorpe Hall, near Oakham, for Mr. W. A. Pochin. Mr. R. W. Johnson, of Melton, architect:—
Halliday & Cave.....£1,510 0 0
Fast.....1,476 0 0
Hrale & Sons.....1,469 0 0

For converting two houses into warehouse, Monkwell-street, City. Mr. Wm. Smith, architect:—
Waters (accepted).....£587 0 0

For rebuilding 189, Camberwell-road. Mr. Janu Tolley, architect:—
Right.....£750 0 0
Baker.....670 0 0
Grover.....664 0 0
Stevens.....655 0 0
Ennor.....509 0 0

For building residence and stables at Teddington, M. H. H. Collins, architect:—
Horse. Stables.
Dawes (accepted).....£1,550.....580

For new lunatic asylum for the county of Berks, boroughs of Reading and Newbury. Mr. C. H. Howarth, architect. Quantities supplied by Mr. John Scott & Messrs. Winell & Trollope:—
Foster.....£47,250 0 0
Lacey.....46,975 0 0
Brace.....45,703 0 0
Browne & Robinson.....45,128 0 0
Webb.....45,500 0 0
Piper & Wheeler.....45,434 0 0
Trollope & Sons.....45,434 0 0
L'Anson.....45,280 0 0
Deunell & Co.....45,100 0 0
Lovatt.....45,050 0 0
Holland & Haugen.....45,070 0 0
Perry.....45,050 0 0
Higgs.....45,190 0 0
Barnley & Son.....45,093 0 0
Mansfield, Price, & Co.....41,618 0 0

For rebuilding infant school, Charlton, Kent. Mr. V. Wigginton, Corinthian architect:—
Ennor.....£592 0 0
Kully.....565 0 0
Axford & Whittier.....555 0 0
Abraham.....530 0 0
Walker.....502 0 0

For simonases, Charlton, Kent, for the trustees of Dutch Church, Austin-friars. Mr. W. Wigginton, architect:—
Abraham.....£3,174 0 0
Kully.....3,122 0 0
Ager.....3,117 0 0
Ashby & Sons.....3,038 0 0
Nissey.....2,961 0 0
Hill & Reddel.....2,960 0 0
Ennor.....2,865 0 0
Axford & Whittier (accepted).....2,833 0 0

For building additional floor, &c., at 107-9, Leaden-hall-street, for Mr. J. T. Morton. Mr. W. Ete, architect:—
King & Sons.....£658 0 0
Greenwood & Sons.....565 0 0
Hoiser.....610 0 0

For completing a tavern and three shops in Trafalgar-road, Camberwell. Mr. Wm. Smith, architect:—
W. Saunders.....£1,497 0 0
Garrud.....1,485 0 0
George.....1,475 0 0
Walker.....1,439 0 0
Pearce.....1,390 0 0
Watkins.....1,382 15 0
W. Saunders.....1,375 0 0
Smith & Simmonds.....1,338 0 0
Mundy.....1,281 0 0
Wood & Munn.....1,216 0 0
Crabb & Vaughan.....1,214 0 0
Sabey.....1,210 0 0
Pither.....1,162 10 0
Blackmore & Morley.....1,100 0 0

For erecting nine houses and shops in Trafalgar-road, Camberwell. Mr. Wm. Smith, architect:—
Walker.....£5,268 0 0
Pearce.....4,779 0 0
W. Saunders.....4,775 0 0
Mundy.....4,767 0 0
Hearle.....4,640 0 0
Garrud.....4,556 0 0
Smith & Simmonds.....4,535 0 0
Watkins.....4,513 0 0
Blackmore & Morley.....3,960 0 0
Crabb & Vaughan.....3,783 0 0
George.....4,365 0 0
Sabey.....4,357 0 0
Blackmore & Morley.....3,960 0 0
Scholfield.....3,783 0 0
Wood & Munn.....3,672 0 0
F. Saunders.....3,650 0 0
Pither.....2,979 0 0

TO CORRESPONDENTS.

A. L.—J. T. D.—T. W.—D.—F. O.—J. W.—F.—K. E. B.—F. H. Driver.—G. P.—J.—J.—Cul.—C.—J.—E.—T.—G.—E.—K.—R.—H.—T.—G.—J.—J. W. H.—H.—D.—H.—A.—J.—R.—S.—R.—F.—H.—R.—T.—T.—A.—R.—J. M.—W.—R.—D.—G. H.—H.—S.—J.—S.—O.—W.—W.—P. (let us see the model).—A. K. E. (already given)—A Country Gentleman (in type).

NOTICE.—Architects who are unwilling (as we are) that their name should not accompany lists of tenders with which they are concerned may prevent the omission by sending lists themselves. We cannot repeat lists on the ground of such omission.

We are compelled to decline printing out books and giving addresses. All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. **NOTE.**—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

GOOD FRIDAY.

NOTICE.—"THE BUILDER," for the week ending APRIL 11th, will be published at TW p.m. on THURSDAY, 9th inst. Advertisements for insertion in that Number must therefore reach the Office before THREE p.m., on WEDNESDAY, 8th.

The Builder.

VOL. XXVI.—No. 1314.

Curiosities of Art.

HO shall write the "Curiosities of Art?" We have "Curiosities of Literature," "Curiosities of Natural History," and Curiosities of this, that, and the other; but we are not aware of any work specially devoted to the "Curiosities of Art." Here, then, is a fresh field for some facile pen. The theme is a suggestive one, and a hook at once amusing and instructive might be written on it. Perhaps a few notes and reflections may prove useful as materials to the future D'Israeli of art. In the *Builder* of the 8th of June,

1867, there appeared a critical note on M. Gustave Doré's illustrations of Tennyson's poems of "Vivien" and "Guinevere," then announced as forthcoming. A hope was expressed that this clever and versatile artist would be allowed time to read what he was to illustrate before making his drawings. This, as was remarked, he could scarcely have done in the case of "Elaïne." We pointed out that in more than one of the illustrations the author's meaning is wholly misrepresented; as, for example, in the drawing supposed to illustrate that passage which says that Arthur, who, "labouring up the pass," had trodden on the crowned skeleton, and sent the skull rolling, plunged down the shingly scarp after the crown,

"And caught
And set it on his head,"—

Arthur is shown on horseback! The publisher took exception to this criticism, and replied to the effect that "while the critic was evidently a stranger to pigskin," M. Doré was a most accomplished and daring horseman, and perfectly understood what he was about when he designed this picture. He (the critic) was advised to consult "Greenwood's Horsemanship," and be taught how to pick any object from the ground at the walk, canter, or gallop. We simply reiterated our assertion that the engraving in question was not an illustration of the author's words. If it be thought that this criticism savoured of harshness, the reply is that it has been fully borne out by various writers who have since discussed Doré's merits as an illustrator. Indeed, certain critics, of no mean repute, have gone much further than the *Builder* in their strictures. A recent writer in the *Athenæum*, for instance, using almost the exact words of the *Builder*, says, "We suspect that M. Doré has never read Tennyson, and never thought of Tennyson while engaged upon this work." Whereupon an artist writes, "Does not this remark of yours involve points of im-

portance? Is not the great curse of our day *untruthfulness*, spreading over the nation that stapor from which no one as yet sees signs of escape? And should not every instance of it be frowned down? Is not the book-illustrator a translator? Why then should he be allowed to falsify his author without disgrace? In his 'Milton,'—the 'Inferno' portion of it,—does not M. Doré treat his great author contemptuously? It appears to me that herein his first characteristic is want of imagination, and his second untruthfulness. Fully enter into Milton's grandly laboured description of Sin and Death; then look at M. Doré's design; and will not a freezing chill seize one?—a feeling that such is a pitiable libel and a disgrace to any person? I hope that English artists will not be led away by the success of this very clever illustrator." Even still stronger language might be applied to Doré's Bible illustrations, many of which are simply worthless and an insult to the sacred text. A writer in the *North British Review* of September last quotes a number of examples of the artist's carelessness and want of sympathy with his subject. In the parable of the Prodigal Son, says this critic, the father is fainting, the whole family are in despair, more like the Jews weeping over Jerusalem. The son, whom the French style *l'enfant prodigue*, is represented as a boy of twelve or fourteen coming slyly round the corner, and down some steps, *pour faire une petite surprise à sa famille!* Again, in the story of the Pharisee and the Publican, it is expressly said the publican stood afar off, and smote upon his breast; but Doré places him close to the Pharisee, and prostrate, with his arms spread, in the attitude of one looking for a needle. The death of Ananias is depicted on a steep hill side; whereas, we are told that the "young man arose and carried him out," and that his wife Sapphira came in. Again, the burning fiery furnace mentioned in Daniel is represented by three logs of wood in a 10-foot ohammer, at the top of which, sure to be smothered with smoke, or suffocated for lack of hydrogen, is the king with his court, calmly looking on. Nothing could be more absurd, more ridiculous. Nay, when the king looked on there were four "walking in the midst of the flames," but Doré has only three. Other examples might be given, but they are unnecessary, for they would only prove more conclusively the charge of carelessness and ignorance, and consequently of untruthfulness.

Gustave Doré is a clever French artist, but he lacks imagination: he is essentially a caricaturist, and it is questionable whether he can draw the human figure correctly. Perhaps the worst compliment he ever received was when it was said of him that, "though not yet thirty-four years old, he has painted, yard for yard, more than any living artist." There is sometimes an evil in doing too much; we may mistake quantity for quality. An artist may paint too many pictures, just as an author may write too many hooks. Did Doré take more time over his work, and produce less, it would be better for his reputation. The French artist's treatment of the fiery furnace reminds one of Holbein's drawing of the same subject. The prophet's words are, "And these three men, Shadrach, Meshach, and Abed-nego, fell down bound into the midst of the burning fiery furnace." Holbein's furnace is a dome, or cupola, having a door like that of a common boiler in front. Looking from out this aperture are the heads of two men—much in the same position as a couple of female gossips might be at a street window; while another face is seen in the background, the door or look-out being too narrow to admit of the three individuals being equally represented. One cannot but be struck with the undisturbed, nay, comfortable expression and demeanour of the three men, all things considered. But we are bound to say the treatment here is not a whit funnier

than Doré's, while the same allowances cannot be made for the nineteenth-century artist as for his fifteenth-century predecessor. The assertion that our religious book illustrations least of all interpret or translate their subjects, seems hardly to require proof: no designs, as a rule, are so unsatisfactorily conceived. For the fault lies more in the conception than in the execution: the great subjects and events of Holy Writ unquestionably offer many difficulties to the artist. In truth, your man of small imagination and mediocre powers is not the man to make designs for the Bible, for Milton, or for Bunyan. Some of the old masters have given at least a grandeur to their notions of Biblical events. They have invariably represented them on a large scale. The figures are massive in design and drawing; they are painted in colours "gorgeous as the sun at midsummer," as if the masters had "dipped their pencils in the colours of the rainbow," and the noble extent of canvas which Raffaele, and Rubens, and Titian have given to their great works, gives them the dignity and splendid effect which they possess. It seems to us that such subjects as God appearing to Moses "in a flame of fire out of the midst of a bush," "Christ's Agony in the Garden of Gethsemane," and the "Ascension," are wholly incapable of being illustrated by the insignificant engravings which we see in pocket Bibles. A woodcut or steel engraving, a few inches square, cannot possibly represent subjects of so sacred an import. Can such a picture inspire any feeling of reverence or solemnity whatever? Does it impress one in any way? It may be questioned, indeed, whether the great I Am, who is a spirit, is—with reverence he it said—a fit or legitimate subject for a pencil. A pictorial illustration must utterly fail to assist us to realize that glorious Being whom eye hath not seen. The extent to which some of the great painters have treated sacred subjects is familiar to all students of art, and the liberties taken by a ruder school are amusing by their mingled absurdity and singularity. In some of his pictures Rembrandt made Abraham a hurgess of his time, and the Messiah a burgomaster of Saardam. In the old paintings representing Adam and Eve it is not uncommon to find the forbidden fruit varying with the country or province. In Normandy and Picardy it is the classic apple, one of the riches of the country; in Burgundy and Champagne, the bunch of grapes; in Provence and Portugal, the fig and orange; whilst in America it is the guava. In Greece it is generally the fig, which is adopted on account of the sweetness and abundance of the fruit. In Italy it is sometimes the fig, sometimes the orange, according to the province or caprice (*Edinburgh Review*). In the gallery of the Convent of Jomits at Lishon, there is said to be a fine picture of Adam in Paradise, dressed in blue breeches with silver buckles, and Eve with a striped petticoat. At either Paris or Versailles may be seen a painting of the twelve apostles represented in wig wigs and swords; and we have somewhere read of a tract printed in 1641 entitled "Nowes from Helle," which has a rude vignette representing the devil ill in bed and attended by several doctors in square caps, evidently meant for Jesuits. Lord Orford relates a curious anecdote of Antonio Verrio to the effect that when this artist was employed at Windsor he quarrelled with Mrs. Marriott, the housekeeper (whose portrait is now at Hampton Court), and horrified her ugly face for one of the furios, in order to gratify his personal pique. To flatter the Court he represented Lord Shaftesbury among the demons of faction, distributing libels. There is also at Hampton Court a study for a proposed ceiling by Verrio, in which he introduced Sir Godfrey Kneller, Mr. May, the surveyor of the works, and himself, in long periwigs, as spectators of our Saviour healing the sick. What is the reader's notion of the fate of King Pharaoh, of Red Sea celebrity? The popular idea is that

his majesty was drowned on the unhappy occasion in question. Nor is the notion of recent adoption; it has been in vogue for centuries, and may have been an article of faith with Solomon for all we know to the contrary. But there is no foundation in Old Testament history for the supposition; and yet, nothing is more common than Pharaoh in the middle of the Red Sea as a Scripture illustration. Thus, in Holbein's Scripture cuts we have the Egyptian king with "the waters closing over him." The host is in the very act of being swamped,—after the grotesque manner of Holbein,—the crowned head of the king occupying the foreground, while the Children of Israel are all comfortably landed on the other side, quietly enjoying Pharaoh's discomfiture. The text quoted is Exodus xiv. 28,—“And the waters returned, and covered the chariots, and the horsemen, and all the host of Pharaoh that came into the sea after them; there remained not so much as one of them.” A more recent instance of belief in this opinion may be found in the frontispiece of Maunders' "Treasury of History," where we have Pharaoh drowned, "done" by W. H. Brooke, A.R.H.A. Some of Holbein's other cuts are equally quaint, as "David killing Goliath." David and the giant are represented as in close combat; the former is in the act of striking Goliath in the face with the sling, while the giant's spear or club is almost touching his antagonist's leg. And, by the way, in the letters recently received from Abyssinia, we have some particulars with regard to Abyssinian notions of sacred art, curious enough in their way. The church of Ardegrath, we are told, is ornamented within by rude pictures of saints and incidents in Biblical history, executed without any idea of perspective. "Nor is the absence of art redeemed by antiquity, as they have been finished little more than half a century. Among other errors of the artist, critics have discovered a glaring anachronism in one design. The subject is 'The Passage of the Red Sea.' Moses, standing on the farther bank, is shaking his rod with mocking irony over Pharaoh, whose horse is rapidly being submerged, while the Egyptian infantry, already nearly engulfed, are holding their firelocks over their heads." How curiously amusing, too, the treatment art—not nature—has bestowed to give us an idea of Paradise. In speaking of the correctness which the last century praised so much, Macaulay, in his essay on Moore's "Life of Byron," says, it "resembles the correctness of those pictures of the Garden of Eden which we see in old Bibles. We have an exact square enclosed by the rivers Pison, Eidon, Hiddekel, and Euphrates, each with a convenient bridge in the centre, rectangular beds of flowers, a long canal, neatly brooked and railed in, the tree of knowledge, clipped like one of the limes behind the Tailor's, standing in the centre of the grand alley, the snake twisted round it, the man on the right hand, the woman on the left, and the beasts drawn up in an exact circle round them. In one sense the picture is correct enough. That is to say, the squares are correct; the circles are correct; the man and the woman are in a most correct line with the tree; and the snake forms a most correct spiral, &c." *Appropos* of this is a story told of old Lord Selkirk in the days when symmetrical arrangement was considered the *acme* of gardening. One day he found a boy shut up in a summer-house at the end of a terrace at St. Mary's Isle, and was informed by his gardener that it was for stealing apples. On reaching the other end of the terrace, where there was another summer-house, Selkirk held the gardener's son looking dolefully out of the window. "Eh! John, what is this? Has your boy been stealing too?" "Ns, na, my lord," was the answer, "I just put him in for sea-metry!" We look for something truer and more advanced now, though, as we have shown, modern art is occasionally singular and eccentric. Not long ago a respectable London publisher issued an "Illustrated" Bible, in one of the parts of which there is an engraving of Joshua before the walls of Jericho. The warrior is mounted on a bare-backed rampant steed; one hand grasps the hilt of his sword, while the other is pointed aloft in the attitude of direction. Supposing the law of gravitation to be in force in those days, which by the bye, is proved by the tumbling walls of the doomed city, the conclusion is irresistible that it is a physical impossibility that the rider could keep his seat. Another Bible, printed at Oxford in 1860, contains an illustration of Ruth gleaning, and represents Boaz wearing a pair of modern-

shaped shoes, such as our grandfathers wore. In regard to the treatment of secular subjects, again, innumerable examples of incongruous art might easily be given. In the present day, while we have plenty of clever artists,—and there is a good deal of original art,—there is at the same time a vast quantity of wishy-washy illustration,—illustration that does not illustrate,—served up to the public. At no other time, perhaps, was there half so much. We speak more particularly of that kind of artistic talent which finds its market in the illustrated weekly and monthly magazines of the hettersort. *Cornhill* and *Cassell's* may be instanced as representing the class of periodicals we mean. The fact is that art, like literature, in these latter days, is to a great extent done to order. It has become an article of manufacture,—the artist being merely a producer, and oftentimes no more than a reproducer. The demand for a certain kind of thing called illustration has reached such a pitch that this, like almost everything else nowadays, must be done on the spur or not at all. Mr. F. Palgrave, writing of London statues, in the *Munch* number of *Brooklyn*, says of Chantrey, that his success was his ruin as an artist. "Rapidly becoming fashionable, he seems to have lowered his standard to the level of his patrons, and henceforth rarely gave himself time to work on anything; substituting a few vague curves and planes in the features, and large empty folds in the drapery, for the thousand lovely subtleties and difficult truths of nature." The description is applicable to some able artists of the present day, who seem to forsake originality for "what 'takes,' and to sacrifice conscientious hard work to success. To judge from much that is to be met with in the way of book and periodical illustration, one would say that the artist had never had a chance of reading his author; at least, the text, if seen, has been very imperfectly read. In illustrating Mr. Trollope's story of "The Claverings," in the *Cornhill*, a clever and graceful artist represents the hero without whiskers and moustache for twelve months, but the month immediately following he appears with hirsute ornaments in the greatest abundance. Perhaps Miss Edwards had a notion that the hero was at perfect liberty to "grow a beard" if he liked. No doubt; but even a lady, not to say an artist, ought to know, that under the most favoured conditions, the thing cannot be done in a month. However, in the very next number of the magazine, we have a vignette of the hero with his moustache, but minus his whiskers; and then in a large plate, which is supposed to depict him as he appeared a few hours after, he has neither whiskers nor moustache. If this be not escapist art, what is? Again, while Mr. Thackeray jests about Clive's beautiful whiskers and handsome moustache, Mr. Doyle persists to the end in denying young Newcome the possession of those tokens of manhood. Once more, in vol. ii. of "Pendennis," there are two engravings to the text at p. 165. Just before Huxter comes up to Captain Costigan, who is drunk in the street, he (the captain) wears a hattered old hat, his well-known cloak, and a dress-coat underneath it. This is illustration number one. In ditto number two, the intoxicated Costigan is represented as having fallen, and Huxter is assisting to raise him. Now the cloak is gone, which is possible enough; but that the stocking, bad hat should have suddenly altered its shape, and assumed a respectable appearance, and the swallow-tail should have changed into a frock-coat, must be left to the explanation of the artist. If we descend the artistic scale, and glance at a lower class of publications, we shall find still greater curiosities of art. Some one said a few of Turner's landscapes, that they were pictures of nothing, and very like. But it might be said of the works of not a few modern illustrators, that they are pictures of something, and very unlike. How seldom, for example, does a picture of some public scene or event in any of our illustrated newspapers tally with one's own recollections of the scene. Instead of a "full, true, and correct account," pictorially, we get for the most part a bundle of caricatures, or a confused mass of impossibilities. We chanced recently to be present at a public meeting in Exeter Hall, where a well-known lord addressed the audience. A view of the weeklies on the following Saturday, with the noble lord in the attitude of speaking. We hope his lordship liked his portrait. He must have felt flattered with the eminently D'Orsay-like appearance which it pleased the imaginative artist

to give him. He was even generous enough to insist upon his lordship appearing in wonderfully fitting evening costume, in place of the ordinary morning suit, in which, as a matter of fact, he did appear, and unlike the thing meant as it was possible for picture to be. A short time since, there appeared in another popular periodical a narrative of the capture of an alligator on the coast of Malabar. The faithful historian, who was an eye-witness of the feat, tells us that "James, without a moment's hesitation, seized the mugger by the tail, and gallantly he stuck to it." The said mugger is described as having been 13 ft. 4 in. long, and a woodcut shows James (who, *mirabile dictu*, is clad in a suit of black, with an ordinary English hat) clinging in his arms the hinder part of the animal, while we may suppose the body to be struggling on the ground. The sketch is called "Catching an Alligator by a new Method." About the newness of the method there can be no doubt. The writer who told this astounding story, the artist who drew the picture, and the editor who printed it for the benefit of a generous public, are equally entitled to commiseration. But even this is nothing to some of the feats performed by the writers and—shall we say artists?—of certain pictorial prints. The advertisement of one of these journals, which has become quite notorious as a chronicle of blood and murder, and filth, and wickedness generally, recently stated that the forthcoming number would contain "a large engraving of the suspected murder of a boy by his father at Hoxton," with "three subjects in connexion with this fearful tragedy." The "dragging for the body," was to form an illustration which would "fill half the front page of the paper." (There was a temptation and inducement to buy!) Furthermore, there were to be engravings of "The Burning of a Ballet Girl"—"The Suicidal Leap of a Young Lady from Westminster Bridge"—"Murderous Revenge of a Negress"—"Inhuman Treatment to a Child"—"The Selling of a Wife at Blackburn"—with half a dozen other equally revolting topics, "all taken from sketches by artists expressly engaged." Of course, we are asked to suppose that in each case the proprietors knew that these events were to occur, and at once despatched special artists, who sketched the scenes on the spot. But it will be said, "You do not call this art?" It is not truth, but in one sense it is art,—the art which finds its patrons and its pupils among the lowest orders. The fact that the publication in question boasts of a circulation of 150,000 weekly,—whether this be so or not, the figure must be large,—the fact, also, that its office-doors are usually "besieged," are indications of its popularity, and the influence which it must exert on the minds of its credulous readers. What the nature of that influence is we need not inquire. The paper is supplying an art education of the very worst kind to the most dangerous and ignorant of the population—the very class which stands most in need of something higher and healthier. In truth, each successive number of this wretched print is an additional obstacle to the efforts of the true art teacher, as well as to moral and intellectual improvement of the masses. Leaving those publications which may be said to confine themselves exclusively to the horrible and revolting in human nature, and give exaggerated and unnatural representations even of that, what shall we say of another class of indolent rubbish of a pictorial kind that has sprung up with so much French effrontery in our midst of late? Portraits from the Mahille and Cremorne, colored sketches of abandoned women who haunt the most notorious streets of the metropolis, valentines of the filthiest description, and photographs of the grossest taste, are at present exhibited for sale to an extent and with a publicity which we hardly believe would have been tolerated a few years ago. As compared with the coarse pictures to which we formerly alluded, we regard this prostitution of art as ten times more harmful in its influence. The principal marts of this vile trash are in the vicinities of Wynd-street and the Seven Dials; but it is a matter of every-day observation that some respectable print-sellers no longer scruple to exhibit half-naked figures of "celebrated" French actresses in the same line with the portraits of English statesmen, poets, and church dignitaries. A paragraph is just now going the round of the newspapers informing the world that "a photograph may be seen in the shop windows of Mr. Swinburne, the poet, sneezing Adah Menken's hand, and looking into her eyes like a

"dying duck." This, it would appear, is the latest thing out in photographic fashions; and a piece of ingenious impertinence it is, to call it by no worse name. The idea is thoroughly Parisian. It may be remembered that the same rather remarkable lady, about whom the public has heard so much in one way or another, and a celebrated French novelist, appeared in a similar interesting situation not long since, and that the affair gave rise to an action at law in the French courts. Where is this sort of thing going to end? Is it not scandalous that the reputation of public men should be thus made traffic of in order to minister to a prurient taste? The gross and libidinous caricatures of Gilray are no longer popular; the taste for Rowlandson's glutinous sketches has died out; but it may be doubted whether we have not something quite as bad, if not worse, in their place. And how such infamous publications as *The Town*, and others of a like stamp, are allowed week after week to flout their indecencies in the face of Lord Campbell's Act is surely a thing to be wondered at and lamented.

THE DESIGNS FOR MANCHESTER TOWN HALL.

IN our last issue we quoted from the letter of Mr. Heron, the Town Clerk of Manchester, requesting further information on certain points from the referees as to the relative merits of the four principal designs in these respects, and the letter from the referees accompanying their second or detailed report sent by them in reply. We will now approach the designs at present on view in the large room of the Town-hall, Manchester. This remarkable competition has arrived at what, we presume, may be considered its last phase. On Monday, March 30th, the second report of the referees, which placed Mr. Waterhouse first in the order of merit, was brought up by the sub-committee, and the City Council confirmed the decision by formally accepting Mr. Waterhouse's design, and resolving that the exhibition of the designs should be opened to the public on Thursday, April 2nd, for fourteen days.

The citizens of Manchester can now judge for themselves as to whether or no the City Council have made the best use of the authority confided to them; and architects have an opportunity of criticizing the award of the judges, the efforts of the several architects, and the strength of their claims to represent the profession in such an important contest.

The beneficial effect of such an exhibition on the public mind must be considerable: it affords to the greater portion of the community the only opportunity within their reach of judging of the dignity of architecture as a profession, and the claims of its professors to the title of artists. To the competitor, occasion is afforded of showing to the world what is really in him, and of breaking a lance with his professional brethren in the arena of architecture, thereby raising or lowering his position amongst them. To the student of architecture a lesson is provided, set forth in its most attractive form, and, if not properly studied, the lost opportunity will be required at his hands.

The City Council have shown every desire to free themselves entirely from the trammels of favoritism and "jobbery" too frequently connected with transactions of this nature. In the first place, by asking for the smallest number of drawings capable of illustrating the intentions of the competitor; secondly, by the liberal remuneration offered to those who might engage in the second competition; and, thirdly, by calling in the aid of professional arbitrators to enable them to arrive at a sound decision.

This liberal and straightforward conduct on the part of the Corporation met with a ready response from the profession. Men of the highest standing from all parts of the kingdom applied for "instructions," to the number, we believe, of 500. Of these about one-quarter submitted designs, amongst whom we noticed the names of men "conspicuous by their absence" in many similar contests; owing, doubtless, to the prevailing distrust amongst architects towards that standing anomaly, a "building committee"—that unapproachable creature, that irresponsible party, possessing neither a soul to be saved, nor a person to be kicked.

The presence of these architects may surely be taken as a compliment to the council—a vote of confidence, in fact; and we have every reason

to believe that the result of this contest will show that the confidence of the architects in the good faith of the Corporation has not been misplaced. The costly and substantial manner in which the council propose to carry out the work is eminently characteristic of the native vigour for which Manchester men are celebrated, and which we are pleased to find is not limited to matters of commerce alone, but also displays itself in public buildings. The result of this competition must be highly gratifying to the citizens, proving, as it does, that one of their number is able to cope successfully with the best men of the profession.

The writer has seen all the drawings, and can confidently say, that either for architectural excellence, skill in planning, or artistic and delineative execution displayed in the drawings, no finer collection (not excepting even that for the London "Law Courts") has ever resulted from one single competition.

The general average of excellence is so high that the race appears to have resulted in a nearly dead heat amongst the first two or three competitors.

The "Instructions to Architects" are so voluminous and explicit that none who have not either worked on the plans, or made themselves thoroughly acquainted with the requirements by patient study, can adequately appreciate the difficulties with which the competitors had to contend. These instructions are the result of four or five years' consideration of the individual requirements of each department of the Corporation, and many plans have been prepared by the city surveyor, Mr. Lynde, from which the dimensions of rooms and other important particulars have been derived. The experience also gained from the first competition decided the council to alter and considerably augment their list of requirements.

For the benefit of those amongst our readers who may not remember the particulars of the different stages through which this competition has passed, the following *résumé* may prove of use in assisting them to understand thoroughly the present state of affairs.

In March, 1867, architects were invited by the Corporation of Manchester to submit designs for a "Proposed New Town-hall." A guarantee was given to those who might compete that "not fewer than six or more than twelve" of their number would be invited to engage in a second contest, to be conducted on a much larger scale than that laid down for the first trial. In this final struggle the prize would be the erection of the building, with the usual professional remuneration; and each of the unsuccessful architects was to receive 300*l.* as payment for his labour, provided that the required number of drawings had been submitted. The council also promised to call in professional assistance to enable them to arrive at a fair decision. The drawings asked for were plans of ground and first floor and elevations of Albert-square, Princess-street, and Cooper-street fronts, it being understood that the elevation towards Lloyd-street should be little inferior in finish to the other three.

The drawings composing a single design occupied a vertical compartment on the walls of the exhibition-room; and, to secure the different panels being filled in a uniform manner, a clause was inserted in the conditions requiring each pair of plans to be accompanied by a separate set of elevations. The dimensions of the mounts and scale of the drawings were also prescribed, in order to secure further regularity.

In reply to this liberal offer 123 architects in August last sent in 137 designs, some competitors having furnished three distinct sets of plans.

A sub-committee was appointed by the town-council for the purpose of examining and reporting upon this large number of drawings. The result of their deliberations, aided by the Conductor of this journal, who was called in by them for that purpose, was the selection of a certain number of designs, found to be by the following gentlemen:—Mr. Salomons, of Manchester, two sets of plans; Messrs. Speakman & Charlesworth, Manchester, two sets also; Mr. Thomas Worthington, Manchester; Mr. Alfred Waterhouse, Manchester and London; Mr. John O. Scott, London; Mr. T. H. Wyatt, London; Mr. Cuthbert Brodrick, of London and Leeds; and Mr. W. Lee, of London; the honours being thus equally divided amongst local and London architects.

An exhibition took place which lasted fourteen days; but the successful designs, the authors of

which were again to compete with each other, were, of course, not shown.

Shortly after the election of the eight architects a fresh set of instructions, supplementing and considerably altering those first prepared, were issued, and February 14th, 1868, named as the last day for receiving the second set of designs. On St. Valentine's Day the drawings arrived, and we venture to say no enamoured swain or blushing maid receiving that eventful morning a more valuable offering than did the worthy mayor of Manchester.

Upon their reception the town-council held several meetings for the purpose of deciding on the best mode of dealing most fairly by their authors. It was finally arranged that Professor Donaldson and Mr. Street should be invited to visit the collection and report on the respective merits of the different designs. These gentlemen accordingly drew up a report, which placed the competitors in the following order, with reference to the different subjects upon which the judges were required to report. The numbers attached to the several designs, and used instead of the mottoes by the judges, for convenience of reference, are as follow—

1. "Arnolfo di Lapo"—Mr. W. Lee.
2. "Faire sans dire"—Mr. T. H. Wyatt.
3. "Fides"—Mr. Cuthbert Brodrick.
4. "Sperandum"—Mr. John O. Scott.
5. "St. Valentine"—Mr. Alfred Waterhouse.
6. Interlacing triangles—Messrs. Speakman & Charlesworth.
7. "True to the line"—Mr. T. Worthington.
8. "Valentine"—Mr. Edward Salomons.

Summary of Judges' Report.

6, 4, 7, 5, for architectural excellence.
5, 6, 8, for arrangement of plan and construction.

5, 7, 8, for economy and likelihood of being executed for the stipulated sum.

5, the best for natural light and ventilation.
5, 6, 4, 7, were considered to be the best in point of general merit, according to the order in which they are placed.

This report pleased neither the council nor the competitors quite, and the judges were required to answer a list of questions, and to state more in detail their reasons for arriving at their decision. A second report was in consequence prepared, the judges re-asserting their previous decision as to the superior merits of Mr. Waterhouse's design, and giving detailed reasons for objecting to the other plans. They requested that the contents of this second communication might be considered as confidential by the council, and not be published or communicated to the competitors. Nearly the whole of its contents has transpired, as the council might have known would be the case. Some of the unsuccessful men are angry at the prospect of having the report only partially known, and have in consequence demanded to see the document, or such portions of it as referred to their own designs.

Up to the present time, however, this has been refused; but the weight of influence which will be brought to bear on the council must eventually compel them to rescind their resolution of secrecy. Considering that a portion has already been divulged, we think it desirable that the whole should be published.

Before proceeding to review the different designs in the order of the numbers used in the report, it would be well to describe the site on which it is proposed to erect the new edifice. The shape is that of a blunt wedge, or a triangle with the acute angle cut off. Along the street line the dimensions of the different sides of the plot are,—Princess-street, to the north, about 300 ft. long; Lloyd-street, to the south, about 345 ft. long; Albert-square, the principal front to the west, about 330 ft. long; and Cooper-street, to the east, about 95 ft. This latter end is about 2 ft. higher than the centre of the Albert-square front.

Up to the beginning of this month strenuous efforts were made by Alderman King, and a strong body in the council, to have the present site enlarged, and converted into a rectangular plot. The Oxford-road, one of the main arteries running south-west could, by that means, be continued into Albert-square, and the narrow and tortuous streets that at present connect them, be swept away.

Let us now look at the designs *seriatim*.
No. 1. "Arnolfo di Lapo." Mr. William Lee, London. This gentleman has dedicated his design to the great architect of the Cathedral of Florence, the pupil of Nicolo Pisano, but we

have grave doubts as to whether this defunct worthy, could he re-assume "this mortal coil" for the nonce, in order to view the result of his pupil's efforts, would feel flattered by the doubtful honour conferred on him. As nearly as we can describe it, the style adopted is intended for a perpendicular treatment of Venetian Gothic, but so crowded is the whole with the most elaborate and diminutive detail, that the effect usually produced by the Venetian, or predominating style, is lost. The clock-tower rises from the centre of the Albert-square façade; and after leaving the roof, ascends in a very plain and unimposing manner until it meets a heavy machicolated cornice, with parapet bounded at the corners by a somewhat squat slate saddle-hipped roof, having dormer windows on its four faces. Two bold flights of steps, isolated from the rest of the building, rise from the street, on either side of the entrance to the ground floor, and land on a terrace or platform over the same. From this access is gained to the great vestibule on the main floor, through which the great hall and state-rooms are approached. This staircase is not, however, shown in the perspective view.

The connexion of the circular angle turrets, with the pavilions flanking the Albert-square front, is not satisfactory. The upper part of their roofs should rise higher above the side gables to obviate the present smothered-up appearance from which they now suffer; and the whole of this group is not sufficiently grand for the importance of its position. The Cooper-street corner of the Princess-street elevation is not sufficiently accentuated, and the central feature in Princess-street is too great for the remainder of the elevation. Four perspective views, very beautifully drawn in line and etched, illustrate the design. The detail shown is, in part, very good, and some beautiful bits of grouping will be found in these views. The interior of the large room is fine, but rather tame. A curved wooden roof, of low pitch, rises from hammer-beams, supported by corbels springing from the wall shafts, the space between the corbels over the heads of windows being finished with a flat ceiling. The windows are too wide for the amount of wall space between. One bay of this hall, drawn to a large scale, and showing the coloured decorations, is given. Frescoes are shown below the windows, and canopies containing statues separate the different bays. Twenty-three drawings, including views, explain this design, and the cost of carrying it out is placed at 250,000L.—the limit assigned by the instructions.

No. 2, "Faire sans dire," by Mr. T. H. Wyatt, of London, the architect of the Liverpool Exchange, is an Italian design, with French treatment, exhibiting great dignity and repose. The main entrance, or grand portal in centre of Albert-square front, is massive and chaste. The clock-tower over it, however, is not equal to its position, being too insignificant for the angle towers flanking this elevation. In the main façade, the basement is quiet and massive, and above it a colonnade detached from the front wall supports a deep cornice, with statues over it. The attic story is so lofty that it detracts from the scale of the lower parts of the façade, and its windows are too like those of a dwelling-house to suit the other parts of the composition. No roof appears over this, although two Mansard roofs abut against the angle towers.

The circular angle towers rise from two bold projections with high slated roofs, between which the colonnade of the main front is continued, terminating above in well-proportioned domes. The interior of the public room is very grand, and shows a circular roof formed by ribs springing from red granite columns. The lower portion of these columns and their dados are attached to pilasters supporting the side galleries, and resembles strongly the treatment of the large room in St. George's Hall, Liverpool. The interior of the council chamber, and those of the dining-room and principal entrance, are very pleasing, and beautifully drawn and coloured; in fact, the manner in which the views of this design are finished is highly creditable to all concerned in them. The plan is simple, practical, and clever, but the internal areas are small. The main floor is gained from the street by three flights of wide steps, an ante leading to the end of the public hall. Passages on either side of the hall are connected with it by doors at the centre and ends of the same. Four small staircases occur at the angles of the hall leading to

the galleries. Committee-rooms and open areas are placed each side of the whole.

The council-chamber and main entrance adjoining come between the mayor's department and the state rooms. The mayor's entrance on the ground-floor is placed in the circular angle tower, 81 ft. in diameter, at the corner of Albert-square and Princess-street. From this hall stairs lead to his rooms above. In the basement a metal tramway laid along the main corridor serves for the circulation of heavy goods. The areas provided are too small, in a climate like that of Manchester, for a proper supply of light and fresh air. Including views, this clever design comprises twenty-one drawings. The estimated cost is placed at the required limit of 250,000L.

In No. 3, "Fides," Mr. Cuthbert Brodric, best known by the "Leeds Town-hall," has collected the largest possible number of small shafts, and, with the assistance of pointed arches, has raised a palace for the,—fairies. The group formed by the large towers is fine when considered merely in outline. All the towers are circular and very large. On the ground-floor the base of the clock-tower, which is of great diameter, is devoted to a large entrance-hall, which swallows up the best portions of the front part of his plan. Part of the colouring of the exterior view is very spirited, especially the foreground. The plan has merits.

No. 4, "Sperandum," Mr. John O. Scott (son of Professor G. G. Scott).—This design is illustrated by no less than twelve beautiful and highly-finished exterior and interior views; some of considerable size and merit as coloured drawings. This is, we believe, the first occasion on which Mr. J. Scott has come before the public. The question naturally presents itself, if his first essay be so successful, what manner of man will he be when he has attained to his father's age and experience? The "Main Entrance," in the centre of the Albert-square façade, has over it a porch of two stages; the upper one gained through the large ante-room on the main floor, provided for public speaking at elections and on similar occasions. In the front elevation it is composed of three arches with angle buttresses, finishing in very graceful pinnacles. The side arches are pointed, but the centre ones are elliptical, and produce an unpleasant effect. This might have been easily avoided by making the side arches slightly wider, and changing the ellipse into a stilted semicircle. Over this porch rises the clock-tower. After leaving the roof, it shoots up straight like a rocket. By an anxious journey heavenwards, the eye at length reaches the clock, and over it a parapet with the usual allowance of pinnacles. The whole is crowned with a lofty hipped roof (too) green slate. Taking the tower as a whole, it is really grand. The lines are plain, but dignified and refined. There is nothing novel about it, and still it is satisfactory. The ground-floor windows are good; and over them, on the main floor, come pointed windows with traceted heads. These two floors are divided into bays by buttresses terminated on level of main floor by canopies containing statues. The windows of the upper story are divided by pilasters, and over the wall behind pierced with an occasional lunette; over this a cornice, and a high-pitched roof. This elevation is terminated north and south by octagonal turret staircases, continued to such a height above the cornice as to give them a somewhat lanky appearance. As the only projections in the front are the porch and buttresses aforesaid, the general effect is flat, owing to the absence of strong shadows and contrasts.

The tower at the Cooper-street end of Princess-street is somewhat similar to the clock-tower, but a better composition on the whole. The main entrance on the ground-floor is under the covered porch. A vestibule leads to the grand staircase, with dome-light over it. The grand staircase lands the public on the state corridor of the main floor. Retraining along corridors right and left of the staircase, the public would enter the grand hall. This is cruciform on plan, the arms of the cross being cut off from the remainder by three arches, and occupied by galleries. Two beautifully finished interior views show different methods of finishing the roof of this hall; the one by a dome springing from roof slightly pointed, and the other by a simple arch springing from wall-shafts, somewhat similar in treatment to that of Mr. Lee's. The drawings showing the grand staircase and council-chamber are works of art of no mean pretensions. The grand stairs leave the ground-floor by a wide

central flight of steps, and after gaining the first landing separate into two flights terminating on the state corridor. Round the whole is a series of graceful arches on marble shafts supporting a glass roof. The estimated sum for carrying out this design, including the dome finish to the great hall, is 201,775L. Mr. John Scott has a career before him that can scarcely fail to be eminently successful.

No. 5, "Saint Valentine," by Mr. Alfred Waterhouse, the architect of the Manchester Assize Courts, and the successful architect in the present competition. The general grouping of the tower roofs and prominent features of this design is most effective, and must have been well studied. The individual parts, however, seem to have had less attention. The Albert-square elevation has a central feature,—a boldly-designed gable, with angle buttresses and pinnacles over, projecting forward from the main building to the street line. On the ground-floor this forms the porch to the vestibule, and is gained by a wide and low-pointed arched door, the whole enclosed by a hood gable, constituting an insufficient main entrance. In this gable over the porch are three windows, of two lights each, having traceted and pointed heads. In the stage above are windows similar in character to those below; and in the gable itself are smaller lights, suited to their position. Behind this gable, and from the main walls of the building, rises the clock-tower. Its outline is plain. The top stage is occupied by three pointed arched openings in each face, and over them a parapet with angle pinnacles. Over this story the tower changes into an octagon, containing four clock-dials. The sides facing the angle pinnacles appear somewhat unstudied and bare. A slated pyramidal roof terminates the whole. The perspective views are lined in brown ink, and coloured in sepia and Payne's grey. They are executed in a bold and artistic manner. The small view on the same mount as the Cooper-street elevation is a gem in its way. The interior view of one of the three winding staircases is also worthy of close examination. We have no doubt that when Mr. Waterhouse has more leisure for the study of the detail of his elevations, a perfectly successful design will be the result. The style adopted is a free treatment of Early French.

The ground-floor is approached from Albert-square by the porch before described. On each side of this porch are small chambers for the use of the porters. Next comes the vestibule, placed immediately under the clock-tower; but how this is to be lighted, except with the most "dim religious light," we cannot say. This vestibule leads into the staircase hall, and from it runs a passage in the direction of Cooper-street, giving access to all the rooms of the police department placed under the public room. In the entrance-hall the grand staircases rise to the right and left landing on the main floor, either side of the entrance to public room. At the extremes of the front corridor on main floor are public entrances into Princess and Lloyd streets respectively. At the junction of this with the side corridors occur winding staircases, and a similar one is placed immediately opposite the entrance from Cooper-street. The treasurer's department is on the left of the main entrance. Then, turning the corner into Princess-street, come the public entrance, the mayor's entrance and staircase, weights and measures offices, paving and highway, and water department. Going from Cooper-street down Lloyd-street we find first the Court of Record, warehouse keys, some distance from the police department, under whose protection it lies, workshops for weights and measures at the opposite corner of the building from the offices connected with it. Then come the gas and scavenging departments, and the inclined cartway leading to the basement. Stairs to porter's residence, and a public entrance complete this frontage.

On the main floor the front is occupied by the state departments in the following order.—At the Princess-street end, the dining-room, reception-room, ante-room to same, under clock-tower, and projecting over the porch, large committee-room, ante and council-chamber. On the Princess-street front, next to dining-room, come the mayor, town clerk, assistant town clerk, and city surveyor; and off the cross corridor, at end of public hall, connecting the Princess-street with the Lloyd-street blocks, is placed the committee clerk. The three committee-rooms are put over the centre of Lloyd-street front. The public hall is placed at right angles to the Albert-square front, and is entered

only at the ends,—an arrangement which would prove inconvenient were the hall portioned out into three different divisions in the event of its being hired for a public entertainment. The hall is finished above with a high-pitched roof, having, large hammer-beamed curved principals, much resembling the hall in the Assize Courts; but not to be highly commended for its acoustic properties.

This plan has been placed first for simplicity of arrangement; but to gain this simplicity, the "instructions" appear to have been a little overlooked. In Cooper-street and Princess-street, for instance, the central features encroach upon the space reserved for areas. The wall of angle pavilion, crossing the dining-room, will, we imagine, be supported by a strong iron girder, but the internal pier that would support this girder is gutted by a hoist, leaving only a shell of brickwork, about 9 in. or 14 in. in thickness.

It is considered by the architect that the whole could be executed for a sum less than 250,000. Out of nineteen drawings, seven are perspective views.

To No. 6, Interlacing Triangles, Messrs. Speakman & Charlesworth, the judges awarded the first place for architecture. The Albert-square front is by far the grandest and most original conception in the room. In this design the central group is formed by a stately porch of three pointed arches, through which a broad flight of steps leads to the main floor. The centre one is nearly double the width of side arches, and is enclosed by a crocketed hood-gable. The middle ones are more massive than the angle piers, imparting a weak look to the latter, where extra strength and abutment are to be expected. Over the porch the façade is carried up one stage higher than the rest of the building; on the centre is a crocketed gable with small canopy for finial. A sculptured circular medallion fills this gable. On either side are beautiful octagonal turrets, two stages in height, rising from a square flat, banded by pinnacles. The construction for supporting these turrets is not hinted at externally, and, as in Mr. Waterhouse's case, they do not grow naturally out of their square bases. Above all, and behind the central gable, rises the lofty clock-tower, too much resembling that of the Assize Courts to be erected within a mile of that building.

In this façade the ground-floor windows are square-headed, and divided into two lights by shafted mullions, having relieving arches over all. The division piers are massive, with alternating courses of different coloured stone. Above this is a rich string and balustrade. Over the piers rise coupled columns sufficiently detached from the main wall as to leave a shallow passage or balcony behind. From these shafts spring pointed arches supporting the front wall of the upper story, and having their soffits the full width of the passage below, thereby producing strong shadows without diminishing to any deleterious extent the light of the main floor windows. Coupled pointed lights, with a circle in the head, form the windows to the state-rooms. Over this bold arcade is a deep string, formed by square panels filled with shields having armorial bearings. Next above come the windows of the upper story, of two pointed lights, separated by coupled granite shafts. These are divided into six bays on each side, by statues resting on corbels, and protected by canopies. Above an open arched balustrade, resting on a rich cornice, and shutting against two dormer-windows; and the angle and central towers bring us to the roof, which is finished with a metal cresting and well-designed chimneys.

The angle-towers bounding this elevation on each side are octagonal, and fully equal to their position. They are more than semi-detached, consequently looking safe and capable of easy execution. The horizontal bands of the façade run round these towers, connecting them with the rest of the building. The balcony of the main floor is also returned: it is supported on short granite shafts, resting on the projecting weatherings of small, but wide, buttresses. These towers rise one story above the cornice of the façade, and are crowned with a boldly-corbelled cornice, having gargoyles at the angles. Above this is a pyramidal slated roof, having an open sort of bell-cote, of pleasing outlines, as a termination. Four dormer windows occur in the roofs, completing these charming pieces of composition. The Cooper-street elevation is not so satisfactory as the main front, the central tower being throttled on either side by tall slated roofs of an alarmingly high pitch.

The interior of the public hall is pleasing. The roof, which is of wood, curved at the sides and flat at the centre, has the look of being suited for concerts or debates. To increase the comfort of this hall, a large wooden ventilator, supported on strong iron trusses, rises from the centre of the ridge, marking the position of the hall from the outside. The council-chamber is octagonal in plan, lighted by a shallow glass dome, supported on pendentives springing from angle shafts. Two galleries are provided, that for the public being gained from the street, and the other, for the use of the press, from the main floor. A view is given of the mayor's hall, which forms a very beautiful composition. The design of the grand staircase is also successful, and, like all the rest, if not even more so, is very beautifully drawn and artistically coloured. The figures introduced are well studied.

In Albert-square the ground-floor is entered by two doors leading off the covered carriage-way under the steps in the grand portal. Near these start auxiliary staircases, which lead to the main floor on either side of the grand staircase. Rooms for the porter are placed between these entrances, one of which is devoted to the use of the mayor. The treasurer's department lies on the right and left of the main entrance in Princess-street, the paving and highways on the Albert-square, and the gas department on the Cooper-street side of the treasurer. The water department occupies the greater part of the Lloyd-street front. The police will be found in Albert-square and that end of Cooper-street. A cartway leads from Lloyd-street by an incline to the basement, for the convenient delivery of coals and heavy goods. The main floor is gained from the street by the external flight of steps under grand portal; the auxiliary staircases on either side leading from the ground-floor. The great hall is gained from the ante-room by three doors, and the corridors, leading to the state rooms, branch right and left of same. On the left will be found the reception, dining, and mayor's rooms; to the right the committee-rooms. The council-chamber is placed next the cross corridor, on the Lloyd-street side of the great hall,—a position which the author considers more convenient than any other, and free from the disturbing noise of passing traffic. The areas are large; all the rooms and corridors are well and directly lighted. The estimated cost of carrying out this design is put down at 253,285*l*.

No. 7, "True to the Line," is by Mr. Thomas Worthington, Manchester, author of the new Albert Memorial in the middle of the square facing the centre of the main front of the proposed new building. He also built the Memorial Hall in the same square.

This design was placed third in order of architectural merit; Mr. Charlesworth's and Mr. John Scott's preceding it. This order applies, we think, only to the Albert-square front, as neither of the above-named gentlemen have treated the Cooper and Princess-street elevations in so masterly and artistic a manner. Take, for instance, the splendid group in No. 16, a view of Mayor's Porch and angle of Princess-street and Albert-square; also No. 15, view of Cooper-street end and Princess-street, with the massive tower at the junction of these streets, rising bold and dignified from the roofs. The broad and powerful treatment of this drawing reminds one strongly of the style of the elder Prot. We may call the style adopted the best period of Feudal French architecture, considerably refined. In the front elevation, as described in Mr. Lee's design, bold flights of steps, separated from the building by the sunk areas, approach a landing or terrace formed by the roof of entrance-porch to grand floor, and placed on the level of main floor. Two square-headed doors are placed under a lofty and shallow-arched portal, the tympanum over the doors being filled by a rose window. An elaborate gable, flanked by angle-piers with pinnacles, completes this grand portal. Above it rises the clock-tower, in five stages, before the machicolated cornice, parapet, angle-pinnacles, dormer-windows, and hipped and slated roof are reached. The façade between the clock-tower and flanking pavilion is divided into six bays. On the ground-floor are square-headed windows, with shafted mullions; on the main floor, pointed windows of two lights and traceried heads; above them a very plain space of considerable height must be passed before the string-courses to the upper stage are reached. This top story has triple lanced windows, with connecting hood-mould over, the division of the bays marked by

statues on corbels and under canopies. Over the parapet come the dormers, having shafts rising from the foot-stones of the gable coping, and supporting figures or finials,—a piece of æsthetic construction that we highly object to. The flanking pavilions are very heavy in outline. An oriel window projects from the front face, and at the sides bay windows, terminated by a graceful pyramidal slated roof.

The plan is constructed on a totally different principle to that of the other competitors, the motive being a desire to finish the angles of the Albert-square front by a square treatment, and also to make the internal areas rectangular and architectural studies. To gain this he has sacrificed much space and light, at the same time taking great liberties with the external sunk areas. From the main front the ground-floor is gained by a porch under the raised terrace arch before described. This is connected by a wide arch with the vestibule under the clock-tower. This vestibule will fare little better than Mr. Waterhouse's in respect of light. On the other side of the main corridor rises the grand staircase; and right and left of it is a spacious vaulted ambulatory,—lighted by one of the arcaded areas before described. North and south of the main corridor are public entrances. On the left of the vestibule are placed the paving and highway, with the mayor's private entrance, and on the right the building and sanitary departments. In the centre, under the great hall, are placed the Court of Record, markets and weights and measures departments. Going from the mayor's entrance down Princess-street we find the treasurer's, and then the gas departments; two doors either side of the central block giving separate access to each. The large gas office has a separate entrance in Cooper-street; and a second door near it is provided for the large room of the waterworks. This latter entrance also leads to the interior corridors. A cart entrance is provided in Lloyd-street, communicating with the basement. On the main floor the arrangement of the state-rooms is very successful; and although this floor can be gained from the street by the external steps, the entrance vestibule can be thrown into the long suite of rooms. At the Albert-square corner is placed the dining-room, with its serving apartment; next the reception, ante-room, and vestibule, large committee-room, ante-room, and council-chamber. Opposite the dining-room is the mayor's room, with a hall between. Of this hall is the mayor's staircase. Town clerk, assistant town clerk, and city surveyor occupy the Princess-street front; the committee clerk is placed by the cross corridor, at back of great hall. In Lloyd-street, next to the council-chamber, are placed the three committee-rooms, clerk of prosecution, and water department. The public room lies at right angles to Albert-square. It is gained from the vestibule, through a large hall, lighted from the tambour of a dome.

The upper flights of the grand staircase land at the sides of this hall. Corridor, at either side, and at the end of the public rooms give access to the same by seven doors,—a good and safe arrangement. The room is provided with a wagon-headed roof, divided into eight bays by curved ribs, and subdivided into small panels by moulded ribs. This shaped roof is not so good as some other exhibitions for true sounding properties. The windows are nicely designed, and the space below devoted to frescoes.

Out of twenty drawings, eight are perspective views, some being amongst the finest pictures in the exhibition. Estimate, including towers, &c., 275,000*l*.

No. 8, "Valentine," by Mr. Edward Salomons, of Manchester, known best by the theatres and warehouses that he has erected. The style he has adopted is free Italian, from a modern French point of view. In the centre of the main front is a wide square door, flanked by caryatides supporting a segmental pediment, filled with carving. On each side of this are massive rusticated dados the full height of the ground-floor, and relieved by a sunk niche holding statues. From these dados rise coupled columns, supporting a frieze and segmental pediment, filled with sculpture, the whole enclosing a semi-circular arched recess, containing three windows with carved tympanum over. Slight projections flank this gable, and, with the clock-tower, which crowns the whole, completes the central feature of this design.

The clock-tower rises by eight angle pilasters from a square base, having seated figures on pedestals at the angles. Under a semicircular arch, springing from these pilasters, is the clock

and below it three windows. A bold cornice comes next, having corbelled circular angles, supporting dumpy pepper-boxes. At this level the tower diminishes in width, and becomes octagonal. In the cardinal faces are windows, and the remaining are occupied by canopies containing figures. A curved roof, with cupola over, completes this very beautiful tower. Wide windows, with segment heads, and divided into bays by massive rusticated piers, having pilasters supporting balcony corbels, compose the ground-floor elevation. Over this comes a balcony. The windows to state rooms have two lights, divided by a column, with semicircular head, and circle over, the whole being enclosed within a semi-circular arch. The next floor has very small windows, in shallow-face dormers, that spoil the whole façade. These windows being very narrow, leave the piers between about double the width of the piers below, a big-upon-little arrangement always to be carefully avoided. The roof dormer-windows are better. This elevation is honned by circular angle towers. These contain the staircases to mayor's rooms and gallery in the council-chamber. They are divided into three bays by four columns, so slightly detached that they appear to support nothing but the staves above their cornice. Three arched openings on the level of roof-dormers, with a cornice and low circular dome, give a very dumpy finish to these towers. The other elevations are inferior to the above, and do not require description.

The front elevation is a marvel of geometrical drawing. The delicacy and precision of the lines, and the softness of the tinting, remind one strongly of some of the French drawings in the late Paris Exhibition, or the *École des Beaux Arts*. The principal perspective view is also tastefully drawn, and the statuary introduced is well composed. In the view the cornice of the nearest angle-towers is, however, dreadfully out of perspective, and gives quite a tipy look to the tower, or that of a slouched hat with the broad brim pulled down over the ears.

The plans are worthy of careful study: they seem to adhere closely to the "instructions," giving, at the same time, the required accommodation in the most economical and convenient manner. On the ground-floor, the door of the vestibule under the clock-tower opens into a wide corridor, running right and left, and terminating in public entrances in Cooper and Princess streets respectively. Opposite the vestibule rises the first broad flight of the grand staircase, which, being covered by a glass dome, would amply light the corridor and vestibule. On the first landing of the grand staircase are placed two ticket-offices, forming a mezzanine under the corridor next the public room. From this landing, on each side of the central flight, and at right angle to the same rise staircases—finishing on cross-passages connecting the state with the business corridors. From the same landing, return flights give access to the state corridor. By this arrangement of parallel and cross passages, the state-rooms are isolated from the business portion of the building, but still having easy communication with the public hall. On the ground-floor, to the left of the grand staircase, are clock-rooms. Additional retiring-rooms are provided above on each side of this grand staircase. To the left, and next to the vestibule, come the porter's room, Record Office, collector's office for treasurer's department. The angle-tower is devoted to the mayor's private staircase.

Turning down Princess-street are the public entrances before alluded to; next the treasurer's department; another public entrance in the centre of Princess-street elevation; and then the water offices, with their large room and separate entrance in Cooper-street. Opposite this public entrance is a semicircular staircase; stretching thence down Lloyd-street are the gas offices. In a cross hall connecting the Princess-street with the Cooper-street block, are placed gas offices, a general staircase, and the paving and highway department. In the middle of the Lloyd-street front is the entrance for carts. On entering the internal area the cart would turn to the right, in order to reach the workshop for weights and measures on the high level, and by the inclined plane the smith's shop below. Adjoining past the smith's shop the cart would reach the level of basement, and by going through archways, especially provided, pass round the whole of the basement story. Next to the cart entrance come the scavenging offices, with a pay lobby for the men. Then the warehouse for a room entered directly from the street. Op-

posite to it the detectives' office and the rest of the police department. The angle-tower at the corner contains the stairs leading to the gallery on the council chamber. On the left of the grand staircase are the market offices; below the public room, the building and sanitary department. On the main floor the whole of the principal front is devoted to the state-rooms, forming a suite about 250 ft. long. Next to the mayor's staircase comes a serving-room, with stairs to kitchen, and rooms over; then the dining-room, reception-room, ante-room, and large committee-room, with serving-room, and stairs leading to basement.

The large hall is placed parallel to Albert-square having the business corridor which connects Princess-street with the Cooper-street corridors, running on one side, and giving access to it by three wide doors. An ante-room lies between the end of the hall and Princess-street in the public room. By placing the public room in this direction the platform is brought near to the size of its internal areas.

Starting from the mayor's staircase and going down Princess-street, we find a vestibule with stairs to mayor's living-rooms, and proceeds into the state corridor and mayor's rooms. Next come the town clerk, assistant town clerk, committee clerk, and city surveyor. In the cross block, contractor's room, general staircase, and water offices. Turning down Lloyd-street from Cooper-street are water offices, porter's staircase, weights and measures offices, with stairs leading to work-shop below; then two committee-rooms, ante, and council chamber. All the rooms are well lighted, their general depths from the windows being very small. Two alternative arrangements to the above are shown. There is, however, a general prejudice against alternatives, from the idea that if the author has produced one, he considers to be the best plan, it is difficult for him to arrange a better. Twenty-one drawings, including four perspectives, constitute this design; and the cost of carrying it out is estimated at 240,900l.

A NEW YORK UP-TOWN HOUSE.

A PAPER on "Domestic Architecture in America," by Mr. Gerrase Wheeler, Fellow, was read at the Institute of Architects, on the 30th ult. In the course of it the writer said, the subject to which I would call attention is an ordinary New York up-town house, such as may be counted by hundreds not only in that large and fashionable city, but in all other new towns of the Transatlantic continent, remarking by the way that it is not offered as an example of what would suit our own mode of living, but as a specimen of the domestic buildings of America. The plan is a type of the class of private residences known as the "big-stoop," or genuine New York house. It is built upon an ordinary lot of 25 ft. frontage, and its arrangements preclude all the peculiarities of an American city dwelling. The block plan of the house shows nearly the whole of the lot, and is recessed walk, as Americans call it, than our London houses generally are. This recess gives a better opportunity for the entrance steps and landing, which are wide and handsomely arranged, the upper level forming a porch or "stoop," which feature gives the name to this kind of house. The hall-door leads into a vestibule, in which are inner glazed doors opening into the entrance-hall. Upon this floor are the reception-rooms,—differing from our customary arrangement which disposes them upon the floor above,—and these rooms consist of one very long saloon, divided by columns into two equal divisions, and in the rear is a drawing-room occupying the whole width of the house. Beyond this room—the American name for which is an "extension-room"—is a wide piazza enclosed with glass, and having steps leading to the garden. For party purposes the whole suite is thus extended to a very considerable space, the reception-rooms being each about 24 ft. by 16 ft., and the extension 10 ft. or 12 ft. more. The drawing-room is shut into the saloon by sliding doors, which are filled with ornamental glass.

Between the staircase-hall and the extension-

room is an inner-hall, shut off by sliding doors, and containing a "lift" or dumb waiter from the service-room below, enclosed shelves and other conveniences for the use of serving refreshments. This is lighted by glass in the sliding doors in the daytime, and by gas in the evening, which is of course the time when principally used. The height of this story is 14 ft., and the staircase is carried up in one continuous flight without the break of intermediate landings.

The floor below is thus divided:—
In front is the dining-room, forming the general living-room of the family, and corresponding in size with the reception-room over—24 ft. by 16 ft. In rear of this is a large private store-closet, and also a serving-room, which communicates directly with the kitchen. The kitchen itself is of considerable length, the rear end being fitted with washing-troughs and other conveniences for laundry purposes. A glazed door leads from this into an open space beneath the piazza, and in the floor of this are apertures filled with sheets of rough heavy glass to assist in lighting the cellar below. By the side of the laundry are a servants' bath-room and a water-closet, and the space not occupied by the staircase is filled with a store-room and several closets, American housekeepers always preferring a large number of separate enclosures, in which their necessities may be kept distinct, to a general store-room. This story is 10 ft. high. Beneath this floor is the sub-cellar, which is always kept as little obstructed by cross walls as possible. The heating apparatus, whether furnace or boiler, is in the centre, with large coal-bunks in front; the rear being left open with larder, milk-room, and the like at the side. The heating apparatus I will presently speak of, merely calling attention to the large air-tough area in front, by which cold external air is conveyed into the heating-chamber, and thence distributed over the house.

The chamber floors are above the reception-rooms, and are arranged exactly alike in each story;—one large room in front, a similar chamber in the rear, and smaller ones at the side; that at the back containing a bath and water-closet, with a large linen-closet, the peculiarity of which is that it is lined with cedar to keep blankets and furs from ravages by moths. Between the two large rooms a considerable space in the middle of the house is devoted to dressing-closets, which are so arranged as to contain washing and bathing apparatus, hanging wardrobes, drawers, and all other fittings for toilette requirements. These are, moreover, lighted and ventilated by an air-shaft, which runs up from this floor through the building, with a cover of thick glass raised a few inches above the level of the main roof, having apertures at the side with closing slitters for admission of air at will.

There are three such chamber stories, of the respective heights of 11 ft., 10 ft., and 9 ft., and in the rear the peculiar construction of the long sloping roof gives an additional story over one half, and affords sleeping-rooms for servants. Although other forms of roofs may be seen, this mode of construction is that generally adopted. Its simplicity, and the ease with which snow or rain can be conducted to the one large overhanging gutter in front, give it advantages which the lightness of the covering need—in, enables American builders to avail themselves of. The beams are principally on the side walls by means of stout purlins, and the rafters overlap and are pinned together in breaking lengths, and tied at the foot to the ceiling and floor joists, forming in reality a series of individual trusses from one end of the building to the other.

The gutter is formed in tin, and is carried upon very hold brackets, the front being treated as a cornice. This part of the front of the house is generally of wood, and very stonily and strongly framed. I know this part of an expensive and often elaborately ornamented front taken an ordinary peep at American town houses will believe that it is; but recollections of actual fact compel me to say that the American workmen and sand woodwork very cunningly, and all must not be taken as mere orthodox material. But it must be conceded that for this particular purpose wood is a good and proper material; the error is in making it appear what it is not. Iron, which has been occasionally used in this situation, has not, I fancy, found general acceptance—at all events, it had not to

the date of my last personal experience in America.

The average cost of building such a house as the one described, with a stone or marble front, and a bandstand but not over-elaborately finished, would be, exclusive of the land, about three thousand guineas. The land, especially in some exclusively choice localities, would often be nearly as much again, and the rental of such a residence would not be less now than from six hundred to eight hundred guineas per annum,—in some situations very much more. The cost to purchase would be from six to ten thousand pounds. Houses built a few years back, and in the less fashionable parts of the town, may be bought for much less than these amounts; and in many very pleasant situations, not so exclusively "the rage," such can be obtained at more reasonable, though still very high, rentals.

A wish having been expressed for information as to the modes of artificial heating employed in the United States, I will endeavour to describe the various apparatus most commonly in use.

Stoves, fire-places, and the like, serving to heat only one apartment, I will pass over, and confine myself to such systems as provide warmth to the whole building.

The first of these is the hot-air furnace, by which air brought from without is warmed by contact with a large heated metal surface confined within a chamber of brickwork, and then distributed through tin pipes of large diameter to the floors of the several rooms above. This apparatus is placed in the cellar, and being comparatively inexpensive and very easy of arrangement, until a very few years back it was in almost universal use. Unfortunately many serious objections were found in the working of the system, which, however, I am inclined to attribute to defects in the apparatus and in the mode of its application, rather than to the principle itself. Hot-air furnaces there are of American make, both good and bad; and the bad being cheaper, and the people on the whole not understanding wherein the advantage of one piece of mechanism consists over another, the country has been overrun with cheaply made red-hot cast-iron appliances, that burn up and vitiate the air, discharging currents into the rooms highly charged with sulphurous and other irritating gases, justly bringing upon their use the condemnation of medical men. The pipes, too, are often contracted in their dimensions, and instead of the warm-air chamber gently giving out large volumes of moderately-heated fresh external air throughout the building, a thin scorching blast of air, almost red hot, is shot through the registers into the rooms, to the destruction of all health and comfort. So great a nuisance this became at last, that a general outcry was raised, and hot-air furnaces are now, I am told, not nearly as frequently used as they once were. But experience and a loving attention to a subject, always somewhat of a hobby, have satisfied me that the old Boston furnace of *Childen's* principle, or its improvements and modifications introduced by *Boynton*, the New York successors of the original house, may be used in such a manner as to answer all the requirements of modern modes of heating.

Recent testimony from New York leads me, however, to conclude that furnaces are less frequently in demand, and the more costly modes of hot water and steam heating are supplying their place; still, with many instances fresh in my recollection, and the disinterested accounts of their continuance in satisfactory working, I do not feel inclined to admit that the evils of this mode of warming are identified with the system, but rather result from bad workmanship and improper application.

The best furnace that can be used is one which gives the greatest possible amount of heating surface, and at the same time is of such simplicity of construction as to readily allow its internal parts and flues to be frequently got at and cleaned. Its parts should consist of a large fire-lined pot of very heavy casting, and above and surrounding that the flue subdivided into such forms as will best multiply the heating surface, and ultimately discharge the smoke into the chimney flue as cool as possible, so that all the heat may be transmitted by radiation. All these parts are enclosed in an air-chamber of brick, which must be of large size, and of double walls so as to allow no waste of heat into the cellar. The cold air is brought by a wide wooden trough from the exterior of the building into this air-chamber, and after passing over the several heating surfaces, is carried by means of tin pipes, varying in diameter from 8 in. to 14 in., or even

more, according to the size of the rooms to be warmed, to just below the floor of the apartment. There it opens into a box, the depth of the space between the floor joists, and set in soap-stone in the floor. The top consists of a metal ornamental grating, below which are flaps working on centres, and moved by a rack and wheel so as to perfectly close or open gradually the apertures for transmission of the heated air into the room. Considerable care and judgment are required in conducting the tin pipes to the several levels, and in carrying them in horizontal directions. Workmen generally contrive to have them as nearly as possible in the centre of the house, and the pipes perpendicular; although there is no difficulty in leading them nearly in a horizontal direction, provided this is done at first on leaving the air-chamber, and then continuing them up to the required point of discharge. It will no doubt suggest itself that the longest pipe will draw off the heated air from the chamber with greatest rapidity; and, aware of this, the mechanics construct these of smaller diameter; but, with all their care, it requires a little nicety in the management of the valves in the registers to secure its fair share of heat to each room. In practice, however, it is very rare that all the registers are required to be opened at one time, and my own experience of domestic life in America reminds me that we rarely had any difficulty on this score, and that the furnace once lighted in the beginning of the winter generally remained without going out until April. Servants soon get into the way of managing a machine that saves so much trouble—no coals to carry up, no fire-places to sweep up and keep tidy: all the furnace asks is a good raking out and removal of the ashes in the morning, a few shovelfuls of coals about twice a day and banking up with cinders, and partial closing of the damper at night, to ensure a constant fire and a regular heat. The coal used for these hot-air furnaces is anthracite; but I know that they can be made, and our own fuel, and that bituminous coal, such as our fuel is, no difficulty the accumulation of soot in the flues is no difficulty. Should our manufacturers be inclined to try the introduction of this system of circulating artificial heat through a building, the principal points to secure must be a large heating surface, an air-chamber of ample size, and pipes of such diameter as I have described.

Ventilation may easily be secured by adit flues or pipes from the rooms; in fact, the indraft of warm air will be too sluggish to raise the temperature of the apartment, unless means have been provided for its outflow; and this necessity compels an efficient ventilation.

Heating by means of circulating pipes filled with hot water or steam does not differ in its treatment in America much from our own modes; but a common practice now prevails of combining the principles of the hot-air furnace and the hot-water boiler. This is done by having the air-chamber heated by circulating pipes instead of by furnace flues, and the atmospheric air from without is introduced, warmed, and distributed throughout the building in the same manner. This system, however, has only been found to answer either on a small scale or as an auxiliary, unless great expense has been gone to in providing a very large boiler, which, moreover, requires an undue amount of room in the cellar. The temperature, too, generally proves insufficient for the severity of an American winter, although in the instances that I remember, in which it had been successfully applied, the quality of the warmed air thus generated was very soft and pleasant.

A new mode, I am credibly informed, now obtains very great patronage and favour. I am acquainted with its details, although it was only just commencing to attract attention when I last left New York. It consists of a boiler in the cellar, by which steam is generated and circulated at a low pressure throughout the building. The heating of the air is, however, effected not always or necessarily in a general air-chamber common to the whole house, but in special chambers attached to each room. This is done by admitting the steam into a radiator consisting of two thin plates of iron forming a case, stamped by machinery with curved indentations to increase the radiating surface, and of a size corresponding to the dimensions of the apartment to be warmed. One or more of these are used and are enclosed in a case which, in fact, forms the air-chamber, communicating with which is a tube carried along the floor-joists, and opening into the external air, through which is admitted the current of fresh air to pass over and around the radiators, and thence through

apertures into the room. The whole of this apparatus may either be below the floor, with a register at top, the same in make to what has been described before, or it may be in the side of the room with an ornamental front. The inventor of this mode of heating suggests it may occupy the opening of the fire-place, and manufactures many highly ornamental gratings for that purpose, but the objection that so doing would cut off a natural and commonly existing mode of ventilation seems to me fatal.

The best apparatus for applying this mode of heating is that known as *Gold's Patent*, as manufactured by the American Automatic Steam Company, and perhaps the best practical testimony that can be offered in its favour is the fact that the New York Board of Fire Insurance have agreed that all the companies of that city will make a reduction of 10 per cent. on all risks where this mode of heating has been adopted.

Professor Silliman—a name, I am sure, well known to all scientific readers—gives very careful and laudatory testimony to the satisfactory results of an introduction of this apparatus into his own residence, and I read the names of many of the leading men of the present day as recording their equally favourable opinions.

It is not likely that we in England will ever willingly, or at all events generally, give up our cheerful-looking open fires in favour of any concealed mode of heating, however economical, convenient, or healthful: with us, all such appliances must be only auxiliary, as, for instance, to warm halls, corridors, and large rooms; nor do I know that in America has the system been so exclusively carried out as to permit but the one smoke-flue required by the heating apparatus, and the omission of ordinary fire-place openings and flues to every room. I notice, however, that such an arrangement is strongly advocated there now, and builders are advised that no smoke-flues need be built but for the cooking range and heating apparatus, and that all rooms should have instead metal or glazed earthen tubes carried up in the walls for ventilating purposes only. It is an open question whether a building will gain or lose in an architectural point by omission of such well-known features as stacks of smoke-shafts above the roof, and meanwhile houses are built as heretofore, each with its own separate chimney opening to every room.

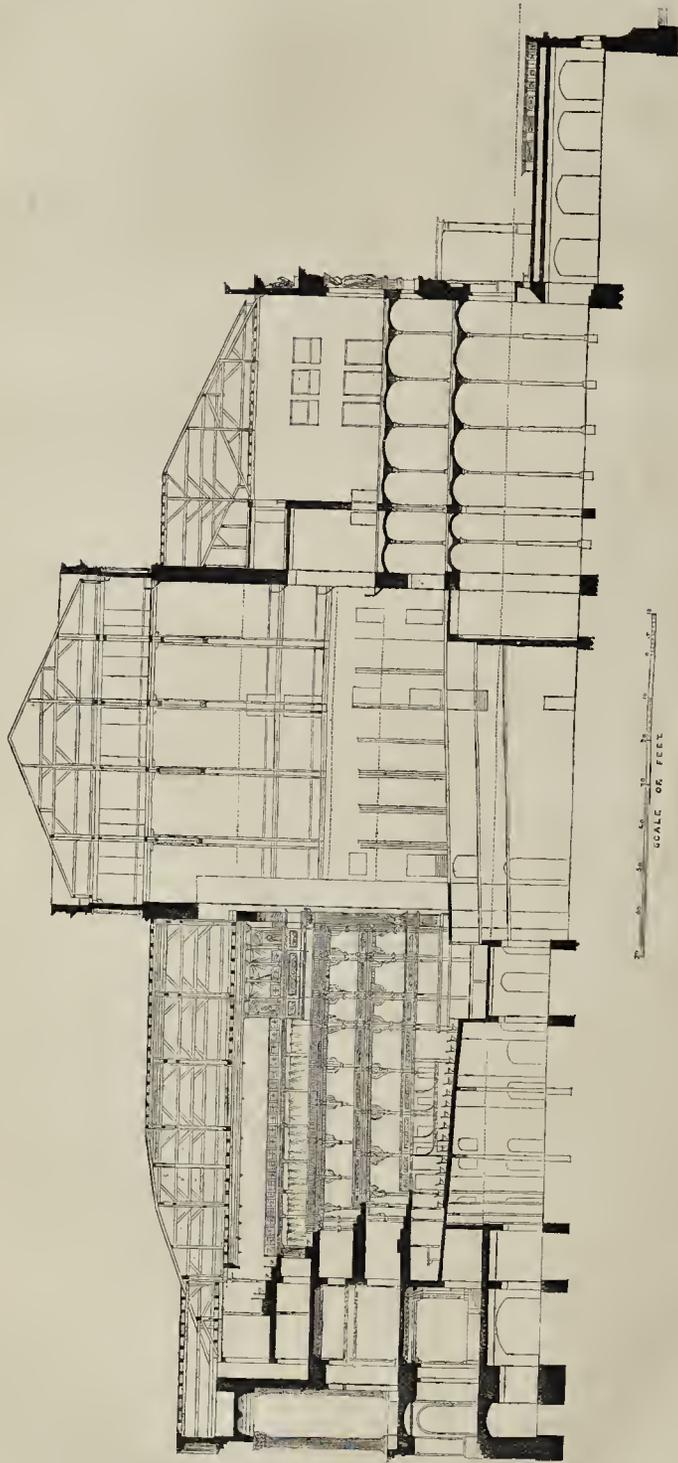

COMPETITIONS.

Hull Church.—In this competition the designs of Messrs. Adams & Kelly, of Leeds, have been selected.

SANITARY MATTERS.

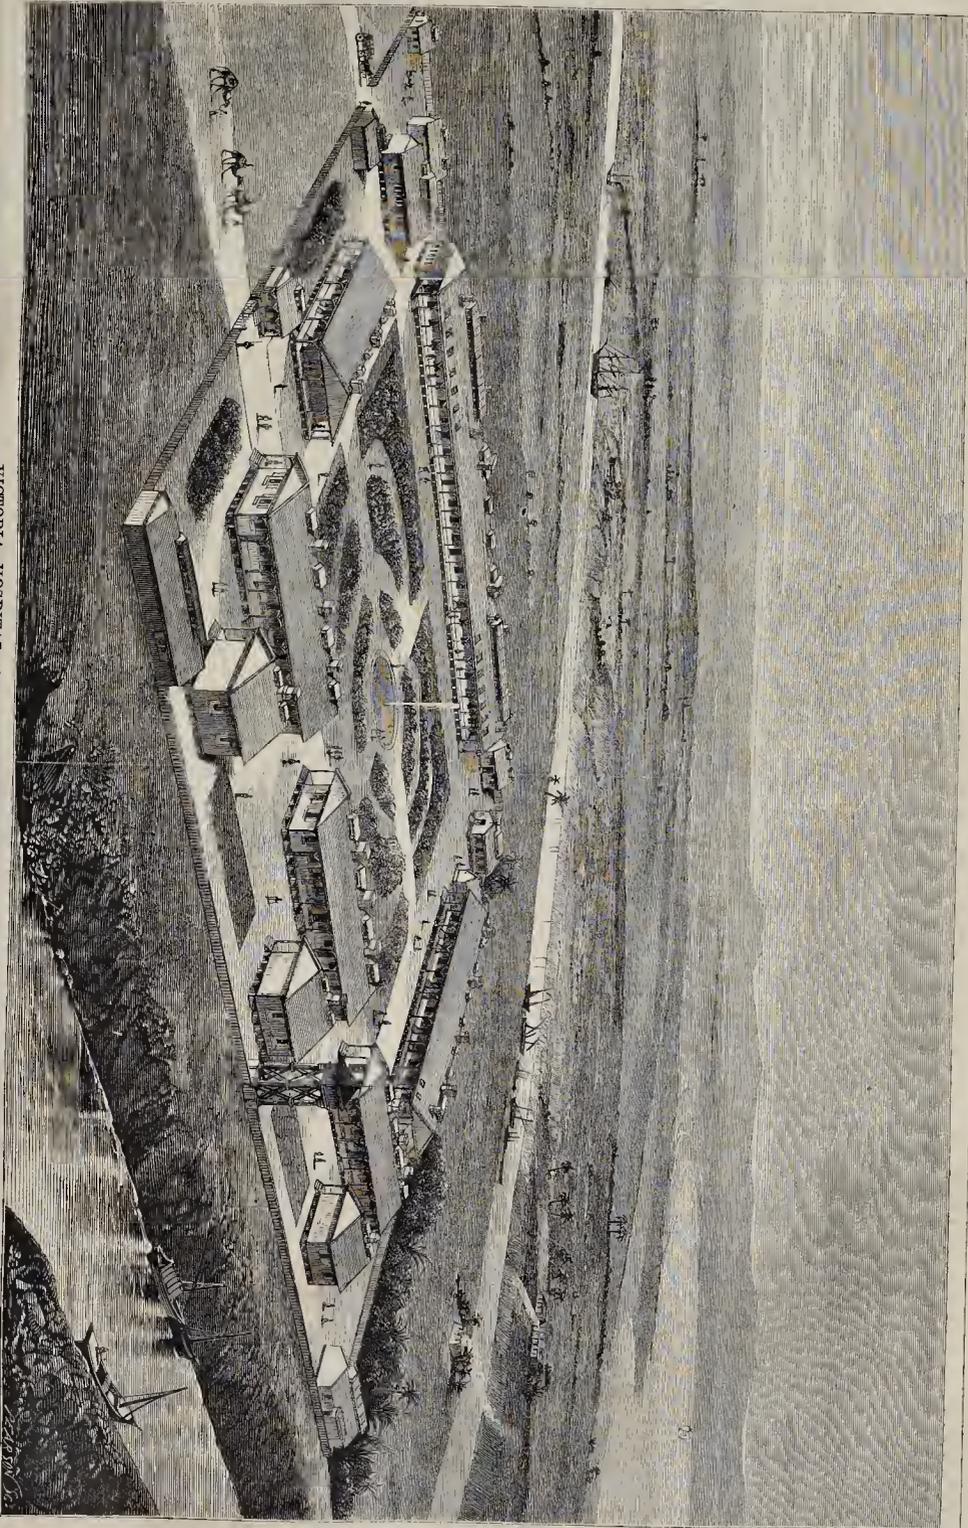

State of Sparkbrook, Birmingham.—A report presented to the Balsall Heath Local Board has confirmed the unhealthy condition of the district about Sparkbrook. It appears from this document that fever has been very prevalent in the locality, and that the cause is to be found partly in the deficiency of drainage and of water supply, and partly in the slovenly habits of the residents. The streets in question are inhabited chiefly by labouring men, whose natural disadvantages are aggravated by pig-keeping, drunkenness, the practice of throwing refuse about the doorways, and neglect as to the cleansing of ash-pits. The two great difficulties are water supply and drainage. As there is no water laid on from the company's works, the people derive their supply from shallow wells, which are corrupted by the infiltration of foul matter from the un drained surface. These two influences acting in combination are clearly producing poisonous effects, for, in a two years' visit, the committee of the Local Board heard of more than 100 cases of fever having occurred within the last few months. The Board cannot see a clear way towards removing the root of this infection, as they have no power to compel the use of other than well water, and have no access to an outlet for the drainage of this part of their district. Something, however, must be done. The Board, perhaps, require the aid of the Privy Council.

Whitehaven.—There must be something wrong with the water supply here; it was stopped altogether the other day in the higher parts of the town, and engines were stopped, locomotives deprived of their usual supply, and the inhabitants had to fall back upon the objectionable pumps, which are still scattered about the town.

SCALE OF FEET

THE NEW THEATRE, LEIPZIG.—*Longitudinal Section.*

VICTORIA HOSPITAL, SUEZ.—CORONEL COLLYER, R.M.E., ARCHITECT.

LEIPZIG THEATRE.

We add, according to promise, a longitudinal section of the newly-built theatre in Leipzig, to the illustrations given in our last.* It should be instructive to notice the monumental character given to the structure, its complete isolation, the facilities of access, and the amount of accommodation provided for the executive. Leipzig (Leipsic, English), though the largest commercial town of East Germany, has a smaller population than Brighton.

VICTORIA HOSPITAL, SUEZ.

This hospital, and the accompanying buildings, of which we give a view, have been erected for the Government of India by Mr. John Kirk, of Woolwich, Government contractor, from designs by Colonel Collyer, late of the Royal Madras Engineers.

They are of a temporary nature, but it is believed they will last for many years. They are of wood, weather-boarded outside, and match-boarded inside, the walls being about 6 in. thick. The roof is double, the rooms having a wooden ceiling, then a space of 7 in., then again a wooden roofing covered with patent felt, and upon that slates.† The hospital wards have verandahs 10 ft. wide, the windows are glazed, and where other verandahs are less than 10 ft. wide, the windows have Venetian blinds in addition. The floors are raised 5 ft. from the ground on cast-iron pillars. There are ridge ventilators, foul-air extractors, Galton's stoves, supplies of hot and cold water, and drainage throughout. There is accommodation for forty-four soldiers, four officers, and four women in the hospital, as also for a hospital sergeant, six orderlies, and two nurses. There is further accommodation for six married non-commissioned officers and their families. There are kitchens, store-rooms, wash-house, laundry, bakehouse, stabling, dead-house, guard-room, and in addition, quarters for six officers, their families and servants. The whole is surrounded with a railing.

A ward for twenty men is 75 ft. long, 22 ft. wide, and 16 ft. high, giving 1,320 cubic feet per man.

The area of the ground containing the above buildings and central garden, with fountain and walks, is eight acres. There is an additional piece of land of six acres immediately to the north of the hospital, which has been reserved for kitchen-garden purposes.

These works were sanctioned in July and August, 1867, and were all constructed in this country, and then sent out and erected at Suez. The work in this country was done under the direction of Mr. John Baker, the contractor's manager and agent; and the work at Suez under the superintendence of Messrs. Joshua Constable and Charles A. Baker, with four foremen sent out from this country. The large number of men that have been employed upon the works were all foreigners, principally Maltese, Greeks, and Arabs.

SMALL-POX IN SHEFFIELD.

Of the eleven large English towns furnishing monthly returns to the Registrar-general, Sheffield has, since the beginning of the year, enjoyed the lowest annual death-rate, which has not exceeded 23·3 per 1,000. The death-rates for the same period, in the other towns, have varied from 23·4 in London, to 25·7 in Newcastle-upon-Tyne, and to 30·2 in Liverpool, and 31·0 in Manchester. Notwithstanding this satisfactory condition of the health of Sheffield, the weekly returns vary from time to time given evidence of fatality from small-pox. This disease may, indeed, be said to have been more or less epidemic in this town for some months; and although it has not been fatal to the same extent as in Woolwich, Hertford, and a few other towns that have recently suffered from the same disease, a few deaths have been recorded in each week of the present year, amounting in all to forty deaths within the borough in the twelve weeks ending the 21st ult. When we consider that there are, in a population enjoying so

low a death-rate as Sheffield, at least five recoveries to one death among those attacked by this complaint, it is very evident that small-pox has recently been, and is still, very prevalent in Sheffield. A sufficiently large proportion of these deaths from small-pox is stated to have occurred among unvaccinated children and adults to prove the neglect of this precaution in the town; but the returns give very incomplete evidence upon this important point. Some of the deaths were of infants who had not reached the age at which they are generally vaccinated, and doubtless many of the adults who are reported to have died from the disease "after vaccination," had not been vaccinated since infancy, when, in too many instances, an assurance of the success of the operation is neglected. The prevalence of small-pox in Sheffield has led to a correspondence between the military authorities at the barracks and the health Committee of the Sheffield Local Board.

It appears that early in February small-pox was prevalent in the barracks, and the staff-surgeon in charge communicated with the local authorities as to its prevalence among the surrounding civilian population, assuming that the soldiers had therefrom been infected, and suggesting that all cases should be removed to a special hospital established for the purpose. The chief sanitary inspector of Sheffield lost no time in making a special inquiry into the prevalence of the disease, and has since reported that he could find no cases within the borough in the direction of the barracks, except in one house, King James-street, where four persons had been attacked, and were in a fairly way of recovery. This house, which was nearly half a mile from the barracks, is admitted to be one of several which are destitute of proper, or, indeed, any drainage. King James-street is a street only in name, says the report, not being formed, pitched, channelled, or drained, and is on the estate of the Sheffield Grammar School. Surely the borough surveyor or some other responsible officer of the corporation should certify that new dwellings are in a fit condition for human habitation before lives are risked by dwelling in them. It is somewhat strange that the chief inspector could only discover this one nest of small-pox cases out of the something like 200 that have occurred since the beginning of the year, but probably his inquiry only extended over that portion of the borough immediately around the barrack, although the soldiers were as likely to catch the infection from any part of the town to which they might resort. In the course of his investigations the chief inspector visited the barracks themselves, and reported to the health committee most unfavourably on their sanitary condition. The privies of the soldiers, in all parts of the barracks, were in a "disgusting and dangerous state;" some of them were structurally defective, and even those designed on a good principle had by neglect been allowed to get out of order. The staff-surgeon, who had in the first instance made the representation to the Local Board, accompanied the inspector during his investigations, and stated that he had only been in Sheffield two or three weeks; and although he believed there existed a "sanitary council" on the establishment, he was entirely ignorant of its organization. As this took place more than a month ago, it is to be hoped that this "sanitary council" has long ere this awoken to action; for in the face of the late liberal expenditure of public money for the sanitary improvement of the condition of the English soldier, it is somewhat disheartening to find such a condition of things existing in any of our barracks.

It really matters little whether small-pox first originated in Sheffield among its civilian or military population; but the inquiry has proved the existence of evils among both most favourable to the development of small-pox and other zymotic diseases. As to the neglect of vaccination, it is to be hoped that the military authorities insist upon all the soldiers availing themselves of vaccination, which is a comparatively easy task to the difficulties which lie in the way of enforcing that precaution upon the civil population. The sanitary committee of the town have appeared inclined to ignore the presence of the disease,—at any rate, the extent of its prevalence. This is surely unwise, and in the face of an average weekly return of three deaths since the beginning of the year, is no longer very possible. It is, doubtless, owing to the general satisfactory condition of the health of the borough that the deaths have been so few; and consideration for the 200 persons who have

been attacked, but recovered, should further stimulate the local authorities, civil and military, to use every endeavour to encourage vaccination, abate all nuisances liable to promote the prevalence of this or other epidemic diseases, and, moreover, to remove from themselves any stigma of supineness, with regard to the prevalence of small-pox in Sheffield.

PROPOSED SCULPTURE FOR THE UNIVERSITY OF LONDON.

The Committee on the new building, Burlington Gardens, presented to the Senate the following recommendations:—

"1. That the four seated figures over the four piers of the entrance-porico should typify the four faculties of the University, as represented by Englishmen illustrious in Arts, Science, Law, and Medicine respectively.

2. That the six standing figures on the roof-line of the central portion of the building should be in the Classical style, and should represent men of ancient times eminent in various departments of study included in the University course.

3. That the six standing figures in the niches of the ground floor of the wings should be portrait-statues of distinguished representatives of modern knowledge; those on the west wing Britons, and those on the east wing foreigners.

4. That the six standing figures on the roof-line of the wings should also be statues of distinguished representatives of modern knowledge; those on the west wing to be Britons, and those on the east wing to be foreigners,—the statues at the angles of the wings being grouped with such accessories as may give the required mass, instead of being double groups as proposed by Mr. Pennington."

The following names have been selected in accordance with those principles:—

Seated Figures over the Central Porico.

East—Bentham, Milton. West—Newton, Harvey.

Standing Figures on Roof-line of Centre.

East—Cicero, Galen, Aristotle.

West—Plato, Archimedes, Tribonian.

Portrait Statues in Niches of Ground Floor of Wings.

East—Cuvier, Leibnitz, Linnaeus.

West—Locke, Bacon, Adam Smith.

Standing Figures on Roof-line of Wings.

East—Galileo,* Laplace, Goethe.

West—Hume, Hunter, Dalton.

We shall hope to hear that the execution of the statues is entrusted to men of known ability.

In the first instance we believe Shakespeare formed one of the four "representatives of modern knowledge;" but Lord John Manners, as First Commissioner of H.M.'s Works, having suggested a doubt as to the propriety of this position, the name was removed, and that of Hume substituted. A place will probably have found inside the building for a statue of the all-wise poet.

THE RUINED CHURCHES OF ORKNEY AND SHETLAND.

At the last meeting of the Architectural Association, a paper was read by Sir Henry Druden, bart., on "The Ruined Churches of Orkney and Shetland." He observed that there were four ways of estimating churches. The first was the ecclesiastical view, which aimed principally to obtain a building fit for public worship, but which was generally in favour of replacing a plain window by a coloured one if the money was forthcoming to do so; the second was that of the artistic gentry, upholding the beautiful and picturesque, and who thought every church ought to be made as attractive as possible; the third was that of the antiquarian, who considered it sacrilege to make the slightest alteration, and who believed that to remove an ancient stone or window was to lose a chapter of history; and the fourth was the view of those who, like himself, were in favour of conservation of architecture as far as it was possible. He alluded to a remark made by Professor Keay on a former occasion, in which it was stated that when professionals made pots of amateurs, they latter generally became poets; and begged to differ from such an assertion, being fully persuaded that when wealthy people had to pay for the erection of edifices of any kind, however much confidence they might have in the architect, they generally liked to have something to say as to how their money should be spent. But he did not believe that there was any reason why there should be any enmity between the two.

With respect to the ruined churches of Orkney

* With astronomical accessories.

† With chemical accessories.

* See pp. 245, 246, and 247, ante.

† We confine ourselves at this moment to describing the building.

and Shetland, on which he was to address them, nearly all the buildings were of Norwegian origin; and as, since the time of the Reformation, the owners had allowed any one to desolate them, most of them were in a great state of ruin, and several had even come down in the last twenty years from the want of a little mortar being here and there judiciously employed. It was asserted that they were not worth preserving because they were not very beautiful, the same argument would apply with respect to the Coronation-stone in Westminster Abbey, and to many other cases. They were, in fact, the materials of history, and should be appreciated as long as history was of any value.

He would first of all touch upon the churches of Orkney, and bring before their notice the ruin of St. Olaf, at Kirkwall, dedicated to the great warrior saint of the country, who, he believed, was said to have killed something like a thousand men in a day. The original entrance was evidently in the south; and the building was in the form of a parallelogram. It was probably built by Bishop Reed some time between 1540 and the Reformation. At the church of Orpha there were the remains of what was evidently a circular nave, and it consequently must have been one of the six round churches in Great Britain. Most likely it was built between the years 1090 and 1160. There was a small chapel in the Brough, immediately in the centre; and it was old to notice how general was the practice of a olden time of erecting sacred buildings on prominent and isolated points. This little chapel was also in the form of a parallelogram, being 20 ft. long by 17 ft. wide. Only 4 ft. in height now remained. There was one door and one window, the latter in the east end. Spread on the top of the ruin were ten huts, evidently for the benefit of pilgrims. The church on the Brough of Bursas was 57 ft. in length and 21 ft. in width; of the west end of it only 3 ft. in height remained. The sole access was on the west of the building, where there was one doorway. Now the question was,—Were there doors in this doorway? And if so, how were they hung? In some cottages skins were hung over doorways; and the Shetland gates were for the most part hung with staples. In his opinion, it was questionable whether there were any doors. He found some three-quarter angle recesses in the eastern part of the nave. Another singular thing was that the entrance to the chancel was only 4 ft. 2 in. wide, and there had evidently been a stair in this entrance. The chancel was 9 ft. 9 in. from east to west. One window only remained. The floor was level to the end of the aisle; but in later times a recess had been built, which had completely blocked out the whole of the apse. Steps had been also put to the altar. There need be no hesitation in assigning the date of this chapel, which was very like St. Margaret's chapel in Edinburgh, to the year 1100 or thereabouts. The Church of Wyre was built of stones; it was 35 ft. 10 in. in length and 11 ft. 10 in. in width. The nave was 19 ft. 2 in. by 10 ft. 10 in. There were two windows in the south side, but only one of them was original. The top of the nave reached up 11 ft. 5 in. above the floor. The chancel arch was 2 ft. 6 in. wide, and the chancel like that of Lipstone Church, Caithness, was nearly square. Enghallow Church had not been known for many years, as it had been converted into a cottage. Its length was 52 ft. and width 22 ft. on the west of it was a building which, in his opinion, must have been a sacristy. The chancel was 12 ft. by 8 ft. on the inside. There was another building close by, 8 ft. by 7 ft. 9 in. on the south side of the church. He did not know what it could have been, but perhaps it was a reb. Some part of the church might have been built in the eleventh or twelfth century, but a new chancel had apparently been added in the fourteenth century. There were the remains of a chancel at Linterna, with an entrance to the south wall. On the Island of Egilsay, 3 miles by 1 mile, there was a church with round tower. The Norsemen had probably built this church, and then named the island after it. A chancel, nave, and the tower remained; indeed, they were in use up to fifty years ago. The size of the stones employed was very large. The nave was 20 ft. 9 in. by 15 ft. The doors had round arched heads. There was a window in the north, which had probably been filled up by a form of parchment instead of glass. On the west was a tower, which appeared to have been built at the same time as the nave, which had apparently contained four chambers. Another odd thing was a vaulted cham-

ber in the chancel, with an arch leading into it. It might possibly have been a munition room, or a priest's room, for there was only one small window in it, facing the north. The church had probably been an important one, and might have been erected about the twelfth century. The tower was the only part which justified the assumption that the building was of ancient date, although in many respects it resembled the early Irish churches. It was, in fact, built after the traditional Irish form with some modifications, and was raised, he should think, after the Irish people were converted to Christianity in 998.

So much for the churches of Orkney. He would now introduce to their notice those of Shetland. The church of Culhishrough consisted of a nave, a north and south transept, and a chancel. It was the only cross church in Orkney and Shetland, except the cathedral of St. Magnus. There was an east window in it. In the churchyard had been found a grave-stone which had excited great interest, and which had given rise to a considerable amount of discussion. On one side there was the representation of a cross, and on it two nondescript beasts, who appeared to be devouring a man. On either side were two bishops with their mitres and man riding. On the other side there was a very well-executed interlaced cross, and also the two bishops again. There was also an inscription, but some doubt existed as to what it really meant.

The Ness was the only complete one of all the churches in Shetland, but in consequence of not being looked to, the whole of the chancel arch was gone. The nave was 20 ft. 5 in. by 14 ft. 10 in. It was used a hundred years ago. There had been two windows and two doorways on the south and west, both of which were original. The chancel was larger than any of the others. There was a sedile on one side, the only one discovered, and on the other side was an arch. To sum up, then, the various facts connected with these ruins; the doorways were nearly all in the west end; Orpha and Egilsay churches had windows with circular heads; four of them had no east windows; and, as far as could be ascertained, no platform to the altar—a state of things which would not be approved of by the Ritualists at the present day. No piscina remained, and the windows were very low. The grave-stones were of four kinds; flat slabs, upright stones with crosses engraved on them, stones without any ornamentation, and upright stones cut into the shape of crosses. The coffins were formed of six smooth slabs of stone. The proportion of these buildings was, in his opinion, geometrical, and not arithmetical; this system extended to the elevation, at all events. The proportion was founded on three figures, a circle, square, and equilateral triangle.

Mr. White, in moving a vote of thanks to Sir Henry Dryden, observed that there was rather a singular fact connected with Egilsay. When he visited it some years ago, he was told that some ten years had been taken from the top; and even then there was nearly 50 ft. of it left. Until Medieval times, he remembered no case of a compartment that had been mentioned being it might have been used to receive people who had no residence in the neighbourhood of the church. Sir Henry Dryden had alluded to the ritual of the earlier churches was exercised to a much greater extent in olden times than it was in these days. And this fact might in some way explain the meaning of the two towers to which Sir Henry Dryden had alluded, and for which he had been unable to assign any use. He thought it by no means improbable that they might have been used, one to read the Epistle, the other the Gospel from. With respect to the blocking up of the apse in the same church, it seemed to him that the general prejudice of the twelfth century was against the Norman apses. In England they seemed determined to get rid of it entirely. Although he had promised not to allude to the question of proportion, he would say just one word about it. There seemed to have been two squares in many cases; but, of course, it could not have been executed so accurately as in later days.

In answer to a question, Sir Henry Dryden said that in the Ness Church there were bar-holes in both the doors, and it was a puzzle to him how, if any one harred them up, he could get out; for the windows were not large enough to enable him to do so.

Mr. White suggested, that perhaps they were intended to har people out, so as to afford a refuge in those lawless days.

Sir Henry Dryden accepted the proposition, believing that the principal occupation of the men of that time was to protect their own throats and cut other people's.

The president observed, that it was always difficult to express an opinion in the face of any one like Sir Henry Dryden, who had so carefully studied the subject. With respect, however, to the hanging of the doors, he did not see that there was any necessity for them to have been hung on the inside; they might have been suspended in the middle, like the swing-doors of the present day.

THE CITY TERMINUS OF THE CHARING CROSS RAILWAY.

At the Institution of Civil Engineers on March 31st, the paper read was on "The City Terminus Extension of the Charing-cross Railway," by Mr. John Wolfe Barry.

This line was authorized by Act of Parliament, dated June 28th, 1861, and the works comprised (1) a bridge over the river Thames, (2) the Cannon-street Station, and (3) viaducts south of the river, for connecting the bridge over the Thames with the main line of the Charing-cross Railway.

The bridge over the Thames, the writer said, had been constructed to carry five lines of way from the south abutment to the pier next to the Middlesex shore, at which point the five lines branched out, and were connected with nine lines of way in the station. There were two footpaths, one on each side of the bridge, intended for the use of the public on payment of a small toll; but they had not yet been opened for traffic. The extreme length of the bridge between the abutments was 706 ft. This length was divided into five spans, the two side openings being each 125 ft., and the three centre openings being each 136 ft. in the clear on the centre line. The width of the straight portion of the bridge outside the railway parapets was 80 ft., and the width of the railway portion between the inside parapets was 61 ft. 8 in. The span, which extended over the Middlesex opening, was widened out to 202 ft. at the abutment, and accommodated, in addition to the lines of way, portions of two passenger platforms, engine sidings, foreman's offices, &c. The height of the soffit of the bridge above Trinity high-water level varied from 24 ft. 8 in. at the abutments to 25 ft. 4 in. in the centre span. The object of this arrangement was to prevent the bridge appearing depressed at the centre. The height of the rails above the soffit of the bridge was 9 ft. 10 in.

The southern abutment was built on cast-iron caissons, sunk side by side, partly by means of divers working in helmets, and partly by dredging inside the caissons with a hag-and-spoon dredger. In the case of the north abutment, neither caissons nor cofferdams were used. Short lengths of ground were excavated at low water, a small "stank" dam of clay was employed, and the water being pumped out as the tide ebb, the excavation was continued and the footings were got in. The piers were each formed of four cast-iron cylinders, placed in a line at right angles to the longitudinal axis of the bridge, and connected by two wrought-iron transverse girders at the top. The outside diameter of the cylinders was 18 ft. below and 12 ft. above the bed of the river; a conical reducing ring being introduced to effect the junction between the two diameters. The cylinder plates were fluted from 5 ft. below Trinity high-water mark up to the level of the ornamental cap mouldings. In sinking the cylinders the bed of the river was first smoothed by dredging; then the two bottom rings, together 13½ ft. in height, which was equivalent to the greatest depth of water at low tide, were put together on timbers, between strong timber guides, exactly over their destined position. This portion of the cylinder was next raised by a travelling crane so as to permit the removal of the supporting timbers, and was afterwards lowered into position. A third ring of plates was then added, and a hag-and-spoon dredger was employed inside the cylinder, to take out the mud and gravel. As the cylinder descended additional rings were bolted on until the London clay was reached, when the sinking was continued by ordinary excavation until the final depth was attained, which was from 59 ft.

to 6½ ft. below Trinity high-water mark. The cylinders were filled with Portland cement concrete up to the level of the bottom of the reducing ring, and on this brickwork, also in Portland cement, was carefully built for the full height of each column, being capped with large bed-stones 2 ft. thick. Each of the cylinders was weighted at the testing-line with 850 tons of iron. This weight was calculated to represent the dead weight of the structure above that line, a rolling load of 1 ton per lineal foot for each line of way supported by the cylinder, and a moving load on the footpaths. The order to remove the load was not given until it was ascertained that no subsidence had taken place for seven days. The greatest subsidence under the full test load was 2½ in., and the least ¼ in. The heaviest weight on the London clay at the bottom of any of the cylinders was 5¾ tons per superficial foot, with a rolling load as stated; and the heaviest weight on the brickwork in the cylinders was about 9 tons per superficial foot.

The particulars were next given in detail of the bed-plate girders, of the outside main girders, and of the intermediate main girders. The girders for the two side openings were independent of the other spans, but those for the three centre spans were continuous over the three openings. The flooring of the bridge was composed of flat plates of wrought-iron ½ in. thick, which were riveted to the top flanges of the main girders, and were further strengthened by angle or T irons; for as the floor of the bridge formed the station-yard, and was occupied by cross roads, as well as by the through lines, it was necessary that it should be capable of carrying the rolling load in any direction. Upon the flooring plates asphalt was laid, which was covered with an average thickness of 5 in. of ashes, as ballast, and on this the ordinary permanent way was placed.

The piers of the bridge, from the bottom of the cylinders to the bed-plate girder, contained in all about 2,500 tons of cast and wrought iron. The superstructure contained about 4,200 tons of wrought-iron in girders, floor-plates, &c., and about 1,100 tons of ornamental castings. The cost of the Cannon-street bridge, including the abutments, signal bridge, and all things connected with the work, with the exception of the permanent way, signals and signal apparatus, gas and water mains, amounted to 193,000*l.* This sum gave 2*l.* 15*s.* as the cost per superficial foot, and 250*l.* per lineal foot, or 50*l.* per lineal foot for each line of way, including the fan and footpaths.

The length of ground occupied by the Cannon-street Station, between the river Thames and Cannon-street, was 855 ft., distributed as follows:—The forecourt was 90 ft. wide, the booking-offices were 85 ft. wide, and the length of the covered portion of the station south of the booking-offices was 680 ft. The width of the station outside the walls was 202 ft., and inside the walls, at the platform level, it was 187 ft. The whole of the station was built on a sub-structure of brick piers and arches, excepting the booking-offices and the part which was over Upper Thames-street. At the crossing of this street, which passed underneath the station at about midway of its length, wrought-iron girders were used. Openings were left in all the piers to allow tramways to be worked throughout the basement if necessary; and provision had been made in the arches for an hydraulic lift to raise and lower the wagons. The cross openings north of Upper Thames-street were mostly carried up through the springing of the large arch, and were groined into it. The groining, which was 27 in. thick, was built in Portland cement, and the keystone was of Bramley Fall. It was adopted in consequence of the height of the ground not allowing communication between the different main archways, by transverse arches below the springing of the large arch. Without intercommunication the value of the vaults would have been commercially much diminished, and they would not have been available, as they were now, for parcels offices, stores, and railway purposes. The station walls were almost entirely of brickwork in mortar,—the only exception being the arch over Upper Thames-street, and a few courses at the top of the walls, which were laid in cement.

The main trusses of the roof consisted of segmental ribs with a tie-bar looped up. The clear span of the trusses was 190 ft. 4 in. The rise of the rib at the centre was 60 ft., and the rise of the tie-bar was 30 ft. The truss was, therefore, 30 ft. deep at the centre. The particulars of the different members were then

given in detail. The ordinary distance from centre to centre of the trusses was 33 ft. 6 in., being the same as the distance between the centres of the piers of the substructure. In crossing Upper Thames-street, however, the distance apart was increased to 35 ft. 1½ in., in order to suit the abutments of the bridge over that street. The weight of a single truss was 47½ tons. The parts of the roof not glazed were covered partly with zinc and partly with slating. A lantern, 22 ft. wide, extending nearly the whole length of the roof, was glazed on the top, and had the sides fitted with louvres, which afforded means of ventilation. Two movable timber stages, designed by Mr. J. Phillips, were used in the erection of the roof. One was as high as the top of the segmental ribs, and was employed in the erection of the trusses; the other was smaller, being low enough to pass under the tie-bar, and was used for painting, glazing, and finishing. The cost of the roof of the Cannon-street Station had amounted to 491,10*s.* per square of 100 superficial feet of area covered, measured between the walls. The cost of the roof of the Charing-cross Station was 39*l.* per square. In both instances the price of iron was high, the contract price for wrought iron in place in the roof being 24*l.* 5*s.* per ton.

The cost of the works of the City Terminus Extension was 505,336*l.*, and of the whole Charing-cross Railway, including the extension, 1,160,118*l.*; or, including land, somewhat more than three millions sterling. In this sum, it was to be remembered, were included about 4½ miles of railway for a double line, two large bridges over the River Thames, a considerable number of expensive street bridges, and two of the most extensive metropolitan termini. The importance of the traffic, which was not at present fully developed, might be gathered from the fact that, during the year ending the 1st of January, 1868, being the first year since the City Terminus Extension Railway was opened, about eight million passengers used the Cannon-street Station, of which number about three millions and a half were local passengers between Cannon-street and Charing-cross. At the present time about twenty-six thousand passengers used the Cannon-street Station daily, and the South-Eastern Railway now conveyed about fifteen million passengers annually.

THE TRADES MOVEMENT ABROAD.

The Strike in Geneva.—It appears that the strike of the Genevese working builders has been met with a lock-out on the part of the masters. In a letter addressed to the workmen by the committee of masters, dated March 28, they say the firms in the building trade will be under the painful necessity of closing their establishments to-morrow. The working masons, stone-cutters, and plasterers have completely left their workshops. But few of the working mechanics, founders, and locksmiths are at work, intimidated by those who have organized the strike. Under these circumstances there is a general stoppage in the building trade.

The chairman and hon. gen. secretary of the International Working Men's Association in London say, in respect to this strike and lock-out:—

"As the promoters of the International Working Men's Association never entertained the idea of establishing an international medium for the settlement of wages disputes, the general council has never yet been appealed to for advice, and has, consequently, no opportunity of investigating or provoking strikes. According to rule 11, every society joining prescribes its existing organization. Hence it follows that every affiliated society manages its own special affairs without any reference whatever to the International Working Men's Association. Strikes were condemned on principle by the Geneva Congress; co-operative production was declared to be the only means to a permanent solution of the labour question. At Lausanne, the discussion of the question of the course of arbitration was recommended, with a view of putting a stop to strikes. The association, as such, never interferes in trade matters; but it uses its influence, when appealed to, in cases of strikes and lock-outs, to prevent the workmen of one country being used as industrial mercenaries against the workmen of another, and, in cases of need, it solicits pecuniary aid. So far from the general council having had a hand in the getting up of the Geneva dispute, it was not even aware that the building trades were trying for a rise until, on the 3rd of March, a notice to that effect, published in the *Voix de l'ouvrier*, was announced in the regular weekly meeting."

They also state that, in January last, the men appealed to their employers for an interview to discuss their grievances. The employers never answered their application, but set to work to form an association for their own purposes. In the mean time the men of each trade made out a "log," demanding a rise of about 10 per cent.

upon their wages, and a reduction of the hours of labour from twelve to ten per day. After the condemnation of the Paris committee, the masters broke their silence, and told the men that they would not employ them on any terms unless they renounced their connexion with the International Working Men's Association.

The Belgian Disturbances.—In the Charleroi district the colliers are idle, and have come into collision with the military. For an extent of several leagues the coal-mines, factories, and furnaces are almost abandoned. The workmen complain that, while the masters wish to reduce wages, they will not lower the price of coal, immense quantities of which are lying at the pits' mouth. Hopes are entertained that nothing serious is likely to recur, but the miners are exasperated against certain individuals; and a cavalry major, who was obliged to order his men to fire on the mob, is in particular threatened.

ST. THOMAS AND THE MAURITIUS.

I ENCLOSE you a paragraph cut from the *Liverpool Mercury*, relative to the dangerous and unhealthy state of St. Thomas, in the West Indies. The Government and the Royal Mail Company have incurred a fearful amount of responsibility and odium in consequence of allowing that island to have been used so many years as the central packet station, and which has been attended with so serious a loss of human life amongst that peculiarly valuable class of men, "our true British tars," who can be so ill spared from our mercantile fleets.

I have known this island ten years, and it would be interesting and instructive to know how many of "our hearts of oak" have been sacrificed in that hotbed of disease during that time. If any patriotic and humane M.P. would move in the House of Commons for a return upon the subject, he would render a benefit to his country, and I think there would be no difficulty in ascertaining the number of men lost in the steamers and vessels employed in the mail service. Its amount I am sure would rather astonish the country.

I have heard of as many as thirty men having been sacrificed in one vessel from yellow fever, while lying there a fortnight for the return of intercolonial mails, and of serious loss from other vessels; and if our marines is to be decimated in this way at unhealthy stations, we may well complain of the scarcity of able seamen. Most opportune and useful questions have been asked in the House of Commons relative to the fever which prevails at the Mauritius, and the answers given have been neither assuring nor satisfactory.

From a seven years' residence in tropical countries, I can unhesitatingly say that, with ordinary care, precaution, and forbearance, an Englishman will enjoy as good health there as in this country, even without the use of the nostrum "quinine;" as, during the time I was there I scarcely tasted it, and did not feel the need of it.

Of course, residents there must conform to the customs of the country and the necessities of the climate, which are somewhat opposed to those of this country; and if they are free livers, they cannot with safety give full scope to their favourite propensities.

In our tropical colonies generally efficient sanitary improvements are little thought of; sewerage is not approved, as drainage on the surface is preferred, with a few exceptions: at the houses cesspool abominations extensively prevail; and one cannot wonder when these objectionable and noxious practices exist in hot climates, that yellow and other fevers, cholera, &c., ride rampant over almost every one, particularly those not thoroughly acclimated.

If disease be rife, they appoint additional medical officers, it is true, and plant the yellow flag at the doors of the houses to warn the unwary; when if it were not for the colour of the flag, the streets would often look like being

* *A Fever-stricken Ship.*—Information has reached the Type of a sad calamity which has overtaken a Newcastle vessel, the *William Miles*, at St. Thomas, West Indies. Within the last two years an alarming number of Tyne shipmasters and seamen, whose vessels have taken course out to the mail-packet station at St. Thomas, have died of yellow fever, and the intelligence which has reached the owners is that Mr. William Folland, a Shields man, the master, and six of the crew of the *William Miles*, have been carried off by yellow fever, while nine more of the crew were at the time the letter was sent off lying ill of the disease in hospital.

checked out for a festival; but they do not strike at the root of the evil, the cause of this disease, which I firmly believe is of as easy remedy as in this or any other country.

I have no doubt if a competent sanitary engineer and medical officer were sent out to the febricitans, they would find almost a total disregard of even the commonest rules and regulations for the preservation of the public health; and the time has arrived when I think active steps should be taken to improve the sanitary state of the cities and towns of our colonies, in a broad and comprehensive scale, similar to the one so advantageously carried out in this country.

It must not be left to the colonists themselves; they, like many of our town magistrates here, are reluctant to introduce any change or improvement, particularly if it be likely to touch the pocket; the ruling authority, to make things less, does not like to place itself antagonistic to them, and the consequence is, when disease visits their towns are almost exterminated or depopulated.

I have visited many of the most unhealthy of the cities and towns of the tropics in the western world, and, after a careful inspection of them, I have not seen one but in which the laws of sanitary science are abused or fearfully neglected, and there is not one of them, I confidently believe, but is capable of being made as clear and healthy as any place in this country; in fact, I would venture to undertake and guarantee to make them so at a very moderate expenditure. If the remedy be so easy and close at hand for those "ills that flesh is heir to," as the poet says, let us at least endeavour to modify and relieve the sufferings of poor humanity.

B. B.

A NUT FOR THE PROFESSION TO CRACK.

Your journal, I am aware, is addressed to the architect, engineer, operative, and artist, though I have not the honour of belonging to any of those classes, I take sufficient interest in it to be a "constant reader" of it. I do not know whether you will allow me to offer a remark that may be of some importance to at least one of the favoured professions.

I can quite confirm the remarkable discovery made by "J. P. S.," that non-professional men are frequently irreverent enough to speak of architects in the way that he quotes,—"Oh, one fellow runs us into such expenses!" But think I can relieve his fear that "the cause is deep in the English mind, in the utter ignorance of art from the affairs of practical life." Were this the real cause the case would indeed be lamentable; for, as English architects are presumed to have English minds, our only chance of securing an architect who united artistic taste with practical knowledge would be ways to employ a foreigner.

The cause, I believe, lies simply in the extraordinary and unreasonable way in which the remuneration of architects is calculated,—that by a charge of 5 per cent. on the amount that they induce their clients to spend in building. For instance, I may be prepared to spend 3000l. in building a house. I may be quite willing to pay my architect 3000l., and I by no means think this would be too much, if he really gave a constant superintendence to the work; but I may not be at all willing to be drawn out an expenditure of 6000l., in order that my architect's fee may amount to 3000l. I doubt it may be said that all architects are not only honourable, but disinterested, and, invariably prefer their clients' interest their own. Be it so; but why expose them to constant temptation, and to the inevitable suspicion of acting in a contrary manner? No similar practice exists in other professions. I do not pay my doctor by a percentage on my baggage's bill, nor my solicitor by a percentage on the amount he can spend in retaining counsel. We may look at the humbler ranks of life, we do not pay our housekeepers by a percentage on the butcher's bill, nor our butlers by a percentage on the wine-merchant's. Yet all these employments would be just as reasonable as the system of paying architects by a percentage on the builder's bill. So long as that system continues, long will people avoid employing an architect, they can possibly help it.

The reason that there is no public movement against this system is that most men have nothing to do with architects, and few employ

them more than once or twice in a lifetime, when their natural tendency is to get over the disagreeable necessity, and to have done with it, as in dealing with an undertaker. But there can be no doubt that the practice of building without an architect is increasing, and that the Greek is being supplanted by the English synonym, the "architect" by the "master-builder." A neighbour of mine is building a house of the value of 17,000l. without an architect. And I have heard that Oshorne was built without an architect, the cause of which, no doubt, was "the utter severance of art from the affairs of practical life in the English mind" of the late Prince Consort.

I have no doubt that such considerations as I have submitted have occurred to many architects. But the system is too strong for individuals to break through: convention heats them down. However, I believe it will be well for the Institute to take into consideration the subject of professional charges, lest, while strictly upholding the etiquette of the profession, they may find that they have little work for the etiquette to operate upon.

A COUNTRY GENTLEMAN.

THE BED OF BUILDING STONE.

In the letter from Mr. A. J. Hiscocks on this subject in your last number reference is made to a recent communication made by me to the Institute of British Architects, in which I considered among other matters building materials and their use. I did not then enter into detail, and little was said either in the paper or in the subsequent discussion on the special point now in question. I fear the space that could be spared in the *Builder* would not be sufficient to discuss it thoroughly, but I will take an early opportunity of putting before the profession such suggestions and explanations as I am able. It is a subject of some difficulty and of vital importance.

Meanwhile, assuming that every architect and builder understands in some measure the law and method of stratification by deposit from water, and the history of the passage of stratified layers of mud into stratified layers of stone, I think it will be perceived that enormous mechanical pressures must have been brought to bear at some time or other on all stones; and, I believe, that in determining the direction of pressure will be found the practical solution of the problem.

The natural bed of a stone originally, and before it has been upheaved and brought to the earth's surface, is clearly the plane of stratification. The original zenith of the stone must then be the zenith of the place where it was first deposited. But after upheaval the case is different. In fissile roofing slate, where the squeezing has entirely masked the original stratification, the bed of the stone is the cleavage plane, and the zenith a point vertically above the plane of cleavage.

In intermediate stones the problem is mixed. No doubt the microscope properly applied would afford a very useful key, but the application for practical purposes would not be easy. Whether also a stone turned inside out would answer its purpose in building, as well as a skin in resisting water, is a different matter altogether.

D. T. ANSTED.

MACHINERY FOR JOINER'S WORK AND THE REDCLIFFE ESTATE.

Sir,—The leading article in the *Builder* of the 21st ult., showing the great saving in labour effected by the employment of a few of the most modern machines for joiner's work, has caused a great many builders to visit our works, as well as those of Messrs. Corbett & M'Clymont, in order to verify by personal observation the statements contained in the article in question.

As, however, many builders have taken exception to the statements in the article, on the ground that the time occupied in finishing the joiner's work, after leaving the machines, is put down at 6d. per hour, we beg to offer a few words of explanation on this point.

It is of course well known that the ordinary wages of skilled joiners in London is 8d. an hour, which is the rate paid by Messrs. Corbett & M'Clymont to their joiners; and, as a matter of fact, the rate quoted in your article is considerably in excess of what is paid for putting together and cleaning off the work after leaving the machines; for as all the operations requiring the greatest amount of skill are done at the machines, the putting together and cleaning off is done by apprentices and improvers, whose wages certainly do not average more than 20s. a week. The work turned out by the machines being all of an uniform width and thickness, and the various parts being planned up perfectly true and square in the trying-up machine, the time and skill required to finish it are infinitely less than where

the stuff is all prepared by hand; and those who doubt whether the joinery prepared at the cost given in your article is equal in quality to hand-work prepared entirely by skilled joiners, at the full wages of 8d. an hour, can easily satisfy themselves on this point by availing themselves of the kind permission of Messrs. Corbett & M'Clymont to visit their workshops, and inspect the joiner's work upon the Redcliffe estate.

SAMUEL WORSSAET & CO.

"THE ROYAL ACADEMY AND THE ARCHITECTURAL EXHIBITIONS."

Sir,—In answer to the letter in last week's *Builder*, on this subject, signed "Adelphi," I beg to state that for some years past, through the courtesy of the secretary of the Royal Academy, some of the hanging committee of the Architectural Exhibition have annually been allowed to inspect the rejected architectural addresses, and have obtained from them some few. I regret to say very few, good drawings for their exhibition, which, from want of space or other reasons, the Royal Academy committee have been unable to hang on their walls. Your correspondent is in error in supposing that the hanging the works of the rejected Academy drawings would contribute to the success of the Architectural Exhibition; and also when he hints that the representation of modern architecture has been almost entirely left in the hands of the junior members of the profession, as he will see by reference to some of the earlier and later catalogues.

The time required for selecting, hanging, and cataloguing the drawings, necessitates their being sent in early in April, in order that the Exhibition may be opened early in May, the time found to be most advantageous for the opening thereof.

If the profession generally would recognize the Architectural Exhibition in the way that they ought to do, seeing that the space allowed for architecture is at the present so limited at the Royal Academy, and would send drawings of their works, we doubt a much better exhibition might be made; and with such, the interest of the public, a very important element in the success of any exhibition, be secured. If "Adelphi" will visit the opening Exhibition, I can venture to assure him that he will find considerable progress made.

ROBERT W. EDIS.

WORKED STONE AND THE MASONS' UNION.

A BUILDER writes:—

"Sir,—At the interview that representatives of the trade unions, including the masons' society, had with Mr. Gladstone in London, Mr. Gladstone asked the question, if a sale, only worthy of savings, was in existence, prohibiting worked stone from being sent from the quarries into the towns. This they most emphatically denied.

Perhaps Mr. Potter, or the secretary of the masons' society, will please explain the discrepancy between the treatment I have just received and their answer to Mr. Gladstone's question.

We have a rule in Manchester, that worked landings shall be introduced. As the only difference between steps and landings is the width, and I wanted about 3,000 feet, and had only a very short time allowed for the work to be done, I thought I should be quite within the rule to order these steps worked on one side at the quarry, time being more an object than a saving in the cost. The masons' delegate pays me a visit, and informs me that it is against the law, and that I must at once promise to desist from bringing any more, or the men would be drawn from the work. However this may surprise the public, it will not surprise your readers that I had to submit to this tyrannical interference with the management of my business.

I have a large contract on hand at the present time that is precisely similar to one that is going on in London, and the stone comes for both jobs out of the same quarry. The proprietor of that quarry sends all the stone for the London contract worked, and he applied to me to do the same. As the London contract was six months in advance of my contract, he was very well acquainted with all that was wanted, and would have executed the order in the most satisfactory manner. The price at which he proposed to do the work, compared with what it is costing me, would make a difference of 5000l., and I must say that, as a free-trader, I feel it a very great hardship that I cannot go to the same market as a London builder to buy either my material or labour.

E. J."

STAINS ON WHITE BRICKS.

Sir,—Will one of your readers inform me of a receipt for removing the stains off white Suffolk bricks, caused by the rain running off the window-sill? A. E.

METROPOLITAN BOARD OF WORKS.

At the usual weekly meeting of this Board a report was brought up from the Works and General Purposes Committee, which stated that three inhabitants of Streatham secured Tooting-common as a place of public recreation for the inhabitants of the metropolis, at a cost of 10,000l. At a public meeting of the inhabitants it was resolved that the Metropolitan Board should be requested to purchase all the rights in and to the common as soon as the parties owning the manor could at their own cost obtain the approval of the Court of Chancery for the sale of their interest in it. These parties sought no advantage for themselves, and were content simply to be reimbursed the outlay of 10,000l. and any further costs and charges they might necessarily be put to. The report recommended the Board to complete the purchase. The motion was unanimously agreed to. The chief engineer (Mr. Bazalgette) presented his monthly report on the progress of the Thames Embankment works. It was similar to the report presented at the last meeting, and reiterated the promise that the main and approach footways on the northern side will be opened to the public during the approaching summer.

SCHOOLS OF ART.

The Wolverhampton School.—A meeting, to which the leading manufacturers of the town and some of the friends of art had been invited, has been held in the committee-room of the Town Hall, "to consider the best way of furthering the interests of the school, and to carry out the suggestions of the Government in reference to technical education." The Mayor presided, but, despite the attention which the subject of technical instruction is receiving at the present time in other places, the invitation was by no means numerously responded to. Captain Lovelidge (who has for the last few years been the chief supporter of the school) said the committee had resolved to call the meeting to consider whether it was not possible in some way to rescindate the school and put it in something like a prosperous state. It was remarkable that in a district like this, with such a superior building, there should be only about 50 pupils, while the schools of Dudley, Stonbridge, Kidderminster, smaller towns than Wolverhampton, were in a state of prosperity, and while Birmingham school had 1,000 pupils, with others who were clamouring for admission, but for whom there was no accommodation. A resolution was passed to the effect that the meeting was of opinion that further exertion is necessary for the purpose of making the school more generally known among the artisan population of the town and neighbourhood, and that the heads of trades and manufacturers and schools, as well as the professional classes, be requested to use their influence so as to increase the number of pupils for instruction in various branches of practical art. The committee of the school were requested to adopt such measures as to them might seem necessary for carrying out the resolution.

The Wakefield School.—Mr. Walter Smith, head-master of this new school, which has been opened in connexion with the local Fine-art and Industrial Institution, recently delivered an address on art education to those interested in the subject. The classes of the school have commenced, and the address was intended to open out the subject of art education, its history, present condition, and objects, to the people of Wakefield. There was a large audience. Around the walls were hung specimens of the art examples which have been obtained for the use of the classes. The chair was occupied by the mayor, Mr. W. H. Lee, who on rising said it was a great satisfaction to the promoters of the local exhibition that the encouragement given to it by the public left them a handsome surplus—no less a sum, indeed, than 3,000*l.*, or a little over.

The committee were anxious that this sum should be devoted to something that should perpetuate the objects for which the exhibition was first promoted; and it was ultimately determined that a school of art and a museum should be founded in the town, and he was now happy to say that that school had been established in eligible premises, that had been purchased and fitted up for it. They had placed the institution in connexion with South Kensington Science and Art Department, and had secured the services of Mr. Smith, who had long been connected with art education, and who had shown a special interest in the promotion and encouragement of schools of art in different parts of the kingdom. Mr. Smith's name was well known, and his talent in this direction was acknowledged. The mayor added that he need not point out that it would be difficult to keep our position among the nations unless we amend our system of primary education, and also give to those who have gone through it opportunities for further improvement. It was for this object that they had determined to establish this school of art, and they should be glad if their efforts were appreciated by the town generally. Mr. Smith, in his lecture, explained what it was intended should be done in that new School of Art. The mayor had referred to the cause of the recent cry that had been heard for technical education. Now, what was meant by this phrase? In the first place he might say that, contrasting it with general education, it is the process by which a human being acquires the power of learning a trade or a profession by the acquisition of knowledge—the formation of the habit of thinking correctly, and reasoning with accuracy. Technical education is the direction in a particular channel of this acquired power. General education is a training of the mental faculties, as gymnastic exercises prepare the body physically, while technical education proceeds on the basis of general knowledge to develop the senses, to sensitize the natural powers, and

to open out the special abilities of the individual in the particular direction in which they are required. Technical education stands as a connecting link between learning and labour, and, by uniting the two, confers what is necessary to all success—theory and practice in their true relations of learning saving labour, and practice rectifying, correcting, and testing theories. Thus, then, technical education ought to be directed to qualifying the student for the particular trade or profession it was intended he should pursue; and, looked at in that light, it embraced the studies pursued in a school of art as well as in science classes. The lecturer then glanced at the progress of art education in England; the importance of the knowledge of drawing to working men; and spoke of the Wakefield Industrial and Fine Art Institution, and the new school in connexion with it. Other towns, he remarked, had preceded Wakefield in establishing Schools of Art or Science Classes, but no other town—not even London, had deliberately set to work to bring both art and science, picture-gallery and museum—the active and present influence of direct teaching and the passive influence of galleries and scientific collections—under one roof and under local management.

CHURCH SERVICE STOPPED BY MOTHS.

A REMARKABLE plague of moths fell upon Sydney and St. Leonard's, Australia, last autumn. The Rev. W. B. Clarke, writing from the latter place under date of October 10th, 1867, says the moths first appeared in the church on the 14th of September, and for a month from that time had gone on increasing in numbers; and, although several bushels had been destroyed, the army was undiminished. On Sunday, the 6th of October, the state of the church was such, from the accumulated dust from the moths' wings, and the incessant swarms that were continually flying through the building, that divine service could not be held therein. More than seven days' hard labour had been spent in vain endeavours to subdue them; and applications of the strongest ammonia, sulphur-smoke, and other contrivances, used for hours, failed to drive them away; for as fast as one swarm was partly destroyed another succeeded. The neighbouring ground and trees were full of them; and when driven away, they mustered again and again. On the 10th of October, Mr. Clarke counted 80,000 on the windows alone; and in the tower and below the floor he calculated there were many millions.

A similar plague visited Australia in 1851, and again in 1855. From specimens forwarded to this country, the creature is ascertained to be the "Boogong" or "Cnariogon" moth (*Agrotis syntina*). It is eaten by the aborigines, either baked in the ground or pounded into a paste for cakes.

STATE OF THE BIRMINGHAM WORKHOUSE.

THE local guardians, by a majority of twenty-two to thirteen—there were only thirty-five guardians present out of a total of 108—have resolved to build a boys' school only, at an estimated cost of 7,500*l.*; whereas last year complete schools for boys, girls, and infants were to have been built for 23,000*l.* The majority of twenty-two rescinded the previous resolution in favour of complete schools. The Poor Law Board, however, has yet to be consulted as to the new plans, and being decidedly in favour of the former arrangement, as our authority the local *Journal* remarks, the Board will not readily allow the guardians to recede from it, especially as the vote just come to was carried by only one-fifth of the whole number of guardians. Besides, the Poor Law Board may possibly find in the discussion as to the schools another reason for interfering—namely, the state of the workhouse. Dr. Barratt, a guardian and medical man, gave the following account of the workhouse:—

"It was overcrowded all through. There was not a single classification that would meet the requirements of the Poor Law Board. The inmates were sleeping on the floor, two and three in a bed. The infants' department was a disgrace to a civilized community. The girls' department was the only one in which there was any approach to comfort, and a new bedroom was required there at once. The infirmary was overcrowded; the surgeon did not know what to do with the cases. It was the same with regard to the imbeciles and epileptics."

Mr. Jones, the late chairman of the Board,

added something to this statement. He said that "the dining-room was occupied by what were called the 'sore-leg cases.' This was a most improper arrangement, and must be altered. The epileptics were wandering about the house instead of being confined to wards of their own."

Mr. Clay, a medical man, and one of the visitors to the workhouse during the last month, corroborated and even strengthened the remarks of previous speakers:—

"He must say that many portions of the house were in a most disgraceful state. In the lying-in ward the cubic space for each patient were 450 ft. less than it ought to be. In the epileptic ward there was not half the cubic space there ought to be for the number of inmates. In the bad-leg wards and the infirmary the beds were too numerous. The House could not be sufficiently relieved without adopting the old plans [for the schools]. This would render further building unnecessary for many years. He saw two and three children sleeping in a bed the last time he was at the workhouse."

Some of the so-called economists having denied certain of these statements, Dr. Barratt replied, "What I state is true, and, if driven to it, I may go considerably further."

The Poor Law Board will do well to institute an immediate and public inquiry into the state of the workhouse.

Books Received.

The Year-Book of Facts in Science and Art. By JOHN TIMBS, F.S.A. London: Lockwood & Co. 1868.

THE new volume of this serial contains a portrait of Sir Samuel W. Baker, accompanied with a pithy and interesting memoir of this distinguished traveller. Mr. Timbs has, with his usual discrimination and zeal, gathered and pressed in between his green covers a large number of facts exhibiting the most important discoveries and improvements of the past year.

Works in Terra-Cotta manufactured by John Marriott Blashfield, Stamford, Lincolnshire. Parts 1, 2, 3.

As a trade book Mr. Blashfield is issuing illustrations of numerous architectural details of which he has moulds,—chimney-shafts, chimney-pots, balustrades, parapets, and so forth. Part 3, just now published, is particularly interesting, including numerous doorways, windows, balconies, copings, plinths, terminals, consoles, and panels. Mr. Blashfield claims that his terra-cotta is made from the finest pottery clays, carefully ground and amalgamated with calcined flint, felspar, glass, and other substances, and brought into a stiff paste. After the terra-cotta articles have been modelled and moulded with this body they are dried in a warm building and then placed in a pottery kiln and burnt. The degree of heat required to thoroughly burn or partially vitrify the ware is equal to that obtained in the firing of porcelain. For all large thick pieces of terra-cotta the heat should be prolonged several days, so that the masses of material may be thoroughly fired to their centres. Many of the imitations of ancient terra-cotta work now offered to the public are little better than kiln-fired common clays, and will soon moulder and crumble to dust. So many works have been produced by this maker during the past twenty years,—including balustrades, Stafford House; frieze and capitals, Duchy of Cornwall Office; large vases and terminals, Buckingham Palace; statues and fountains, Sydenham; terminals for the Royal Italian Opera House; cornice, capitals, panels, &c., London and North Western Station, Broad-street, London; and the architectural dressings and details, Sun Fire Office, Charing Cross;—that it cannot be difficult to test the goodness of his ware.

Rating of Railways. By EDWARD RYDE, Surveyor. London: Cassell, Petter, & Galpin. 1868.

THE little pamphlet before us is, it seems, to form part of "A Handy-Book, in a Series of Letters," wherein Mr. Ryde intends treating of various professional subjects, such as land measuring, levelling, compensation cases, parol assessments, rating of water companies, light and air questions, and so on; and as each letter will be complete in itself, and there is some uncertainty as to the time within which the whole of them may be finished, those which possess special interest will be published in pamphlet form from time to time.

In the letter before us the accepted mode of

ing railways is set forth clearly and com-
pensively, cases which establish the various
points being quoted. Mr. Hyde has had plenty
experience personally, and speaks with
authority.

VARIORUM.

“BOARD of Works for the Limehouse District: Report of Medical Officer of Health for the Year ending Lady-Day, 1867.” This is virtually a re-
cense on the causes of cholera, one chief ob-
ject of the author, Dr. Orton, being to disprove
the truth of the conclusion that foul water pro-
cesses cholera. — “Board of Works, White-
chapel District. Report on the Sanitary Con-
dition of the Whitechapel District for the
year ending 28th December, 1867. By John
Fiddle, Medical Officer of Health.” The rate of
mortality in the Whitechapel district for the last
year was 24 per 1,000, or 1 in 41 of the total
population; and indeed, including the London
hospital, it was 29 per 1,000, or 1 in 34 of the
population. — We find a trade pamphlet,
amongst those before us, descriptive of Herring
Son’s self-acting apparatus for warming build-
ings, manufactories, &c. The apparatus is
worked in connexion with a high-pressure steam-
engine, and it is self-acting; and, apart from
the cost of working the engine, which is not
supposed to be erected for that purpose, there is
no cost connected with the working of the
warming apparatus; the hot water being sup-
plied from the waste water of the engine-boiler
and returned to it again, so that the water sup-
plied to the engine becomes pure distilled water,
avoiding all encrustation of the boiler, and
saving fuel by the supply of water already
heated. — “Report on Health of Liverpool.”
The report of Dr. Trench, the Liverpool medical
officer of health, has been issued in a printed
form. The death-rate of the borough for the
last year was 23·4 per 1,000, or 3 per 1,000 less
than the average during the previous ten years.
The following particulars refer to the overcrowd-
ing of houses during 1867:—

No. of rooms found overcrowded at night.....	1,261
Total cubical area of the above rooms.....	974,758 ft.
No. of adults found sleeping in the said rooms.....	4,595
No. of children below fifteen years.....	2,430
Average cubical area for each individual.....	157 ft.
Average cubical area for each adult (in- cluding therein two children under fifteen years as one adult).....	230 ft.

As our readers know, this is an evil which the
corporation and its able medical officer are
actively engaged in mitigating, as also is the
hidden and privy system. In 1867, the local
health Committee ordered the conversion of
3,371 privies into water-closets.

Miscellaneous.

TECHNICAL INSTRUCTION: MR. WHITWORTH’S
MANIFEST OFFER.—Mr. Whitworth has offered
to found thirty scholarships of 100l. each for the
promotion of education in engineering and
mechanical science open to competition amongst
all natives of the United Kingdom; and his
splendid offer has been accepted by the Depart-
ment of Science and Art. Mr. Whitworth will
manage the proposed trust during his lifetime,
and the President of the Council of Education
hereafter. This must be equivalent to a gift to
the nation and to science of no less than
300,000l. The Lords of Council on Education
suggest that technical instruction will be
rendered easy if the magnificent example set by
Mr. Whitworth shall be extensively followed by
others.

MR. HENRY LESLIE’S CONCERTS. — The last
two have been particularly successful. At the
concert on the 2nd there was a medical certifi-
cate instead of Mr. Sims Reeves, and an ap-
ology for Miss Angelo; but Mr. Hallé was so
perfect, and the choir sang so charmingly, that
every one was satisfied. Mr. Cummings took
the place of Mr. Reeves, and sang with so much taste
and excellence, that all forgot to be disappointed.
Mr. Cummings is deservedly rising high in
public estimation. On the 6th the concert con-
sisted of sacred music. Mr. Sims Reeves was in
admirable voice, and never rendered with deeper
pathos and more perfect expression the recitative
from *Uphthah*, “Deeper and deeper still;” and
the exquisite air “Wafe her, ye angels;” and
Leslie’s fine trio, “Love, gentle, holy, pure,” by
Fiddle, Carola, Madame Gardloni, and Madame
Lately-Whytack, was beautifully sung. These
concerts will be resumed on the 29th inst.

CIVIL SERVICE ESTIMATES.—The sum required
to be voted on account of the civil services for
the year 1868-9 is 15,230,479l. the votes for the
previous year being 14,190,353l. There is a con-
siderable increase in the department of public
works and buildings, the vote on account of
embassy houses showing an advance on the pre-
vious vote of nearly 26,000l.; and on account of
harbours of refuge there is an excess of 16,274l.
The Commissioners of Works in England will
require an advance on last year’s vote of 14,110l.,
for the maintenance and repair of Royal palaces.
The other principal items of increase are for
public buildings, 6,352l.; Royal parks and plea-
sure gardens, 12,198l.; public record repository,
20,580l.; enlargement of the National Gallery,
15,000l.; Burlington House, 40,000l. The Govern-
ment also requires a new vote of 10,000l. for a
natural history museum; 10,000l. for the new
Home and Colonial Offices; and 20,000l. for the
Glasgow University. There is also an increase
of 32,962l. in the estimated cost for the year of
public buildings in Ireland.

THE THAMES EMBANKMENT AND RAIL.—Some
further information respecting the Embankment
and the railway is contained in a letter which
Mr. Bazalgette has sent to the *Times*. From
Westminster Bridge to the east end of the Temple
Gardens, a length of 5,807 ft., the Embankment
is practically completed. It now only remains
for the railway contractors to cut their trench
through it from end to end, and build their rail-
way within that trench. It will then be arched
over, and the roadway formed on the top. From
the east end of Temple Gardens to Blackfriars
Bridge, a length of 853 ft., it is not proposed to
form a solid embankment; but the road will for
this length be continued upon arches up to
Blackfriars Bridge. The river will flow through
and barges will pass under those arches up to
the wharfs as heretofore, and the water space
between the viaducts and the wharfs will vary
from 100 ft. to 125 ft. in width. There will be
no connexion whatever between the works of
the railway and this viaduct. At the east end
of the Temple Gardens the railway will leave
the Embankment, and be carried close in front
of the wharfs to Blackfriars Bridge. The rail-
way and the viaduct will for this length be two
perfectly distinct works, with a wide water space
flowing between them.

THE NEW BRIDGE AT BLACKFRIARS.—The struc-
ture, it may be remembered, is to consist of five
arches, namely, two of 135 ft. span each, two of
175 ft. span, and one of 185 ft. The width of
the roadway on the bridge, including the foot-
paths on either side, will be about 75 ft., and
the average gradient will be 1 in 40. Some of
the foundations have been sunk 52 ft. below
high-water mark—in other words, a long way
into the London clay; and with respect to two
of the piers which are to occupy the sites of the
old ones the work has been necessarily tedious
and protracted, involving, as it did, the unroof-
ing of the old foundations before those of the
new piers could be laid. On the Survey side of
the river, at which the erection of the structure
commenced, the works are in a very forward
stage, much of the granite masonry being
finished, as also the ribs and ironwork of the
arches. The fourth pier, or the one next to the
Middlesex side of the river, has been raised
nearly to the half-tide level; and with respect to
the third pier the caissons have been sunk to
the extreme depth and filled in with concrete,
except the two end caissons, which are being
gradually lowered to the proper depth. Four
of the piers will be ornamented by two columns
each of polished granite, about 11 ft. or 12 ft.
high, and some of them 23 ft. in circumference.
The granite is being quarried in the Isle of Mull,
and conveyed by sea to Glasgow, where it is
adapted and polished by machinery, and re-
moved thence to London by railway. Each
column consists of three blocks of granite,
weighing from 11 tons to 12 tons each block,
and each column costing upwards of 500l. The
drawback to the structure will be the railway
viaduct on the eastern side, which will greatly
mar the appearance, running parallel with it, as
it does, at a distance of 50 ft. If all goes well
the new bridge will probably be opened to public
use about the spring of next year. On Monday
last, the chairman of the Bridge-house Com-
mittee, in the presence of his colleagues; of Mr.
Brand, the controller; and of Mr. Joseph Cubitt,
the engineer; Messrs. Thorne, the contractors;
and Mr. Bryant, the engineer of the contractors;
publicly laid the foundation-stone of one of the
remaining piers, with the accustomed ceremony.

PROJECTED IRONWORKS AT MARYPORT.—Messrs.
Gilmour, Brothers, & Co., of Glasgow, have made
arrangements for erecting smelting furnaces at
Maryport. The site they have selected consists
of about twenty acres, on the Bent Hill, west of
Norman-terrace. The plans exhibit four blast
furnaces, and it is estimated that one furnace
will require nearly 1,000 tons of material per
week, and employ perhaps 100 hands.

REPORT OF ST. PANCRAS GUARDIANS.—A report
by the chairman, Mr. W. H. Wyatt, to the Board
upon the proceedings of the guardians for the
last nine months has been printed for circula-
tion, from which it appears that some sweeping
amendments have been made in the management
and treatment of the poor. A lax system had
prevailed, and new officers were appointed to
carry out the new system resolved upon by the
guardians; and it would appear, with decided
advantage both to the really deserving poor and
to the ratepayers. They have since, however,
announced the necessity for a heavy rate, which
is exciting some commotion; but the rise of
rates is not limited to St. Pancras.

BRICK BURNING.—In the case of *Roberts v.*
Clark, before Sir W. P. Wood, as Vice-Chancellor,
it was held that where a nuisance had been of
more than twenty years’ standing, but with tem-
porary interruptions, the party asserting the
right to continue it was bound to show that it
had been exercised at least in the first and last
year of the period of twenty years, in order to
preserve it from being lost. The Vice-Chancellor
said it was not necessary to prove that any
special sickness had resulted to plaintiff or his
family from the effluvia arising from the brick-
burning, nor that the vapour was more than
usually injurious or offensive. It had been held
at law that brick-burning carried on in the
ordinary way was a nuisance to the persons
living within the limit affected by it; and it was
such a nuisance as the Court of Chancery would
restrain by injunction.

DESTRUCTIVE FIRES.—The Gilnow Cotton
Spinning Mills, Bolton, have been totally
destroyed by fire. The flames broke out while
the mills were in full operation, and in half an
hour the entire structure was brought to the
ground. All the workpeople got out in safety.
The damage is estimated at 70,000l. The
premises are largely insured.—A fire has
occurred at Eastwell Park, near Ashford, the
seat of Earl Winchelsea, producing damage to
the extent of 10,000l. or 12,000l. It broke out
in the north side of the main entrance and above
the dining-room, schoolroom, and governess’s
apartments. The roof gave way, and almost
simultaneously the expansive glass dome, and the
grand staircase fell in; the former burying the
contents of the school room and governess’s ap-
artment, and the latter a number of valuable books
and other costly property. The result of this
was that the flames were communicated to the
dining-room beneath, and valuable pictures,
some family portraits, and many articles of
vertu, together with costly furniture, were
destroyed. Great fears were entertained that
the entire mansion would be sacrificed; but
luckily the fire was confined to the dining-room
and apartments above.

RATS AND MICE.—If the police are wanting in
expertness when most needed, they make up for
it by being very expert where least needed.
They lately brought before Alderman Hale a
ratcatcher named Samuel Humm for poaching
in the sewers without leave asked or given.
He had just come up through a manhole with
thirty rats, in a bag. Alderman Hale fortunately
did not take the policy view of the matter,
and not only discharged the prisoner, as one who
was doing good by extirpating rats from the
sewers and houses of London, but also promised
to use his influence in obtaining for him a rat-
license to sport in the sewers for the future as
often and as long as he liked. We only hope
that Humm will not have a monopoly of the busi-
ness.—Certain hungry mice having gnawed
a piece of gas-piping in a house at Warrington
till the gas escaped, a disastrous explosion took
place; two persons were badly burnt, and serious
damage was done to windows, ceilings, walls,
and flooring. Gas-plumbers have a bad practice
of rubbing gas-pipes over with grease, or strap-
ping them with greasy rags, where they leak
slightly. This must induce mice and rats to
chew the lead. The gas-men’s practice is one
they ought to eschew, for it clearly leads the
rats and mice into temptation, and their betters
into danger.

NATIONAL PORTRAIT EXHIBITION, SOUTH KENSINGTON.—The collection of portraits will be opened to the public on Monday next.

DISCHARGE OF GOVERNMENT WORKMEN.—About 200 workmen of various grades were on Saturday discharged from Woolwich Dockyard, and 800 mechanics and labourers will leave the establishment at weekly intervals.

TWISTED WROUGHT-IRON BARS.—We observe that wrought-iron bars, generally of + section, but twisted as it runs along, are being made by Messrs. Macanight, Robertson, & Co., of Bankside, and recommended by them as particularly applicable for balustrades, balconies, balconets, verandahs, railings, columns for shop-fronts, stanchions, circular stair-posts, and ornamental iron-work generally. Although light, they are said to have considerable strength.

PROPOSED COLLEGE FOR WOMEN.—A conference was held on Saturday at the Architectural Gallery, London, to consider the proposed establishment of a college for the education of advanced female students. The Dean of Canterbury occupied the chair, and a large number of ladies and gentlemen attended. It is intended to place the college in a healthy locality between London and Cambridge, thus putting it within reach of the best teaching in all the subjects of the college course. It has been roughly calculated that a building with accommodation for 100 students may be erected at a cost of 30,000l.

CORPORATION MODEL LODGING-HOUSES FOR NEWCASTLE-UPON-TYNE.—At a recent meeting of the Town Council a report was adopted in favour of the Corporation erecting model lodging-houses for the poorer classes. The mover of the resolution said, after detailing the history of the movement, that the estimated cost of the lodging-house would be 4,433l.—3,500l. for the cost of the building, and 933l. for the cost of the ground. He believed it would pay 5l per cent. They could obtain the necessary money from the Loan Commissioners for 4 per cent, and in this way the council would make 1½ per cent. Another of the council said it was a great experiment, and strongly advised the council to follow as far as they could the example of Mr. Peabody in London. He believed they would, by carrying out the scheme, provide better houses for poor people.

TELEGRAPHIC PROGRESS.—The adoption of the telegraph by the Government will be a decided step in telegraphic progress. The Bill to enable the Postmaster-General to acquire, work, and maintain electric telegraphs is not binding on the telegraphic companies so as to compel one and all of them to hand over their telegraphs to the Government, but it is compulsory in certain circumstances on the Postmaster-General to purchase telegraphs that may be offered. He is also authorised to negotiate with companies for the purchase of their lines of telegraph with money to be given by Parliament from time to time for the purpose. The charges for messages are not to exceed one shilling within the United Kingdom for twenty words or less, exclusive of names and addresses, and sixpence for each additional ten words or less. There are arrangements and restrictions also as to portage and transmission by post, &c.

THE BIRMINGHAM STATUE OF SIR ROWLAND HILL.—Some three years ago a public subscription was set on foot at Birmingham, to provide for the execution of a statue of Sir Rowland Hill, as the promoter of penny postage. A commission was given to Mr. Peter Hollins to execute a marble statue at the price of 950 guineas. The statue has just been completed, and is now about to be sent to the approaching exhibition of the Royal Academy. It has been cut out of a block (three tons weight) of Carrara marble, and the sculptor has been fortunate in securing some of the finest grain, and without flaw. In the right hand Sir Rowland holds a roll of penny postage stamps. The figure is 6 ft. 8 in. in height. The statue, from the fine quality of the marble, is too delicate to stand exposed to the weather, and will be placed indoors. The late recorder of Birmingham, Mr. M. D. Hill (brother to Sir Rowland), and other members of the Hill family, who have seen Mr. Hollins's work, pronounce it a characteristic likeness, whether as regards feature, expression, or attitude. It has just been determined by the Government to go on with the erection of a new General Post-office at Birmingham, and it is not improbable that this may be the ultimate destination of the statue.

TENDERS.

Table of tenders for Kingston-on-Thames Workhouse Infirmary. Messrs. T. H. Rushton & C. L. Luck, architects. Quantities supplied by Mr. Northcott. Includes items like Collings, Little, Myers & Sons, Foster, Hart, Saunders, Nightingale, Gibson, Higgs, Simpson, Howard, McLachlan, Wells, Gammon, Hatten, Lacy & Flexman, Manley & Rogers.

Table of tenders for a pair of semi-detached cottages, to plans and specification, and quantities supplied by Mr. J. T. Matthews, architect. Includes items like Peters, Scrags, Holdworth (accepted), Winkworth.

Table of tenders for the erection of villa residence, at Epson, Surrey, for Mr. John Barnard. Mr. A. F. Williams, architect. Includes items like Hooker, Cooper, Chuter, Brothers, Andrews.

Table of tenders for warehouse, 34, Gutter-lane, Messrs. John Young & Son, architects. Includes items like Lawrence & Sons, Mansfield & Price, Hart, Patman, Myers & Sons, Brass, Webb & Sons, Newman & Mann, Ashby & Horner, Heushaw.

Table of tenders for Abingdon Grammar-school. Mr. E. Dolby, architect. Includes items like Nightingale, Dover, Gawland, Thomas & Dicks, King, Troy & Son, Selby, Bull & Sons, Claridge.

Table of tenders for building chapel, at Bexley. Messrs. Habershon & Pile, architects. Includes items like Butler, Patman & Co., Nightingale, Longson, Falkner, Yeagb, Dabs, Wata, Pearce & Booth.

Table of tenders for completing erection of villa, for Mr. W. Hall, Mr. Danby, architect. Includes items like Willes, Parks, King & Sons, Nightingale, Regis, Garrod, Rogers & Richards.

Table of tenders for a villa, Grove Park, Camberwell, for Mr. Benj. Hooper. Mr. R. Nixon, architect. Quantities supplied by Messrs. Mann & Saunders. Includes items like Thompson, Cooper & Cullum, Heushaw, Nixon & Son, Colls & Co., Higgs, Gammon & Sons.

Table of tenders for a printing warehouse, in Hatton-garden, for Mr. J. Hazell. Messrs. Lander & Bedells, architects. Includes items like Grover, Bamford, Patman & Co., Dove, Brothers, Manley & Rogers, Browne & Robinson, Mann, Axford.

Table of tenders for alterations, No. 14, Hyde Park Gate, for Mr. J. R. Haig. Includes items like Mansfield & Price, Patman & Fotheringham, Nixon, Liberal, Saunders (accepted).

Table of tenders for road-making and drainage, on the Woodbridge-road Estate, Guildford. Mr. Henry Peak, architect and surveyor. Quantities not supplied. Includes items like Walkins, Garnett, Ayers (accepted).

Table of tenders for alterations to the Norfolk Arms, Hart's-Jane, Bethnal-green, for Messrs. Truman, Harbury, Buxton, & Co., brewers. Includes items like Gray, Marr, Kelley, Brothers, Lengshead & Way (accepted).

Table of tenders for new buildings, Great Tower-street. Messrs. John Young & Son, architects. Includes items like Jackson & Shaw, Ashby & Sons, Mansfield & Price, Browne & Robinson, Heushaw, Ashby & Horner, Conder.

Table of tenders for rebuilding No. 29, Mark-lane, Messrs. John Young & Son, architects. Includes items like Lawrence & Sons, Ashby & Horner, Hart & Brier, Ashby & Sons, Webb & Sons, Brass, Heushaw, Condar, Newman & Mann.

For erecting a warehouse, at Batley, near Leeds, for Mr. John Blackburn. Mr. Walter Hazstock, architect. Quantities supplied:—

Table of tenders for Mason and Bricklayer's Work. Includes items like Atkinson, Hepworth & Son, Brier, Mortimer & Sons, Hart & Brier, Booth, Chappell, Robinson & Hirst, Goldthorpe, Preston & Webster, Winstadales.

Table of tenders for Carpenter and Joiner's Work. Includes items like Jackson, Tyles, Ibberson, Petty & North, Williams, Hodgson.

Table of tenders for Plumber and Glazier's Work. Includes items like Brumitt, Firth, Heushaw, Sanior, Lobley.

Table of tenders for Slater's Work. Includes items like Rawthorne, Thompson & Son, Thornton.

Table of tenders for Ironfounder's Work. Includes items like Shillito, Messrs. Horsfield, Bagshaw.

For paving footways, and for facias, of the Thames Embankment, from Westminster Bridge to the Temple Gardens:—

Table of tenders for paving footways and facias. Includes items like Hitton, Furness, Turner, Nowell & Robson, Goech, Bentball, Thirkn, Booth, Hill & Reddie, Mowlem & Co., Knight & Son (accepted).

For rebuilding premises, High-street, Stoke Newington, for Mr. S. Brampton. Mr. F. G. Widdows, architect. The quantities were supplied by the architect:—

Table of tenders for rebuilding premises. Includes items like Patrick & Son, Birt, Conder, Brass, Ashby & Son, Newman & Mann, Heushaw, Hill & Kaddell, Ennor (accepted).

For erecting two cottages, in the Sydenham-road, Snarebrook, for Mr. Rowbotham. Mr. F. G. Widdows, architect:—

Table of tenders for erecting cottages. Includes item like Innt & Elkington (accepted).

For painting the inside of the Agricultural Hall, Islington, for the Agricultural Hall Company:—

Table of tenders for painting the inside of the Agricultural Hall. Includes items like Patten, Grant, Cbild, Sharnam, Davis, Kellaway, Brown & Sons, Barnes, Harding, Gray, Markham (accepted), Allard.

Table of tenders for new building, and raising additional story, Featherstone-street, City-road. Mr. H. J. Haman, architect:— Includes items like King & Sons, Eston & Chapman, Heushaw, Perry & Co., Macey, Praddy & Son.

For villa residence, at Acton, for Mr. T. L. Edwards. Messrs. Lander & Bedells, architects:—

Table of tenders for villa residence. Includes items like Bywater, Harding, Adamson & Son, Palmair, Sale, Perry & Co., Bick, Bray, Cowland, Mann.

The Builder.

VOL. XXVI.—No. 1315.

Exhibition of National Portraits.

OR one who has mixed actively in the world during the past twenty or thirty years, to walk through the third collection of National Portraits now on view at South Kensington, is to go amongst old friends and acquaintances. Whatever may have been his particular path,—politics, war, the stage, art, literature, or science,—he sees around him the men with whom he has worked or quarrelled, whom he admired or envied. The departed, with one great exception, reign here alone. Dead! dead! is the echo everywhere. And yet not dead, for their works and doings are still operating. As Milton says,—

"Where all life dies, death lives."

What hosts of memories arise as we pass before the well-remembered faces; what pegs to hang stories on start out in all directions! Without making great pretence to largeness of connexions we would undertake to fill a volume right off with personal recollections and anecdotes of the men whose portraits are to be found here. And, if we, so most. This collection, therefore, although it contains a considerable amount of poor art, will probably interest the multitude more than the last did. It commences with the present century, and includes the last twenty years of the reign of George III., the ten years comprising the reign of George IV., and the seven comprising that of William IV.; with the first thirty years of the reign of Queen Victoria. As supplementary to the exhibitions of the two previous years, the present collection also includes the portraits of many persons who were then either omitted or inadequately represented, with the works of some painters to whose art due justice may not have been hitherto done; and this part of the collection is not by any means the least interesting. Containing works of the chief portrait-painters whose names and art have been known in the country from the earliest times, it serves to show the influence they had on the works of their successors, and the sources of many later excellencies. It contains a series of paintings in which portrait art may be traced from the time of Holbein to the present day, including the works of Antonio More, Vansomer, Jansen, Vandycck, as well as those of our own countrymen, Reynolds, Gainsborough, Romney, Lawrence, Raehurn, and Knapton. Of course there are many omissions, and there are many circumstances to account for them. The series proper consists of 624 works, the supplementary collection brings up the number to 946, making the whole that have been shown in the three exhibitions that have taken place 2,842, many of them, of course, containing more portraits than one. The catalogue has been written by Mr. R. H. Soden Smith, a member of the committee, and

Dr. Althaus, and contains a large amount of information concisely given. The general direction of the exhibition was entrusted as before to Mr. S. Redgrave, who has prefixed some introductory observations, in the course of which he says, truly,—

"The series of exhibitions may surely claim one great merit, if it prove the means of awakening the owners of pictures, many of which are of national interest, to the true value of their possessions, and lead to greater care that the identity of family portraits is not lost by consignment to the housekeeper's room, or even to the attic; if it saves portraits themselves from destruction by cruel exposure to the sun till all traces of colour and the finer qualities of the art are hopelessly dried out; or by exposure to damp or changes of temperature, so particularly injurious to early portraits on panel; or, worst of all, subjection to greater danger in the hands of incompetent repairers, who, in the attempt to restore what is irretrievable, destroy the only remains of original art which may have been spared."

A peculiar example of the mischief following the latter practice is afforded by the remarkable portrait of Richard II., which will be found in the supplementary collection (653). This portrait—large life-size, throned, the most important contemporary representation that we possess of any English sovereign—used to hang in Westminster Abbey, above the Lord Chancellor's pew, on the south side of the choir, next to the pulpit; it was removed in 1775 to the Jerusalem Chamber, where it has hung ever since. It is believed to represent the king enthroned on the Feast of the Translation of King Edward the Confessor, and was exhibited in the first National Portrait Exhibition, 1866, in the state in which it had been left after many attempts at restoration or repainting. It has since been cleaned with care, as we have before mentioned, under the superintendence of Mr. George Richmond, R.A.; the comparatively modern painting that concealed almost every part of the original portrait, has been removed, and there now remains the genuine contemporary work of the fourteenth century. What connexion is there between the painter of this remarkable work and the artist of the angels remaining in the Westminster Chapter-house?

Near the Richard II. hangs an elaborate picture, attributed to Hans Holbein, "Lady Guildford" (659), a wonderful piece of realistic work. In this part of the collection, "Edmund Waller" (690), and "George Gordon, Marquis of Huntly" (717), both by Vandycck; "Lord Keeper Coventry" (697), by Cornelius Jansen; the Cromwell group; "Mrs. Margaret Woffington" (754), one of Hogarth's best portraits; the poet Cowper (777), by George Romney; "Mrs. 'Perdita' Robinson" (828), by Gainsborough (the most delicious female head in the whole collection); the head of Wesley; Mr. Townley (913), with guests, amongst his marbles; and several others, will be looked at with interest. In the Townley picture, the exquisite bust of Clytie, now in the British Museum, and made common property by the Art-Union of London, is on the table. Townley's affection for this bust was remarkable. The story runs that when it was feared that his house would be sacked by Lord George Gordon's rioters, he took his Clytie with him into a coach, and said, "Now let them do their worst."

In this portion of the Exhibition, although we do not quite see why, is a portrait of James Wyatt, architect (788), who died in 1813. Also up-stairs; but in the last bay of the Exhibition proper, hang, of architects, Pugin (588), Cockereil (617), and Sir Charles Barry (618). A series of portraits of members of the Dilettanti Club, painted by George Knapton, Sir J. Reynolds, and others, have a room to themselves up-stairs; and being all glazed, and for the most part of a highly-finished kind, make a distinct feature. This society, it will be remembered, was established in 1734, by several noblemen and others (Viscount Harcourt, Lord Middlesex, Duke of Dorset, &c.), who were desirous of advancing the fine arts in

Great Britain. The society consists of fifty members; and by its aid or encouragement there have been published from time to time several important art works. In 1764 they sent an expedition to Asia Minor, and recorded the results in the "Ionian Antiquities;" they aided in publishing Stuart's "Athens," and Chandler's "Travels;" in 1814 they sent an expedition to the Levant. Quite recently they published "Principles of Athenian Architecture, with reference to the Optical Refinements of the Ancient Buildings at Athens." In 1740 it was ordered, "That every member of the society do make a present of his picture, in oil colours, done by Mr. George Knapton, a member, to be hung up in the room where the society meets." Judged by our present standard of portrait-art Mr. Knapton was no mean painter.

Below stairs we have, amongst architects, Sir John Soane (107), G. Dance (135), Sir R. Smirke (137), Sir Jeffrey Wyattville (220); but we may not here begin to signalise special works on this floor. Suffice it just now to add that all our readers will find pleasure and much matter for musing on in the gallery of National Portraits now open.

UNIFORMITY OF ACTION WANTED.

LARGE works are being carried out on every available site through the vigorously expanding metropolis. Many of these works are individually calculated to reflect credit on their designers, but the want of harmony which they evince between the different originating bodies is most painfully apparent. The instance most prominent at the moment is the "difficulty" between the Board of Works and the Metropolitan Railway Company. The engineer of each of these powerful bodies has rushed into the columns of the daily press, intent to throw on his opposite neighbour the blame of the public inconvenience. The river-wall, that has replaced the pestilent mud-banks of the Thames between the Temple Gardens and Westminster, has been for some time in such a state that a small amount of exertion would have given the public an outlet for overcrowded traffic, and an open and welcome promenade. But the same principle which seems to regulate the operations of all concurring interests in England, or at least of all interests that ought so to combine their operations as to reduce the outlay of each, while at the same time all unnecessary disturbance of the public traffic is avoided, exerts its ordinary influence. How often have we groaned under the shameful bivalence to metropolitan intercommunication caused by the independent action of the various gas and water companies, each of which seems only to watch for the occasion of a road being thoroughly repaired in order to rush furiously to tear it up again for some tinkering of the vast and complicated system of pipes or of sewers. There are at present but two instances in London in which due provision has been made beforehand to avoid this characteristic and intolerable nuisance—Garrick-street and Southwark-street; and these are not fully taken advantage of. In the case of the Holborn Viaduct, we believe, sewage, water supply, gas supply, will all be provided for; and if a pipe leak, or a drain become foul, the workmen in charge will be able at once to proceed to the spot without turning a single carriage aside from the "crown" of the causeway, or going to the expense of a gang of men furnished with pick and shovel. It is to be hoped that the arrangements of the new riverain parapet will be equally perfect; but in the mean time we are sufferers by the conflict between open air and subterranean travelling. It is intended that a branch of the Metropolitan Railway shall occupy the lower story of the new terrace, the traffic being carried on in two stages alongside of the river highway, as in the case of the New-road. But the road-makers and the railway-makers are not in accord. The Embankment people, in the first instance, state their own case and that of the railway in a breath. "It is no use for us to make our road," has been their plea, "for you to come upon us as soon as it is finished and tear it all up again, in order to build your gallery underneath. And, as you have no money, you are only making excuses

for delay." The railway people reply that this is by no means the cause of the hindrance. They are ready and willing to make the line from which they anticipate,—and that not without good reason,—an ample and remunerative traffic. Only the line must go *somewhere*. It is not to be stopped short at the present termination of the embankment, and carried on a joint at a time, as people fix the rungs in a ladder. Now, the mode in which the Board of Works will carry on their own open day traffic eastwards of the Temple is yet undetermined. The Board appear to have alternative powers, and may either construct a continuation of river wall and roadway, or a narrower terrace upon arches. The Metropolitan Railway people require that this question should be decided before they commence a large outlay.

It is not creditable that we have two bodies, which between them are carrying on public works of the first magnitude and the greatest importance, at a cost of many millions, thus hampering each other. The object of one of them is the convenience and the practical welfare of the public, and the provision for an improved mode of conducting the self-strangling traffic of one of the most crowded thoroughfares in the world. The other company has a financial *raison d'être*. It lays out capital for a return. But this return is entirely dependent on the mode in which the wants of the public are provided for. The aim and object, then, of the two bodies, and the principle on which their works should be carried out, are, or ought to be, identical. And yet there is such an entire absence of that practical common sense for which Englishmen are wont to take credit that, instead of having arranged, long since, a common plan of operations, the Boards are glinting at one another with angry eyes from behind their respective board-fences, and their engineers are explaining matters, not to one another, but to the neglected public.

New secretaries of State are regarded by some politicians as a panacea for old and intolerable grievances. By others they are regarded as a remedy worse than the malady. Into such a question as the advisability of the appointment of a *bona-fide* minister of public works, or of a machinery that shall tend to save the large amount of time and of money that is annually consumed by the cross-purposes of independent improvers of London, we do not now enter. But that some means of knocking the riotous and over-grown principle of irresponsible independence on the head must be adopted, we hold to be indispensable. The hitch between the Board of Works and the Metropolitan directors is not an exception to the general harmony of our constructors. It is the rule. The state of hitch is the normal state from which the public suffer. Every one for himself, cry the Brighton board, the South Eastern board, the London, Chatham, and Dover board; but they do not add the time-honoured conclusion of the adage, "and God for us all." They seem incompetent to understand the moral of the faggot which could not be broken when united, but which was readily snapped stick by stick. Each kicks out its passengers at the first possible outlet from the terminus, heedless of what becomes of them,—utterly careless of that decent attention to the comfort and the need of the customers on whom they live that would so well repay the cost.

Enormous sums have been expended within the last few years on very large terminal stations. Without saying that these are in every case such as to impress us with the highest sense of the taste or the constructive ability of their designers, they are still ample and imposing erections, capable of the comfortable discharge of an immense amount of business. We cannot forget how they arose rather from the interecine and frantic rivalry of the companies than from the desire to serve the public. But we are told that in this respect we have entered on a new *régime*. Why should not this peace and amity be inaugurated by the new and grateful feature of attention to public convenience? The companies would find it pay. A consultation of the several engineers as to the best method of combining the operations of the London lines might readily, and at no great expense, lead to such improvements as would effect an incalculable economy in the time, fatigue, and even outlay of that vast stream of population which is ever pouring to and from the great centres of business. Why should the passenger who arrives at Paddington from the west have to climb into the attic to gain the

long and inconvenient gallery through which, if he lights on any one to show him the way, he may finally reach the Bishop's-road platform, and thence, after a proper divergence to the ticket-window, set off for the City? Why should the passenger who arrives at the lofty and spacious terminal station erected at London Bridge by the Brighton Company have to dive through those insufferable dog-holes, and to wait on that ill-shaped and wind-swept platform for the next train, which, if it please Providence, may take him to Charing-Cross? Why is the threefold set of lines that couple the inconvenient platforms at London Bridge with the great wagon-roofed stations at Cannon-street and at Charing-Cross laid out with such perverse imprudence, such unnecessary bungling, that every train must cross the line of some other train, and that safety is made to depend, not on the proper arrangement of up and down and "shuttle" lines of way, but on the untiring and vigilant watch that is kept on the very complex system of signals? All these things would be so easy to amend. The public would be such great gainers by a little arrangement. And statistics so clearly show that every facility to traffic increases the amount of that traffic, that it is a false economy to neglect not only the convenience but the comfort, not only the convenience but the safety, of the metropolitan passengers.

We are not a people incapable of combined effort. In those cases where difficulty has been fairly met, and where competent men have set their wits to work to meet new necessities by adequate machinery, we are very apt to succeed. Look at the railway clearing-house, for instance. Does it not seem, on the first blush, that it would be a much easier thing to send a certain number of passengers, at fixed and definite hours and dates of arrival, from Sydenham to Charing-cross, or from Windsor to the Great Northern Station at King's-cross, than to ascertain where, on the previous night, wagon No. 2,000,672, or tarpaulin No. 5,000,099, had been left. Yet the latter can be done with ease; the former is yet an impossibility. It was, if we remember, Sydney Smith who, speaking, of course, of a foreign resting-place, said that if the fleas had been unanimous they would have pushed him out of bed. If all those constructors whose name is "the Board" were but unanimous, what would be the result to London? Suppose the engineers of the southern lines were to spare a little leisure (most of the profession have but too much of the commodity just now) to the attempt to remove the last vestiges of the old destructive and obstructive rivalry, and to the endeavour to carry, with the least delay, each other's passengers to their several destinations when these were on each other's lines. Why should not all the arrangements for transit and traffic be carried on in central and accessible positions, so that the man who, arriving from Dover, wishes to send a parcel to Oxford, a telegram to Southampton, and a letter to Birmingham, might be enabled to do so without stepping from beneath the roof of the terminus where he leaves his carriage? The junction of the metropolitan line with the Shoreditch and the Fenchurch-street Stations; of that system with Cannon-street, of Waterloo and Charing-cross, of Euston-square with the latter great point of departure,—all these things are matters of much more moment to the public than they are to the several companies. But they are none the less the duty of those who have assumed, for the sake of its financial return, the control of the whole traffic of the country. The want of this unity of arrangement is a national scandal. Not only so, but it is a personal loss and inconvenience to four passengers out of five. The full benefit of our great outlay is very far from having been reaped. The time lost by the suburban resident, in his daily transit, is frequently more than the time actually occupied in travelling. The damage is repaired at the cost either of business or of health. Either the daily traveller has to rise so much earlier, and to reach home so much later than necessary, thus incurring, say four hours' more fatigue, and fatigue of a wearing and unhealthy description, every week of his life, or he has to take that wasted time from his hours of business. With prompt and punctual arrangement his daily trip may be almost a pleasure; with liability to constant interruption and disturbance, it is a daily cross and anxiety. Let any man of business compare the time which is devoted to the actual transaction of his affairs with that which is wasted, partly unavoidably, but in great measure from want of system, and multiply the individual

result by the factors indicated by the hankers' clearing-house, and he may form some conception of the injury caused to the commerce of the country by the independent and uncombined action of those on whom he depends to convey him from place to place, to pave his streets, to light his ways, to purify his dwelling, and to run his errands.

If anything he needed to enforce this important lesson on the mind it is a comparison of our own liability to censure in these respects with that of some of our neighbours. England is the cradle of steam locomotion. But that is not a good reason for the fact that steam locomotion should linger longer in the cradle in England than it does in other countries that were once only too happy to follow humbly in the wake of the English engineer. It is in the absolute neglect of small but essential links that we are so much behindhand. Portage with us bears an undue proportion to carriage. We see coal quoted one day at 18s. 6d. per ton; a week later it is quoted at 17s. 6d. per ton. In either case we find it has cost us 26s. per ton by the time it has reached our cellars, and something for civility into the bargain. It is by attention to such details, among others, that our German neighbours are now neutralizing the disadvantage of distance from the markets from which they are driving our manufacturers. Their railways are organized, not for conveying passengers and goods to the verge of their estate, wherever that limit may be, and then for turning them out to shift for themselves, but for the most convenient and economical method of conducting traffic. The traffic of the country must be conducted in the most efficient manner. That is the common law. It is not such a circumstance as that one company stops short at Shoreditch and another at Paddington,—so that if you wish to go from Chesham to Slough, the intermediate passage is your affair, and not that of either company,—that will inconvenience you abroad. All parties interested in the matter are aware that it is only by a thoughtful and prudent harmony, by forethought and good arrangement, both of structure and of system, that ironwork from the North of Germany can be delivered in London at a less cost of carriage than ironwork from Manchester. The North German manufacturers wished to obtain that advantage; therefore they took the proper steps to obtain it. In that effort they have succeeded: such, at least, is the testimony of those respectable firms, long known to the Post-office Directory, who live by selling German goods to English consumers. By closing the intermediate links, in the absence of which the main chains end "in the air," our neighbours and rivals secure a unity and economy of action, the want of which amongst ourselves may be estimated by such tests as that of the price of coal.

WHAT IS AN ARCHITECT?*

An opinion which was formerly almost universal, and which still lingers amongst us, is that an architect is a man who draws plans of houses suited to the wants and purse of his client, looks after the interest of said client, keeps an eye on the doings of the joiners and plumbers, goes through the accounts and cuts down the extra bills, and, in short, acts generally as a sort of bridge over the great gulf which is fixed between the refined and aristocratic client and the gross building element, and for these good services pockets 5 per cent., besides pickings. It is matter for congratulation that this specimen is likely soon to vanish, like the dodo, into the limbo of forgotten things; indeed, it is known that even in the instances in which it is still to be found, it has generally been thought necessary to import a little fine art into the outer office, in the shape of a draughtsman, who may be cunning to devise ornaments and elevations, while his employer, in the *sanctum sanctorum*, improves the shining hour in the more congenial occupation of letter-writing and arbitration, or administering soft soap to his clients. But although this type is passing away, "the evil that men do lives after them," and it is probably mainly owing to the long prevalence of the above-named view of the profession that the architect who takes a higher view thereof is so constantly exposed to the attacks of respectable people, who wish him to look at their orders, to poke his nose into their drains, and to tell them why the

* From a paper by Mr. H. H. Statham, jun., read at a meeting of the Liverpool Architectural Society.

shower-bath does not act properly, in all confidence that this is his proper duty and calling. What that calling really is I have to consider presently, but, at least, it has not necessarily to do with such things as these; for does it not stand to reason that the manufacturers of grates and cisterns and shower-baths, who are constantly engaged practically about them, must know more of them than a man who lives outside of trade and manufacturing operations, and only knows partially by theory what they are practising every day of their lives? The fact is, that this notion of an architect's business proceeds from the idea that tradesmen will always deal unfairly unless there is an architect to check and oversee them. Now, the fact is that the architect cannot check them efficiently, for the simple reason that, in nineteen cases out of twenty, they know much more about the matter than he does; and if there be a foundation for the idea that such a check is necessary, I believe it arises from the fact that as long as you will not trust men they are not likely to be worth trusting, and that contractors and workmen who find a man pretending to overlook and find fault with them about things with which they are much more conversant than he is, are likely to be tempted out of a mere spirit of reticence, to "chisel" the architect in some way or other. And I really cannot see why such a strong line should be drawn between the honesty of the professional man and the tradesman or labourer; or why it should be supposed that a good workman, if treated honourably, would be any more likely to shuffie over his work or to make a job for himself than the architect. Are "jobs" entirely unknown in our own profession?

To go to another extreme, there is a class of architects and art-critics, including some of our cleverest men, who very constantly affirm that the only business worthy of an architect is to design sculpture; and that the building is only a frame to contain sculpture, and is without it perfectly lifeless and expressionless, and unworthy to be classed as a work of art. At first sight it would appear that this amounted merely to a reduction of the number of artistic professions by one, that of architecture being simply merged in sculpture, and disappearing gracefully from the scene, as a superannuated myth. But those who have taken stock at all of the sculptured works from the designs of architects will see that there generally is a difference between these and what passes for sculpture with the leading professors of that art; and that architects' sculpture generally shows remarkably stiff figures and expressionless faces, with very large heads, and legs and arms "of the period" before *biceps* and *gastrocnemius* muscles were invented. The simple fact is that to be a good sculptor or designer of the figure on a large scale is of itself an aim which will demand all a man's time, energy, and study, unless he be one of those exceptional geniuses who appear once in three or four centuries; and as some one must contrive and draw the buildings that must be erected to receive the statuary, it is clear that the architect cannot successfully combine the ordinary business of his profession with the acquirements of a really high power of design in sculpture or painting. He who would succeed in this path must give himself entirely to it. Then there is another theory, tending in quite a different direction, but which is gaining ground a good deal in certain quarters, that an architect is, in fact, only a constructor; or, in other words, that an engineer and an architect are very much the same thing—especially an engineer. That the professions of architect and engineer might be much more closely assimilated than they generally are is probable enough, but what is required is rather that the engineers should know more of architecture than that the architects should be better engineers. The structures erected under the superintendence of architects are generally stable enough; at least failures are not more common in them than in engineering works, though it may be admitted that the engineers have tougher constructional problems to grapple with. But what are we to say of the engineering structures of the day, considered from an artistic point of view? With regard to most if not all of them I must, I fear, he said, that they show either an utter disregard to anything like beauty of appearance or decoration, or else the decoration is attempted in such a manner that it had better have been let alone altogether. The usual engineer's notion of bringing a work under the denomination of "architecture" consists

not in emphasizing and ornamenting the various parts of the construction, so as to render the aspect of the work pleasing while not concealing its strength, but rather in masking the whole construction behind a screen of what is supposed to be architectural design; that is to say, an imitation of some features which have belonged to some period of architecture, and are readily laid hold of and copied. Thus an ordinary brick or stone bridge for carrying a railway over a road or brook, which, if simply built in the strongest possible manner, with a pointed arch and deeper ribs of masonry where the principal lines of pressure act upon it, would be a really pleasing object, is turned into a kind of quasi-architectural sham, with pilasters affixed, and a weak and purposeless-looking blocking and cornice on the top. There is, indeed, a kind of engineer's style, unlike anything that was ever seen in architecture, which is most commonly developed in buildings devoted to the purposes of waterworks; it is not easily describable, but once seen can never be forgotten. Then there is again another theory to the effect that all architectural beauty consists in polychromatic decoration, about which some very fine things have been and frequently are written concerning walls "glowing with colour," "suffused with all the tints of the rainbow" ("throbbing with colour" is an expression I have seen used), and the advocates of this theory would have us believe, on the evidence of some nearly obliterated appearances of colour on the stones of some of the Greek temples, that the Greeks, after selecting the whitest marble from the quarries of Pentelicus, were at the pains to daub it all over with colour, an opinion which, I think, with Mr. Garbett, is against all common sense, and not to be believed on any amount of circumstantial evidence; indeed, if the most indubitable evidence were produced, it would seem far more probable that the buildings were painted over at a later period of debased taste, just as our own Gothic cathedrals were daubed with whitewash; a circumstance which Macanlay's New Zealander, in writing his history of the architecture of ancient England, might adduce to prove that the Medieval architects abhorred colour and invariably whitewashed their buildings to bring them to a uniform tint.

The first time that my attention was drawn to what I venture to think the exaggerated importance attached to coloured decoration by some of its adherents was on the occasion of the reading of a long and valuable paper on the subject by Mr. Audsley in 1860. In the course of that paper, after remarking on the singular absence of coloured decoration in the interior of our buildings, and the bad taste which ordinary house decorators generally showed in such things, when they were attempted, he continued, "Wily, may I ask, are the architects employed upon what is often the mere shell or foundation for artistic display, and the work taken from their hands when (if they are worthy of their profession) their real office begins? An architect is not a constructionist alone, and more, an architect need not trouble his head about it at all, beyond the dictates of common sense."

I have always borne Mr. Audsley a grudge for that sentence, and determined to have it out with him some time or other; for I think that if the building itself is left to be the mere shell for artistic display, then in that case the architect certainly has not been "worthy of his profession," and this brings me to the real point, what after all is his profession? If we deny that it is a mere house-builder and inspector of workmen; if we will not allow him to be merely a decorator; if he is not, as Mr. Audsley truly said, a constructionist alone, and if we cannot admit him to be a designer of sculpture, what ground is there left for him? Simply this—he is a *building artist*. It is his office to use stone, brick, and timber as the painter uses colour and the musician uses sounds; though the analogy with music is the truer one, because both the arts are alike in having no definite expression, or, as it is the fashion to call it, no *phonetic* power—they can appeal to the imagination or feeling, but not to the reason. And if this view of architecture seems at first sight a dry and uninteresting one, after so many writers in the present day have been endeavouring to impress upon us that we are (or ought to be) painters, sculptors, and what not that is grand and exciting to our imaginations, I think a little consideration will show that architecture, pure, as the art simply of building well, has high claims enough upon our interest. For it is the

special privilege of the architect to turn that which would be a mere utilitarian necessity into a source of pleasure, by, in the first place, arranging the plan of his building so as not merely to afford convenience and economy of space, but to be effective in its disposal and arrangement, and in the second place, by the arrangement and grouping of the windows, and of the various masses of building; and by the effects of shadow carefully studied and considered, to see that the building gives some positive pleasure and interest to those who behold it, in recompense for the amount of light and air that it shuts out; so that, instead of being a mere nuisance and excrescence, it should be an object conveying a definite meaning and expression; and, finally, by the judicious application of well-studied ornamental detail where it may help to emphasize and bring out the expression of the building without being too obtrusively prominent, to give the last touch of refinement and point to the design. And I cannot but think that this treatment of a building in the mass is as much entitled to be called a separate art as that of painting, sculpture, or music, though under somewhat different conditions; I believe it is a source of beauty quite complete in itself, and whose place cannot be filled or supplied by anything else, and that we are therefore fully justified in thinking that the architectesque employment (to use Professor Kerr's new word) of the ordinary durable building materials of stone and timber is the real duty of the architect, and is to be regarded as of more importance than the designing of coloured detail in more fleeting and perishable material for the decoration of the interior. If the architect tries to be a sculptor, the sculptor can beat him; if he would shine as a constructor, the engineers can commonly beat him; but, in his own line, as indicated above, he is doing what no artist of any other profession can do for us, and furnishing an important link in the chain of art. And it is certainly desirable at present that we should insist upon this view of the building art as a thing existing distinct from and in addition to the other generally recognised branches of art, for it is only thus that we can rebut the theory which has been of late years so noisily propounded in certain quarters, that there is really no defined profession or art of architecture, and that any one who knows how to construct a building has a right to call himself an architect. Certainly one or two structures which were erected by the upholders of this theory went far to give it the lie, by showing practically that something was wanted to make a building satisfactory, besides what the mere constructor, however talented, could give to it; and it is probable that this theory of the mythical character of the architect would never have been broached, had not we ourselves been untrue to our colours, in neglecting comparatively that which should be really the object of our studies, to run off and try to lay hold of the skirts of the other arts, which have resented the insult by showing plainly enough that they will not be half-worshipped, and that with regard to each branch of art it may be said,—

"Oh, trust me not at all, or all in all."

At the same time, as there can be no doubt that the designing of a building, with its accessories, does call for some acquaintance, on the part of its designer, with certain branches of art and science which are auxiliary to it, it may be well to consider for a moment how far such accessory studies must be carried, in order to render the architect's power of treating his work more complete, while not distracting him too much from his main and principal study—that of building effect. It is unquestionable that a knowledge of construction and of the strength of materials, and the most effective way of employing that strength, must be part of the architect's education; because, in the first place, one of the chief desiderata in his art is durability, both in appearance and reality, and therefore it may be fairly urged that we may go a little further in our constructional studies than merely the "common sense" rather vaguely demanded by Mr. Audsley would take us. I should say that what is wanted is an acquaintance with the leading and broad principles of mechanical statics and dynamics, coupled with as much practical experience as the architect can acquire by a frequent attendance on buildings in progress, and personally inspecting the results of his own constructive design. I think there is scarcely enough of this in the profession, and that the architect, as a rule, remains too much

in his office working over a drawing-board and designing details on paper, when often a personal visit to the building and the sketch of a few details on the spot, with the position in which they are to be placed actually before his eyes, would result in a greater life and expression being given to the building, though the sketches might be rough enough compared with those which can be elaborated in the retirement of the office. But here, I think, the demands of construction stop. It is not to be required of the architect that he go into all the mathematical studies requisite for the engineer. This would be to rob him of much precious time which is wanted for other studies; and his aim is not the same as that of the engineer; he is not required to economise material and accurately calculate how to make the least amount of material do the most possible work; on the contrary, no architectural work can have a satisfactory effect in which the strength of the material is not evidently and palpably greater than the occasion absolutely requires, since it is only thus that the expression of stability and repose, so invaluable in architectural design, can be secured. In short, with regard to practical and constructive knowledge, I should say, if I may be permitted an illustration from another art, that the architect is in the same position with regard to the materials he uses and the workman he employs as the composer of a piece of orchestral music is with regard to the instruments and players in his orchestra. It is not necessary that he should be able to play upon all the instruments himself, or direct all the players how to use them, but merely that he should have a general knowledge of their capabilities and peculiarities, and by constant attendance at performances familiarize himself with all their various effects.

And so with regard to the power of designing sculpture, which has been so much insisted on lately. Perhaps no other study can so much promote the training of the hand and the eye in the use of the pencil, and contribute so much to the attainment of artistic power of design, as the drawing of the figure, either from casts, prints, or life. But with the architect this should be a means, not an end. He should aim at improving his hand and eye, in the first place; and in the second place, when sculpture is to be introduced into a building, it is desirable that he should be able to give a sketch showing the style of design and the grouping which, in his opinion, will harmonize best with the lines of the architecture, and be in keeping with its spirit and purpose. But to aim at the power of making detailed cartoon drawings for the whole design is, I believe, to attempt the impossible, when the number of an architect's other occupations and claims on his time are taken into account. The late Benjamin Haydon had one day been sketching rapidly some figures on a stray sheet of paper, indicating with his usual precision every leading feature of their anatomy. "Oh, Mr. Haydon," said some delighted bystanders, "could you not teach us to sketch figures in that way?" "Certainly," was his reply, "if you will give it eight hours a day for four or five years;" an answer which pretty clearly indicates a painter's estimate as to the possibility of succeeding in figure-drawing as a mere accessory branch of study.

The real art of an architect then resolves itself, as I think, into what may be called artistic building, which consists of three main branches—first, the arrangement of plan, so as to produce an interior combining convenience with effect, while it furnishes the groundwork for a picturesque or architectresque grouping of the various parts of the design; secondly, the main design itself, shown in the grouping, the sky-line, the arrangement of the window-openings, and the contrast of light and shadow; and thirdly, the heightening of the effect by the introduction of ornamental detail; and these three branches must, I believe, always receive consideration in the order above-named. If the elevation or perspective effect of the building is conceived and sketched out before the plan is properly considered, the inevitable result will be that the latter will be sacrificed to the former, and the building will be more or less untruthful. The general design should grow and expand naturally from the plan, combined with the constructive principle employed, whether it be the arch, the lintel, or the tie; and this general design finally determined on, the parts of the building which seem to require or offer opportunity for it may then be brought out, and the rest of the building relieved, by appropriate and

judiciously applied ornament, which, I think, should be more sparingly used than it often is in the present day, and which should, and on the principle just indicated probably would, have the appearance, not so much of an extraneous natural outgrowth inborn in it and necessary for its complete expression. And whoever will consider all that is involved in worthily and adequately carrying out these three requisites of a purely architectural design must surely admit that it affords matter enough of itself to employ a man's time and talents, and that no slight education must be required fully to develop the power of successful architectural design as just defined, and that it is even matter of importance that the time and exertion of the architect, both while he is a pupil and after he has entered into practice, should not be unnecessarily diverted to studies or work which will not directly promote this object. And, considered in this point of view, the subject of an architect's education assumes an aspect of serious importance, and the more so as it must be admitted that the system of architectural education in this country at least is very defective, or it might be more correct to say that there is no system at all. A young man is articled to an architect for five years, without the slightest understanding or stipulation as to what he is to be taught, or how he is to be taught it, only with a general understanding that he is to learn the profession. In some cases it is to be feared that the matter, so far as the architect who takes (or "takes in") the pupil is concerned, ends here, and that perhaps no attempt at all is made to give any special instruction, but that the pupil has just the run of the office and picks up what he can or will, which is often little enough. And even in cases—let us hope not infrequent—where the master accepts his responsibility and conscientiously endeavours to do all he can for his pupil, what can this amount to, amidst the daily duties and routine of an office, but a series of desultory bits of instruction, given at odd times, not bound together or arranged into any definite system which could give a clue to the real importance and value of each scrap of information communicated, and its relation to the whole scope of the profession of architects?

What is it that a pupil learns by this process? Not certainly the art of architecture, but rather the peculiar practices of his master. The whole thing appears to me to be a commencing at the wrong end; isolated facts and lessons being given to the student before he has had any general education which would enable him to take a broad view of the meaning and object of the profession, and refer the information which he picks up in the office to its proper place in the scheme, and give it its proper value. The first thing surely that an architectural student should be taught is the general history and principles of the art which he intends to practise; the practical details and more minute instruction should come afterwards, when he has gained sufficient knowledge of the real object and tendency of his profession to be able to understand how the practical lessons and instruction which he receives tend to aid that object, and what their real value is. To act otherwise is about as reasonable and philosophical as if we were to attempt to teach a new language by explaining the meaning of a word here and there, without giving any analysis first of the grammar, construction, and idiom. I believe such a thing as an architectural college or academy might be very valuable in remedying this defect, by giving a general education on the subject previously to the student coming to the office to learn the practical details and working of the profession; but there are great difficulties in the way of establishing such an institution, and the history of some other art-academies of a similar nature in this country proves that such things are not always successful in accomplishing what they profess. Failing this, I think something might be done by private tuition with this special object; and the efforts of any competent and thoroughly educated architect, who might be able and willing to establish a class for preparatory tuition in the history and principles of architectural design would deserve the highest encouragement; and if our profession could once be put on the same kind of footing as those of Law and Medicine, and a diploma, given after a sufficient examination, could be made the condition of any one practising as an architect, it would probably very much aid architectural education, by marking out a definite path of study and affording a

definite standard to work up to. Not that I would advocate a competitive examination, but merely one which would afford evidence that the candidate had learnt the history of his art, knew in what it consisted, and was sufficiently instructed in the practical part of it. The rage for competitive examination I consider to be one of the evils of the present day, and in matters like architectural design success in such an examination is no test of real power, because one man may be a much readier and more rapid draughtsman than another, and may dash off, with little thought or consideration, a kind of *bravura* drawing, which will look very well, while another, with less of this ready facility of execution, might in a rather longer time furnish a design exceeding in thought and originality anything that the more rapid draughtsman could produce under any circumstances. And this leads me to mention what I have often thought a very serious evil in the practice of the profession among us, namely, the time frequently spent over work which can have no effect upon the actual success of a design when executed, and more particularly I refer to the absurd and disproportionate time and trouble constantly spent in "getting up" drawings and perspectives.

It cannot be too often repeated and urged that the real value of an architectural design is exactly in proportion to the amount of thought bestowed upon it; and I cannot but regard the time frequently spent in elaborating elevations and perspective views as the waste of so many precious hours which might have been so employed as to ensure the design being a greater success when executed than it can be expected to turn out when so much of the architect's energies have been employed in making it look pretty on paper. With regard to the rage for perspective views especially, we might take a lesson from our French neighbours, many of the best critics among whom expressed their astonishment at finding scarcely any plans or elevations among the English contributions to the recent Paris Exhibition, one of them plainly saying that the English architects seemed to think of nothing but making beautiful pictures. Yet, I believe, the annual Architectural Exhibition invariably consists almost entirely of perspective views, often unaccompanied by any plan; and, if the exhibition is intended as a pleasing and attractive resort for young ladies and their admirers, who may please themselves by fancying they are studying architecture, this is all very well; but no exhibition on such a principle could really afford matter for valuable study to an architect, who, if he is to learn anything from drawings, must have such as will show him the progress and construction of the design, not merely the final result, and that too in a form which may be, and often is, cooked up to look much better than the reality. Paradoxical as it may seem, I believe that the architect might often be more profitably employed in general study not specially connected with architecture than in producing drawings; for the last and not the least important answer which I shall hazard to the question "What is an architect?" is that he should be emphatically and truly an *educated* man. There are special reasons for this in architecture beyond what exist in sculpture or painting; for in these arts a good deal of the effect of a work depends upon its reproduction of forms and effects already existing in nature, and the mere evidence of power on the part of the artist thoroughly to understand and reproduce nature will frequently of itself raise a work into the class of high art; nor have there been wanting instances of men whose paintings will always take a high rank, who were themselves in private life both vicious and vulgar, but whose works were redeemed from these qualities simply because they were so faithful a transcript of nature and gave such unmistakable evidence of power of hand and correctness of eye. But the architect has no such guide; he does not anywhere directly copy nature, but rather has to lay bold of her principles and adapt them to his use in grouping buildings and designing ornament; he has to look beyond the natural, the *τὰ φυσικά* of the Greeks, to the *μετὰ τὰ φυσικά*, the metaphysical principles and motives which underlie the separate forms which appear to the eye; and similarly in availing himself of the works of his predecessors he should study not the actual forms employed by them, but endeavour to catch their spirit and principle, and apply it to his own purposes. But to do this, to make this kind of analysis of the principles of beauty which alone will save us from dropping

into pure copyism, either of nature or of our predecessors, requires no small mental training, and presupposes a generally high cultivation of the intellect. I cannot do better than quote here the admirable words of Mill, in his address delivered at the university of Glasgow, which apply as fully to our own profession as to those to which he alludes.

"What professional men should carry away with them from a university is not professional knowledge, but that which should direct the use of their professional knowledge, and bring the light of general culture to illuminate the technicalities of a special pursuit. Men may be competent lawyers without general education, but it depends on general education to make them philosophic lawyers, who demand, and are capable of apprehending, principles, instead of merely cramming their memory with details. And so of all other useful pursuits, mechanical included. Education makes a man a more intelligent shoemaker, if that be his occupation, but not by teaching him how to make shoes; it does so by the mental exercise it gives and the habits it impresses."

And with reference to our own profession it may be observed also, that, in consequence of its forms and development being much more under the control of the designer and dependent upon him, than in the case of sculpture or painting, it follows that much more of the tone of the designer's mind, and the refinement or otherwise of his taste, is often apparent in his works than in those of the sculptor or painter; and indeed it may be said that there is no profession, save that of a literary man, in which vulgarity of mind and want of general education on the part of the worker more surely show themselves in the work, than in that of architecture. And though a man who is content to take this view of his profession, and to give less attention than is usual to the acquirement of the facility in drawing and throwing together a design which is considered nowadays so valuable an attainment, but which, in fact, deserves little higher name than mere "sleight of hand," will find that for the present at least he will probably be distanced in the race by the rapid draughtsman who falls in with the fashions of the day; he will at least have the satisfaction of feeling that what he does execute is based upon some fixed principles, and that he may be quietly laying the foundation for the power of producing, at some later period, work which will not only satisfy himself and please his contemporaries, but may continue to give pleasure to people of cultivated taste in future generations, when the productions of the mere draughtsman will be counted things of a worn-out fashion. And even if he never have the opportunity of doing this, he will still be repaid by the broader view of his art, and the consequently greater enjoyment of what is best in it, which his superior education will afford to him; and amidst the vexations and littlenesses which will jar upon him in the daily pursuit of his calling, he will be able, to quote again the words of Mill, "to keep up the tone of his mind by frequent visits to those higher regions of thought and feeling, where every work seems dignified in proportion to the ends for which, and the spirit in which, it is done."

I cannot but feel that in vindicating the existence of architecture as a separate and independent art, and consequently the profession of the architect as a real and important one, I have not said half as much as might be claimed in its favour, nor have I even attempted to do so, as, not wishing to rhapsodise, I have confined myself to merely defining it as the art whereby that which would otherwise be an exorcism and eyesore on the face of the earth is converted into a source of pleasure. But of architecture, in its highest forms, much more might be said than this; for there have undoubtedly been structures, even the ruins of some of which still tell us, which may claim a place among the finest and most inspiring forms in which the spirit of art has ever been manifested on this planet. And, in opposition to those who on the one hand would reduce architecture to mere mechanical contrivance, and those who on the other would represent it as merely the vehicle for the display of elegant ornament, irrespective of its total effect, let it be remembered that many of our greatest poets have drawn their finest similes from pure architecture, considered as the display of vast proportions and contrasted masses of building; and when Milton would describe to us the fame that of his fallen angels enjoyed in brighter regions, as the archi-

tect of the celestial palaces, he does not refer to his proficiency either in sculpture or colour, or in the minute details of ornament; it was with greater objects than those that his name had been connected:—

"His hand was known
In Heaven, by many a tower'd structure high."

TASTE.*

THE subject before us has for its object beauty, concerning which much has been written, but, to us it seems, in a much too metaphysical manner, and our endeavour will be to put it before you in as plain and practical a way as possible.

To convey the exact meaning of the expression good taste is almost impossible, and in attempting a definition we seem in danger of circumscribing nature within the bounds of our own notions, formed, perhaps, from a limited and personal consideration; but, for convenience sake, we shall consider good taste (applying more particularly to nature and art) to be the perception of intellectual pleasure, and that beauty, the object of this taste and the source of this pleasure, is appreciated by the understanding, exercised either upon the works of nature or the productions of art.

There are some who have written on the theory of beauty, who maintain that the perception of it arises solely from the association of ideas which crowd upon our imagination as we gaze upon the objects of our contemplation. Now, we think otherwise, and will attempt to show that it is not so, but that the association of ideas only enhances that beauty which is appreciated by the understanding.

If our perception of the beautiful were only in proportion to the association of ideas, we could not well understand how such a taste could be cultivated to any degree of perfection, or well brought under the dictates of reason and reflection; whereas, if we consider it subject to reason and reflection, as appreciated by the understanding (in conjunction with association), we can more easily perceive how good taste, or, what is the same, a just appreciation of the true and beautiful, can be improved or acquired in any useful degree, and that only by persevering and well-directed study, reflection, and cultivation.

From the opinions opposed to this have resulted the worst effects, not only among those who practise art, but in many of its patrons. How often do we find those whose attainments by no means qualify them for judges, condemning, or eulogising, with a degree of peevish confidence and impunity, works of art from what they are pleased to designate as a natural taste. Now this, if it means anything at all, simply signifies an untutored and consequently imperfect taste. It seems the grossest illusion, with an odd admixture of ignorance, in any one to imagine that he should be capable of judging or criticising an art of the very elementary principles of which he is utterly ignorant.

Goldsmith, in describing Sir Joshua Reynolds's conduct towards those somewhat of this class, says,—

"To excoarce averse, yet most civilly steering,
When they judged without skill, he was still hard of hearing."
When they talked of their Raffaels, Correggios, and stuff,
He shifted his trumpet, and only took snuff."

It is such as those now described whose maxim is, that taste is not to be disputed, which proverb has arisen, no doubt, rather from the acknowledged prejudices than from the deductions of sound reason.

We do not wish to be understood as maintaining that individuals do not possess a certain amount of natural taste; on the contrary, they generally do; but we firmly maintain that unless this taste be assiduously cultivated, it is of very little value, if any, to its possessor; and this same principle applies to the other arts.

Those who boast this natural taste are attracted most by compositions, such as interiors we often see by Dutch painters, in whose efforts pots, clear glistening pans, and garden-vegetables abound; in fact, scenes from ordinary life have greater attractions for them than those which represent a more cultivating and refining feeling. Nor is this to be wondered at: such subjects are exceedingly easy of comprehension.

* By Mr. Alexander Fraser. Read at a meeting of the Edinburgh Architectural Association.

and require almost no effort of the mind to feel their merit; but to appreciate the ideal beauty, the cultivated and ennobling sentiment in the compositions of those worthy the name of painters, is a vastly different acquirement, and only, as we have said before, to be gained by patient and properly-directed study, even as the improvement or perfection in the knowledge of any art can possibly be attained; and again, the artist who succeeds in gratifying this so-called natural taste, is, in relation to refined taste, one of the lowest order of true artists, being endowed with that poorest and lowest aim—mere imitation.

We will now explain the expression, ideal beauty,—the beauty of which we speak: it consists in bringing perfections existing in various individuals or natural objects into one grand harmonious whole, making an aggregation of beauties which are constantly to be found in nature, but never altogether in the most favoured individual or natural object.

We will not attempt here to state the necessary acquirements to perceive the true and beautiful, especially in works of art, and will content ourselves in saying that correctness of eye is absolutely necessary in judging of form, grace, and proportion; and we are compelled to admit that this correctness is only acquired, in any useful degree, at all events, by well-directed study and practice. If we be wanting in this qualification, it is absurd to suppose we can be imbued with the true feeling of good taste.

But to return to the association theory of beauty. Mr. Alison in his work describes the emotion of a spectator on his first prospect of Remo. He says, "It is not the scene of destruction which is laid before him," &c., "but it is the country of Cæsar, of Cicero, and of Virgil," and concludes by saying, "Take from him these associations, and how different would be his emotion." But let this spectator be one whose object is the acquirement of knowledge and the study of beauty, to him this distant view is not sufficient;—no, he approaches nearer to those magnificent remains, from which, through association, he has derived so much pleasurable emotion, and there beholds the perfection of that beauty which is perceived only by the cultivated mind, capable of appreciating the delicacy, grace, and proportion presented there in such glorious and wonderful profusion. Now, if the beauty of these remains arose solely from association, piles of meaningless, unsculptured stones, massed rudely together, would suffice, instead of that which bears the stamp of true genius and the unmistakable evidences of the works of minds of the highest state of cultivation and refinement; and, we would ask, for what reason is it that artists of the first standing visit these and similar scenes? Is it to feed their imagination and to overcome by dreamy influences? Surely not; their mission bears a higher and more practical issue, as may be discovered from their respective works, when again among us, their minds elevated and refined by the study and contemplation of the works of the older and more perfect masters. And again, what to the man influenced solely by association of ideas is the effect of the play of delicate light and shade, thrown charmingly on these venerable piles by the mellow rays of a golden sunset? To him all these beauties are speechless; but to the man who gazes with a critical eye, these, and more than these, are not displayed in vain or unperceived, but only lend enchantment to that which is the source of so much intellectual gratification.

It would seem that what is considered true beauty is often applied to objects, the admiration of which arises solely from mere selfish sentiment. An individual may be in possession of really ugly objects, but which (from the interesting associations of ideas they recall to his memory, on which he loves to dwell) may be interesting, but surely not beautiful, as some would uphold.

It would be needless, we think, to adduce more instances of the difference between that beauty which is perceived through association, and that through reason, study, and reflection, or what is the same relative and abstract beauty, or that beauty which exists in the object or objects themselves.

Indeed, it seems to us that this associated beauty (if we may be allowed to call it so) is not altogether the beauty which is the object of the taste we here speak of. To illustrate what we mean, the law of gravitation possesses a first principle of the beautiful,—simplicity; so the refined mind must receive gratification from

of the study of this theory; but this beauty and gratification are perfected by associating with this simple law the fact that worlds are thereby governed in their course through space.

And again, the bolier and lovelier sensibilities awakened by moral beauty, being distinct in their principle, are not, we think, to be classed under that beauty of which the taste we speak of is the object.

To us it seems that combining the influences of these distinct beauties, as affecting good taste, has occasioned a considerable amount of unprofitable dissonance; and that while the one applies almost solely to the heart and feeling without any direct reference to cultivation, the other applies almost entirely to that cultivation which is governed by, and subject to, certain rules,—rules by which we appreciate a beauty, an excellence, the offspring of truth and reason, and like these ever consistent and imperishable.

As we have shown how beauty, the object of taste, is not solely derived from association of ideas, but is governed by rules, we will now attempt to show that there is a standard of this beauty.

If there were no stable and unerring principles of judgment, there would be neither merit nor dignity in the works of the most gifted mind.

Good taste is not only progressive, but inductive, being the result of a series of experiments, the object of which is beauty; and as in all experimental sciences these researches, most carefully conducted and in their inferences most consistent, are accepted as the canons of scientific truth; so in the liberal arts, those productions which for the longest period have afforded most delight to those capable of appreciating their true merit, are rightly considered standards of taste, by which succeeding works must be tested.

Such standards in the science of taste we possess in literary compositions, sculpture, painting, and the architecture of antiquity, and of modern masters, adept pupils of their ancient masters.

It has been adduced as proof of there being no standard of taste, that mankind do not agree in their estimate of beauty; but this objection can be removed by the principle we have attempted to establish, namely, that taste is the result of intellectual cultivation; and this principle accounts for the diversity, the consequence of the varied extent of knowledge enjoyed.

We will now cite one or two objections to the existence of a standard of taste. We are told that the savage Indian considers his squaw to be the most perfect type of beauty in woman-kind. This is right enough; so would the refined European, judging from the benighted Indian's standard. This savage acknowledges a standard, but which, of course, is formed and modified by his moral and physical condition, and the amount of enlightenment enjoyed.

And, again, we are referred to the various and contradictory objects of beauty existing in the lower animal species,—that this one is admired for the length of his neck, the other for its shortness; this one for its length, the other for its breadth, and so on; but this does not prove the non-existence of a standard, but the very essence of our principle, and shows that each separate species will have its own standard, which excellence is only learned and appreciated by properly-directed study.

Taks man himself, the most perfect animal created. Now, because he possesses two legs, are we to consider every four-legged animal ugly? The absurdity of this is at once apparent. Voltaire even says that a toad will consider the perfection of beauty as resting among toads: this is further proof of our principle; if the toad had had the least amount of brains (which he has not), he would have had more sense, and considered nothing of the sort.

What we have attempted to show is, that the possession of good taste, or a true perception of beauty, is, as Dr. Samuel Johnson has defined it, "skill."

Nothing has tended more to retard improvement than placing taste and genius in opposition to reason and application, and investing the two former with some intangible, undefined excellence, incapable of being properly tried by any test, or regulated by any standard, and superior to the drudgery of study. How does this accord with fact? The greatest geniuses who have bestowed on mankind the most perfect productions have applied themselves as much to the study of rules and principles as to the production of new works. If there were no standard

of taste, of what advantage to succeeding knowledge could the works of the greatest masters prove? Nothing, save a passing pleasure, degrading excellence in the most refined minds to a mere knack, an unaccustomed aptitude, rendering the very progression of knowledge or improvement among men uncertain.

We would urge, in conclusion, the advantages to be gained by the cultivation of taste: it is one of the most ennobling and refining pursuits of the human mind, and possesses peculiar incentives of its own; for the more we cultivate this faculty, the greater will be the inducements to continue our researches.

"To love the beautiful in all things," Sir E. Bulwer Lytton observes, "to surround ourselves, as far as our means permit, with all its evidences, not only elevates the thoughts and harmonizes the mind, but is a sort of homage we owe to the gifts of God and the labours of man."

DIGGINGS IN ROME.

The Government of Pins IX. has been, and continues to be, active in carrying on public works to a degree which, if short of what is desirable, is yet somewhat beyond what might be expected from a habitually slow-moving system under present embarrassments. One of the undertakings now in progress has the object of displaying more fully to view than hitherto the beautiful ruins of the Octavian portico, sunk in and in part hidden by the buildings of an insignificant church and of obscure streets, near the *Ghetto*, or Jews' quarter. The earliest mention of this portico is found in Suetonius, where he recounts the public improvements of Augustus, and the edifices raised by him in the name of other persons, his relatives. And Dion tells us that in the great fire under Titus, A.D. 70, a library, which the widowed Octavia had dedicated to the memory of her lost son, Marcellus, probably in the vicinity of the building, which suffered from the same disaster, was destroyed with all the books contained in it. "The building and the books were at the same time burnt." Majestic in ruin, notwithstanding unsightly incumbrances, is that portico, dedicated by Augustus to his virtuous sister, who, by her second marriage, became the neglected wife of the Triumvir Antony. On the ancient plan of the city (now in the Capitoline Museum) we see a portion of it preserved sufficiently to explain its character: a parallelogram surrounded by a double colonnade, about 750 Roman feet in length, 500 in breadth, and with a propyleum, or porch, projecting from the narrower front, with four columns and two ante, from which to right and left extended the front colonnade, eight shafts in double file on each side; the lateral colonnades having each more than twenty-five in double file at the least, since twenty-five is the number of columns in the fragment of the heap, presenting to us a portion only of this building. In the centre stood the temples of Jupiter Stator and Juno Regina, also a Curia, and a *schola*, called after Octavius; the former of those temples, founded by Metellus, named (from his victories) Macedonicus, about the year of Rome 606; the latter by the Censor M. Emilius Lepidus, who had made a vow to build it during the war against the Ligurians, A.U.C. 575,—both temples having been rebuilt by Augustus in the year 721, with the architecturæ of the two Creeks, Sarcos and Batrachos, of whom Pliny relates the contrivance to transmit their names to posterity by sculpturing a lizard and a frog on the torus of the bases to certain columns in this same portico, where they were not permitted to chisel their names in letters. The portico itself is known to have been not a completely new structure, but an amplification, with increased magnificence, of another, founded, on this site, by the above-named Metellus after his Macedonian campaign. What we now behold is nothing more than the ruins of the propyleum; all the rest, the colonnades, enclosed parallelogram, the two temples, and curia, having totally disappeared, except a few fluted shafts and capitals to be seen walled up in the houses of the narrow streets adjacent; and this remnant of classic architecture, as it stands before us, is not the original building of Augustus in every detail, but the restoration by Septimius Severus and Caracalla, as conveyed in the last words of an inscription on the frieze with the two emperors' names, "*incendio consumptum restituerunt.*" Within its quadrangular area was built, so early (it is supposed) as A.D. 755, a

small church, *S. Angelo in Piscaria*, modernised in the poorest Italian style, first in 1611, and again in 1700. The intercolumniation, behind which stands that church's front, was walled up; a great part of the colonnade and triangular pediments on the inner side concealed by the modern building; but still were left, in graceful antiquity, the Corinthian capitals, the fluted marble shafts (though but in part visible), and the mutilated reliefs of eagles holding thunderbolts (allusive to the worship of Jove in the temple adjacent) on the abacuses; a lateral cornice, under which remains of the pediment on one side still retaining its ornamentation of sculptured antefixes. The arch of this ruin is flanked on one side by the church; on two others, by brick arches, the work of Severus, resting on architraves of white marble adorned with rosettes in relief, and we may conclude that the same marble originally encrusted those arches now left in the naked brickwork. The outer side, or front, originally formed of four Corinthian columns and two ante, now presents but two columns, the place of the others which are wanting filled by a brick arch, added (as inferrible) either in the restorations by Severus, or (as perhaps more probable) in later and inferior restorations, perhaps A.D. 442, after injury done to this, as to many other Roman buildings by earthquake (c. *Mnatori, Rev. Ital. Script.*, t. i., p. 1). The works now in progress have already effected the uncovering of three columns and of the entire pediment on the inner side, also of the basement and threshold beneath, down to which we can now see in an excavated area opened before the church, and crossed by a bridge of masonry; that church's front having been taken down and rebuilt on a line thrown farther back, so as to leave the columns almost isolated, instead of concealing them within its walls, as formerly. This is a great improvement; and the graceful ruin now stands amidst the gloomy buildings of the fish-market, whence that dedication, *S. Angelo in Piscaria*, presenting a very different aspect from that seen in past years, and familiar in engraved or coloured views of Roman monuments. We read of the profusion of Classic sculptures that adorned the Octavian portico, the temples, and the spaces intervening. Celebrated paintings were seen in the *schola*. The seventy-five equestrian statues in bronze, by Tisippos, of the officers of Alexander the Great, who perished in the crossing of the Granicus, were placed before the two temples by Metellus, who had brought these bronzes from a city of Macedonia; and the most precious earnest of the artistic wealth lost, destroyed,—who knows how much may still lie buried under the ground near the extant ruins?—was obtained in the seventeenth century, by the discovery of the *Venus de' Medici*,—if indeed the report be true, first given by Santa Bartoli, that the celebrated statue was found beneath a spot occupied by some of those Augustan buildings.

But the works that have lately excited most attention, and attracted throngs of visitors to the spot, are those also carried on by Government, and directed by the well-known secretary of the Roman Archaeologic Academy, Signor Visconti, on the site of the ancient Emporium, upon the steep bank of the river between the Aventine and the Porta S. Paolo. The extent of level ground in this region, within the Honorian walls, though far from the inhabited streets of Rome, is well known as the ground once occupied by the various buildings of that Emporium and the *Navalia*, to which are referred several vague and formless but picturesque brick ruins among the gardens, on the western slope of the Aventine, besides others more conspicuous, in gardens near the river, as well as the arch of brickwork, crossing the high road between that hill and the Ostian (or S. Paul's) gate, called from a little chapel and hermitage close by, *Arco di S. Lazzaro*. The Emporium, a harbour and market for foreign goods here unshipped, was founded by the *Ædiles M. Emilius Lepidus and L. Demetrius Panlus*, in the year 193 B.C., between the Aventine and the Tiber; and farther off, southwards, were constructed the *Navalia* (dock-yards), with magazines on the level nearer to the city walls. The excavations on the bank of the river, reached by a narrow path that strikes off from a platform, still used for the deposit of sculptors' marble brought hither up the stream, and therefore called the "*marmorata*"—these works that have won such praise for Visconti,—have laid open, on a steep slope immediately above the water, a considerable extent of business wall, in firm *opus reticulatum* mixed, in the usual ancient style, with layers of interstitial

masonry; and at the foot of this a ledge paved with tiles, from which is an ascent by a zig-zag path, similarly paved, to the summit of those walls, where we must find the place of deposit of goods here unshipped. The wharf, with its pathway for trucks, is here recognizable, and this purpose of the whole is made still more evident by the accumulation of hewn marble blocks, that lie strewn around, in the greater number of green-veined Carylitan called *cipollino*, with some specimens of African *breccia*. Forty-eight such blocks were left buried for ages, having (as the official gazette informs us) been found before the 14th of February. Several smaller fragments, more finely wrought, in porphyry, rosso antico, and other coloured marbles, as well as pieces of glass vessels and terra-cotta lamps, are spread out on sale, under care of some superintending workman. The Pope, who has inspected these discoveries, has rewarded Signor Visconti with a gold snuff-box, set with diamonds. More imposing ruins of the Navalia are seen in an extensive garden of Prince Torlonia, between the road under the Aventine and the river-bank; but at some distance from the site of those excavations. Here, too remote to be seen from any highway, and therefore very little known or visited, we find considerable remains of a lofty structure, in brickwork, forming three sides of a quadrangle, the fourth side having, as apparent, been left open to the river, with whose banks it corresponds, to be approached by steps from the water-level. On one side the ancient walls are opened by a row of wide arches; on another they are pierced by round-headed windows in the upper part, which, as they do not seem to belong to the original plan, we may suppose to have been formed at some Medieval period, and to have served for habitations, thrown up against the antique building. It is assumed that the date of these structures may be about the same as that of the Emporium; their masonry is of concrete, faced with brick; not of the better Roman style. The Aventine, with its contents, Monte Testaccio, the Trastevere quarter of the lower banks of the Tyber, are seen in a picturesque grouping of objects from these spacious garden-grounds, a pleasant sunny spot, which, with its solitude and ruins, forms one of the interesting byways, little known, or named, so many of which may delight the explorer in Rome.

THE TECHNICAL INSTRUCTION MOVEMENT.

A PUBLIC meeting has been held in Hulme Town-hall, under the auspices of the Amalgamated Society of Carpenters and Joiners, in support of a movement by the members of the Society in the Manchester and Salford district, for the promotion of technical instruction among the artisans employed in these trades. The numerous lectures on the subject given in the principal centres of industry in England, and the comments of the press in reference to foreign competition, have had the effect of stimulating some members of the Society to take the matter practically in hand. Their efforts have been directed to the formation of a school for technical instruction in mensuration, drawing, practical geometry, mechanics, and other matters relating to their daily work; and they have resolved that all the classes in connexion with the school shall be open to those who desire to attend, whether they be members of the Society or not. The executive council of the Society, located in London, has warmly recommended the project, and its promoters state that they have received during the past month from several gentlemen of prominence conversant with the subject, assurances of the high estimation in which they hold a movement which, as they remark in the prospectus of the new institution, "stands amongst the first instances, in the industrial history of our country, of a trades' union undertaking to promote a plan for the education of its members." The use of St. John's Schools, Gartside-street, has been obtained for the accommodation of the classes, the services of efficient and practical men as teachers have been secured, and the classes meet every Tuesday and Thursday evening. The aim of the promoters is not confined to mere class-work, though that of course forms the most important feature of their plan; but the members of the institution are to be invited to engage in a series of competitive prize essays on subjects connected with their practical

studies; and it is also proposed to have lectures and papers from gentlemen of scientific eminence, and to establish orders of merit and honourable degrees in connexion with the subjects of study. The meeting was numerously attended by artisans of both crafts. The chair was occupied by the Mayor of Manchester (Mr. R. Neill), himself a practical builder, and a large employer of skilled workmen in the trades for whose benefit this institution is intended.

Mr. Scott Russell, in moving the chief resolution, said he was one of the—he would say fortunate—men who had enjoyed the two things rarely combined—the blessing of a university education and the blessing of a workshop education. If he were asked which of those two privileges he valued most, and which had been the greatest pleasure and comfort to him, he was sure he could not answer the question; but he said for himself, his children, and his friends, if it could be given to the rising generation, let them have both. He strongly deprecated the practice of introducing hard names for things which could be easily rendered intelligible in plain English, and strongly advised that the promoters of this school should procure the services of a master who possessed that qualification. He was glad to see they proposed to teach geometry—although that was a hard name, and the use of it was bad—which simply meant, in plain English, the knowledge of shape. He dwelt upon the importance of elementary geometry, and the far higher geometry which we know nothing about, the knowledge of curved shapes. He instanced the wonderful aptitude of the Greeks for this description of work, and contrasted the inferior knowledge which the English workman possessed in this respect as compared with the foreigner. He did not know an English joiner who knew how to make an oval, but those of them who had visited the Paris Exhibition must have had their attention directed to the fact that the French could make ovals, and if they studied a French oval, they would find it one of the most exquisite specimens of carving they ever saw. Therefore, he was glad that they were going to learn the principles of shape. The next set of principles he observed they were going to learn was that of mechanics, and he need hardly tell them that if they were well-taught mechanics, a knowledge of those principles would give them a thorough mastery of their tools. With regard to the methods of learning, he would say this: begin first by learning the profound and essential principles. And they should not understand that because a principle was profound it was difficult to learn. If they procured a clever master, he would put the profoundest knowledge in the simplest possible language; and he knew nothing that was intelligible and worthy of knowing that could not be conveyed in plain English. He was not one of those who said they were afraid of the foreigner running away with the laurels of the English workmen. He was not afraid of the English workmen being beaten, because he knew, first, that from youth upwards they took a pride in doing a good job; and, in the second place, that they could put energy and heart into the work. Mr. Russell concluded by moving the resolution,—

"That this movement for the promotion of technical education amongst the carpenters and joiners is deserving of all support, not only on account of its value to the trade, but for the interest it will give to the workmen in their work; and that, as intelligent artisans, their work will be done better, and they will feel a greater pleasure in doing it."

Dr. Parkhurst, Mr. Jacob Bright, M.P., and the Rev. J. P. Hopps having addressed the meeting, the resolution was unanimously agreed to, as was another, moved by Dr. John Watts,—

"That as this movement will have the tendency of removing that prejudice existing against all trades' unions because of the deeds of darkness perpetrated by a few, this meeting calls upon all artisans, builders, &c., connected with the trade to assist in its successful adoption."

STEALING A STATUE.—At one time "stealing a statue" appeared about as likely a feat as that of stealing a railway arch, but the former feat has lately been accomplished in France. The men in the employment of M. Hoyaux, founder, at Meux, were astonished, on going to their work a few days back, to find that a bronze equestrian statue of the Emperor Baudoin, of Constantinople, placed for safety under a shed, had disappeared. Notwithstanding its great weight, a robbery was possible from the fact of the casting being in four pieces. The watchman of a neighbouring factory heard during the night one or more heavily-laden vehicles pass.

THE PROPOSED MEMORIAL OF THE LATE LORD FEVERSHAM, HELMSLEY, YORKSHIRE.

WE mentioned some little time ago that it was proposed to erect in the Market-place of Helmsley, a Memorial of the late Lord Feversham, from voluntary subscriptions by friends and tenants; and that a design, obtained from Mr. Charles Barry, architect, had been approved of by a public meeting, and was to be carried into execution forthwith. This being settled, an illustration of the design was prepared, and is published in our present issue. It appears, however, that a change has been brought about by some means, and it may be useful to report briefly the proceedings.

At starting it was proposed that the Memorial in question should be wholly independent of any memorial or monument which the family might erect either in the parish church, now in course of restoration, or elsewhere. This course was taken with the full approval of the present lord, as evidencing a more emphatic and unflinching desire to do his father honour on the part of those among whom he had lived so many years.

A market-cross was finally decided on (after a good many suggestions) as the shape the memorial should take. An influential committee was appointed, and they requested Mr. Barry (who had been identified with the estate and the late lord as his architect for twenty years) to advise and act for them.

A design was accordingly sent down, and at a meeting held directly after, it was adopted "by an overwhelming majority," with such additions as an expected increase of the funds should admit of. To meet this resolve a more elaborate design, to cost about 800*l.*, was sent down, was submitted to Lord Feversham, and approved. Another meeting was then held, when the improved design was adopted, and some additional subscriptions were announced.

The material of the memorial was to be a fine-grained warm sandstone from Bilsdale (to be given by the present lord); the emblematical figures of Justice, Mercy, and Truth were to be in red Mansfield, giving relief of colour and individual importance to them as works of art. The pedestal was to have a portrait bust, in alto-relief, of the late lord on one of its faces; on the opposite one a dedicatory inscription; and the other two panels were to have bas-reliefs illustrative of some of the tastes and pursuits of the late lord. A contract was arranged with a local mason, and an eminent London sculptor had agreed to execute the figures and panels.

At the final meeting, however, 7th of March, called to receive the report of the committee appointed to collect subscriptions and to proceed with the work, a design by Professor Scott was handed in by a member of the family, and its acceptance urged on the subscribers by an undertaking (as its cost far exceeded the design which had been made by Mr. Barry, to meet the means at command of the committee) that the amount of its extra cost would be found by some of the members of the family. This design was made by Mr. Scott in ignorance of previous proceedings, and he naturally hesitates, as we are told, under such circumstances, to proceed.

We have here another instance to be added to the long list of those where a committee seems utterly to forget, or trifle with, the honourable obligations they enter into with professional men.

OFFICES OF THE SCOTTISH PROVINCIAL ASSURANCE COMPANY, DUBLIN.

THE offices for this company, in Sackville-street, Dublin, have been erected from the designs of Mr. T. N. Deane, architect. They stand at the corner of a street, so as to show two sides, and the style adopted may be spoken of as a free treatment of Scottish Gothic. Elliptical and straight-headed windows are made use of. A turret at the angle, corbelled out over the ground-floor and terminating with a conical roof, gives importance to the structure. On the ground-floor are the offices of the company, including public office, waiting-room, board-room, and secretary's room. The upper floors are arranged for letting as offices, and the basement will be let for wine stores. The total cost was about 4,000*l.* The materials used are granite, Scotch stone, and lime-stone from Skerries, near Dublin. The builder was Mr. G. Carolin, of Dublin.

THE FIRST ACCEPTED DESIGN FOR THE FEVERSHAM MEMORIAL, HELMSLEY, YORKSHIRE.
By MR. CHARLES BARRY.

THE SCOTTISH PROVINCIAL ASSURANCE OFFICES, SACKVILLE-STREET, DUBLIN.
MR. T. N. DEANE, ARCHITECT.

THE TRADE MOVEMENT.

The Potteries.—A dispute between the builders of the Potteries district and the carpenters and joiners, as to the hours of labour, was lately referred to Mr. J. E. Davis, the stipendiary magistrate of the Potteries. The masters proposed that the carpenters and joiners, who go to work at six and leave off at 5-30, should begin later in the winter time, and leave off at six all the year round. The men resisted this proposal, and Mr. Davis has decided in their favour.

Bradford.—The unionist journeymen painters of this town have struck for an advance of wages. In 1864 the wages of the men were 22s. to 24s. per week of fifty-eight hours; but in the following year the mode of payment was altered to the hour system, and was fixed at 54d. per hour. In the two succeeding years it was raised 4d. per hour; and when they left their work they were receiving 54d., and now demand 6d. an hour. The employers say they are determined to make a stand against these annual exactions, and, as business is not very brisk, they have resolved not to accede to the demands of the men. On the other hand, the men say they asked for 6d. per hour in 1866, and were told it was a reasonable demand, but that the masters were not prepared to give it all at once. They did not strike, but agreed to take 4d. advance for that year, and the same last year; but now the masters refuse the men's request to settle their portion of the agreement, and refuse to meet them, and decline arbitration.

Oltham.—The Springhead Spinning Company have got an *ex parte* injunction in Chancery against John Riley and John Butterworth, as chairman and secretary of a trade-union called "The Operative Cotton Spinners' Association," to prevent them from printing and publishing placards injurious to the business of the complainants, by hindering persons from working for them or otherwise.

Glasgow.—The dispute between the ship-builders on the Clyde and the operative joiners is assuming a somewhat formidable magnitude. Messrs. Napier & Son posted a placard in their works, warning the joiners in their employment that, if they supported the workmen on strike in Greenock, they must leave their situations. In consequence of this intimation, the men convened a meeting, at which they resolved to cease work at once. As matters now stand, the following yards are said to be all but clear of joiners, viz., Messrs. Randolph & Elder, J. & C. Thomson, Barclay & Curie, Wingate & Son, Laurie, C. Connell & Co., Aitken & Mansell, and also Messrs. Simons' and Henderson's, Renfrew.

Scotland generally.—The strike in the moulding trade in Scotland is now at an end, the men having accepted the written conditions under which the men are to be allowed to resume work, the restrictions hitherto enforced by the union are all to be abandoned. In point of fact, the whole policy of the society is to be given up, although the men are not required formally to renounce their union. The strike or lock-out lasted for nine weeks. Upwards of 1,800 men were thrown out of employment at the commencement of the struggle; and although many of them obtained work in other places, there still remained a large number dependent upon such assistance as could be afforded from the society's funds. It is estimated that the cost to the union has been about 4,500*l.*, or an average payment of 500*l.* per week.

Geneva.—The strike here has terminated. The walls were lately placarded with the following notice:—"Department of Justice and Police.—The delegates of the masters have communicated to the Department of Justice and Police, in a document signed by them, the conditions on which it would be possible for them to open their workshops. These conditions, having been communicated to the workmen, have been accepted by them. It is, therefore, decided that the work will be resumed on Monday, April 13th. The friendly relations which always existed between masters and workmen will be consolidated by the crisis just past,—a crisis which, thanks to the liberty we enjoy, has ended peacefully and happily. Long live the Confederation. Long live the Republic of Geneva. P. B. CAMPERIO, Councillor of State." The result of the strike has been that the masters in the mason, plaster, polishing, marble, whitemith, glazier, joinery, and carpentry trades have consented to diminish the day's labour by one hour,—that is to say, from twelve

to eleven hours, and to increase the wages of the men by 10 per cent. The masters of the locksmith, mechanic, and founding trades have consented to the reduction of one hour's labour, and to an increase of 5 per cent. in wages.

Italy.—Many thousand persons, mostly workmen, paraded the streets of Turin a few days back, shouting, "Down with the Ministry!" "Down with the grist tax!" Much difficulty was experienced in restoring tranquillity and preventing serious disorder. This demonstration arose out of the strike of the men employed at the arsenal, in the tobacco manufactory, and on the railways of Upper Italy. The authorities had deducted 5 per cent. from the wages of these persons as payment of the tax on personal property, the act being illegal, since wages of small amounts are declared exempt from the impost. Other strikes, more peaceful in their character, have taken place at Bologna, Naples, and Milan, especially a strike of the owners of public carriages, on which was placed so onerous a duty, that if it had been persisted in, it would have led to the ruin of many undertakings. The tax has been suspended.

ST. SEPULCHRE'S, SKINNER-STREET.

FOR the purpose of the enormous work now being carried out by the Corporation of London in forming the Holborn Viaduct, part of the churchyard of St. Sepulchre's is required. A new street is designed to branch north-westward into Farringdon-road, very near to the ancient tower of the church. The parish are very anxious that the opportunity should be taken to isolate the church, and put the tower, the outline of which is very bold and striking, prominently in view in passing over the viaduct. The opportunity is so favourable that we cannot resist expressing a hope that it will be taken advantage of. Mr. W. Haywood, the architect of the Corporation in this work, is so fully alive to the value of aesthetic improvements, and knows so well the interesting character of the church and its neighbourhood, that we feel tolerably sure of his willingness to assist in bringing about what is desired, if circumstances can be made to allow of it.

CHURCH OF ST. HELEN, BISHOPSGATE.

THE reopening of St. Helen's, Bishopsgate, took place on the 31st ult. The unsightly partition and organ-gallery, which obstructed the proportions of this ancient church, have been removed, and the organ re-erected in the south chantry. The floor of the church has been lowered in many places to its original level, and the chancel paved with tiles made by Messrs. Minton, after the pattern of some ancient remnants discovered *in situ*, embedded in the walled-up opening leading from the nuns' choir into the cloisters of the convent, at a depth of 3 ft. 6 in. below the present floor. This opening, together with a staircase in the thickness of the wall, and several hagioscopes from the cloisters, are now visible, as is also the base of the fine monument of Sir John Croshy.

The ancient brasses are relaid under the east window in the chantry. The flat plaster ceiling over the east end of the nuns' choir has been replaced with one more in keeping with the rest of the church; and a new roof, with additional lights, constructed over the chantry. The old pewing has been removed and other seats provided; the old carved stalls from the nuns' choir are re-used in forming the present choir-seats.

Several windows filled with stained glass have been added to the church by various generous donors, amongst which most conspicuous is that erected by Messrs. Hodgson, at the east end of the church, to the memory of their father, for fifty years a parishioner and resident merchant in the parish. Messrs. Heaton, Butler, & Bayne were the artists. The centre light has the Ascension, and the other portions are filled with various scenes of the life of our Lord.

The window at the east end of the nuns' choir has been put up to the memory of Sir Thomas Gresham, Knight, by the Joint Grand Gresham Committee; the glass is by Messrs. Powell & Sons, and represents St. Helen and the four evangelists, with the arms of Sir Thomas Gresham and the Corporation of London and Mercers' Company. A small window in the chantry has been restored and filled with por-

tions of old glass, by Messrs. Heaton, at the cost of the present churchwardens, Messrs. Rolfe and Richardson. On the south side is a stained-glass window, by Gibbs, presented by Mr. Williams, an old parishioner, representing the legend of finding the cross by St. Helen, the patron saint of the church. Another window, by Gibbs, was presented by Alderman Wilson. A small ancient light has been also filled at the cost of one of the architects, in memory of his ancestor, Bishop Robinson; it adjoins the tablet to John Robinson, merchant of the staple, A.D. 1599.

The collection of monuments is one of the finest in the City of London; that to the memory of Sir John Spencer has been moved to allow the opening of an arch which it formerly obstructed, and has been restored in colours by Messrs. Poole, at the cost of the Marquis of Northampton.

The cenotaph containing the embalmed body of Bancroft has been removed by the Drapers' Company.

The work has been carried out under the superintendence of Messrs. Wadmore & Baker, architects.

A MASONIC HALL, IRELAND.

THE *D Belfast Newsletter* announces the opening of Leamne Masonic Hall. The hall is situated in St. John's-place, at the north end of the town, and is approached by a spacious avenue. The style of the building is Tudor Gothic. It is built of black stone from quarries in the neighbourhood, the dressings being of Scarab freestone. The gables are capped by ornamental cast-iron finials, and over the porch is placed a globe. The grounds about the building are enclosed by iron railing, and are planted with shrubs and flowers. The hall in which the lodge meeting will be held is 35 ft. long by 20 ft. wide, and is so adapted that in it all the higher degrees of Masonry can be practised with great facility. There are two ante-rooms, one of which will be used as a cloak-room, the other as a sitting-room. In the east is situated a throne on a raised dais, over which is a draped canopy of crimson merino, surmounted by a gilt crown, and in the centre of the room is placed an altar, on which are the Doric, Ionic, and Corinthian orders of architecture; also three candlesticks in a triangular form, the implements of the craft, and other Masonic symbols. In the east is the seat of the senior warden, and in the south the seat of the junior warden, opposite each of which are benches of the form of a double cube. The hall is illuminated by means of a large sunlight, 3 ft. in diameter, which is placed in the centre of the ceiling. The architect of the building was Mr. William E. Kelly; the contractors were Messrs. Dixon & Son, of Larne.

RAILWAY INTELLIGENCE.

THE extension of the Underground Metropolitan Railway to St. John's Wood, has been inspected. It extends from the Baker-street station to the Swiss Cottage station. The length of the line as now open is one mile, seven furlongs, and six chains. Leaving Baker-street new station, the next come to a St. John's Wood-road Station, near Lord's Cricket Ground. The next is Marlborough-road Station, close to the Byre Arms, Portland-town. The next station is the Swiss Cottage. The railway is constructed as far as Finchley-road, and only requires a station to be opened to place it in full working order. The entire journey from Baker-street to Swiss Cottage Station is travelled underground, with the exception of the approaches to the stations and the stations themselves, which are all lighted from the top by glass roofs. Both in the stations and in the tunnels ventilation is secured. It is intended that trains shall run to the City from the Swiss Cottage and intermediate stations every twenty minutes; but during the business hours of the day there will be local trains run between Swiss Cottage Station and Baker-street every ten minutes.

In the course of the trial of an engine-driver for manslaughter, of which he was acquitted, at the Gloucester Assizes, counsel for the defence incidentally gave an easy rule for remembering the railway signals,—

"White for right, red for wrong,
And green for 'gently go along.'"

The traffic receipts of railways in the United

Kingdom amounted, for the week ending March 28th, on 13,146 miles, to 691,059l., and for the corresponding week of last year, on 12,810 miles, to 677,105l., showing an increase of 267 miles and of 13,954l.

Mr. Thomas Payne, conductor of the Detroit and Milwaukee Railway, has lately invented an ingenious contrivance to indicate to railway passengers the station which they are approaching, its distance from the one last passed, and from that point to each terminus of the road. It is placed in the centre of the car, and has two arms projecting about 2 ft. from each side of the car, which, coming in contact with posts placed for the purpose, turn the indicator immediately after passing each station.

The railroad bridge at Burlington, Iowa, now nearly completed, has required over 3,000 piles and 1,000,000 ft. of pine lumber. The bridge is 2,237 ft. long; and 7,500 cubic yards of stone have been laid.

OVERLAND ROUTE TO INDIA *via* THE BLACK SEA.

Sir,—In a few years Russia will have extended railway communication to the frontier of India. The line between Balta and Odessa has been opened some time, and the section from Balta to the Austrian territory is commenced, as also the line from the Black Sea to the Caspian is being pushed with vigour. The entire journey from Charing Cross to Bayreuth, on the southern shore of the Caspian Sea, will not exceed six days, including the passage of the Black Sea. It is in contemplation to continue the line through Persia to the frontier of India. Upon this scheme some of the chief thinkers, chief workers, and chief engineers of Russia have been engaged for some years. The journey by this route from London to the Indian frontier will not exceed eight days.

Is it not an insult to the genius and enterprise of Englishmen that Russia will be the first to drive a railway through this solitude, and leave it no longer a huge void on the earth's surface? The line will traverse many a gwañ, and cross many a dried-up nllāgh, that has played its part in the world's history. The benefits which it will confer on the native population are incalculable; there the people will multiply, and religion and civilisation and commerce will be promoted. Beds of clay, granite, sandstone, schist, white kaskin, yellow, red, and other coloured ochres, are to be found in abundance in many sections of the line; as also *kunkar*, or lime and gravel.

Had our Government adopted a positive instead of a negative attitude towards the projectors of the Enphrates railway, Russia would never have contemplated a great rival and shorter line.

PIERRE ARTHUR, India.

ST. BARTHOLOMEW'S, SMITHFIELD.

Sir,—We are not surprised at the disappointment experienced at seeing the ugly girders thrown across the east end of St. Bartholomew's Church in place of the apse itself; but, in justice to the committee, we should be delighted by your allowing us to state that they have need every exertion to rebuild the apse in its entirety. The upper part (as is well known) is occupied as a factory. This place a zealous member of the committee endeavoured ineffectually to purchase. The opinion of two eminent counsel was then taken as to the course to be adopted, and after their report we consulted with the architectural committee of the Incorporated Society, whose unanimous feeling, we believe, was, that the best plan would be to show the complete form of the apse on the ground-floor at least, leaving the upper to be added whenever circumstances would allow.

There are a few other points connected with the restoration which we should also be glad to have noticed if your space will permit. The whole church was, as you are aware, filled up with rubbish about 3 ft. 6 in. deep, the paving of the floor being made up to a great extent with tombstones. In order to lower the ground these had of course to be temporarily removed, and though the committee undertook to have each one restored to its precise position on the lower level, the necessary facility was at first refused. When the difficulty was, with some trouble and expense, got over, and the earth dug out, it was found that some of the grave-vaults had, in comparatively recent times, been dug in a most dangerous way under the piers. In two cases

the excavations were so completely under them as to render it a matter of surprise to every one that the piers had been able to stand at all. There seemed to be literally nothing for them to rest upon. On trying the ground still further, we found that a number of the piers had been built on a layer of very soft material (almost peat), and this had so far given way as to cause very serious settlements in the work over; so much so, indeed, that two of the piers had to be shored up with extreme care, and entirely rebuilt. The south clearstory wall had been seriously injured by the fire which occurred some twenty years since, and had to be taken out and replaced pier by pier. A curious circumstance we have noticed during this work which we do not remember in other cases, that, in the drying of the church after the removal of the earth inside and the formation of the area externally, the joints of the stonework shrank perceptibly, as was shown by an iron bar cut to the exact length between some of the mouldings.

Of the above work there is of course little now apparent; and there is, perhaps, less to be seen than in many other cases, as it has been our greatest care throughout to leave every portion of the old work so far as possible untouched.

THE ARCHITECTS.

A NUT FOR THE PROFESSION TO CRACK.

Sir,—The remarks by "A Country Gentleman" were well meant, and deserve the careful consideration of the profession, but quite fail to answer the problem put by me. The payment by per-centage was so far from being the point objected to, that the engineer engaged in lieu of an architect is to be paid as an architect would be, by per-centage. I maintain, therefore, that the cause does lie "in the utter severance of art from the affairs of practical life," and that the reason of this strange selection was that it was thought an engineer would have no temptation to run up expenses for ornament.

As regards the point raised by "A Country Gentleman" I am not disposed to give much weight to it. Fortunately, few amateurs are so foolish as to expend 17,000l. without professional advice; and those that do (unless they are Heaveu-born architects, and then they are perfectly wise and justified in acting for themselves), will be mulcted to a far greater amount than 5 per cent. by their unchecked employes. They do no damage to any but themselves, and, perhaps, their successor, who will, doubtless, if he has any taste at all, pull down and rebuild all such amateur work.

Country gentlemen are quite at liberty to act as their own architects, just as they would be to act as their own doctors; and nice pills would be the result of their own concocting in either capacity.

Cannot "A Country Gentleman" see that honesty is the best policy for architects to follow, and that they would be killing the golden goose for the sake of a paltry single egg or two, if they were to act as he thinks them so tempted to do? At any rate, I believe the world does give them credit for more worldly wisdom than that, and, perchance, for a trifle of proper principle besides. If the mode of their payment be open to criticism, the Institute has declared, after due consideration, that it seems to be the best that can be devised under the circumstances; still, if "A Country Gentleman" can suggest a better, the thanks of the profession, as well as of the class he represents, will be most ungrudgingly accorded to him.

J. P. S.

THE "EGYPTIAN HALL" IN THE CITY.

Sir,—Your correspondent under the above head, whose letter appears in your number for March 21st ult., page 214, would be in error if he considered his communication the first that has occurred with reference to that appellation.* The subject was taken up by me in August, 1826, now upwards of forty years ago; and as the letter I then wrote contains the whole in as concise a way as I could otherwise explain it, together with the circumstance that then induced me to notice it, I beg to hand you a copy. I received a friendly letter from Mr. Britton in answer to it, in which he says,—"I have to

thank you for your polite and judicious letter respecting the Mansion House, which appears written by myself," &c.

Your correspondent says there are three-quarter columns in the upper tier. They are, however, shown as only half columns. The reason is obvious, since, however more correct a three-quarter column would be *per se*, it could not have been placed over the lower column in addition to the surrounding wall without one or other overhanging on a false bearing.

H. G.

Copy of Letter to Messrs. Britton & Pugin, Editors of the "Illustrations of Public Buildings of London."

August, 1826.
Gentlemen,—In No. 15 of your "Illustrations of the Public Buildings of London," under the head of 'The Mansion House,' and in pages 123 and 124, I observe the following:—"To the south of the saloon is the Egyptian Hall, for the appellation of which see an engraving, as it is, as it displays no vestige of Egyptian architecture or following observations, which may, perhaps, prove as satisfactory to you as they are to me."

It will be requisite first to consider the hall not as it now exists springing from the entrance with its support, but as it existed before the 'attic' was taken down, a representation of which you will find in plates 33 and 34, vol. ii. of 'Vitruvius Britannicus,' by Woolfe and Gandon, where you will observe an upper range of half columns placed against a wall, in which is a tier of windows, the whole resting on the lower range of columns.

Referring now to 'Vitruvius,' book vi., cap. 5, where he treats of the Egyptian 'Zeus,' which precisely corresponds to the Egyptian Hall at the Mansion House as it was originally executed, I may not be amiss in saying, therefore, denominated given from its resemblance to the double 'Zeus' denominated Egyptian, and from which, no doubt, the idea was taken. The authority of Vitruvius, of course, suffices; but he is also followed by Palladio, who in his book iii., cap. 10, treats of the hall in an 'Egyptian manner,' which is further explained by a plan and section exactly corresponding with that of the Mansion House as first built; and these matters are followed by Ware, who, in his book iii., cap. 30, and in two plates, each numbered 37, gives the same description of the Egyptian Hall. It may not be here to notice that this hall at the Mansion House, as now altered, corresponds exactly with the hall which Vitruvius in the very same book and chapter denominates 'Corinthian,' where he states that the difference between the Corinthian and Egyptian orders is that the latter (the Egyptian) has two tiers of columns disposed in the way he there mentions, and with the upper range surrounded by the unsheltered floor (the lead flat of the Mansion House), and that the former (the Corinthian) has only one tier of columns, from at the Mansion House now is, I would therefore suggest that, as since the alteration the name Egyptian Hall no longer applies, and (as the circumstance which has occasioned this letter proves), it is the cause of some perplexity, since the name has been altered to 'Corinthian Hall,' an appellation which at once accords with the Corinthian Hall of Vitruvius, and with the order of architecture used in its embellishments. It is also the name by which, if originally constructed as at present, it would, no doubt, have been then called. It has the advantage also of conveying to our ideas a juster conception of its character and style, and it would be also less liable to censure from critics.

SIDMOUTH, DEVON.

Sir,—I have read the interesting article on Sidmouth, Devon, contained in your number for April 3; and, with reference to the origin of the improvement to the sea wall, I beg to inform you that the scheme for an improved outfall, which appears from your article to be at present being carried out at Sidmouth, was originally proposed by me in a report made last April by request of the Local Board of Health, upon one or two other schemes submitted to them by Mr. Phillips and another gentleman.

WALTER BRADLEY.

THE EDUCATION OF THE WORKING CLASSES.

Sir,—I feel sorry that I should intrude on your valuable space, but, being had a number for the sensible letter of "Jack Plane" on the 27th ult., and the reply of H. Morell, secretary of the Sunday League, to what "Jack Plane" calls "nostrum-mongers on technical education," I fully agree with "Jack Plane." Mr. Morell writes a quotation from the Society of Arts on the artists' reports, being one of those reports, and one of those whom H. Morell had up in *Daily News* as having great discernment, and quoted a remark from my report to support his purpose, totally reversing the meaning of the sentence. Therefore cannot give him credit for his discerning faculties, and endeavoring to conceive idea of technical education, and endeavoring to have no, as he opened on Sundays, as in Paris; which at once convinces me that he knows nothing of the means which enable the Parisians to acquire a knowledge of the fine arts, nor the reason that engineers and architects are now stipulating when they let contracts that the work shall not be carried on on Sundays. It is not on Sunday that the Frenchman studies the fine arts, but the evening. It is the easy manner of transit that enables him to do so, as he can ride in any part of Paris and back to his home again for 3d. (30 centimes). If we had the same easy and convenient means of transit in London, there are hundreds of London artisans who would visit there three hours of an evening for the purpose of study. When I go there it costs me 1s. for omnibus fare. If I could ride for 3d., as in Paris, I feel certain I would go four times,—

* There was no supposition to that effect.—Ed.

times, for once that I had now. The grand evil in it is too much talking and too much management, by far at a number living by their orations out of subsidies obtained from working men and other sources...

ARTISTIC CURIOSITIES.

—Apropos of the article on Curiosities of Art, appeared in last week's Builder, I think I can point out a slight instance of inattention to the text in a note by J. E. Soden, in the Exhibition of the Society of English Artists, in Suffolk-street. "Talking Treason," is the name of the picture, and the artist's name is not given in the catalogue...

AN OBSERVER.

PROPOSED WORKHOUSE FOR ISLINGTON.

—In reference to this competition, will you allow me to state that the positive instructions of the Guardians that the buildings committee should not exceed the cost of £1,500. On these instructions I prepared and submitted designs, including central ward and ventilation, and the infirmary arranged on the principle, and so on to which was awarded the second prize...

J. ELIUS.

ARCHITECTS OF THE CEMETERIES.

—Will some of your numerous readers give me information as to the names of the architects who made the plan of the cemeteries at Kensal Green, Highgate, and New-road Cemeteries, and the best monuments found in each of the distinguished persons? W. G.

ARTESIAN WELLS.

—I would be obliged if any of your readers could inform whether the machine invented by Dr. Potts, and used some years ago in your pages, has been applied to artesian wells; because, in my opinion, it is applied with advantage, having been used several times with great success in sinking iron pipes of bridges. J. D. J.

THREEPENNY RAILWAY SYSTEM.

—A rather startling proposal has been made by Mr. Raphael Brandon, the architect, in a paper which he has read at the Society of Arts, and is printed, showing "how to make railways profitable to the shareholders, beneficial to the public, and profitable to the State." Mr. Brandon proposes that the railways shall, by legislative enactments and Government authority, be placed under one management, and the fares be at a uniform rate for all distances, somewhat on the principle of the postage system, which he alludes as an analogy, though not by way of example or argument. In making an estimate he says:— "I suppose that the numbers at present travelling would be increased sixfold if they could travel one journey of distance in one direction for the sum of threepence, is the minimum sum I have based my calculations on. Existing fares under the proposed minimum prices would be as successful; they are comparatively few, could not affect the calculations. In the general summary, I find that during the year 1866, passenger trains to the number of 3,448,660 produced 1,208,918,350 passengers; and during the year 1867, produced 1,472,802; this gives an average of nearly 1,340,860 passengers for each train, that is about 34 passengers for each mile, the average fare paid by each passenger is 1/6d. I suppose that the number of passengers could be carried for 1/6d. small (if any) additional expense; and if a uniform rate of threepence was charged for any distance for each person, at a very moderate computation six times

the present number would travel, and would produce 18,866,984, being 4,172,187, in excess of the present receipts.

The above calculation is made supposing that each person pays only a threepenny fare; but as it will be necessary to divide the passengers into different classes, a much larger receipt may be reckoned upon. For this purpose I would divide the traffic first into half, supposing that half the passengers would travel by single fares (that is to say, would pay for each journey at the time), and these I would sub-divide into three classes as follows: at one shilling for first-class, sixpence for second-class, threepence for third-class."

There will, no doubt, be many readers of this paper who will at once say that the idea of carrying a passenger from London to Edinburgh for 3d. is preposterous, but we must remember that it was not until Sir Rowland Hill had shown its feasibility that any one thought it reasonable to take a letter from London to Edinburgh for the same charge as from London to Richmond. It may be said that the analogy does not exist, that the half ounce of a letter is nothing, but that a passenger is really heavy and makes some difference in the cost of running a train. In reply, I say that the delivery of a letter is the most expensive part of its cost to the Post-office, whereas a passenger takes himself away; that the average of trains run could each carry six times as many passengers as are now conveyed by them, and though the expense might be slightly increased, the increase could be but extremely small, while the receipts, as I show, would be enormously augmented. The increase of expense would also be further much more than met by doing away with a large number of ticket-clerks and others, who would not be required under the new system. The foregoing calculations have been based upon the returns of 1867. Those for 1868 show more favourably for the correctness of my views; and I have no doubt those of 1867 will yet more fully justify my calculations, and the soundness of my plan and arguments.

Without writing, under one management, all the railways in the kingdom, no considerable saving can be made, and the system cannot be developed as it ought to be, and no board representing different, and, in many cases conflicting, interests, can ever be made to work for the public benefit. The interests are national, and the management, to be effective, must be national also. At the present moment the Government can safely guarantee 4 1/2 per cent. to the proprietors of railway stock, and this guarantee would at once raise the value, and, consequently, leave a large profit to the Government; therefore all railway proprietors would be benefited by the Government taking up their lines. The public would speedily reap the advantages of a complete and harmonious system of management, with regular and continuous trains running in all directions, and a general diminution of expense; trade would be benefited enormously by the increased facilities of traffic; while the effect upon the money market at once occurring 433,000,000, of sunk capital into readily convertible securities, would be a stimulus of enormous value to the country."

In the discussion which followed, Mr. Hawes and others naturally opposed some strong objections to the scheme.

BUILDERS' ACTIONS.

WITTER F. WILLIAMS.

THIS was an action, tried at Liverpool, before Mr. Justice Mellor, to recover the balance due upon a contract for the alteration of certain building premises in Liverpool.

Mr. Charles Russell was for the plaintiff; and Mr. Pickering, G.C., and Dr. Cummings were for the defendant.

The plaintiff is a builder and the defendant is an attorney, both living in Liverpool. The latter also carries on the business of a clothier, and the contract in question had reference to certain alterations in the defendant's business premises. The contract, which was made in February, 1865, contained some very stringent provisions binding the plaintiff to finish by a particular day, and imposing heavy penalties for non-compliance. It also contained a provision making the defendant's architect the final arbitrator in case of difference between the parties. The defendant sought to deduct from the plaintiff's bill, which in all amounted to a sum of 298l. only, no less than 136l. for delay. He also sought to charge the plaintiff with a further 100l. for failing to observe an award which his (the defendant's) architect was alleged to have made. The plaintiff denied that any award had been made, and also denied that the delay in the completion of the work was attributable to him. When the case had proceeded some way the learned Judge suggested a compromise, and it was ultimately agreed that a further sum of 50l. should be paid by the defendant to the plaintiff.

CASES UNDER METROPOLITAN BUILDING ACT.

Necessary Repair.—Mr. Brist, of Henley-street, Battersea, was summoned by Mr. Jennings, jun., district surveyor, before Mr. Dayman, at the Wandsworth Police Court, for doing work without notice.

The district surveyor contended that the whole of the shop-front and stall-board at the corner of Henley-street and Lower Wandsworth-road having been removed and replaced by a new one, in which the position of the door was altered from the corner to the front towards the Lower Wandsworth-road, the work required notice, under sec. 38, and was a work subject to the Act under sec. 3, 2. The defendant argued that the shop-front having been blown in, what was done was merely necessary repair.

The magistrate held that, in sec. 3, the words "done for any purpose, except that of necessary repair, not affecting the construction of any external party wall, or referred to as any alteration or addition," as well as to "any other work," and that, if the work in the first instance came under the head of necessary repair, the fact that it was not retaken exactly the same as before would not render it subject to the Act unless such alterations prejudicially affected the construction; and that the words "any work," Act, in sec. 38, were limited in their signification by the latter part of sec. 3.

INVENTORS' INSTITUTE.

THE Hon. Auberton Herbert, B.C.L., has presided at a second conference on the reform of the patent laws, at the Inventors' Institute, 4, St. Martin's-place, Trafalgar-square. The secretary of the Institute, Mr. R. Marsden Latham (barrister-at-law), read the report of the proceedings of the committee nominated a month since, and composed of members of council, together with representatives of various public bodies. From this document it appeared that arrangements were in progress for an effective agitation in the interests of inventors, and that already Mr. A. H. Layard, D.C.L., M.P., had kindly consented to preside at a large public meeting in London. The report was adopted, and it was unanimously resolved to adopt a petition to Parliament, which the committee had prepared; and to appoint a deputation to her Majesty's Government. It was also unanimously resolved that technical instruction would be valueless if the results to which it must lead were not secured by improved laws on the subject of inventions. The petition was ordered to be signed by the chairman in the name of the meeting. An American gentleman gave an interesting description of the working of the patent laws of the United States, showing their immense superiority over those of our own country. It was announced that at the next meeting Mr. J. T. Dexter would read a paper "On the value of industrial exhibitions in their relation to skilled work and inventions."

CONSULTING ARCHITECT TO INDIAN GOVERNMENT.

THE Calcutta Engineers' Journal says,—"We understand that Mr. W. S. Granville, Consulting Architect to the Government of India, has obtained two months' privilege leave of absence prior to resigning his appointment on the 31st March, upon which date his present agreement expires. Mr. Granville's position in the D. P. W. is that of Superintending Engineer, first class, first grade, and we have not heard whether the appointment is to be done away with, or another architect to be brought out from England. The works at present in process of construction in Calcutta from Mr. Granville's designs are the new High Court, the new Post-office, and the Calcutta University, the Indian Museum, and the Dalhousie Institute.

The works at the High Court are at a standstill; the University building is in the same state; the dome of the new Post-office is progressing slowly; and the Indian Museum and Dalhousie Institute are both being proceeded with.

We hope that it is not intended to abolish the office of Architect to the Government of India; we would rather see a move in the other direction, and see a number of architects employed in the Public Works Department, because amongst engineers few have the taste, and fewer still have had the special education, which is necessary to success as an architect."

PROVINCIAL NEWS.

Hastings.—At the usual meeting of the Board of Guardians, the report of the committee appointed to endeavour to find a site for a new workhouse was read. They suggested that probably the best site for a new house was the site occupied by the present building with additions. They also reported that Battle workhouse, for 440 inmates, cost about 12,000l.; the new house at Lewes, to hold 123 adults, exclusive of casuals, is to cost 10,651l., with a detached infirmary; the building at Brighton, capable of accommodating 861 inmates, cost 34,193l. 17s. 6d.; the workhouse at Cuckfield, for 363 inmates, cost 7,500l., including the purchase of 14 acres of land. The committee thought these figures might be of service in guiding the Board to a rough estimate of the probable cost. The consideration of the report was deferred.

Saltburn.—The new pier and sea-wall have been commenced at Saltburn, the former to extend 1,500 ft. into the sea, so that passengers may be landed at the lowest tide. There is also a hoist being constructed, for the purpose of lifting passengers from the beach up to the level of the town. An extensive sea-wall, fitted for a promenade, is also being carried along the foot

of the cliff, under the personal superintendence of Mr. Barry, one of the contractors for the stone work. Mr. John Anderson is the contractor for the new pier, which is to be composed of wood and cast iron.

Norwich.—A drinking-fountain has been presented to St. James's parish by Mrs. Peter Wells, from the design of Mr. J. H. Hakewill, London, architect. It is erected at the corner of St. James's churchyard, Cowgate-street. In character it is Gothic: the material, Portland stone; the bowl for receiving the water being rose granite, polished. The bowl is surmounted by a triangular canopy (with foliage carved in the hood moulding) supported by three grey granite shafts, polished. Above the canopy there rises an hexagonal shaft, surmounted by a cross. The entire height of the structure from the ground is 17 ft. The work was executed by Mr. R. A. Margeson, of Norwich; and Mr. A. W. Morant, surveyor to the Board of Health, has given assistance in superintending the work and procuring the material.

COMPETITIONS.

St. Matthew's Church, Anlaby-road, Hull.—In reply to advertisement, fifty-three competitors forwarded designs. After consideration, the sub-committee finally chose four: those of Messrs. Adams & Kelly, of Leeds; Mr. Blesley, London and Eastbourne; Mr. T. C. Sutton, Nottingham; and Messrs. Clarke & Son, Nottingham, as those to be submitted to a full meeting of the general committee. From these, ultimately, the design of Messrs. Adams & Kelly was selected. About 3,000l. are still required, and it is hoped that the churchmen of the town will come forward and help.

CHURCH-BUILDING NEWS.

Folkstone.—A meeting has been held in the District Schools, Sir C. Maclean in the chair, having for its object the enlargement of Christ Church. Plans had been prepared by Mr. J. Gardner, providing for an increased length of 35 ft. to be added to the west end; the organ-gallery to be widened, and the organ removed to the north-east of the chancel; a new porch on the south side of the church; and the present south porch removed to the north side; while access to the gallery would be gained by an entrance at the base of a tower at the south-east angle. The increased accommodation would be 450 sittings, and the cost nearly 2,000l. Resolutions declaring the necessity of enlargement were carried, and a general committee for the work and for procuring subscriptions was appointed.

Burley.—The church here has been re-opened. It is in the internal arrangements that the principal improvements have been made. The chancel was formerly filled with high pews, and the nave with comfortable seats, some with low backs and others mere forms. These have all been cleared away, and new stained benches take their places. By this, which is the chief improvement, accommodation for more than sixty additional hearers is provided, and there are now sittings for about 275. The roof, which is wagon-shaped, used to be a plain, celled affair; the plaster was taken down, but, as the roof was found to be rough unfinished oak, it was recelled, and stained wooden beams placed at short intervals. The chancel is raised two steps above the nave, but there is no chancel arch, and the division is marked in the roof simply by some amount of ornamentation to the beam, and the ancient caken screen separating the two portions of the church has been retained. An improvement has been made at the east end; the communion rail formerly just enclosed the east window, but the new rail extends across the chancel and is of oak, supported by bronze standards. The floor of the chancel is paved with Maw's encaustic tiles and the passage of the nave is paved with red and black tiles. A new pulpit, with panels ornamented with carving, stained so as to be in unison with the benches, has been erected on the north side of the passage, and a reading-desk on the south side. The walls are whitewashed. Accommodation is provided for the school children in the west gallery, and the lower part of the tower is screened off by a curtain to serve as a vestry. In the course of the restoration several discoveries have been made. When the flooring of the chancel was taken up a large vault was found, which ex-

tended quite across the chancel, but it contained only one coffin, and this so far decayed, that no indication exists to show whose remains it contained. At the north-east-corner another smaller vault was found. In the splay of the easternmost window openings, in both north and south walls of the nave, a niche was found, in one of which were the remains of an image, and it is supposed that these niches were small shrines, dedicated, the one to St. John, the patron saint of the church, and the other to the Virgin Mary. The old oak door to the southern porch remains, and when the paint with which it had been covered was removed it was found that some three centuries ago one "Augustine Brore" had roughly carved his name just below the lock. The date, 1571, is the only date in the church. The restoration of the font has been carried out by Mr. Walter Allen, of Rendlesham. The church is warmed by hot-water pipes carried down the centre passage, the apparatus being supplied by Messrs. Page & Girling, of Melton. The alterations were carried out by Mr. Beeden, of Marlesford. The total cost is about 300l.

Birkenhead.—The new church of St. Peter, which has been erected in Cathcart-street, Birkenhead, on the principle of all its seats being free and unappropriated, has been consecrated by the Bishop of Chester. The edifice is surrounded by a dense population, for whose special behoof and benefit a free church is most required, and being built entirely of brick, with very little stonework and no plaster in its details, is dependent rather upon symmetry of outline and depth of its reveals for light and shade and general effect. The church, when completed, will consist of a nave and aisles, of five bays, chancel aisles, and large chancel, with lofty tower on the south-east front. Of this portion, however, simply the nave and aisles, with western narthex, have as yet been erected. The nave being unusually lofty and spacious, whilst the peculiar form of roof, prepared for polychromy, and the somewhat unusual height of the clerestory, which is supported upon well-proportioned arches and white limestone columns, add to the effect of the whole. Provision has been made, when funds permit, for decorating the arcade walls by a series of pictures in Venetian mosaic, illustrating passages in the life of St. Peter; and a mode of gas-lighting has been introduced by the architect in anticipation of the mosaic being used. The benches are simple in construction, and are open throughout. The present pulpit and other fittings are merely of a temporary nature. Two of the south aisle windows adjacent to the font have been filled in with painted glass, as a memorial of children of the incumbent, and have been executed by Messrs. Pilkington, of St. Helen's. The west front towards Cathcart-street is flanked by buttresses, within which is the triple entrance to the narthex, and immediately over are large two-lighted windows, filled in with tracery of an early French type, which are again surmounted by a circular window of plate tracery, with deep reveals and labels of moulded brick. The side windows are varied in outline. The roofs are covered with Bangor slate of two colours, the ridge tiles being of red fire-clay. The church will accommodate about 700. The cost of erection and furnishing has been about 2,500l.

Trowbridge.—The foundation-stone of St. Thomas's Church has been laid. The total cost will be 5,000l. It is intended for the poor people of the district, and will seat 500 persons.

Louth.—North Reston Church has been re-opened, after having been restored by Mr. C. Clark, of Louth, under the supervision of Mr. Wither, architect, London. It is a small building of rough stone, and slated, and consists of chancel, vestry, and nave, with small octagonal bell-turret. Internally the great feature of the old church, the Saxon (?) chancel arch, remains unchanged. The thick walls of the nave also remain; the chancel is altogether new. The window tracery is filled with two shades of cathedral glass, with transparent borders, in quarrels and diamonds.

Llangathen.—The church here has lately undergone a restoration, which was effected by a rate passed unanimously by the parish, the Earl of Cawdor undertaking a portion of the building pertaining to the estate of Berllandywyll. The total cost incurred is about 700l, including the extension of the churchyard, the land for which had been given for that purpose by the Earl of Cawdor. The pews are all of Memel fir, stained and varnished, and are of middle height.

The pulpit and reading-desk are made of pine. The entire flooring is composed of red and black Staffordshire tiles, laid diagonally, and the warmth of the congregation is provided by hot-air apparatus laid underneath the chancel. The walls of the edifice, as well as the tower, are raked and pointed. The roof is composed of Carnarvon slates, and the ceiling is formed into panels with moulded ribs. The architect was Mr. T. W. A. Tompson, of Carnarvon, and Mr. D. W. Williams, was the contractor. It is in contemplation to build a vicarage, a plan for which has been already given.

Durham.—Cockfield church (date 1210) re-opened on the 2nd inst., after having undergone restoration. The works have been carried out by Messrs. Robert Robson & Son, under the superintendence of Mr. C. Hodgson Fox, architect.

Brede.—The parish church has been re-opened. The old hoarding has been removed from the roof of the chancel, and timbers, cornices, &c. fixed, the whole of which are now left open and stained and oiled. A new open timbered roof with moulded tiles, king post Gothic ribs, &c., extends the whole length of nave and north aisle. The south aisle roof restored with the best of the old timbers, and the roofs are plastered between the rafters and coloured grey. The walls are now covered with stucco, and the stonework of all the arches has been cleaned and jointed with grey mortar. The gallery has been removed, and the long-obsolete tower arch is now a prominent object. A pulpit of Caen stone, with emblematic tiles, a reredos, also of Caen stone, with panels of encaustic tiles, and several other works in the rector's chancel are among those done. Messrs. O'Connor, of London, have executed three new windows of stained glass; one in the tower, and two in the rector's chancel. The stonework of the tower window is new, and the tracery is like the old window, which was rebuilt up in part with brickwork. The stained glass of this window is a geometrical pattern well marked out in various colours, yet so as to admit much light. Of the windows in the chancel, one is a memorial of the late Mr. Aylward in two compartments; one represents Mary sitting in rapt attention at the feet of Jesus, while Martha is serving; the other is raising of Jairus's daughter. The other chancel window is the east one, in four compartments filled with the four Evangelists. Texts of Scripture have been placed over the windows and arches of the chancel, and brass plates with inscriptions in several places, both in the chancel and chancel. The private chapel of Mr. Thomas Frewen has also been restored to correspond with the church. The whole of the works have been carried out under the direction of Mr. Hand Price, architect, Weston-super-Mare; and contractors were Messrs. Crisford & Sons, Brede. It should be added that the unfashioned high pews still remain.

STAINED GLASS.

St. Stephen's Church, Ipswich.—The west tower window of St. Stephen's Church has just been filled with stained glass, in memory of the late Mr. Henry Miller. The window is inserted by the window and the sons of the deceased, and the Rev. John Miller, and consists of three lights, all filled with designs of stained glass, and in the centre compartment the "Stoning of St. Stephen," the protomartyr, is represented. The window is by Messrs. Powell & Sons, Whitefriars. The work of putting the window in its place was done by Mr. John King, Ipswich.

St. Mary's (R.C.) Church, Warwick.—Another stained-glass window has been placed in the western portion of this building, representing Jesus in the house at Nazareth, between his parents, assisting Joseph at his handiwork. Mary, standing behind, appears to be absorbed in the contemplation of her divine son. The window has been erected by the Rev. T. Louman (founder of the church) in memory of his mother; and the subject forms one of a series of chronological order, illustrating the mystery of the infancy of our Saviour. The work was executed by Mr. T. Dury, of Warwick.

St. Michael's, Basingstoke.—The new east window of this church has been put up. The stained glass has been executed by Messrs. Lavers, Barrand, & Westlake, of Bloomsbury. The general design has reference to the ministry

angels, associated in the five principal scenes with the Annunciation, the Nativity, the Ascension, the Resurrection, and the Assumption. Beneath these are five minor subjects, the Angels at the test-door of Abraham; Michael contending with Satan; the sacrifice of Isaac; Daniel in the lions' den; and the raising of Elijah. The head of the window contains our Saviour enthroned; the emblems of the four Evangelists, and the Angels hearing the words, &c., as described in the Book of Revelation.

Books Received.

Cutting and Perforated Carving, with practical Instructions. By W. BEMROSE, Junr. Messrs. G. and S. Paternoster-row, London; and W. Derby.

The author of the "Mannal of Wood Carving" has published this volume on the sister art of cutting and perforated carving for the pleasure of a large class of amateurs whose inclination does not permit them to attempt the more elaborate art comprised in the woodwork. Much pleasure and amusement in spare hours may be derived from the practice of these easy yet graceful and useful art, which does not require any special workshop, and may be carried on at a table in an ordinary parlor-room. The volume is illustrated by a number of engraved examples of brackets, ornaments, picture and other frames, book-ends, &c., some of them more tasteful than others, but all useful in learning the art.

Lathe and its Uses. With an Appendix. London: The "English Mechanic" Office.

Mr. Holtzapffel advertised a forthcoming series of seven volumes on tools, which had been prevented from being completed; and although his successors have since repeatedly promised the completion of the work, of which three volumes have ever appeared, the others are still without any complete work on the subject. No doubt the prospect of a work by so competent an authority as the late Mr. Holtzapffel has hitherto prevented any other work of the kind being prepared. But one has at length appeared which enters pretty fully into the subject of the elaborate branches of the subject. The series under notice is based upon a series of papers published in the *English Mechanic*, the whole has been revised and improved, and the volume contains an appendix, in which are described an entirely novel form of lathe for turning and rose engine-turning; a lathe and egg machine combined, and other valuable improvements relating to the art. The work gives instruction in the art of turning both in wood and iron, and includes a description of the most improved appliances for the ornamentation of straight and curved surfaces: it is copiously illustrated.

Miscellaneous.

THE JOAN OF ARC TOWER AT COMPIEGNE.—The Joan of Arc Tower at Compiègne has been blown down lately, and the crash caused great alarm. There was no loss of life; but when the tower fell the bed which a child had been lying in was smashed into atoms.

THE NEW RIVERS COMMISSION.—The Queen has appointed Sir William Thomas Denison, Bart., colonel in the corps of Royal Engineers, and Edward Frankland, and Mr. John Chalmers, Esq., to be her Majesty's Commissioners for the purpose of continuing the inquiry as to how the present use of rivers or running waters in England for the purpose of carrying off the sewage of towns and populous places, and the nuisances arising from industrial processes and manufactures, can be prevented without risk to public health or serious injury to such processes and manufactures; and how far such sewage and refuse can be utilized or got rid of in any other way than by discharge into rivers or running waters, or rendered harmless before being thrown into them; and also for the purpose of ascertaining into the effect on the drainage of towns and inhabited places, of obstructions to the natural flow of rivers or streams caused by weirs, locks, and other navigation works, and into the best means of remedying any evils arising.

A CALENDAR FOR FORTY YEARS.—On a small card, a simple calendar for forty years has been published by Foss, printer, Coleman-street, with instructions for its use printed on the card, which has a sliding slip of the days in the week for adjustment in connexion with the days of the month, and with alphabetical letters for the years. The idea is not new, but the card is useful.

PRESENTATION TO A BUILDER'S LATE MANAGER AT UXBRIDGE.—About twenty-four artisans in the employ of Mr. G. E. Kearley, of Uxbridge, builder, &c., met recently at the Railway Hotel, Uxbridge, and presented Mr. Robert Henson, late manager of the firm, with a handsome box of mathematical instruments, of the value of 8l. 8s., previously to his leaving the town. The event was celebrated by a supper, of which about thirty persons partook.

THE PROMENADES OF PENZANCE.—The *Cornish Telegraph*, after quoting some observations made recently in our columns as to the desirability of planting trees on the Thames Embankment, adds,—"Our excellent contemporary, the *Builder*, is always making some useful suggestion such as this, for which all should be obliged. That paper also sends out special commissioners, to note the sanitary or unsanitary, improved or unimproved, condition of towns. If one should travel westward, what would he say to the neglected planting of the Alexandra-road, Penzance, and the failure to make it one of the prettiest promenades in the west? When will the managing Boards of our country towns appreciate rightly the value and importance of artistic adornment?"

ARCHITECTURAL AND ARCHAEOLOGICAL SOCIETY OF DURHAM AND NORTHUMBERLAND.—The annual meeting of this society has been held in Bishop Cosin's Library, Palace-green, Durham. The Rev. W. Greenwell, president of the society, occupied the chair. The chairman alluded to the search that had been made for the remains of St. Cuthbert. The search, he said, had been productive of no results as to the finding of any body; and it was the opinion of many members of the Roman Catholic Church that St. Cuthbert's remains were interred behind the altar of the cathedral at Durham, as had always hitherto been represented. He next referred to excavations which had been made at the west part of the cathedral, where an ancient staircase and some chambers had been discovered, but these investigations had been brought to a close without any result having been arrived at.

CRYSTAL PALACE.—The sale of vouchers securing tickets for the great Handel Festival in June next, has, during the past few weeks, very considerably exceeded the amount it was anticipated it would have reached thus early. As in 1857, and subsequent years, the clergy from various parts of the country are still among the best supporters of the festivals. At the Clearing-house of the superintendents of the various railways, it has been decided to afford the greatest facilities for attending the festival. Three days' excursions from long distances, and single-day excursions for distances not exceeding 100 miles, will run for the great rehearsal day. For the three days of the festival excursion rates will be given. For the great rehearsal and the "Messiah" excursions will run from the northern and midland districts, for a distance exceeding 200 miles, returning the same evening. Such facilities are among the wonders of the age. The Crystal Palace season-ticket holders will enjoy the right of entry, for the first time, during all the four days of the festival. Our readers, generally are aware, no doubt, that an annual or season ticket can now be had, for the usual charge of a guinea, beginning and ending any month in the year, as from April to April, May to May, &c. The issue of tickets for the Handel Festival commences at Exeter Hall and at the Crystal Palace, on Monday, April 20th; and everything gives good promise of a most successful issue to this great undertaking. We had occasion to make a run out to the Palace the other day, and were delighted with the spring progress in the beautiful gardens. The tropical end of the palace is restored to a certain extent, and is as favourite a resort as ever. The Alhambra decorations were in progress. There is an interesting exhibition of photographs in one of the galleries, from the Holy Land, belonging to the Exploration Fund. We had a glance at a group of our Hindu fellow-subjects, female as well as male: the sight was an interesting one, although they were only jugglers and acrobats.

EMBASSY AND CONSULAR HOUSES.—The estimates before the House of Commons propose votes of 6,000l. towards 10,000l. required for the erection of an embassy house at Therapia; 8,000l. towards 20,000l., the amount of the estimate for a new house for her Majesty's mission at Teheran; a second sum of 40,000l. towards 175,382l. for consular buildings in China; and 15,000l. for consular buildings in Japan.

NUISANCES.—The Lords Justices have affirmed the decision of Vice-Chancellor Stuart, in the case of *Viscountess Gort v. Clark*; holding that the plaintiff was entitled to an inquiry as to damages for a nuisance occasioned by the noise and vibration caused by a steam-engine and circular saw, which were at work in the defendant's factory from morning to night, and by the smell of paint used in painting the "self-coiling revolving shutters" of which the defendant was maker and patentee.

FATAL SCAFFOLD ACCIDENT.—On Monday evening, Frederick K. Hame, a bricklayer, working at a new house in Crown-street, Wyndham-road, Camberwell, was descending from a scaffold, by one of the expeditions but dangerous methods of sliding down one of the poles, when his hand slipped, and he fell with great violence to the ground, striking his face so severely as to shatter both jaws and heat in his forehead and eyes. He was conveyed to St. Thomas's Hospital, but life was found to be extinct.

THE HOWARD ASSOCIATION.—An important address has been printed by this Association on the treatment and prevention of crime, with special reference to reformatory and economic labour in prisons, the Irish test system, capital punishment, the double license system, and prostitution and mendicancy. The Howard Association was instituted under the patronage of Lord Brougham, and others. It is a society for the promotion of the best methods of penal treatment and crime prevention. The committee invite information from home and foreign sources, especially from magistrates and prison-governors; also subscriptions in aid of expenses, to be forwarded to the secretary, 5, Bishopsgate-street Without, London, E.C.

IRON STOVES.—Some of the French doctors have started a [fresh] crusade against iron stoves. Dr. Carret, at Chambery, noticed a great deal of unaccountable disease in schools and institutions; and thought he could trace the mischief to the introduction of cast-iron stoves. Dr. Deville, in a paper read before the Academy in Paris, says that he proved by a mechanical contrivance that such stoves do give off noxious vapours. He had two bells so connected with electrical apparatus that they should ring when hydrogen or carbonic oxide was given off. Not long after the stove had got thoroughly heated both the bells began to ring. If it is proved that iron heated beyond a certain point gives off unwholesome gases, we had far better adopt the German stove—so much more capable, by the way, of being made a graceful piece of furniture, than our cast-iron abominations. Such a reform would naturally lead to the disuse of the wretched frontage of painfully black-leaded iron round our fireplaces, and a return to the good old Dutch tiles.—*Imperial Review.*

COVERED MARKET FOR BURY.—It was determined in the summer of last year to cover the whole of the market area, Bury, with a roof of iron, having a large proportion of the same glazed to give ample light to the area. The plan of the work was intrusted to Mr. Green, architect, Portsmouth, near Todmorden (who was also architect for the Earl of Derby's estate workshops at Redvales, near Bury). The roof is constructed chiefly of wrought iron on the tie and tension principle, and has a central roof of 60 ft. span with two side roofs of 50 ft. span each, with hipped sides at the angles. The form of the market, being an irregular triangle, presented difficulties in covering over the area without disturbing the existing shops. It affords accommodation for 146 stalls. The entire market, with shops round the three sides, occupies an area of about 6,300 square yards, or rather more than 1½ statute acre. The contract for iron roofs, pillars, and gutters, was taken by Mead, Wrightson, & Co., of the Teesdale Iron Works, Stockton-on-Tees. The rest of the works have been executed at Lord Derby's works, under the direction of Mr. Lofthouse, and the whole under the superintendence of the architect. The cost of the ironwork alone has been about 1,450l., and the total cost between 4,000l. and 5,000l.

COTTAGE ACCOMMODATION: FRAMLINGHAM FARMERS' CLUB.—At a recent discussion meeting of this club, held at Framlingham, Mr. S. G. Stearn, of Brandon, introduced the subject of "The Cottage Accommodation for the Agricultural Poor." The president, Mr. F. S. Corrance, M.P., presided, and there was a numerous attendance. Mr. Stearn stated that in the proposed new double cottages, a model of which he produced, the living-room was 12 ft. by 11 ft. 6 in.; back-house or scullery, 11 ft. 6 in. by 10 ft. 6 in.; store-room, 6 ft. 5 in. by 6 ft.; bedrooms, 12 ft. by 8 ft. 3 in., and 10 ft. 6 in. by 9 ft., 11 ft. 6 in. by 11 ft. His model cottages, as before them, excepting the pigstyes, could be built for 200l. each, the double dwelling. He had a man who would sign an agreement to build 100 at 200l. each, exactly like the models. A builder who was present said he could build the cottages for that sum; but there was some incredulity manifested during the discussion. Mr. Stearn said the rent would be 4l. 10s. In his estimate he included copper and ovens, convenient closets, and everything anybody could desire. Cottages built like this would be scrambled for. The cottages would require but little repairing, unless from accident, for 100 years. It would be ample to allow half a crown a year for repairs. He insisted that if private individuals could not take the movement in hand Government should. The President reviewed the discussion, and quoted from the *Builder* as to dimensions, minimum percentage, &c.: they wanted certain specifications, he remarked, into which Mr. Stearn had not entered.

TENDERS.

For building villa, St. Thomas's-road, South Hackney, for Mr. Robert Entwistle. Mr. Gathercole, Crown surveyor:—
Brett £1,280 0 0 Extra for building £38 0 0

For erection of warehouse at Narrow-street, Ratcliff, for Mr. H. Vane. Mr. C. Bunch, architect:—
Stuttle £875 0 0
Hearle 653 0 0
Johnstone 650 0 0
Rivet (accepted) 693 0 0

For sundry alterations and additions at the Prince Albert public-houses, Union-street, Bishopsgate, for Mr. Riches. Mr. W. Lambert, architect:—
Richardson £540 0 0
Ockley 388 0 0

Thomas & Dicks 5,115 0 0
King 5,032 13 6
Trow & Sons* 5,000 0 0
Selby 4,998 0 0
Bell & Sons 4,983 0 0
Claridge 4,910 0 0

* Not received in time to be opened with the other tenders.

For residence for Mr. Frank Campion, Derby. Messrs. Thompson & Young, architects. Quantities supplied by Messrs. Waile & Jones:—
Bridgart £2,400 0 0
Fryer 2,379 0 0
Gadaby (accepted) 2,174 0 0

For residence at Toddington. Mr. Charles Aldridge, architect. Quantities supplied by Mr. L. C. Kiddett:—
Warr £2,090 0 0
L'Anson 1,884 0 0
Gammon 1,661 0 0
J. & W. Sanders 1,648 0 0
Capps & Ritso 1,568 0 0

For finishing a villa residence (the carcass being already erected) on the Mountlands Estate, Taunton, for Mr. H. D. King. Mr. J. Houghton Spencer, architect:—
Durham & Hawkins £820 0 0
Giles & Manning 620 0 0
Aplin & Woolfrey 649 0 0
Shewbrooks 654 0 0
Smith (accepted) 492 0 0

For raising warehouse, 107, Leadenhall-street. Mr. William Eve, architect:—
King & Son £685 0 0
Greenwood & Son 665 0 0
Heiser (accepted) 610 0 0

For enlarging house at Theydon. Mr. William Eve, architect:—
Turner £285 0 0
Cuthbert, Bros. (accepted) 275 0 0

For new schools and class-rooms in Drummond-street, Euston-square. Mr. John Farring, architect. Quantities supplied:—
Sherman £2,294 0 0
Shepherd 2,120 0 0
Richards 2,068 0 0
Saunders 1,883 0 0
Mann 1,973 0 0
Hill & South 1,985 0 0

For alterations and additions to Croft Lodge, Highgate-road, for Mr. Henry Gotto. Mr. S. C. Cipes, architect. Quantities not supplied:—
Serviner & White £1,085 0 0
Till 1,048 0 0
Brown 899 0 0
Mann 879 0 0

For new warehouse, St. Ann's-lane, E.C., for Mr. Geo. Hartley. Mr. Herbert Ford, architect. Quantities supplied by Mr. J. W. Dennison:—

	Brick Front.	Stone Front.
Brass	£1,775 0 0	£222 0 0
Piper & Wheeler	1,750 0 0	230 0 0
Brown & Robinson	1,698 0 0	228 0 0
Henshaw	1,688 0 0	330 0 0
Pritchard	1,672 0 0	248 0 0
Turner & Sons	1,669 0 0	250 0 0

The Builder.

VOL. XXVI.—No. 1316.

A Proper Welcome to Mr. Whitworth's Donation.

HE patriotic munificence of a man of whom all those in any way interested in the arts of construction may well be proud, whether they regard him as a mechanician or as an artilleryist, has a special claim to commendation in our columns. It will be in the recollection of our readers that we have on more than one occasion brought before their notice some of the most important features of Mr. Whitworth's projectile system. To give an absolute and authoritative decision on a matter of military engineering is somewhat beyond the scope of the *Builder*. The great beauty and utility of some of Sir W. Armstrong's inventions we very heartily recognise.

Yet we lean to the opinion that Mr. Whitworth has been rather hardly dealt by as regards the recognition of his claims as an artilleryist. Foreign Governments would seem to have been more prompt to recognise them than has our own. In reading the evidence printed in the several Blue Books, moreover, there sometimes appears to have been scant courtesy shown to the distinguished mechanic. He was at times sharply cross-questioned by men whose interest in rival schemes should have prevented them from coming into collision with him except in the character of avowed rivals or retained advocates. Nor does Mr. Whitworth seem to possess that rare, that almost unique, genius, which is equally at home in doing and in talking, in designing and in describing, in free command of the hand and of the tongue.

It is in accordance with the usual principles of human action that Mr. Whitworth may have himself felt the force of some such reflections as our own. The man who, having laboured long at a difficult subject, has acquired a large amount of positive knowledge, is apt to feel a natural impatience at the criticisms of those who have not yet mastered, and do not seem to care to master, even the A, B, C, of his science. If called upon to explain and to dilate he is apt to refer you to the "two-foot rule." A true mechanic is always happy when explaining his inventions to a pupil or an attentive listener. He is apt to shunt up closely if attacked by a critic, or pumped by a rival. While then in the European celebrity, and in the substantial wealth, which he has attained, Mr. Whitworth is one of the last people who should be called a disappointed man, it is more than probable that he has read the text that a prophet is not without honour save in

his own country with a certain soreness of self-application.

If so, he has taken one of the noblest revenges recorded in history. With the sole exception of what the munificence of commerce has done for the intended relief of poverty, in the instance of Mr. Peabody, the Whitworth donation of 3,000*l.* a year for ever to the nation is unrivalled as an act of noble patriotism. It is liable to no distortion by criticism. It is not a legacy, which often means a gift at the expense of others, perhaps at the expense of the rightful owners, of that for which we have no further use. It is not the lightly-handed-over gift of lightly-won money; the godsend of an unexpected bequest; the lucky result of a risky bet; nor even the fruit of a commercial venture. It is not the consecration to self-glorification of a sum earned by trade, strictly so called—that is, the mere profit between wholesale and retail price,—which knows no limit but that of the amount of custom. It is the fair, hard, honourable earnings, won by the head that can plan, the hand that can execute, and the will that can persevere unto success, that Mr. Whitworth has laid upon the altar of his country.

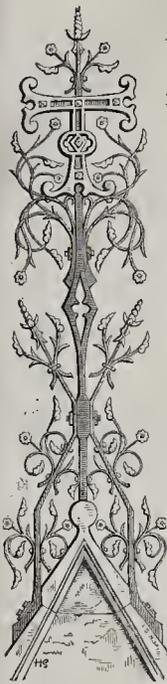

The gift is no less wise and appropriate than noble. It is, above all things, timely; and it indicates a new issue from a perplexed and most important controversy. In the absence of the information which the result of the *Realschulen* of Germany, and of the non-classical and secondary instruction now organizing in Italy and in France, may supply in a few years for our guidance, the most ardent admirer of the time-honoured method of classical education must regard with approval the foundation of mechanical scholarships. The details will be matter for future discussion, but an endowment of this kind is enough to form the nucleus of an Industrial University. For boys who in early youth show mechanical talent, no definite, well-adapted means of tuition are now open. The course of education given to the articled pupil of an architect or of a civil engineer depends on the talent, the occupation, and the conscience of the master. If all these be of the best, and if, into the bargain, the pupil be industrious, there is not only a good preparation for, but generally a fair introduction to, his future life. Still the risk is often great; the premium is usually heavy. We knew an instance recently of the acceptance of several pupils, and their premiums, by a professional man who had plenty of business going on in his office. It all, however, related to a single large public work, which came to a natural conclusion—an honourable conclusion, for the undertaking was completed, and, though not beyond the reach of criticism, was a success. But with this event came also the conclusion of the labours of office. The master had nothing more to do. There was nothing for the pupils to do either. Education and professional introduction vanished in smoke, and if the lads wanted practice they had to find it for themselves.

In the case of mechanical engineers some also take pupils. The same remarks apply in this as in the other instance. A practical knowledge of the interior of a workshop is in itself an advantage, but that scientific training which is needed to raise a man from the rank of a mechanic to that of an engineer is more rarely to be met with in the manufacturing than in the civil branch. For military engineers we have an admirable education in the Royal Military Academy, but we have no special secondary education to fit young men for the examination at Chelsea Hospital. A general education, however excellent, would enable but few to pass this severe ordeal, and the services of special tutors, men who prepare merely for passing the examination, are in most cases requisite to success. Apart from these unsystematic means of professional tuition one or two chairs have been erected in connexion with the London and the Scotch Uni-

versities. That the whole educational power now in existence might be organized and combined, and secondary schools for the preparation of students of engineering, of architecture, and of mechanics, might be invested with the sanction of professional recognition, and of examinations that resembled rather those of the Prussian system than those of our own inadequate competitive method, and that a faculty should be organized for the superior education of those pupils who are intended for the higher stations of the profession, is a hope to which the donation of Mr. Whitworth seems to give a practical prospect of fulfilment.

Disinterested as this noble benefaction is, it cannot fail of ensuring a more ample recompense to its author than could have been bargained for by any political combination or obscure intrigue. First element of this imperishable recompense must be the satisfaction of the conscience, and the reflection, which we trust will for many years be present to the benefactor, of what his own labour has enabled him to do for his country. Next will be the undying memorial to his name which generation after generation will welcome in the persons of those Telfords, and Stephensons, and Watts, and Whitworths of the future, who shall have been trained at the cost of the donation. We cannot for a moment doubt that the thoughtful and gracious Lady who has omitted, even in her deepest affliction, no proper occasion of proving that a constitutional sovereign is not a mere blank form, has already considered when and how the highest expression of the gratitude of the nation can be most fitly awarded to the founder of a systematic technical education for England. While ever leaving political action to the charge of those who are responsible to Parliament for the conduct of the affairs of the State, the Queen has shown that she is herself the true minister of that function of the Crown which is regarded when we speak of the Sovereign as the fountain of honour. The miners and mechanics of England can never forget that on every occasion when the perils which they so constantly dare have overborne their vigilance, and overwhelmed their efforts, the first services of the telegraph, to condole with and to inquire after the sufferers and those bereaved by their loss, have been employed by the first Lady in the land; the readiest contribution in alleviation of sudden distress has come from the privy purse of her Majesty. Where institutions different from our own have disabled the citizens of another country from accepting any of those marks of recognition of which Englishmen are justly proud, the Queen has known how to originate special and peculiar badges of honour proper to the occasion, as in the gift of her Majesty's portrait to Mr. Peabody. We have no wish to anticipate any condescending proof of the Royal recognition of what Mr. Whitworth has so opportunely done to forward the solution of the great English difficulty of the day; but we are sure that, whether the public ever learn it or not, all that good feeling, good taste, and good sense would consider most appropriate will freely flow from the *motu proprio* of Queen Victoria.

There is yet another response which we sincerely trust it will need little more than so humble a voice as our own to elicit. For the sake, not of himself but of ourselves, Mr. Whitworth's gift must not fall flat, and without an echo from the great centres of commercial and manufacturing industry. Hardly one great employer of labour can have read the few words that announced the donation to the House of Peers and to the House of Commons, without feeling a tingle in his veins. Hardly a corporate meeting can have been held at Manchester, Liverpool, Leeds, Birmingham, or any of the local capitals of industry, without reference to, or at least without thought of, the example

given of the heat method of employing the fruit of successful enterprise. It is our custom to greet less important exertions on behalf of our country with municipal marks of honour, which are gratifying to their recipient, but barren in themselves. Freedom of towns and cities, enclosed in gold-plate boxes, are the usual signs of corporate gratitude.

We trust that the thanks of the industrial leaders of English enterprise will, in this instance, take a more practical form. In whatever manner the Whitworth donation be carried out,—whether it form the nucleus of a technical university, whether it lead in the first instance to the preliminary step of the creation of a Faculty of Constructive Science, or whether only the organization of the thirty scholarships occupy the sole immediate attention of the trustees of the fund,—it is highly desirable that there should be a Seat and a Home for the administration. To provide this is a necessary complement to the donation itself. A noble and worthy building should at once be constructed for the purpose, and a very moderate contribution from each of the great towns, the prosperity of which depends so intimately on the maintenance and advance of constructive science among us, would suffice for the establishment of such a collegiate edifice. The Whitworth College should be the echo given by the industry of the nation to the Whitworth donation.

The site of such a building should be in a position central, as far as possible, amid the industrial districts of England, and yet removed from the actual unhealthy vicinity of any great mass of human habitations. Some spot like Crews or Norwood, some great railway centre of communication which is not itself a city, would seem to be the best locally. Thus, too, any local rivalry would be avoided. The great Lancashire towns might hesitate to aid in founding the college at Birmingham, in itself a very natural site. Staffordshire and Monmouthshire might feel less anxiety to support a Liverpool or a Manchester college than one chosen so as to be as far as possible central to manufacturing England. The determination of the site is, of course, only a detail; but the determination of the principle on which the site should be selected is a matter essential to the fair starting of the subscription.

We suggest, therefore, to the lord mayors and corporations of London and York, to the mayors and other municipal authorities of all great cities and towns dependent on mechanical and manufacturing industry for their welfare, and to all those great employers of labour who desire to see the industry of Great Britain resume that pre-eminence which is now slipping from our grasp, that a subscription should be at once opened for the purpose of acknowledging Mr. Whitworth's gift to the country by providing him a foundation with a Home. A very modest echo to a very loud call for gratitude will do this. How far the heart of the country is stirred by so noble an example, will soon become apparent. It is our hope and belief that all which is requisite is that a prompt example should be set by some leading city in the matter. Considering that vast amount of private beneficence which, while perhaps often misdirected in its course, enriches England with voluntary good will, we cannot doubt that it is only necessary to make a proper appeal to the country to receive a proper response. It would cost England little to double or to triple the donation. Great as that gift is, it ought to be most precious as a nest egg. Around the thirty scholarships will group—if we are not anxious to show that Mr. Whitworth is Quixotically in advance of the public spirit of his countrymen—college, and chairs, and lectureships, and full machinery for affording to the youth of the country a sound technical education which shall not be inferior to that now obtainable in the first institutions of the Continent. A centre of aggregation is now provided. It is, to a certain extent, independent of further contributions. But, to make the most practical use of that central benefit, we must hasten to surround it with subsidiary advantages. Primary schools, in connexion with each great industrial establishment, should receive an impulse from the constructive centre. Secondary schools, in each great seat of industry, should be in direct communication with the college. Education in the higher parts of constructive science should then be provided for those who are able and willing to pay for it, as well as for those who, by a fair and wise selection, not by the mere chance of a single examination, prove their claim to the enjoyment of the thirty exhibitions. A few

months' activity might make the present donation the prolific source of that which the reports of the Royal Commissioners admit to be so great a desideratum for England, a sound technical education, one in which practice and science may combine to do for the English engineer all that human skill and human wisdom can do to perfect his accomplishment.

For any communications on this subject the columns of the *Builder* will be open. While we wish the movement to be locally spontaneous, we shall be glad to afford the means of ready and public correspondence between the different movers in the matter. We shall be happy to give any aid to the formation of a central committee, each subscribing town to nominate a member, or to charge a member already nominated with the representation of its own voice. The occasion is most apt. The attention of the public is called in the very nick of time. Great questions, after the solution of which some are groping in the dark, some are seeking for information from other countries, and as dogged fight, will receive unexpected and most welcome solution from an organised, centralised, voluntary effort to supply at once and adequately one of our most miserable deficiencies. We call upon all who rank in the yard of the builder, upon all who live by the trowel and the pick, the hammer, the adze, and the chisel, the drawing-board and the pen, the foundry, the forge, and the loom, to echo our proposal, that the gratitude of industrial England for the Whitworth donation be shown by providing a Home for its reception.

ON THE UTILIZATION OF SEWAGE BY IRRIGATION.*

In the cases of large towns upon small rivers, and those rivers impeded by numberless bars or weirs,—both of which conditions are exemplified by the river Melkook at Manchester, and the Sheepscar Beck at Leeds,—the injury is not the effect of sewage hourly delivered as it is produced, but that of a putrid mass of organic matter, which, floating for days upon the surface, develops into a filthy scum, revolting to the senses. At Carlisle, where there are no weirs to retard the rapid flow of the sewage after mingling with the volume of the Eden, a complete system of main drainage conveys every particle of the sewage from beneath the city within a few hours of its production; so that, not having time for putrefaction, the river is less than usually contaminated, and salmon and trout abound in it.†

At Norwood, where the irrigation works are in the immediate vicinity of the town, this fact is so far from proving the source of a larger death-rate than the average in that district, that a comparison of the bills of mortality for the six years between 1860 and 1865 shows that during the period of irrigation the mortality was the lowest—a conclusive answer to those who insist upon its deteriorating effects on the atmosphere.‡ Mr. Albert Latham has also recently stated that while the mortality of the town districts for the year 1867 was 2.38 per cent, the country districts being 1.95, the mortality of the town of Norwood was only 1.47 per cent. At Edinburgh, where sewage has been utilized for centuries, no injury to health has arisen from the proximity of the irrigation works, although the applications have been in enormous quantities.§

Though opposition has tended to retard the progress of irrigation in its first stages, and thus, in the opinion of many, injured the cause of sanitary reform, yet it is impossible to doubt that it has done negative good. The tendency of speculation is to lay hold of and carry to a disastrous degree discoveries which are of fair promise, without consideration as to their limit of practicable application, or indeed as to their full development for commercial purposes. Consequently, that which raises up doubt and

caution in the mind, and conducts us by a searching process of argument, analysis, and experiment, to a comprehensive knowledge of every side of a question, must not be viewed as altogether valueless, since it is by this means alone that we can hope to acquire perfection without the costly teachings of experience. The attempts, therefore, to prove the unwholesomeness of sewage irrigation have had the result of producing in evidence a record of facts showing the groundless nature of such a fear, and establishing on sanitary principles the expediency of its adoption.

Quantity of Sewage to be put into the Land.

The expediency of sewage irrigation having been shown, we have endeavoured to explain some of its advantages, and also to answer the chief objections which its opponents have urged against it. To complete the present analysis of the subject, it now remains to inquire in what quantity it is necessary to bestow sewage upon the land, in order to ensure the greatest possible benefit. Notwithstanding all that has been hitherto accomplished in this country, it can scarcely be said that the experience so gained has been sufficiently extensive to justify our forming exact conclusions upon this important point; and, indeed, it is highly probable that in the end it will be found that no two soils are alike in their capacity for profitably absorbing sewage. At present nothing can be more diverse than the opinions of the various authorities upon this subject. Some of these incline to light and infrequent dressings—amount to from 100 tons to 500 tons per acre per annum; others substitute thousands for hundreds, and go as far as 9,000 tons; while there is a small minority who consider that there is actually no limit to the quantity to which sewage may be beneficially supplied. These latter, however, ignoring the fixed laws of economy, qualify their statement with the proviso that the sewage is to be had for nothing, not seeing that what is waste in a price-bearing commodity must be equally waste in a commodity which is of free cost, but of which the supply is limited.

The following is evidence given before the Select Committee in 1864 in this regard:—

Mr. J. J. Moore did not think it would require more than 5,000 tons per year to the acre.*

Mr. E. Smith considers that 800 tons would be more than sufficient, but that grass lands would absorb more.†

Mr. Ellis says that it is a mistake to suppose that the returns are in proportion to the sewage applied; and, in making his calculations for the area over which he proposed to distribute the sewage of the metropolis, he allowed 500 tons per annum to the acre; this to be applied in several dressings, amounting in the aggregate to a depth of 4.9 inches.‡

Mr. Chubbert Johnson stated that at Croydon, of whose local Board he was chairman, 1,000,000 gallons per day were being put on 250 acres, which gives 6,500 tons per acre per annum.§

Mr. Whitehead considers the sewage of even to ten persons sufficient for an acre; while Alderman Mechi would apply four or five dressings of 100 tons each to grass lands.¶

Mr. Walker, of Rugby, recommends from 500 to 1,000 tons per annum to the acre, in five or six dressings.‡

Mr. Lawes, employed by Government to investigate the value of sewage applied to land, found by experiment that with 3,000 tons per acre, 22 tons of grass, producing 5 tons 1 cwt. of hay, were obtained; with 6,000 tons, 30 tons of grass and 5 tons 15 cwt. of hay; and with 9,000 tons, 32 tons of grass and 6 tons 9 cwt. of hay per acre; whilst without sewage 9½ tons of grass and 3 tons of hay were the result. He considers 6,000 tons to be the most profitable quantity; but if the sewage cost nothing, would put on 30,000 or 40,000 tons.**

Professor Way recommends 3,000 to 6,000 tons per acre.††

The amount consumed on the Craigentinny meadows was stated to be 6,400 tons per acre.‡‡

At Barbing the quantity varies between 2,400 and 4,000 tons per acre.§§

†† Report. Met. Sewage, 1864: 4351, 4567. Mr. Lawes also stated that he had experimented with no less a quantity than 3,000 tons per acre.

‡‡ Rep. Met. Sewage, 1864: 4949-50.

§§ Rep. Met. Sewage, 1864: 4373.

§§ Agricultural Gazette, July, 1867.

The Earl of Essex applies the sewage of Watford to hay meadows at the rate of 225 tons per acre, in two dressings, and to Italian rye-grass 270 acres after each cutting.*

In the report of the Rivers Pollution Commission we find it stated that on poor land 5,000 to 20,000 tons of sewage per acre per annum may be filtered; whereas on good land, where paying crops and perfect purification are looked for, 6,000 tons are as many as can be profitably applied.†

Baron Liebig says that to produce four tons of hay on a pure sandy soil, 2,430 tons of sewage are required; but that the necessary quantity is ruled entirely by the nature and condition of the soil. If the soil contains more of the constituents of the plant, less sewage will be needed; if it contains less, then more sewage will be needed. Thus, on a soil which will supply one-half the necessary food in the growth of hay, not more than 1,215 tons need be applied to produce the four tons of hay.

But inasmuch as it is not the object of agriculturalists to exhaust the fertilizing properties of the soil, and throw the whole burthen of reproduction upon the action of sewage, this manner of calculation is subject to modification. If, therefore, four tons of hay represent twenty tons of sewage-grown grass, and it is considered that, according to Mr. Lawes's experiments, more than twenty-two tons cannot be obtained without a disproportionate sacrifice of the fertilizing medium, it would appear that 2,430 tons of sewage are as many as can economically be supplied. In bringing, however, Mr. Lawes's experiments to bear upon this point, it must not be forgotten that many doubts have arisen as to their integrity, and that by many authorities of weight they have been condemned as utterly worthless. The very fact that he never experimented with a smaller quantity than 3,000 tons, which we have from his own lips, would of itself appear to justify these doubts. Mr. Walker, upon whose land the experiments were conducted, states point-blank that they are calculated to mislead the public as to the true value of sewage manure, in so far that the applications of sewage were made at certain fixed intervals, which were rigidly adhered to, without consideration as to the condition of the soil, and its adaptation for the favourable reception of the liquid.‡ The position also of Mr. Lawes as a manufacturer of a rival manure, in which it was stated before the committee that he was interested to the amount of 40,000, or 50,000, annually, together with his reckless assertion of the enormous quantities, 40,000 tons,§ with which he would deluge the land, are further evidence upon which to found grave doubts as to the worth of these experiments. The weight of 40,000 tons per acre represents an annual depth of no less than 33 ft.¶ and yet we are told that even this quantity may be exceeded. Such is the authority into whose hands the charge of these important experiments has been entrusted by a confiding Government.

We have not, in fact, sufficiently decisive evidence as yet to determine this question with precision. Its importance is rendered greater by the influence it will have on the mode of administration. If the sooty dressings applied on the one side be finally determined upon, there can be little doubt that the hose and jet system can be found more advantageous in many cases than the special preparation required by the open carrier system, especially for grain crops. There is also another point to be considered. If—as doubtless has hitherto been the case—sewage is a drug in the agricultural market, of which its holders desire to rid themselves as speedily as possible, or if it can be bestowed but on a limited area, then the use of enormous quantities may be the better policy, taking care that too much is not passed through the soil to ensure proper purification. But if, on the other hand, as sooner or later will be the case, the demand for this commodity comes to exceed the supply, then excessive applications signify a waste of national resources.

In default, therefore, of convincing practical demonstration, we are as yet in the dark as to when the limit of the economic use of sewage on various soils is reached. When corporations take the land into their own hands for purposes of irrigation, a small area doubtless admits of easier management than a large one; and in the discus-

sion of the sewage question this will form an item of consideration, as such bodies are justly cautious in meddling with undertakings in which the ownership or lessorship of land is involved, although by existing Acts, local Boards are empowered to assume these relations. The existence of so much doubt and uncertainty as to the proportionate application of sewage may, perhaps, be a difficulty in the way of adopting irrigation, because, it may be argued, the extent of the proposed area of utilization is dependent thereupon; and whereas, on the one hand, too extended an area would leave the controlling Board in a position nowise different from that of ordinary farmers,—on the other hand, a too limited area would defeat its own purpose. This timid policy should not prevail. In projecting works of this kind, a Board should act with caution and judgment, confining their first tentative operations to a safe area—taking care, however, that the site is so selected as to afford ample provision for future extensions. A trader who, having a perishable commodity on his hands, allows his donkey as to its exact value, or its best possible market, to prevent his turning it to account, would be justly ridiculed; yet his position may be held analogous to that of a corporate body whose impulses towards the utilization of sewage are checked by uncertainty as to the exact distributing area.

Actual Results of Sewage Irrigation.

The following is a list of the chief of these towns which, in a greater or less degree, have dealt experimentally with sewage for irrigation purposes. Aldershot, Alwrick, Bingley, Birmingham, Bury St. Edmund's, Carlisle, Cheltenham, Coventry, Croydon, Edinburgh, Leeds, Mansfield, Melton Mowbray, Milverton, Mold, Norwood, Nottingham, Oswestry, Rugby, St. Thomas Exeter; Swaffham, Tavistock, Uckfield, Warwick, Watford, Worthing; and, as has already been said, the sewage of the northern portion of the metropolis is being at present experimented upon at Barking. For the present purpose, it will be sufficient to select from these, Aldershot, Croydon, Norwood, Edinburgh, and Rugby, as practical and successful illustrations of the principles of sewage irrigation, wherein the most approved forms of application may be said to be fairly exemplified.

Aldershot.—After, as has been stated heretofore, the Government filtration works erected at these camps were condemned by an injunction from the Vice-Chancellor, the sewage of Aldershot, comprising a population of from 12,000 to 15,000 people, was leased to Mr. Blackburn, of Aherdeenshire, for the purpose of being utilized on the waste land of the adjoining Aldershot Heath,—a barren common consisting of loose white sand, drifted here and there into irregular heaps, and covered with heather. This experiment has now (1867) been in hand for two years, and gives every appearance of ultimate success. At the southern outfall, a 12-horse engine has been laid down, which drives a centrifugal pump for the purpose of lifting the sewage on to the higher portions of land not accessible by gravitation, upon which it is distributed by means of the hose and jet system. At the northern outfall, the sewage discharged by which flows on to the land by gravitation upon the open conduit system, a very simple and well-devised arrangement exists, by which the grosser obstructions contained in the liquid are retained. This consists of a small wooden tank, provided with a strong close grating at the lower end, slightly inclined from the horizontal, through which the sewage is passed into the main conduit. This grating is in the form of a lid, and is moveable upon hinges; any overflow being prevented by a bar placed transversely across the tank, dipping below the level of the grate. About forty acres of land have been reclaimed,* and during the year 1866 six crops of Italian rye-grass were cut, averaging from ten to twelve tons per acre, and of excellent quality. When complete, the irrigated area is intended to comprise a farm of 140 or 150 acres in extent, reclaimed from the barren wilderness of Aldershot Heath. The scheme is exceedingly simple and effective, and is capable of economical management.

Croydon.—This town, perhaps the most complete modern exponent of the principles of sewage irrigation, certainly occupies a distinguished position in all matters pertaining to town-drainage. Forced by unavoidable necessity to have recourse to this method of dealing

with the sewage of a large town upon a small river, it has been truly described as the theatre of conflict, in which the most eminent improvements in modern town drainage have been fiercely and repeatedly discussed. Injunction after injunction was discharged against the local board by the proprietary of the river; and that body, driven to extremity by lawsuits on every hand, cast about for and grasped at every conceivable expedient for extricating themselves; and at last, having exhausted them all at an enormous expense, besides creating a debt of 10,000, for law costs, irrigation was tried, and ultimately proved perfectly successful. This success was not, however, of immediate growth. Croydon being, after Edinburgh—whose experiences was then viewed as something not in the nature of ordinary things,—the pioneer in this movement, the Board were compelled, from lack of precedent, to grope their way. In 1857, the quantity of land upon which the sewage of 20,000 people was disposed was but 15 acres, and, in consequence, this area became covered with muddy silt, which turned putrid and stank foully. In 1860 the area was enlarged, and the sewage was applied to 56 acres, which also, in its turn, proved by infallible signs inadequate. In 1862, the Vice-chancellor, Sir William Page Wood, granted an injunction to Mr. Bidder, the engineer, who is interested in the conservancy of the river, restraining the flow of the water after irrigation thereon, on the ground that, it having been proved decisively that sewage could be rendered pure by irrigation, the impure results of the Croydon process must be owing to some defect in application. It was then put on an area of 250 acres, after which the water went off in a pure state, and an end was put to all litigation.* Since that time sundry additions have been periodically made to this quantity, so that the total extent now exceeds 340 acres.

The cultivation of this area has been attended by complete success, the pecuniary fruits of which, however, had not been reaped by the ratepayers, but by the tenants,—Mr. Marriage, lessee of the Beddington Farm, and Mr. Cousins, lessee of the Norwood Farm,—who take the land under them. The Board, acting under an injunction, were forced to lay hold of the first land which presented itself, at the exorbitant price which is always exacted by necessity, and also to obtain a tenant, upon very disadvantageous terms, to whom they allowed 3l. or 4l. per acre towards preparing the land, upon which, although otherwise excellently adapted for irrigation purposes, many woods and shrubs had to be grubbed up. The rental paid by the Board for a lease of the land was 4l. per acre; that paid by their tenant, 5l.; whilst, as was stated by Mr. Cathbert Johnson before the Commission, four crops per annum were being taken off the land, each sold at 8l. per acre uncut; from which it would seem that the farmer, with no outlay save his rent and the wages of two or three attendant labourers, is in receipt of 32l. per acre.† It has already been stated, on the authority of Mr. Baldwin Latham, that the actual profit realised from the sewage of Croydon is 6s. per head of the population contributing to the sewers.‡ Despite these facts, however, we see that the Board are only profiting by their dearly-bought experiment to the extent of 300l. or 400l. per annum, an insignificant result due to the enforced nature of the enterprise. Yet, when we consider that at one time Croydon was expending at the rate of nearly 3,000l. per annum in attempts at filtration and deodorization, it cannot be viewed otherwise than one of the most successful of modern enterprises. So satisfied are the authorities, that they have recently (1867) expressed their determination to pump their sewage to an altitude of 200 ft., if necessary, for utilization. Had the policy of the Croydon Board been the result of their own deliberate conviction, unquickered by the formidable penalties of the law, a revenue of possibly not less than 8,000l. or 10,000l. would at this moment have been relieving their district of a material portion of its rates. Even under the circumstances in which they acted, the experimental conduct of the works might have been better placed in the hands of a hind or manager until a proper assessment of the value of the sewage could have been arrived at.

¶ Nearly twelve times the average rainfall throughout England.

The whole of the irrigation at Croydon being conducted on the principle of gravitation only, the works at the outfall are of no great extent. One feature, which might perhaps be remedied, is the large area of the settling tanks, which admits of the stagnation of the lighter solids floating upon the surface of the liquid. This in dry weather, is apt to cause a stench, which might easily be avoided by providing a much smaller receptacle, in which the impulse of the outfall discharge would prevent putrefaction. The refuse which is retained in this tank is sold to agriculturists in the neighbourhood, by which the expenses of overlooking the outfall works are nearly paid.*

M. P.

DOMESTIC ARCHITECTURE OF MEXICO.†

In treating of the domestic architecture of a country, and the selection of places for laying out cities and towns, there are many important matters to be taken into consideration, as to their geographical position, and the nature of the site, the geological substrata on which they stand, and their general aspect as to admitting light and air, particularly in a tropical country, and other important matters bearing on their physical and sanitary condition.

The records of ancient history attest that many of the cities of Mexico were laid out by its ancient conquerors, the Tonilics and Aztecs, wandering, nomadic, barbaric tribes, whose sole end and aim appeared to be to overrun and subdue the primitive inhabitants, and to subsist by partially cultivating the land, hunting, and fishing where water existed; and although they have left some very extraordinary monuments of their industrious habits, and constructive skill in the early ages of the world, still an attentive observer will discover, from the mode adopted, and the manner the Mexican cities are laid out, that they bear upon them the impress of well-studied design, skill, and science, the fruits of an advanced civilization, the workings of master-minds; and therefore their present state could not be the productions of those wild barbaric tribes, but of the subsequent conquerors of that country, the Spaniards, at a period when they had attained considerable eminence and skill in the constructive art and sciences, and had established a system of architecture, possessing many points of beauty and attraction, in its decorated arcades, horse-shoe arches, and fretted vaults.

Like the ancient Romans, the Spaniards evidently devoted considerable attention to the selection of a site for their cities: the geographical position, as well as their general aspect, were carefully studied, and its applicability for sanitary purposes, such as an effectual system of surface drainage and good water supply.

In giving a description of a large and ancient city, in which we resided some time, we shall be rendering a general and faithful representation of the great majority of the large and populous cities of that country, as the constructors appear to have been governed by one general design and plan, and which was adhered to as closely as local circumstances would permit.

The general direction of the streets was evidently regulated by magnetic bearings, running principally north and south, and crossed at right angles by others running east and west; and this mode of construction was rendered necessary so as to enable the prevailing cool and refreshing trade winds which blew from the east to circulate through the streets and also through the houses, thus promoting the health and comfort of the inhabitants.

The whole streets were laid out 40 ft. wide, the centre part allotted to the carriage-way, and footpaths on each side; and the physical position was such that slightly inclined ground, or easy gradients, were secured for the contour of the streets. Their cities are laid out in a series of blocks or plots of land, about 280 ft. long and 225 ft. wide; and in the particular instance of the city alluded to there were twenty such blocks from east to west, each divided by a street, and ten from north to south, also intersected with streets; and nearly in the centre of the city some blocks were omitted in order to afford space for the "Plaza des Armes," where all the military displays and public games and entertainments take place, and some extensive blocks of this city were laid out but were not built upon.

These plots are generally divided into four building lots, each 140 ft. by 112½ ft., and upon that site are erected four substantial houses, in the peculiar system and plan of the architecture of the country; and each house, therefore, faces a street, and they are built back to back.

Around the outer area of each lot, the buildings are erected with thick substantial walls of small rubble masonry, and roofed in and covered with bright red horse-shoe tiles, and with broad overhanging eaves, some 5 ft. wide or more, on the outer side, completely covering the side path of the street; and with broad overhanging eaves on the inner side, usually supported on pillars, and forming a covered passage or corridor around the inner part.

On each side the Plaza are erected the principal public and other buildings; on one side the cathedral, a large and imposing structure, a rough adaptation of the Mosque or Saracenic architecture,—the interior elaborately decorated and highly embellished in all the gorgeous splendour of Roman Catholic countries, and adorned with a large dome, covered with bright porcelain of many colours and patterns; and its open space in front fenced off with ornamental railing, and the ground laid out and tastefully planted with the brilliant and ever-blooming flowers of this warm and glowing clime. On the opposite side of the cathedral in the plaza is the prefecture, a one-floor arcaded building; and conveniently situated at the back of that building is the gaol. At the former, the prefect and alcaide preside daily,—the former of these functionaries to carry out the local government of the state over which he presides, and the latter to administer the laws; and that is usually conducted in such an arbitrary and cruel manner, so peculiar to the race of people whence many of them have sprung, as to savour very strongly of the dread and horrid inquisition.

The prisoners, who are generally employed on the public works, are bound and shackled with heavy chains, and in this barbarous manner they are compelled to labour, watched by the eagle eyes of the warder, armed with the stern authority of the rife.

On the side of the Plaza are the hospital, the post-office, quarters for the officers of the garrison, and some of the principal stores or "tiendas;" in fact, the Plaza is a place of the first importance, the centre of great attraction to the inhabitants as well as the traveller, and the general rendezvous, on all occasions, of public entertainments, military spectacles, and national fêtes.

The Plaza is not only used for the purposes just mentioned, but also is a public market-place, and the market is generally held on a Sunday, which is usually the case in Roman Catholic countries, the Sunday being made a day of recreation and enjoyment, rather than one of rest and religious observance, as with us, and the whole place is occupied with stands or movable stalls, for the display of the articles and produce to be sold. The Indians attend the market for many miles round, the city forming the centre of a large district, the produce of which is brought to this market; and they frequently arrive the previous evening, and take up their abode for the night under the arcades that are erected in front of the stores and public buildings.

It is no uncommon thing, if one is out after dark, to find numbers of men, women, and children stretched across the side-path,—in fact, pedestrians frequently stumble over them,—and their couch is the hard paving covered with Mexican matting (which is nicely and skilfully made) and their "serapes;" and by early dawn they are up and stirring, selecting their standing in the market, and preparing to display their wares and produce.

The whole of the area of the Plaza is occupied for the market, except a thoroughfare on each side, which is used for the traffic of the country, diligences, mule-trains, &c., and the stands and stalls are fixed in rows, with avenues between them, running up the square, for the public to obtain access to them; and they frequently make a fine display of fruit and vegetables, both tropical and of the European species, that would gratify the most fastidious taste, dried meats, and crockery, and, though last, not least, the national stall of tortillas and frijoles, around which you may see crowds of Indians gathered, devouring the favourite diet with much gusto—indeed, as fast as the female vendor can prepare them. To protect themselves from the weather, either the rains or the tropical sun, they frequently erect covers of matting on a

light framework, or on a pole with cross-piece attached to the end, upon which they stretch a piece of matting, something like a large umbrella, and this they move about on the other end of the pole as its axis as the sun changes its position or the rainfall drives, so as to shelter themselves effectually; and the different shapes and original forms of these coverings are striking and sometimes ludicrous, and with the moving figures of the people and the bustle of the throng, the scene is highly animated and interesting, particularly when we add the variety of costumes to the groups, amongst them not the least interesting the Indian women with their brown faces and jet black hair in tresses hanging down their backs, and dressed in white ornamented robes, broad "sombrosos," and gay-coloured serapes, the men also attired in white shirts or slops, short-legged trousers or drawers, the broad Mexican hat, sandals, and serapes, the whole combined forming a very picturesque, stirring, and strange scene to English eyes in the glowing climes of the tropics, with clear unclouded skies, and a brilliant sun, setting everything off to the brightest and best advantage.

The bustle of the market takes place in the early morning; as noon approaches the throng sensibly diminishes, and towards three o'clock there is a general clearance as the time for "evening vespers" approaches, which they attend in great numbers, depositing in the offertory as they enter the cathedral their mite to support the splendour and gorgeousness of their religious establishment, and to satisfy the wants of a grasping, overbearing, and dominant priesthood.

After the market and vespers are over they make what purchases they require at the stores, and return to their homes, sometimes on mules, horses, or on foot, and it is very rarely you see any of them intoxicated, although "aguadente and pulky" are plentiful. Occasionally such scenes may be witnessed; but whatever their other faults, it cannot be said they are greatly addicted to drunkenness.

Having briefly described the Plaza, we may further observe that the streets of the city are well and regularly laid out and built upon, and at frequent intervals you meet with large and imposing buildings,—the town mansions of some of the many-acred Dons of Mexico,—at others the stores or "tiendas" for the sale of goods and merchandise, and each merchant sells a motley variety of articles, almost everything you require, a sort of jack-of-all-trades or general merchant on a small scale.

The "tiendas" are sometimes made out of some of the apartments of the town mansion, generally a corner room, so as not to interfere much with the occupation of the other part of the house, and some of them appropriate rooms open to the street for billiards, so that the passing stranger may soon be made acquainted with the Mexicans' evil habit and desperate passion for gambling; and these rooms are frequently kept open all night, gaily decorated and lighted up to make it attractive, and you might hear the stroke of the cue, and the click of the balls, and the shout of triumph or the groan of despair, and sometimes the deadly strife in the dead hour of night, when one was hoping to obtain repose from the fatigues of the past day, and to gather strength for the trials of the morrow.

At the corners of some of the streets you would meet with large buildings, formerly churches or chapels, at others nunneries; and these are mostly in ruins, brought about by their perpetual intestinal wars, as they have been used as places of military defence, and have been broken down and destroyed when carried by assault.

Most of the buildings, both public and private, of this city, exhibit numerous marks of being struck by cannon shot and bullets upon the stone and wood work from the frequent battles that have occurred in the streets, spreading death and desolation around, and have left these enduring mementoes of their bellicose propensities, and their love of the gay guerilla's life.

This city was originally laid out on a bold and magnificent scale, and intended to be one of considerable extent and importance, as from its geographical and physical position it was well and admirably adapted; but the original conception was not fully and properly carried out, as a considerable extent of the part laid out is still unbuild upon, and this space is devoted to gardens or plantations, and generally cultivated, and on which grows the valuable produce of the tropics: thus the orange, lemon, lime, banana,

* To be continued.

† See also p. 7, ante.

and mango, and other fine fruits luxuriate; also coffee, sugar-cane, cocoa, and tobacco, and, at the season of the year when they are in full blossom, the beauty of the bloom delights the eye, and their refreshing fragrance scents the very air around with delicious perfume.

In addition to the beauty of the fruit and vegetable productions of these gardens, we must not omit to mention the splendid tropical flowers that adorn the fences, that separate them from the roadways, jessamines, Virginia creepers, purple wreaths, roses, &c., flourish in all their wild magnificence and beauty, enlivening the dark-green foliage with their brilliant and many-coloured blossoms, and shedding their sweetness on the desert air.

These suburban roads are much used as pleasant walks by the inhabitants towards the cool shades of evening, to breathe the pure and calm air of heaven and admire the glowing beauties of the gorgeous setting sun, and the bright and sparkling flowers, and indulge in the fragrant cigarro or cigarette.

The carriageways of the streets of the city are laid out on a different principle to that adopted in our towns, the channels are formed down the middle of the carriageway, which carries away the surface drainage, and the flood-water in times of heavy tropical rains, without incommencing the houses or the side-paths; there is a gradual declivity in the cross section from the sides towards the centre, and the side-paths are flagged, with a curb-stone; at other parts it is formed of small broken stones grouted and plastered over (a sort of concrete), which makes a hard and enduring surface.

The streets are usually well paved with regularly sorted boulder-stones, well arranged and set, which system might be profitably copied by many of our towns authorities who are not proverbial for well-paved streets of this kind.

The drainage is principally on the surface, and to cesspools situated at the rear of the premises, which filter away through the crevices of the rocky foundation on which the city is built.

The water supply is obtained by means of pipes laid from the stream that flows from the adjacent mountains, brought in pipes and delivered into tanks situated in the Plaza; but recently a lofty obelisk has been erected in the centre of the Plaza about 30 ft. high, the base of which is 4 ft. square and 10 ft. high, and the shaft 2 ft. square, tapering to nearly a point at the top, surmounted with a gilded star. Around the obelisk is constructed a circular tank to receive the water that falls from four fountains fixed at each angle of the base of the obelisk. The whole is elaborately ornamented with the egg and tongue and other mouldings, and a gilded wreath on each of the sides.

The obelisk was erected entirely of small rubble stone to the top, and smoothly plastered over, the mouldings, and the ornaments are also made of plaster, which appears to be well and substantially executed,—a remarkable and striking instance of what may be accomplished in small rubble masonry when well and properly put together.

The obelisk was commenced and completed while the writer resided there, and the day of inauguration selected was the anniversary of the one on which the Mexicans achieved their independence! Poor benighted creatures! to fall into a worse species of despotism—the despotism of mob law, or the strong arm of unprincipled chiefs.

Besides the cathedral, there are several other ecclesiastical buildings in other parts of the city, but one only except the cathedral is now used for religious worship. The system of architecture generally adopted is the Spanish, adapted from the Moresque or Saracenic styles, rather roughly executed on the exterior, and very sparingly ornamented; and where it exists it is executed in plaster. The domes are generally covered with coloured porcelain, of diverse pattern, which produces a light and bright effect when viewed from a distance, and under the bright rays of a dazzling tropical sun.

There are also some nunneries executed in the same style, covering a considerable extent of ground, and doubtless affording accommodation at one time to a great number of nuns and their attendants; but these are all scattered by revolution or civil war, and confiscation. The premises are deserted, and nothing but bare walls and roof remain. The churches that are in ruins and these monasteries were taken possession of by the French troops, and used for barracks for the soldiers and stables for their horses; and

during the time the writer was there, these interesting buildings were destroyed piecemeal by the troops for the wood for camp-fires, or in a wanton spirit of mischief.

It too often happens, instead of being the means of spreading civilization, and disseminating abroad a spirit of subordination and good order, it produces an opposite effect, desolating the country, destroying important and interesting buildings, and instilling into the inhabitants a spirit of vengeance, retribution, and anarchy. In the instance alluded to I have no hesitation in saying that the high-handed conduct of the French troops annoyed and exasperated the Mexicans, making them reckless to the consequences, and resolved to destroy everything that afforded a stronghold or a convenience to the French; and that accounts for the very ruinous and dilapidated state many of the Mexican cities now present since the evacuation of the French troops. The writer has seen them pull down and destroy interesting buildings, and has cried shame upon them; but the spirit of war and plunder was abroad: as the poet says,—

“Cry havoc, and let slip the dogs of war.”

The lighter part of the religious paraphernalia of these structures, we suppose, had been carried off, but much of the interior gorgeous decoration still remained, broken up, scattered about the building in glorious confusion, and inducing one to moralize on the sad spectacle, and to deplore the necessity and misery of war, that produces so much needless wreck and desolation.*

NAMES ENDING IN “ON.”

We have recently, on more than one occasion, drawn attention to some striking coincidences;—coincidences in names and trades, coincidences in averages, and so on: the fact that the same number of thousands will, each week, for many weeks together, visit some public museum, or go night after night with few to spare to some particular dramatic entertainment. Boxed up alone in a railway carriage a few nights ago, the observation, belonging to the same class of facts, occurred to us that a large proportion of our most eminent men in their various paths bear a name ending in “on.” Thus we have,—

Bacon, our greatest philosopher; Byron and Thomson, our greatest descriptive poets; Clarkson, Buxton, and Colston, some of our greatest philanthropists; Gibbon, our most eminent historian; Clarendon, not far short; Gibson, one of our best sculptors; Hilton and Haydon, amongst our best historical painters; Incedon, our greatest ballad-singer; Jameson, our greatest female writer on art; Johnson and Addison, our most distinguished essayists; Lytton, our greatest living novel-writer; Milton, our greatest epic poet; Marchison, our most distinguished geologist; Newton, our greatest astronomer; Palmerston, the most English of statesmen; Stephenson, our greatest railway engineer; Tennyson, our greatest living poet; Wellington, our greatest military commander (with Napoleon for adversary); and Nelson, our greatest sea-captain.

As amongst men of lesser rank, Den Jonson, Chatterton, Hinton, Wharton, Emerson, Simpson, John Britton, Alison, Paxton, Rawlinson, Bonnington, Watson Gordon, Noel Paton, Hepworth Dixon, Mark Lemon, Gardner Wilkinson, James Fergusson, Donaldson, Sir Thomas Watson (our first physician), and many others will recur to the memory. Surely this is very remarkable, and, so far as we know, the observation has never been made before. All these names speak of progress: they cry, “Excelsior!” Echo herself says, as each name is repeated, “ON!”

The circumstances that London may be given as the scene of their labours, and that these lines were penned in Brompton, may serve curiously to carry on the terminal coincidence, though they do not bear on the original observation.

TRAMWAYS IN LONDON.—The vestry of St. George's, Southwark, contemplate laying down a tramway in the centre of the London-road, for the use of all kinds of vehicles, according to the *South London Press*. If successful, similar trams will be adopted on other roads in the parish.

* To be continued.

CONCRETE SEWERS.

Sir,—The article which appeared in the *Builder* on the 4th instant relative to the concrete sewers constructed by me at Sidmouth, Devon, has induced many gentlemen to write to me, asking for information as to the best shape for concrete sewers, the proper materials to be used in their construction, and the best method of executing the work.* As this question is of great public importance, I should be obliged if you would kindly permit me to reply thereto in the pages of the *Builder*.

In the drainage of towns two classes of sewers are put down, namely, main or outfall sewers, and branch-sewers. As the latter collect the drainings from the houses and deliver it into the former, the streams running in the latter are usually small, becoming at times mere driplets, while those running in the former are usually large, becoming, in times of heavy rain, considerable torrents. As the sewers are also laid at various depths in the ground, for properly draining the houses, they are subject to great strains from the weight of the surrounding earth. It is necessary, therefore, that both classes of sewers should be made of proportional capacity for receiving the sewage and rainfall from the houses, streets, and districts which they are to drain; and also of suitable form, not only for imparting velocity to the currents, and so aiding the discharge of the sewage, but for sustaining the lateral and vertical pressure of the ground.

For main or outfall sewers, the best form is undoubtedly that of a circle, for three reasons,—1st, because the circle offers the greatest resistance at all points to the pressure of the surrounding earth; 2nd, because the circle affords the largest transverse area or capacity for receiving the sewage from the branch sewers, with the smallest quantity of materials and labour in construction; and 3rd, because the circle offers the least periphery, or frictional surface, to the flow of the sewage, with the same amount of inclination.

For branch sewers the best shape is unquestionably that of an egg, with the narrow end downwards, for three reasons:—1st, because the egg-shape, like the circle, while it possesses the property of resisting the pressure of the earth around it, distributes the weight thereof throughout the thickness of the arch without collapsing; second, because the egg-shape, like the circle, while it affords the largest capacity for receiving the sewage and rainfall from the houses, requires the least consumption of materials and labour in constructing it; and, third, because the egg-shape, with the narrow end downwards, forms a deeply-curved channel, which, by concentrating the drainage and heaping it up on a small frictional surface, imparts the utmost scouring power to the stream, and enables it to hold in suspension and carry away the heavier matters discharged into the sewers by the house-drains, without deposit or accumulation.

Hence the circle for main or outfall sewers, and the egg-shape for branch sewers, are not only the strongest and cheapest, but the most efficient forms that can be adopted.

The above principles, the result of much observation, practical experience, and study of the subject, were advocated by me first in the *Builder*, and before the Westminster Commissioners of Sewers in 1845; and subsequently before the Metropolitan Sanitary Commission in 1847. They were afterwards adopted by the Metropolitan Commission of Sewers, and also by the present Metropolitan Board of Works when it came into power. In fact, the plans, sections, specifications, and schedules for sewers, gullies, and house-drains, now in use by the Metropolitan Board of Works, by the Metropolitan District Boards and Vestries, and by Local Boards of Health throughout the country, are either those which were drawn by me between eighteen and twenty years ago, or modifications of them. This can be verified by reference to my original reports, drawings, specifications, and schedules at the office of the Metropolitan Board of Works. I may also observe that glazed stoneware pipes, which have been so extensively used in the drainage of towns, and in the drainage of houses, and by means of which brick-drains have been

* With reference to a letter in our last signed “Walter Bradbury,” Mr. Phillips writes denying the correctness of the statement it contains, and describing the circumstances which have led to the writer's misconception. We have also received letters from the Chairman of the Local Board, and the Editor of the *Sidmouth Journal* to the same effect. It is unnecessary to insert them, and we must decline any controversy on the subject.—Ed.

entirely superseded, were first practically used by me for house-draining and sewerage purposes in the metropolis in 1845. The benefits derived by the ratepayers in reduced rates, and in increased comfort and health, by the adoption of these principles, I will not now dwell upon, but they must have been very considerable.

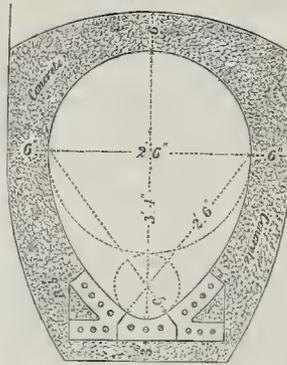

Formerly it was the practice to build sewers without reference to any general arrangement as to plan, fall, or sizes, with wide flat bottoms and upright sides, and of inferior bricks and mortar,—the bricks in the inverts being laid dry, or sometimes grouted. Part of the liquid discharged into these sewers from the house-drains was thus lost by seepage in the ground beneath, while the remainder, by being spread over wide flat surfaces, had no scouring power to keep the sewers free from decomposing deposit. The consequence was, that the sewers gradually choked up until the outlets of the house-drains were buried, and could no longer discharge their contents; then complaints were made by housekeepers that the house-drains were stopped, upon which the sewers were examined, and emptied or cleaned, by hoisting the soil to the surface, and carting it away. Nothing could possibly be worse than this state of things, and the sewers in consequence acquired the not inappropriate name of "elongated cesspools." For some time as clerk of works, and subsequently as chief surveyor to the Westminster and Metropolitan Commissions of Sewers, I waded through miles and miles of these sewers almost daily for years, to the permanent injury of my health, for the purpose of examining their condition, experimenting on the currents, and discovering, if possible, a remedy for the evil. The remedy came at last by the introduction of egg-shaped sewers, with the narrow end downwards, and by their systematic arrangement as to plan, fall, and sizes. The materials used were also of the very best quality, consisting of good, hard-burnt, square bricks, laid solidly in cement in the inverts, and in lime mortar in the sides and crowns. New plans of trapped gullies, with pipe-drains, were also adopted and largely used in the districts. Architects and builders were also "educated" in the principles of house-draining, and strongly urged to abandon brick drains for houses, and to use the cheaper and more efficient stoneware pipe-drains instead. Permeable brick-drains, which are now the exception, were then the rule for house-drainage. The saving to the rate-payers, and also to builders, by these improvements, has been enormous. I hope I am mistaken, but I believe the Metropolitan Board of Works knows little or nothing of what the condition of the metropolitan sewers was in years gone by. I think they have no idea of the great labour and persistent study which I gave to the subject day and night for years, for the purpose of bringing to perfection the improved system referred to, and upon which their drainage works have been and are still being executed by their officers. This, of course, is known to few persons, but the general public are now unacquainted with it after the lapse of so many years. The practice now is to build the sewers with bricks specially made for the purpose, laid in Portland cement, and to give to the face of the work the utmost degree of polish and finish. The expense of this method of construction is very great, the labour alone costing from 5*l.* to 5*l.* per rod, or from 9*s.* to 14*s.* per cubic yard.

The manufacture of Portland cement, of late years, has been brought to such perfection, that concrete made of it and clean sharp shingle or gravel, mixed in proper proportions, sets as hard and becomes as solid as ordinary stone,—indeed, so hard and solid does the admixture become in a week or two after it is made, that it would be as difficult to cut through it then as it would through Portland stone itself. As regards the use of concrete instead of bricks for sewers, there can be no doubt that if sewers be carefully constructed of this material, and with glazed stoneware invert blocks for the sewage to run on, they would become not only as strong and durable as brick sewers, but would cost considerably less. In truth, the cost would be about one-half that of the brick sewers, as now constructed,—that is, two miles could be laid at the present cost of one mile; and I have no hesitation in saying that they would be equally as sound, durable, and efficient. The inside surface above the inverts could be rendered quite even and smooth. The sewers which I have constructed of Portland cement concrete are perfectly hard and sound; indeed, they are like a

stone throughout. The three courses of stoneware invert-blocks, with bird's-mouth joints, used in the works, were made and supplied by Mr. George Jennings, to whom we are indebted for many useful sanitary improvements and inventions.

By using concrete instead of bricks from the invert upwards, there is also this advantage, that the entire spaces between the centering and the excavation, can be filled up and rammed quite tight against the ground, which not only prevents the earth or gravel outside the excavation from giving way or subsiding, but enables the runner-planks or poling-boards to be drawn, and the spaces they occupy to be filled up solid with concrete as the work proceeds. In tunneling, also, the whole space between the roof of the tunnel and the centering can be filled and solidly rammed with the concrete, which cannot be, or is not so well done when the arch is turned with bricks.

I submit herewith a section of an egg-shaped sewer, which I would recommend to be constructed in Portland cement concrete. The

height is as 4 to 3 of the width; the radius of the sides is equal to the width, and the radius of the invert is one-sixth of the width. The curves blend well together, and form a perfect egg-shape. The sides have more batter than is usual in egg-shaped sewers; but this I consider to be an advantage, inasmuch as the battering side-walls act like raking struts against the ground, and so tend to carry or deflect the weight down to or under the invert. The invert is also by this means made deep and narrow, which gives velocity to the current, and prevents, as before observed, any deposit from taking place.

The invert is formed of three courses of glazed stoneware blocks, in 18-in. lengths, with bird's-mouth joints. The blocks are perforated longitudinally with small round holes to facilitate the drying and hard-burning of the material in the interior, and to give a key to the cement at the end joints, which will prevent the sewage from leaking through and saturating the ground beneath. The blocks are laid solidly in concrete, properly jointed in cement, and half-banded. The blocks so made are nearly solid (a most essential thing) and imperishable, and they are not likely to be broken or shivered by the weight. In fact, they are far superior to anything of the kind hitherto used for the purpose. By being glazed they also afford a perfectly smooth channel for the sewage to flow on.

The sides and crown of the sewer are formed of concrete, the thickness of which should vary with the depth in the ground; but ordinarily it may be about one-fifth of the internal width of the sewer. The concrete should be composed of six measures of clean sharp shingle, or well-washed gravel, not large, but of various sizes, down to very coarse sand, and one measure of best tested Portland cement. The ingredients should be turned over twice in a dry state on a ganging-board, then wetted, and again turned over twice, so as to ensure thorough admixture, before using. The concrete so made should then be well and solidly placed in the work, and when it has set hard enough the trench may be filled up and rammed, and the centering removed, in the usual manner. The centering for supporting the concrete may consist of pairs of stout hard-wood, or T iron, half-bricks butting together at top, and resting on

stout hard-wood foot-blocks, placed across the invert blocks at bottom, with plating laggins (cleaned and oiled each time of using) laid loose on the ribs as the concrete is brought up. After the concrete has set and the ground is filled in, the centering can be easily removed by knocking away the foot-blocks. The face of the concrete can then be stopped and pointed, and made quite even and smooth with cement.

JOHN PHILLIPS.

VENTILATION.

In the 18th of January number of the *Builder*, Mr. Leeds has discussed, in some detail, statements made by me in a communication which appeared in the number for the 14th of September last, on the mode of ventilation adopted for the Drummond School. I beg, before commenting on his remarks, to thank him for the courteous terms in which he has animadverted on what he considers to be my erroneous operations and conclusions, and at the same time to thank him for pointing out, for the benefit of your readers, those matters which require from me further elucidation, as well as those inferences drawn by me which he deems to be wholly untenable. In *ultima*, however, I must protest against an assumption which appears in more than one part of Mr. Leeds's remarks, and which I cannot perceive to be warranted by anything which appears in the paper which you did me the favour to print. He says he thinks the theories upon which I have based my operations are entirely incorrect, and that I have been mistaken as to the results; and again, lower down, that my neglect of variations of temperature and density vitiates my theory. Now I beg to assure Mr. Leeds that I have no theory whatever to uphold; and if, as I believe it does, a theory means a true explanation of all the phenomena present, then I can further state that I am unable to offer explanation of many of the facts (noticed in the paper) which fell under the observation of myself and friends.

Mr. Leeds contrasts the mode carried out by me at the Drummond School with that of which he himself approves, and marvels at the discrepancy of our views; but it ought not to have escaped his penetration that he and I approach the subject under very different conditions: he has a prolonged and intensely cold winter to contend against, has abundance of fuel, and ample means at his disposal, and propels heated air into an air-tight compartment with two holes in it, one for the admission of the warmed air, the other for the escape of that which is displaced; while here at the Drummond School, since it has been opened there have not been twenty fires lighted in any of the sleeping-rooms, for the simple reason that we did not need them, and cannot well afford them: nor at the Royal Hibernian Military School, one wing of which is provided with Ross & Murray's batteries for heating, has warmed air been passed into the dormitories a dozen times these three years. Herein lies an amazing difference, quite enough to justify me in adhering to the present plan until it can be shown to be insufficient or objectionable: it, moreover, has certainly the merit of being very inexpensive.

Mr. Leeds next gives reasons for thinking that I have mistaken the results which I had supposed to have been realized, and which appeared to me to be so perfectly satisfactory. To this I am a little puzzled how to reply, further than to say that the facts were as I described them, and were recognised as facts by competent judges; that I took the readiest measures which suggested themselves to me for remedying the evils I perceived to exist, and that I was gratified to find an amount of success I had hoped for had scarcely anticipated. That the house was in a bad state and unhealthy, can admit of no doubt; that it is eminently the contrary now is just as certain—the conditions remaining precisely the same, excepting that the ventilators were introduced as described. Mr. Leeds computes accurately the amount of air intro-

* We have within the last few years passed through two epidemics, one of cholera, very prevalent in our immediate neighbourhood without any of the boys being affected; the last, just passed off, scarlatina, of most fatal character in all directions about us, eighteen boys were admitted into hospital, and not mild cases either; but so healthy are they that the fever and sore throat disappeared in four or five days, ushering in a rapid convalescence. I could point to a time in this very school, before sanitary matters engaged so much attention as they have done since the Crimean war, when during an epidemic boys died at the rate of one a week: it is not so now.

duced by the ventilators,* and finds it far too insignificant in quantity to permit him to entertain the notion that the results are solely dependent on them: in this he is so far right that the rooms do not depend on the ventilators exclusively, the windows and doors are by no means close fitting, but with the small steadily inflowing current through the ventilators which communicates motion to the mass, there proves to be sufficient to preserve the inmates in excellent health, provided their numbers be carefully adjusted to the area of the room. The fact is, my early difficulty was to know where to stop when enough, yet not too much, was being introduced through the ventilator, and this amount was only arrived at after several years' experience. I have been somewhat more enterprising lately, and have enlarged the ventilators; two of 2 ft. 6 in. by 6 in. having been introduced at a height of 13 ft. into a room at each side; but the room (664 ft. area) in this instance is not a sleeping apartment, though a large number of persons are in it at a time. It will be seen from the accompanying letter that the ventilation has been successful. But I should doubt the propriety of such a large quantity of air finding admission at a time when all the inmates were, being asleep, in a state of passive resistance. In reality, the purpose to which the rooms are applied and the area told off to each person must be taken into account.

"I beg to state for your information, that on my assuming the duties of 'Band Master' at this institution, I found the room to be, from want of pure air, most unhealthy, and, in fact, totally unfit for the purpose of practice. When the boys, to the number of fifty, were assembled in the room, for instruction, I found the stifling and unpleasant atmosphere most offensive, and to these causes I attribute a fit of illness which confined me to my bed for some time.

I have now to state that having reported this condition of the room to the commandant, he most promptly satisfied himself of the accuracy of my statements, and caused a thorough reformation to be made.

The room, which is about 25 ft. square and 20 ft. high, is now well ventilated, wholesome, and comfortable. I have never since felt any sensible draught nor undue lowering of temperature, and I may also state that the walls which used to be streaming with water are now always dry. As BARRY, Band Master R.H.M. School."

Since, then, we do not in these countries seal up our rooms and urge into them the entire of the air to be consumed, it behoves us to take every care to preserve the utmost purity in our rooms that may be practicable, by assisting natural ventilation in unobjectionable ways, and by cutting off all sources of noxious emanations.

Our first duty is to see that all sleeping-rooms, intended to be occupied by as large a number of persons as can be suitably accommodated, have fine open fireplaces with well-constructed chimneys. At one time, cast-iron stoves were largely introduced into barracks-rooms and dormitories on the fallacious pretence of economy. This was a serious mistake. In the first place, it deprived us of a most effective means of ventilation; next, it is by no means certain that the whole of the products of combustion are removed by the smoke-flue; lastly, depending almost entirely on connexion for diffusion of heat, the radiating power being exceedingly low, the exposed surface was quite inadequate to generate the heated air with sufficient rapidity or in anything like sufficient quantity; and the air so warmed was carried to a part of the room where it was not wanted, and where it was speedily and uselessly dissipated if proper ventilation were maintained. What we desire to have is a plentiful efflux of radiant heat from a large open fireplace; and, to gain as much effect as possible from the fuel, the grate should expose a broad front to the room, with as little fore-and-aft depth as may be practicable and convenient.

When it is borne in mind that each fan gas-light is equivalent to the addition of four men to the occupants of a room, the importance of rapidly removing the carbonic acid, watery

vapour, and other deleterious products, cannot be overlooked. Unless where some positive necessity exists, it would be far better, in lieu of gas escapes, which are troublesome to put up, and not entirely effective, to place the lights outside the room. The jets would then occupy the position of wall-shades, he at about 5 ft. from the ground, and in long rooms he placed alternately on opposite sides of the room. The jets should not be countersunk, should be cut off from the room by thickish curved glass-plate, and have a plentiful supply of fresh air from below to prevent undue heating.* Behind the gas jet should be two silvered reflectors, inclined at an angle of 130° to 140° to each other; and I find that glass silvered by precipitation with oil of cloves stands the heat well, but silvered metal plates may be preferred. The gas-escape pipe must lead into the roof (never into the chimney or outside the house), which always has sufficient leakage for the removal of the produced gases, and the steadiness of the flame is unaffected on a stormy night.

At one time the urinals and privies connected, for night use, with the dormitories of the Royal Hibernian Military School, were exceedingly unpleasant, notwithstanding that every care was taken by plentiful ablution, open windows, and well-fitting doors, to prevent any smell from them penetrating into the dormitories. Boys in the vicinity of the door leading to them suffered from ophthalmia, and it is possible their health was otherwise injuriously affected. This was obviated so completely some time back, that a description of the plan adopted cannot be otherwise than interesting to those who are watching sanitary improvements.

The urinals and privies are placed in a nearly square tower in rear of the dormitories; on each story a well-aired passage leads into them. The urinal is sheeted with 1/2-in. plate glass, a yard high, carefully cemented to the back wall, and along the upper edge a brass pipe sheds water over the surface continuously at night. The channel course is also of glass plate, and leads into a well-trapped sewer-pipe, so that everything here is as near perfection as may be. A difficulty was felt about the flooring of the urinal, it being very difficult to get the boys in the middle of the night to invariably go quite forward to the wall, and this is the only not quite satisfactory part of the arrangements. The floor declines to the channel course about an inch the foot, and is covered with sheet lead, but, being so cold under the boys' feet, is covered at night with a deal grating, which is carefully washed and deodorized each morning: notwithstanding every care, however, the grating acquires in time a rancid smell; it is then removed, burnt, and replaced by a new one. The privies, which are not often used, are on Macfarlane's principle "improved" and are very satisfactory. At the dormitory end of the passage, leading from the urinals, is a carefully hoarded-in compartment (each hoard related into that adjoining it), 10 ft. high and 5 ft. 9 in. by 5 ft. 9 in. in area: it projects 2 ft. into the dormitory, and has double doors in front and rear, closing with very strong springs, so that in passing in and out one set of doors must be securely closed before the other set can be reached to open. Right above head, nearly in the centre of the compartment, a jet of gas burns all night, which, through the fan-lights in front and rear, and in so much of the sides as projects in front of the wall, gives light to the urinal and to the dormitory. Above the lamp is a conical inverted funnel, with an eduction pipe for the escape of the heated products of the combustion of the gas and of any impure air from the urinals which may be carried up along with them. A visit to the end of this pipe in the roof will satisfy the most sceptical that this operation is conducted to a successful issue.†

What I have been describing has been some time in use, and the purity of the air in the dormitory is now completely preserved thereby from this source of contamination.

I cannot do better than conclude these remarks with the following quotation, which

"A small tube, with longitudinal slits or perforations, should lead up to the jet from the room, be filled with gas at half-turn of the stop-cock, so that the jet may be lighted; but closed off when the gas is full out.

In private houses a narrow frosted or tinted stripe should traverse the plate-glass, so as to cut off the glare when standing or sitting in part of the room usually occupied by the family, otherwise the more light in the room the better. It is more trying to the eyes to be in an ill-lighted room than when the illumination is equal to that of daylight.

† Of course if it were necessary ventilators could be introduced into the roof without any fear of the gases being put out on a stormy night.

announces in terse language the problem to be solved in these countries.

"How to supply at all seasons and temperatures, and by day and night, each room by itself, and independently of every other room, with a sufficiency of air to keep the room healthy, and at the same time to prevent the temperature from falling below what is required for the comfort of the men. To do this with the least possible interference with the structure of the rooms, on a plan not easily deranged, and at a minimum of cost."

We believe in these schools that we have advanced a step. ROBERT TEMPLETON, Deputy-Inspector General, Dublin.

THE EDUCATION OF AN ARCHITECT.

At a meeting of the Architectural Institute of Scotland, held in Edinburgh, on the 3rd inst., a paper on "The Education of a Young Architect" was read by Mr. GOWAN. In the course of his remarks, Mr. GOWAN said,—No man can be proficient in the science of architecture unless he has studied the theory and practice of it—the two being so closely linked to each other that the want of a knowledge of either is sure to be fatal to the success of any one who adopts architecture as his profession. This being so, no question to my mind is of more consequence to the rise of architecture than that of "Whether architectural students receive such an education as will make the most of their abilities and do justice to the science?" I am strongly of opinion that there is no thorough system for the study of architecture, and that it is lagging behind the sister arts in consequence, and therefore it is that I have brought the subject of this paper before you. There is a great cry-out at the present time for technical education; and, although no amount of such an education will ever result in imbuing that genius which the architect requires, still, in the maturing of the architect it is indispensable. Architecture, in my opinion, suffers from causes which sculpture and painting, in a great measure, are not liable to. As it would serve no practical use for me to point out what I consider to be the drawbacks to the progress of architecture without being prepared to suggest that which would be a remedy, I venture to bring before you what I consider necessary for providing the means of training which the architectural student should have within his reach. First, as to geometry: there is no doubt in my mind that geometry is at the root of all design, and that nothing good in architecture can be done without it. A thorough knowledge and application of geometry by architects would not only advance themselves, but would tend to educate or call for a better education of those who had the carrying out of their designs, as I am sorry to think that the holders in general know little of all of the science of their business; and to go from them to the workmen, I know as a fact that few of them know more than the use of the tools which are put into their hands. Second, as to geology, or, perhaps, mineralogy, these may be considered by some as outside of architecture; but I hold otherwise, as it requires few words to show the value of a knowledge to an architect of the stratification of the country from which he must get his material for building. The want of this knowledge in architects and engineers I have known to lead to useless expense, in carrying material from distances, while material equally suited for their purpose, and better adapted to the nature of the district, was lying almost underneath the structure they were erecting. And let me notice this, that if an engineer or an architect, from his geological knowledge, knows that a certain kind of material is within reach, the nature of this material in its structural use should determine the style of his buildings; and, if this be done, he may be sure that the structure he erects will always harmonise with the district. Third, the nature and strength of material, and the true application of it. Every kind of material requires a special constructive application—wood, iron, and stones require different treatment—that is, taking them separately; and when combined, it requires very great care indeed to use them so that they may amalgamate together, and bring about the required result. Mr. GOWAN, after giving some hints as to the treatment of different kinds of stones, and also as to the application of iron for building purposes, said:—Fourth, light and its properties. Now that there is no tax upon

either the number or size of windows, it is wrong to shunt out what conduces not only to health but to cleanliness, and yet you find buildings being erected at the present time where closets and such-like places are lighted by openings of the very smallest possible dimensions.

Another important point in the proper arrangement of a house, which is very much abused, is the position of water-closets, sculleries, and such places, which require the utmost amount of ventilation and light that can be got. Houses are now being erected where these places are in the centre of the building, and lighted and ventilated from the common stair, notwithstanding the clause in the Provisional Order recently got by the city, whereby it is provided "that all such places should be ventilated from the outer air." The proper drainage and piping of a building should also form the careful study of the architectural student. If water-closets and such places be in their proper position, neither the sewage-drain nor water-pipes require to go further into the building than the thickness of the outer wall. The ventilation and the elastic properties of foul and impure air are also worthy the attention of the student. The position of the various apartments also requires to be carefully considered, and disposed so as to receive the greatest possible quantity of light and air, and have free access without passing from one into another. After referring at some length to the laws of proportion and the principles which guided the Greek and Gothic architects, Mr. Gowans concluded as follows:—"There is nothing I wish for so much as that some lover of architecture who has the means at command would endow a chair of architecture in the same liberal manner as has been done by Sir David Baxter for engineering; and I am satisfied that no monument would be so lasting as a chair of this nature would, as the beneficial effects of architecture along with other arts are not easily traced, and never die.

THE GROWTH OF LIVERPOOL.

At the last meeting of the Liverpool Architectural Society Mr. Samuel Huggins read a paper on "The Growth of Liverpool and its Architectural Results." The rapid growth of Liverpool, he said, had been among the marvels of the present age; perhaps it was as unrivalled as regarded the quality of the material which in the course of its enlargement had entered into its composition. While the old or business part of the town had undergone one continued process of improvement in architectural character, the private department, or that devoted to residences, had retrograded. The extension of Liverpool in every direction had been mainly by the erection of dwellings for the poorer classes of people, and this had been left for the most part to men profoundly ignorant of art, and with scarcely an idea in their heads; and the consequence was that art in these productions had not only been ignored as out of the question, but a degree of meanness and wretchedness had extended over wide districts of this town that could scarcely have been deemed possible by those who had seen its pristine beauty. But he should not have brought this matter forward but for the conviction that these things had been growing worse of late, and that at no former period had such houses been built as were then outraging themselves on the pleasantest and most respectable neighborhoods. Assuredly a more melancholy contrast was never presented in architecture than was then presenting between the character and quality of the buildings they were pulling down and those they were rearing up. He was quite sure the New Zealanders would build for themselves, with the same means and materials at command, more pleasant-looking, less heart-sickening habitations than those now rearing in many parts of the town, which appeared to him more like a superior class of pigstyes than abodes of humanity. The destruction was not confined to one locality. Every beautiful and retired spot of private residence, in whatever direction in the town, north, east, or south, was in course of destruction; and there was not a private house or neighborhood anywhere but was in danger of being at any moment rendered valueless for private and genteel abode, not by the erection of small houses, but of ill-built houses. He had little hope of any effectual remedy for the evil being forthcoming: a new building Act might do something. But nothing less than the extension of legal protection to

certain neighborhoods would be effectual;—protection by laws which would be no more inimical to the proper and rational liberty of the subject than those that were enacted against theft. The remedy he mentioned had not been, and probably would not, for some time, be applied, owing to the indifference to architecture that everywhere prevailed, and was operating prejudicially on most of our towns and cities. A striking instance was seen of it at Chester, which had lately exchanged some of its characteristic and best Italian buildings for the most entire abortions that ever insulted the eye. Even the cathedral itself was in danger at least of serious injury, and had been already roughly handled by the new dema in the course of carrying out some new arrangements for the public services. Dr. Howson would, he had no doubt, in other ways do honor to his new appointment and to the church; but, from what had already occurred, the friends of art had reason to tremble for the material church in such hands. It was under the impression that it was the duty of all who felt this to raise their voice in the matter that he now ventured a word in behalf of the venerable pile, the nave of which, hitherto unbroken by hench or pew, was dotted all over with a myriad of little bedroom chairs of the meanest and slimmest description, furnished by the maker, he was told, at 1s. 9d. a piece. There was talk of restoring the cathedral, which to the ear of an artist simply meant destroying—destroying its antiquarian and historic interest and picturesque beauty. The most important operation in the central or business part of the town was the erection of the new Exchange-buildings. In a former notice of this work he had condemned it for being dissimilar in style from the old one, and so departing from that of the Town-hall. But, on a walk round it the other evening, he was glad to perceive an advantage resulting from this which had escaped him before, namely, that he had caused it to become one with the chief buildings around it, uniting several hitherto discovered blocks of commercial buildings into one continuous series. It united, for instance, Mr. Cockerell's block on the east of it with Messrs. Picton & Son's on the west, and so on of others at the northern extremities, till there would, when it was finished, be a complete district of fine commercial buildings, all in perfect accord, and unmistakably commercial in character, that he believed the metropolis only could parallel in this country.

THE WANT OF A FEVER HOSPITAL IN BRISTOL.

LAST week Mr. Alderman Proctor attended before the sitting magistrates, to ask their advice on an important matter, with which he felt himself unable to deal. A very respectable man, whom he had known for some time, kept a lodging-house; and about a fortnight ago a man, named Paul, who came from Cheltenham, took up his lodgings there. This man, it appeared, was now ill of maculated typhus fever, and he was in such a state that it was exceedingly dangerous for the owner of the lodging-house to remain there. He had called the attention of the officer of health, Mr. Davies, to the case, and Mr. Davies had written a letter, in which he showed that Paul, although he said he came from Cheltenham, lived in Picton-lane, Bristol, next door but one to Millett, now lying dead of fever there, where he had reported fever for three months. A fortnight last Saturday he (Thomas Paul) left Picton-lane for Cheltenham, and lodged there. After being there three days he sickened of his present complaint. He came back last Monday, and travelled in a railway carriage, in the middle of an attack of typhus fever. "If White and his family remain, White's life is not worth two months' purchase. Typhus has a great predilection for the life of the bread-winner. If we could get a separate house we might get Paul removed, but he will not go to the work-house." He (Alderman Proctor) thus felt a difficulty in the case. It appeared that there was an Act of Parliament in force to the effect that if there was a place to send the patient to, the magistrates would be able to order his removal. Unfortunately there was no such place in existence in Bristol, and it was such an important matter that he felt it necessary to place the responsibility with the magistrates.

Mr. Brice, the magistrates' clerk, said an order for the removal of the patient himself to

the workhouse had been obtained, but the patient would not avail himself of it, because, as he said, he was not a pauper. Then the only course for the officer of health to take was to fall back upon the Act of Parliament, authorising Local Boards in different localities, to provide hospitals for sick persons; and where such a hospital had been provided, there was power under the statute 29 & 30 Vic., chap. 90, section 26, as follows:—"Any justice may, with the consent of the superintending body of such hospital or place, order the removal to such hospital or place of such sick person." The short answer to that enactment was, that the Local Board of Health in Bristol, who were the nuisance authority under this Act of Parliament, had not provided such hospital or place; consequently, the application to the magistrates to remove a patient to a place not in existence would be simply ludicrous. It was not for him, nor probably for the bench, to say what was the duty of the Local Board; suffice it to say the necessary machinery did not exist, and let the consequences be what they might, the responsibility could not rest with the magistrates.

It is to be hoped the people of Bristol will take this case; and will, moreover, immediately insist on the provision of a proper place to which such cases may be sent. An epidemic of typhus would be costly.

RESTORATION OF BRISTOL CATHEDRAL.

WITH grand Masonic ceremony, on the 17th of April, the corner stone of the nave of the Bristol Cathedral was laid by Lord Liverick, the Provincial Grand Master of the mystic craft.

In 1866 considerable alterations were made in the road at the north side of the cathedral, access on this side being improved by the removal of the earth to a depth of several feet. The excavations thus made laid open to view the foundations of a nave and north porch. Previously to these discoveries, a movement had already been set on foot for the completion of the cathedral by the erection of a nave. The public attention drawn to the discovery gave an impetus to the efforts of Canon Norris and his friends; the private subscriptions increased; and on the appointment of Mr. G. E. Street as architect, he submitted plans for the building of the nave with western frontage and steeples or towers. His report was considered at a public meeting in June, 1867. The general design of his plan was to copy very closely the work in the present choir, with a few minor alterations, such as the sections of mouldings, the design of window traceries, and the character of the sculpture, sufficiently to show that the new nave was really a work of the nineteenth century and not of the fourteenth. He believed, however, that this would be in such complete harmony with the old work that in the general *coup d'œil* no difference would be noticed between the two works. With regard to the west front, he believed that the old plan did not contemplate steeples, but in his opinion the cathedral would in all respects be a more striking and effective building if it were finished with two western steeples than if it had simply a nave and aisles corresponding with and very nearly repeating the outline of the existing eastern portion of the church. The addition of the nave and western steeples would give the whole a bulk and importance which would make the cathedral—as it ought to be—the most conspicuous object in the distant view of the city; and it would then have so unmistakably the character of a cathedral church, that every one would be at once impressed with its appearance. The plan was adopted. The cost of the whole work was estimated at upwards of 50,000*l.*, and having obtained promises of subscriptions amounting to upwards of 15,000*l.*, the committee felt themselves in a position to commence work so early as October or November last.

The whole nave will have a length of 117 ft. from the transept tower, and a width of about 80 ft. It will be furnished with north and south-western towers, 130 ft. high, and have a northern and western frontage, and connected with it on the southern side will be the original cloisters, the architect having introduced an arcading or arched corridor in this part of his plan. The nave will be built of Donning stone; and in harmony with the walls of the old portions of the structure, the new walls will be 5 or

6 ft. thick, with the triforium or passage running between the windows in a similar manner to the design of the present building. The first contract, comprising two of the six bays of the nave, and the foundations and walls of the whole of the remainder to a height of 6 ft. above the ground-line, was undertaken by Mr. George Booth, of Gosport, the contract being taken at a sum rather exceeding the amount of subscriptions promised up to the present time. On the completion of the two bays, it is proposed to close them in on the west side by the erection of a temporary wall, so that the cathedral will be provided with a short nave during the completion of the undertaking.

ST. MATTHEW'S CHURCH, HULL, COMPETITION.

The following additional details have been furnished us in reference to the designs sent in for this church. The church is to hold 800 adults. The cost, including only lower portion of tower, was not to exceed 4,000l. The premium for the selected design is 25l. There were fifty-three competitors. The designs of all the competitors were numbered and arranged on tables and on the walls of a well-lighted room. The committee of selection, after spending several hours, picked out some twenty odd: from these ten were at the next meeting selected,—viz., those of Adams & Kelly, Leeds; Bellamy, Hardy, Lincoln; Besset, Norwich; Blesley, London; Clark & Son, Nottingham; Linklater, Manchester; W. H. Lockwood, London; Scamell & Inskip, London; R. C. Sutton, Nottingham; and R. G. Thomas, Menai Bridge.

The result of two other meetings was to reduce the number to four—viz., Adams & Kelly, Blesley, Clark & Son, and Sutton; and finally the design of Messrs. Adams & Kelly was selected; the chairman having decided by his casting vote that it, and not that of Mr. Blesley, for which an equal number of votes had been recorded, should be taken.

The style of the proposed new church is Early Decorated Gothic. The total cost, with tower and spire completed, is to be 4,500l.

No names were furnished with plans marked "Delta" and "Let there be Light."

THE TRADES MOVEMENT.

WE understand that the Liverpool master builders and the bricklayers in their employ have just taken a step which may prevent in future any resort to lock-outs or strikes to enforce changes in the rules of the trades. Both sides have agreed to a series of regulations, to come into operation next month, which will place all questions relating to overtime, country work, travelling expenses, payment of wages, &c., upon a basis satisfactory to all concerned; and they have also agreed, that in the event of any dispute arising, it shall be referred to a court of arbitration, composed of equal numbers of employers and workmen, with a final reference, if necessary, to an umpire. The rule headed "Authority of Employers" says,—

"Each employer shall conduct his business in any way he may think advantageous in the matter of letting piece-work, taking apprentices, using machinery and implements, employment of society or non-society men, employment of town or country bricklayers, and in all details of management, not infringing the individual liberty of the workmen."

Some London trades unions are about to call a conference between "large employers of labour and representative working men connected with trades unions, for the purpose of considering whether the relations between capital and labour cannot be brought into more harmonious action, whereby the disputes which are now constantly arising between those interests may be averted." By this means it is thought that some modification of objectionable rules may be obtained. The question of trades unions having ceased trade to go from this country to foreign countries is to be entered upon, and the unionists or some of their leaders say that it would be well for an understanding to be come to between capital and labour, that funds may be lessened and strikes and lock-outs limited by all subjects of difference being referred to arbitration.

A general meeting of the Yorkshire branch of the Master Builders' Association has been held at Wakefield, the chair being occupied by Mr. John Fawcett (Messrs. Wm. Fawcett & Son,

builders), of Huddersfield. After certain formal business had been transacted, and the report of the committee, read by the secretary, Mr. Wm. Longley, of Badsowley, had been adopted, the consideration of payment of men by the hour came on for discussion, and after a number of the members had spoken on the subject, it was agreed that the principle was just, fair, and reasonable; and that information should be obtained on the subject, in order that the matter might be fully discussed at the annual meeting to be held at Hull in August next. At the dinner which followed the conference, the chair was occupied by Mr. Fawcett, and the vice-chair by Mr. Longley, and the speakers included Mr. Beanland (Bradford), Mr. Crofts (York), Messrs. Whiteley & Woolley (Leeds), and other gentlemen.

It is now definitely settled that there is to be a trades union congress held this year in Manchester. At the quarterly meeting of the local Trades Union Council, held in Salford, the chairman stated that in consideration of the profound ignorance in the public mind with reference to trade societies, and the probability which existed that legislation would be proposed shortly on the subject, it had been resolved to hold a congress in Manchester, to which it was expected most of the combinations would send delegates.

At Bradford the painters' strike still continues. The *Bradford Observer* says the employers observe that it seems to be implied that 5½d. per hour is the highest wages which journeyman painters receive, whereas many men who are on strike were already paid at the rate of 6d. per hour, and some men up to 8d. and 10d. per hour, according to ability; and such men, they say, are on strike for the purpose of compelling the masters to pay 6d. per hour to the lowest men. As regards the refusal of the employers to meet a deputation from the men, they state that the question at issue has been thoroughly discussed in all its bearings, and that further meetings on the subject could add nothing new.

A letter from Geneva, dated the 10th, says: "The strike has suddenly come to an end as if by enchantment. Every one read this morning a white poster, signed by M. Camperio, the head of the department of Justice and Police, announcing that the propositions of the employers and contractors had been accepted by the delegates of the different sections of journeymen, and that, in consequence, all the workshops would re-open on Monday, the 13th. The document, moreover, declared that the present crisis would leave no trace of misunderstanding, and that its cessation testified the spirit of conciliation which had always animated masters and men."

As to the recent disturbances in Belgium, according to the *Journal de Liège*, the judicial authorities have discovered the source of the distribution of money made by the leaders of the late strike at Charleroi. The funds are believed to have been furnished by the "International Association of Workmen," which had also lately influenced the workmen at Geneva.

RAILWAY INTELLIGENCE.

National Conference of Railway Shareholders.—A conference of the railway shareholders of the United Kingdom has been held at Manchester, in connexion with the Railway Shareholders' Association. The object of the meeting was for the reading of papers and discussion of a practical character, "with a view to influence beneficially the interests of railway proprietors, by aiding in effecting improvements in the railway administration and legislation of the country." The first paper was read by Mr. Wrigley. "On the importance of securing a more effective control over expenditure, with a special view to an accurate division of capital and revenue charges." Mr. Parkes read the second paper, which was entitled "On the desirableness of enactments restricting any outlay by directors on capital account until the requisite funds have been provided; and on the expediency of making inquiry before Parliamentary committees into the financial arrangements made by promoters of new railways."

Traffic Receipts.—The traffic receipts of railways in the United Kingdom amounted, for the week ending April 4, on 13,215 miles, to 715,740l., and for the corresponding week of last year, on 12,913 miles, to 701,531l., showing an increase of 302 miles and of 14,209l.

A STEAM ROAD ROLLER.

THE Town Council of Sheffield have recently purchased a steam roller from Messrs. Aveling & Porter, of London and Rochester, at a cost of 900l., delivered in London. The machine arrived in Sheffield last week. The roller was driven through the streets to the bottom end of Bram-mall-lane, from which point there is a new street called Ellin-street, which emerges on Sheffield Moor, near to the end of Ecclesall-road. There was formerly a reservoir on the site of part of this street, and in comparison with other streets in the town, the ground was soft and shifty. It was covered to the depth of about 10 in. with the loose stony material used in road-making, and before the ponderous machine was driven upon it was as rough and untraversable as it well could be. The Mayor and several members of the Council, chiefly members of the Highway Committee, went to the place where the test was to be made, and steam being up it was not long before the huge machine began to cranch along the new highway. The weight of the roller is 26 tons. When the machine had gone over the street two or three times it had transformed it from a rough, impassable thoroughfare to one almost as level and satisfactory,—of course not so smooth,—as an ordinary asphalted footpath.

We give a view of the roller. It consists of four wheels or rollers, the two front ones being 3 ft. 6 in. apart, and the hinder ones running close together, 6 ft. diameter and 2 ft. broad. The hinder wheels overlap the front ones 3 in. The total width covered by the roller is 7 ft. 6 in.

The whole machine weighs 25 tons, equally distributed over the rollers. The boiler is horizontal, and the working parts are on the top of the engine out of the way of the dirt of the road. The power is communicated to the rollers by an improved endless chain of great strength.

The two hinder rollers are fitted in a turntable, and become the steering of the machine, which is perfect in its action. A boy twelve years old can steer the machine, and it can be completely turned in a road 30 ft. wide with great ease. We may add that the roller can be worked backwards or forwards. It is therefore seldom necessary to turn it.

A somewhat similar engine to this, but much heavier, is, we understand, working satisfactorily in the streets of Liverpool.

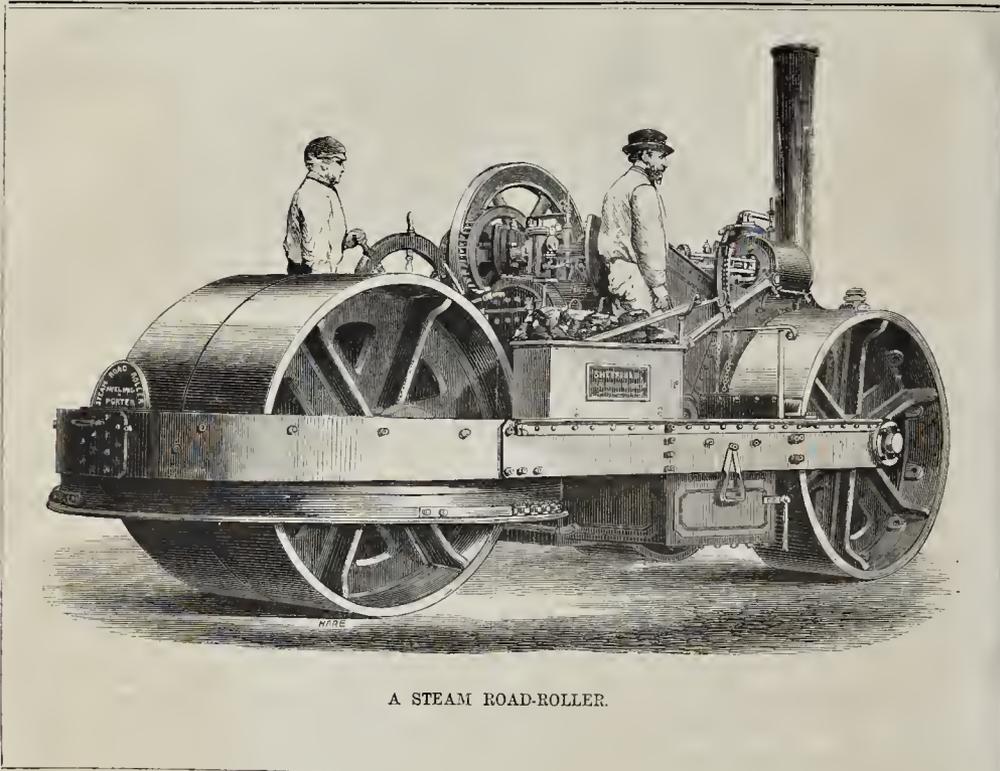

THE VICTOR EMANUEL GALLERY, MILAN.

THE completion of the Victor Emanuel Gallery is but the commencement of the work being carried out by the City of Milan Improvements Company, and consisting in the reconstruction and establishment of the whole quarter, including the Piazza del Duomo to the Piazza della Scala, and in the construction of an entirely new street, which is called the Via Carlo Alberto.

The ceremony of laying the first stone was performed by his Majesty Victor Emanuel on the 4th of March, 1865, and the gallery was publicly opened by the king on the 15th of September, 1867, the time occupied in its construction being thirty months, during which time about a thousand workmen were daily employed.

The gallery consists of two passages, on each side of which is a handsome row of shops. These passages cross each other at right angles, and form a nave, 640 ft. in length, leading from the Piazza del Duomo to the Piazza della Scala; and a transept, 460 ft. in length, from the Via S. Raffaele to the Via Silvio Pellico. The transept and nave are each 47 ft. 6 in. in width, and contain ninety-two shops. At their point of intersection an octagonal space, 118 ft. in diameter, is formed, which is surmounted by a dome rising to a height of 164 ft. above the level of the pavement. The shop-fronts are each glazed with a single sheet of plate-glass, and are separated by pilasters in the Ionic order, enriched at the level of the entablature and first-floor windows with panels containing ornamental designs in *bas-relief*.

Immediately above is an entablature in the Roccoco style which serves as a balcony for the second-floor windows, which are partly hid from view. A light and elegant balustrading, with a medallion bearing the arms of the principal cities in Italy in front of each window, completes the balcony. The third-floor windows are ornamented bandsomely, and are separated by

A STEAM ROAD-ROLLER.

caryatides, which support an entablature at a height of 85 ft. 6 in. above the level of the pavement, serving as a base for the light curved iron ribs of the glass roof. This roof rises to a height of 104 ft. 9 in. above the pavement; above this is thrown a small roof, likewise glazed, at a height of 6 ft. above the other, so as to admit of ventilation.

The gallery is paved in the Venetian style, consisting of geometrical designs in coloured pieces of marble embedded in hard cement; and in the centre under the great dome are the arms of the House of Savoy, the city of Milan, and the Royal arms of Great Britain and Ireland in Mosaic, in the Byzantine style, by Dr. Salvati, of Venice. Below the pavement are cellars and subways for the water and gas pipes.

The dome consists of sixteen curved double-webbed ribs united at the top to circular casting forming an opening 32 ft. in diam.; these at intervals are cross-braced by horizontal segmental ribs, on which are laid the bars of T section to receive the glass. The circular opening at the top of the dome is protected from the weather by a conical glazed roof, the apex of which is 187 ft. above the ground. The sides of this lantern are left open for the purpose of ventilation.

Under the dome, in the spandrels formed by the intersection of the arched roof of the transept and nave, are eagles with extended wings, supporting alternately the arms of Milan and Savoy; and over the four corner shops are frescoes, 47 ft. 6 in. by 23 ft. 9 in., representing Europe, by Angelo Pietrasanta; Asia, by Giuliano; Africa, by Eleuterio Pagliano; and America, by Casnedi. The frescoes over the archways at the entrance of the transept represent Agriculture, by Pagliano; Industry, by Pietrasanta; Sciences, by Giuliano; and the Arts, by Casnedi. At the height of the entresol are placed statues representing eminent persons of Italy, which add considerably to the general effect.

Entering the gallery from the Piazza del Duomo, the first statue on the left hand is that of Giovanni Battista Vico, by Amiconi; then Volta, by Magni; Lanzone da Corte, by Tabacchi; Giovanni da Procida, by Argenti; C. Bec-

caria, by Crippa; Vincenzo Monti, by Manfredi; Ferruccio, by Pierotti; Michelangelo, by Magni; Dante, by Tabacchi; Galileo, by Magni; Raffaello, by Barzaghi; Girolamo Savonarola, by Boninsegna; Ug. Foscolo, by Rossi; Marco Polo, by Pagani; Macchiavelli, by Garneri; Pier Capponi, by Magni; Romagnosi, by Santardini; Beno dei Gozzadini, by Pandiani; Christoffer Columbus, by the same sculptor; Galeazzo Visconti, by Corti; Vittor Pisani, by Calvi; Filiberto, by Romano; Cavour, by Magni; and Arnaldo di Brescia, by Solerani.

The archways at the entrances from the Piazza del Duomo and the Piazza della Scala are 78 ft. 9 in. in height by 40 ft. in width. The entrances from the Via Silvio Pellico and San Raffaele are 75 ft. 6 in. in height by 39 ft. in width.

The gallery is lighted by eleven sun-lights or chandeliers, and round the base of the dome by a ring of 300 gas-burners, and three rings of lights at the top, under the lantern; the total number of burners employed for the illumination being upwards of 2,000.

This work was designed and has been carried out by the architect to the company, Giuseppe Mengoni, to whom great credit is due.

It is not alone upon the creation of this really fine monument that the municipality of Milan is to be congratulated, since this forms but a fraction of the great scheme of improvement which has been organised for that Imperial city.

Our readers will, many of them, recollect the huddled buildings which crowded upon the splendid cathedral, and the narrow and tortuous alleys by which they could alone wind their way from the Piazza del Duomo to the vast, but not very beautiful, Theatre of La Scala. Already the Piazza is nearly cleared of the old buildings which disfigured it, and the Gallery itself provides a magnificent line of axis between the two great foci of attraction to all visitors to Milan.

The English company, by whom these improvements have been effected, have always looked upon the erection of the great Gallery as the least remunerative portion of that undertaking; but, already, they have succeeded in letting almost every shop and a large proportion of the apartments it contains.

The place wears the aspect of the greatest possible commercial activity, and it is difficult for any one visiting the gallery not to feel that for the purposes of trade, the rents must very speedily rise in the same proportion to those in other parts of Milan which the rents of the Palais Royal at Paris used to bear, in its palmiest days, when contrasted with those in the less popular streets of the same capital.

The next portion of the works with which the company will proceed, and for which the foundations are already brought up to the ground level, will consist of the extensive range of buildings which will form the southern side of the great Piazza del Duomo. The demolitions have already begun for the side of the same Piazza facing the west front of the cathedral, and a beautiful opening has been obtained to the very picturesque old Palazzo del Mercolanti, and the place surrounded with buildings which were famous as the head-quarters of banking and commerce, when the Lombard goldsmiths and hawkers were the great financiers of Europe.

Our countryman, Mr. Digby Wyatt, who, as one of the directors of the company, has taken an active part in assisting Mr. Mengoni to the realisation of his great scheme, has been fortunate enough to receive an honourable recognition of his services, both from the King of Italy and the Academy of Fine Arts of Milan, having received from the former the Officer's Cross of the Order of St. Maurizio and Lazzaro, and from the latter a nomination as honorary Academician.

Mr. Charles Barry, it will be remembered, was employed professionally to test the financial organization of the scheme prior to the establishment of the company.

The unprecedented state of the money market has, no doubt, operated in retarding the full realization of Mr. Barry's prognostics; but no one acquainted with the great commercial importance of the city of Milan, and who has once seen the crowds who continually throng, and make purchases in the Gallery we illustrate, can doubt that, sooner or later, the tree the company have succeeded through so many difficulties in planting will bear a due amount of golden fruit.

THE VICTOR EMANUEL GALLERY, MILAN, ITALY.—SIGNOR MENGONI, ARCHITECT.

FROM IRELAND.

Dublin.—The statue of Burke, by Mr. Foley, R.A., has been erected on its already prepared pedestal.

The Varty Waterworks.—The Irish Times says:—"The citizens will be glad to learn not only that the Varty Waterworks are practically completed, but that financially they are in a much better position than they could have expected. The works have been in progress for nearly seven years, but at last the accounts are closed, and closed with a balance of 2,000l. in hand in favour of the citizens. The great reservoir has been rendered watertight, and the water is now within 11 ft. of the summit. A sum of about 12,000l. is yet to be expended in completing the suburban works, but from this source an income of between 5,000l. and 6,000l. a year is expected. The waterworks committee have unused powers to borrow to the extent of 75,000l. in case of necessity."

The Dublin Exhibition Building.—A meeting of the proprietors of the Dublin Exhibition Palace Company, presided over by Sir Benjamin Lee Guinness, M.P., has been held, for the purpose of taking into consideration the offer of the Government to purchase the building for 45,000l.—the sum at which it had been valued by Colonel M'Kerlie and Mr. Ward Hunt. The directors had offered to sell the entire of the company's property (including buildings, grounds, engine, machinery, organ, &c.) to the Government for 60,000l.; but the proposition would not be entertained. A very strong opinion was expressed at the meeting against disposing of the building at so great a sacrifice as 45,000l., which would not be sufficient to cover the liabilities of the company. Several influential shareholders thought that another effort ought to be made to rescinate the undertaking, by raising money by the issue of preference shares, thereby preserving the palace and grounds for the purposes for which they were originally intended. Finally, a committee was appointed to consider how this object could be best effected.

FROM SCOTLAND.

Newhaven (near Edinburgh).—The Society of Free Fishermen at Newhaven have just completed the erection of a tenement of dwelling-houses, says the Scotsman, in a manner highly creditable to them. The tenement is situated in a Fountain-place, opposite the stone pier. The building contains six dwelling-houses, each consisting of room, kitchen, light bed-closet, and scullery, with water-closet for each flat. In addition to the range of dwelling-houses, the fishermen have erected a public clock, with an illuminated dial, 36 in. in diameter, placed in a prominent front of the building. The clock will be illuminated all night for the accommodation of the fishermen leaving and entering the harbour.

Kirkcaldy.—A commencement has been made with the execution of the Kirkcaldy and Dysart water-works, which are to supply one million gallons of water per day to the two towns, being at the rate of fifty gallons daily to each inhabitant. It is hoped that within a year the Lothrie water will be brought into and distributed over the burghs of Kirkcaldy and Dysart. The supply is said to be abundant, even for a great increase of population; and the quality is also very fine. According to the report of Professor Penny, of Glasgow, there are only 7 grains of dissolved impregnate in the gallon, of which 1.66 grain is organic matter, and the hardness is 3°.

Ayr.—The improvements on the north side of the harbour are approaching completion. These works have been executed by the Glasgow and South-Western Railway Company, who intend to ship coals at the new quay. The new quay wall in course of erection, by Mr. Stewart, is in a forward state. By other improvements the harbour has been widened from 30 ft. to 50 ft. The Harbour Trustees have accepted an offer from the Messrs. Hunter, Edinburgh, who have contracted to execute the necessary work on the pier and breakwater at a cost of upwards of 10,000l.

Cottage Accommodation in Scotland.—Mr. McLagan, M.P., and Mr. Thomas Graham Murray, M.P., having recently been in communication with the Enclosure Commissioners in reference to the commissioners' requirements for cottages erected on estates in Scotland under their sanction, a letter, addressed to Mr. McLagan, has

been received from the commissioners, in which they state that as the cost of four-roomed cottages has operated as a restriction on improved cottage building, every facility shall be given to extend the practice, which already has in many cases been adopted, of sanctioning cottages composed of three rooms, to be charged on the estate. In such cases it is recommended that the living-room should not be of a less size than 16 ft. by 18 ft., and 10 ft. in height, but in no case should the size be less than 12 ft. by 15 ft., nor the height less than 8 ft.—they think 9 ft. preferable. They are further of opinion that the method of structure which encourages the practice of having recesses in which box-beds are placed, should be avoided. A scullery or wash-up place, as well as the usual out-offices, they add, should of course be also provided.

ANCIENT CRUCIFORM PLATFORMS.

We hear of the discovery, near the village of Swinton, North Riding, and close to the old Roman road from Eboracum to Prætorium, of a cruciform excavation 8 ft. 9 in. in depth, cut into the solid rock. The arms of this cross were to the cardinal points, were exactly of a length, measuring from north to south and from east to west 19 ft., being 6 ft. wide at the point of junction, and 5 ft. at the ends. The sides were perpendicular, and the bottom was a flat surface of coralline oolite. Upon this level bottom of the excavation was raised a platform, also in the form of a cross, the arms of which extended the whole length (nearly) of the cutting, and were 2 ft. in height and 2 ft. wide. At the point of intersection was a large square block of calcareous freestone, and the whole of the platform was made of the same rock, in large blocks at the bottom and smaller stones upwards, all carefully placed. The excavation was filled up with soil, containing Roman pottery, beds of clay and charcoal, quantities of Medieval pottery, a worked hone pin, &c. A very similar structure, but formed on the natural ground, with a mound over it, was found at Helberthorpe, on the Wolds, about eighteen months ago. The cruciform foundation in the area of Richborough Castle, Kent, will be remembered on reading this notice.

SURVEYOR TO THE HON. SOCIETY OF GRAY'S INN.

The regretted death of Mr. Francis Wigg, the late surveyor to the Hon. Society of Gray's Inn, has left a vacancy, which does not appear to be generally known to the profession. He was appointed to the office on the 22nd of May, 1833, and he held it until his death, on the 28th day of February last. It is rather curious that his immediate predecessor was appointed to the office in the year 1800, so that they each held the office for nearly equal periods.

Upon the death of Mr. Wigg being reported to the benchers of the society, they declined, we have been informed, to fill up the office immediately, thinking that the vacancy might not be generally known amongst the profession, and that sufficient time had not been afforded to gentlemen to compete for the appointment.

OPENING OF THE NEW WORKHOUSE FOR WEST DERBY UNION, LIVERPOOL.

The new workhouse at Walton, the first stone of which was laid on the 29th of March, 1864, by Mr. Thomas Haigh (the then chairman of the West Derby Board of Guardians), has been formally opened. The edifice has been constructed to accommodate 1,000 inmates, and has cost, including the price of the land (purchased from Lord Sefton), 65,000l. The grounds extend over an area of 37 acres, and it is intended to devote a great portion of the land to cultivation, so as to afford useful employment for the inmates. At either end of the building are hospitals for male and female inmates, and it is intended immediately to proceed with the laying out of a cemetery and the erection of a church. The main building is already nearly full; and it is probable that in course of time the accommodation will not be too much for the numerous poor chargeable to the rates of the West Derby Union. Messrs. Culshaw & Summers are the architects, and Mr. James Walters, the builder.

SCIENTIFIC LECTURES FOR THE PEOPLE.

A SERIES of lectures, in connexion with Mr. Twining's Economic Museum at Twickenham, for the instruction of the poorer working classes in the principles of elementary science, and its applications to health and the requirements of everyday life, has been in course of delivery in various parts of London during the autumn and winter, the last for the season having been given at the Mayfair Literary Institute, Hertford-street, Mayfair. The course consisted of eight lectures. Mr. Twining prepared his lectures in clear and simple language, taking care to define and illustrate every technical term, however common it might be, before using it. The illustrations, consisting of diagrams, specimens, models, and experiments, were all likewise of the simplest kind. The lectures were provided gratuitously in all respects by Mr. Twining, and have been delivered two or three times every week (holiday times excepted), to audiences varying from 100 to 200 up to about 1,000 persons, at school-rooms, literary institutions, workmen's clubs, mission-rooms, and at the Lambeth Baths. They have been read by Mr. W. Freeman, curator of the Twickenham Economic Museum, the experiments being performed and the illustrations exhibited by Mr. George Whipple, of the Royal Kew Observatory. This attempt to bring elementary science within the reach of the poorest and most uneducated will be highly appreciated by all sanitary reformers, who find their greatest obstacle in dealing with the poor themselves to be their complete ignorance of the laws of science and health.

THE NUT FOR THE PROFESSION TO CRACK.

PAYMENT OF ARCHITECTS.

SIR,—The nut that "a country gentleman" gives "the profession" has surely been cracked by every professor his own way, and I cannot see what "convention" or "system too strong for individuals to break through" can possibly have to do with it. If ten "architects" or "engineers," or a thousand, whether forming an "Institute" or not, have each decided to be employed in the way he calls "unreasonable," it is simply that to each of these ten or thousand reasoners this appeared reasonable,—nay, the highest reason (to quote your other correspondent), "the best that could be devised under the circumstances." Others, as myself, to whom it never appeared reasonable at all for one instant of course never adopted it, but whatever appeared the best each of us could devise. Now, is not "devising" the architect's and the engineer's whole specialty? What is meant, then, by "convention beats them down" in this very first matter of devising? Has the professional deviser not devised the very first thing he had to devise?—how to reckon his own pay? Of course he has. The architect, the engineer, has devised, and this is his device! If it be not to your taste, or sense of the "reasonable," observe this is his architecture,—this is his engineering. Take it or leave it. What do you want either "profession" for, but for their devising?

If the "Country Gentleman" had been a "constant reader" any considerable time, he would know that his "Nut" is a very old acquaintance in the Builder's pages. I have noted the following times of its special appearances:—

- 1845 ... No. 150, p. 605 (Leader).
- 1847 ... Nos. 469-72, pp. 76, 91, 122.
- 1857 ... No. 748, p. 320.
- 1865 ... No. 1185, p. 752.
- ... No. 1187, p. 767.
- ... No. 1188, p. 788.
- ... No. 1189, p. 821.
- ... No. 1190, p. 829 (2 letters).
- ... No. 1192, p. 876.
- ... No. 1193, p. 884.
- ... No. 1194, p. 913.

Your correspondent would find the "professional" mind very satisfactorily displaying itself, I think, in No. 1187 (letter signed "Thomas Harrie"), No. 1192 ("E. L. Tarbock"), and an answer to the letter in No. 1194. What I presume "A Country Gentleman" and his public (as distinguished from the Institute's public) really want, is an alphabetical list occasionally advertised, like the annual list of "sworn hokers," of those who are declared or sworn owners' architects, as distinct from contractors' architects, being headed by some such declaration as this:—

"We, the undersigned, practising as owners' engineers, or owners' architects, building designers, or building surveyors, do hereby declare,—

1. That for no service on any building are we employed or paid, or will be so, by any but the owner or occupier of the same.

2. That we are not in partnership with any builder or other tradesman, or will be so.

3. That we have never received per centage on the cost of any work, nor will receive any."

As one of the latter of the four classes for whom the *Builder* is intended, I must say the really difficult and sole "nu." I find to crack, and which I consider a real hardship and grievance, is that one cannot practise in this country the useful and necessary art of building-design without being confounded popularly, and by writers like "A Country Gentleman," with the order of men that, of all others, from the palace to the goal, I most object to be classed with, the producers of your public buildings (things called "works of art"), in a word, professors of *Percentage-Art*—a style, not the smallest fragment of which, be assured, will ever be mistaken for aught else as long as a stone of it can be dug up. But whether one calls oneself architect, engineer, haulder, or mere surveyor, it is all the same. Each now is taken to mean what I abominate beyond all trades, penal or not.

AN ARTIST, NO PERCENTAGE.

DAMP.

In reply to your correspondent "G. D. B." in your publication of February last, I would recommend his trying, on a small scale, a "bright American varnish," laid on with a brush like paint. It should be kept warm during the process, so as to retain the consistency of paint.

A few days' delay in painting over the varnish will be sufficient, and a dry day should be selected. The cost per gallon of the bright American varnish is about 4s. outside. I shall be glad to know the result if "G. D. B." will forward it.

The "bright American varnish" may be procured at most sea-ports. F. R.

STORAGE OF RAIN-WATER.

RECENTLY Mr. Bailey Deuton has drawn attention to the storage of water. He tells us that we may expect a dry summer, and therefore it is well to look for economy in the use, and the careful preservation, of the supplies. He points attention to storage reservoirs, but I think there is another part of the subject which deserves more attention than it has received, and that is the preservation of rain-water for domestic use, by having a cistern specially to receive the roof-water.*

When I rebuilt my house, I put up a large cistern capable of holding 1,000 gallons, and it has been one of the greatest luxuries we have enjoyed ever since. The whole of the roof-water goes into it, and the overflow is connected with the rain-water pipe, which empties itself in the usual way. The cistern is carefully covered, so that the blacks are kept out, and the water is not more discoloured than I have seen water taken from streams in healthy districts. We use it for the bed-rooms, and other purposes of a like nature, but not for culinary or drinking purposes. Although mine is a large house, we have only once been without this water for four years. It might be made much clearer by a simple system of filtration, but I have never found it necessary to adopt this precaution, as we have become quite reconciled to its appearance, from the much greater softness it possesses than the water supplied by the company. To say nothing of the greater ease, comfort, and effectiveness with which the process of washing is performed, I am sure that I save the interest of my outlay in soap.

At this time all such measures are important. Quite apart from all consideration as to the saving of water it is of moment, but it is now understood that the report of the commission on the London water supply will be in substance against the large schemes for supplying London which have been proposed to us, but will

* We have specially urged this on more occasions than one.—Ed.

strongly recommend a constant supply. It will, therefore, be necessary that the public as well as the company, should look carefully at the question so as to check waste, and to economise the use of water. The erection of a rain-water tank in every house would greatly conduce to this end, while it would tend to promote cleanliness and health. S. S.

HORNCASTLE TOWN SEWERAGE TENDERS.

We have received the following list of propositors tenders sent in for sewerage Horncastle. The quantities were supplied, so that the differences are in price only:—

Barstow & Co.	£9,388	0	0
Speight & Sons	5,781	0	0
Morton & Sons	5,509	0	0
Monkton & Co.	4,900	0	0
Buns	4,600	0	0
Abell & Co.	4,534	0	0
Moore	4,139	0	0
Beard	3,162	0	0
Freery	4,074	0	0
Wainwright	3,812	0	0
Williams	3,723	0	0
Waller	3,710	0	0
Finsley	3,677	0	0
Esary	3,571	0	0
Finson & East	3,500	0	0
Hadsforth & Co.	3,348	0	0
Yeung	3,238	0	0
Edwards	3,230	0	0
Ford	3,223	0	0
Peter	3,185	0	0
Frow	2,992	0	0

"After the tenders had been opened and their sums made known, Mr. Young (3,288l.) pleaded an error, and was, in consequence, allowed to make a private proposal of 2,977l., which, being 15l. below the lowest, the Board, with the Rev. W. H. Miner, vicar, in the chair, accepted the new proposal or amended tender, to the discredit of the four contractors originally lower."

We give this statement as sent to us by more than one of the persons who tendered.

FOOTINGS ON ANOTHER MAN'S LAND.

A CORRESPONDENT, signing "Stylus," is very facetious as to "Surveyor," who asked a question, a few weeks back, concerning the right, or otherwise, of allowing the projection of his footings on the adjoining ground:—

"You can no more build," says "Stylus," "under another man's land than you can upon it, and the reasons are quite plain, and, if I may add, natural."

"In all buildings the walls, and the earth upon which they stand, are one and indivisible. In the case of leasehold land and freehold house, the person building the house hires the land upon which it stands for a given term, as a yearly tenement, which is called ground-rent. When the ground-rent falls, or the lease expires, the house then merges into the ownership of the soil.

This has been the law of England for more centuries than we need care to go back to. If a man chooses to widen the base of his building surreptitiously, so as to touch, or rest on, under, another man's land, then that other man, upon discovery, can call in the force of the law and have that portion of the building removed."

"Stylus" is evidently not aware that Building Acts which are or have been in force, have at times given this special right to builders. The Metropolitan Building Act of a few years ago did so. "Surveyor," however, must consider that, where there is no special Act in force, he cannot touch or encroach upon the soil of his neighbour.

HUSBANDRY IN HYDE PARK.

SIR,—Would it not be well that Londoners should be informed that in Hyde Park the rural scenes for the year have already commenced?

The other day, standing on the rising ground north of the barracks (in the centre) I was surprised at the truly rural scene before me. Looking in the direction of the bridge, scarcely a sign of London is to be seen, and, to enhance the view, an acre or more of grass had been removed, leaving the ground bare, and over which a fine horse was drawing a harrow, giving one the idea of a field under cultivation; men at work cutting sods, carts slowly moving to and fro to carry them away and bring earthy material to take the place of the green herbage removed, each cart making evident its progress and the route it had taken by the long depressions left in the sward, in some places two or three inches deep. It was, indeed, a truly rural scene; it required no stretch of imagination to believe oneself miles in the country. I say "it was," but it will be continued, sir, after these holiday times are over, if we may judge by the last two seasons, when on each occasion some three or four acres of the most beautiful grass in this park were removed as sods, and as yet this year they have cut but about one acre. And if Londoners very much approve of husbandry being thus carried on in Hyde Park, the authorities might, perhaps, this season be induced to continue it till all the grass be removed, and then we might be favoured, perhaps, with a ploughing match, as an accompaniment to the Cattle Show at Christmas. Is it not kind and thoughtful thus to

bring these rural scenes into the heart of London; and at the same time, you know, it saves purchasing sods elsewhere?

Unfortunately, going on a little further one comes to that drawback to the pleasure of a stroll over a farm, viz., the dung-heap, or, as it here must be termed the rabbit-heap. I regret to say I cannot admire their choice in placing it in the very centre of the Park, at the side of a course of trees, and in the hottest part. This would be one of the prettiest parts of the Park if it were but clean and sweet. Here, from time to time, one may see mud-carts rolling over the sward to add to the heaps their load of road-scrappings and coarse rubbish. Here it remains till wanted, being occasionally turned over to facilitate decay, and which I am sure it does, by the smell then given off.

Last year much of this (without sifting) was spread over the Park, and its contents might have furnished starting points to some Hervey for volumes of "Meditations." It seemed to contain remnants of everything in civilized society:—old shoes, rags, snuffboxes, sadine boxes, broken canisters, plates, dishes, wires of umbrellas, brickbats, broken bottles and glass, the sharp points of which sparkled on the ground amidst the relics of almost every conceivable thing, and which most allowed that to remain for many weeks, if not months, to be moralized on.

R. F. C.

DEATH IN THE ALLEY.

SIR,—The *Builder* has done much to enlist sympathy in behalf of the poor creature living (or rather dying) in narrow courts, dismal passages, and back streets, in London. Let me appeal to those who have the power and the will to aid in this work of mercy, for it is imperative we ought to obtain the width and wholeness of every tenement in the kingdom. Subsequently to an Act to be passed, all such places under 2 ft. wide in any part thereof should be closed as human dwelling-places the first year, under 3 ft. the second year, and so on till the third year, and so on up to 12 ft.; the minimum to be allowed by law. I have had plenty of sympathetic (pie-crust) promises from Members, but no good has resulted yet.

R. T.

CHURCH BELLS.

SIR,—In a late number of your interesting journal there is an account of the building of a church at the north of London, in the neighbourhood of Somers-town. Now, sir, it is a remarkable fact that there is not one church-steeple in the parish of Saint Pancras that contains a peal of bells, or in fact any part of the north of London, with the exception of the parish church of Islington. This church in Somers-town is building, I read, by the munificence of a gentleman, and a peal of bells would no doubt be novel to the inhabitants of the neighbourhood of the church.

AN INHABITANT.

EFFLORESCENCE ON BRICKWORK.

SIR,—All exposed brickwork in these parts (Swansea) becomes, after a short time, covered with a white powder or efflorescence, which renders any attempt to produce coloured patterns in that material quite futile. As a constant subscriber to your valuable journal, we beg to say that we should be greatly obliged if you or any of your readers would inform us of any means by which such disfigurement can be prevented, or effectually and permanently removed.

T. W. & J.

A SURVEYOR'S CLAIM AGAINST A LOCAL BOARD.

In the case of *Shuffelbotham v. The Wilms Local Board of Health*, the plaintiff, who had been surveyor to the Board, claimed for salary due on his dismissal, with the period of his previous notice of resignation. In consequence of disagreement with certain members of the Board, who seem to have had the appointment of an engineer-in-chief in view, the surveyor gave notice of his resignation in three months, and in the meantime performed his duties as usual, but had not attended two meetings of the Board, which were not included in his duties, but which he had been in the habit of doing. In a letter to the clerk, he had explained that in the one case he was unwell, and in the other, the Board were to discuss the appointment of an engineer. The Board dismissed the surveyor within a month or so of the expiry of his notice of resignation, offering him his salary up to the time of dismissal, which he refused. The defence was rather a shuffling one. It was argued that by the Act appointing local Boards, the Board had "a power of summary dismissal of which they could not deprive themselves," to which the County Court Judge, before whom the case stood, replied that he was not bound to discuss what must become of any local Board if their most confidential officers could go and leave them at any moment." The Board, however, contended that they had contemplated such an absurdity, or, as was also urged, that the Board could not do anything "which might work to the injury of the ratepayers, and the embarrassment of a subsequent Board." It was admitted, nevertheless, that a contract had been made with the surveyor which had not expired at the time of dismissal; and the idea seems to have been that the contract was binding upon the surveyor, but not upon the Board.

As the Judge was obviously against the defendants on these points, neglect of duty was next urged; but it was shown that evidence of any neglect or dereliction was not forthcoming. It was admitted, and that calling much into question, which the surveyor had punctiliously done, was a duty of the clerk to the Board. The defendants' counsel then contended with the plaintiff's, and agreed to a verdict for the 37l. 10s. claimed. The Judge seemed to be of opinion that more might have been claimed; for he said, "If the plaintiff gave three months' notice, and you wrongfully dismissed him within one month, you would be liable to claim the whole amount, even from the moment of his discharge." There was also a claim for special damage, which could not be entered into, so notice to that effect had not been given. On the whole, the Wilms Local

Board did not come out of the affair with credit to themselves, and they established no charge against the plaintiff. Indeed, that he was an efficient officer was declared in relation to the committee, and the finding of the Board said at the close of the case, that "the plaintiff had been able to relieve his character from an imputation, and make himself stand properly before the public as a respectable person entitled to the full trust."

The plaintiff, we understand, had given up the employment of Crews, with a good private practice, to undertake the surveying of Widnes, and had done some heavy and arduous duties for the Board over and above his ordinary duties.

THE DUKE OF BUCKLEUCH v. THE METROPOLITAN BOARD OF WORKS.

This action has been again before the judges in the Court of Exchequer.

Mr. Pollock awarded to the duke a sum of 8,325*l.* The jury found a verdict not only for that amount, but for interest upon it, and for the expenses of the award. Mr. Hawkins, Q.C., contended that if it should turn out that the empire had awarded any sum, however small, which he had no jurisdiction to give, the award was bad, and the defendants would be entitled to the verdict. Mr. Hawkins submitted that there was no grant of the jetty to the duke under either of the leases, that the jetty was really public property, and that, therefore, he was not entitled to compensation in respect of it.

Mr. Baron Martin said it appeared that the jetty had existed from the time of Charles II. He did not know whether Sir Walter Scott could be considered an authority upon such a matter, but he spoke in one of his novels of a jetty from Montagu House to the Strand.

Mr. Hawkins wished he could avail himself of such an authority, as the process would be both instructive and amusing.

Mr. Baron Martin said there could be no doubt the stairs belonged to the Old Palace of Whitehall, and the Crown could make a grant of them to any one.

Mr. Baron Martin said, as at present advised, I am of opinion there was abundant evidence to prove that the jetty was an easement and right of way belonging to Montagu House, and that it passed by the general words in the lease of the Duke, who is consequently entitled to compensation for the loss of it.

Mr. Hawkins then argued at some length that in regard to various other matters for which the empire had allowed the sums the plaintiff was not entitled to compensation.

The court granted a rule generally; rule nisi.

THE LIABILITIES OF ARCHITECTS.

SWATRIDGE v. COLSON.

This was an important case to professional men, heard in Sherborne. The plaintiff, a marble mason, of 17 Yeovil, sought to recover 16*l.* 13*s.* 8*d.*, for two stone chimneys erected at the house of the plaintiff's defendant, an architect, of Sherborne, conducted his own case. The defendant had been engaged in erecting a rectory at Sandford, and, in accordance with his instructions, the plaintiff made two stone chimneys, which were fixed there, and he now sued for their value. His Honour asked if the defendant undertook to pay for the chimneys. Mr. Watts gave the order.—His Honour: They are generally given by architects, and tradesmen are very much obliged to them; but the principal says.—Mr. Watts said the principal was not disclosed.—His Honour: The principal was not disclosed, and a person gave an order, and there was fraud, then he would have to pay; but in this case it seemed the order was given simply in the capacity of architect.—Plaintiff said he had always considered Mr. Colson the responsible party, and had entered the charges for the work done to him in his account-books.—His Honour said application must be made to the person who was liable.—Mr. Colson: He has become bankrupt, and you cannot get his money.—His Honour: Mr. Watts: Exactly; that's just what we say. Mr. Colson cannot get his money, so he disputes his liability.—The plaintiff then stated his case, and said that he had never seen the order.—Mr. Watts: The order had been given by Mr. Colson, who had looked at the books, and pointed out what items were to be charged to him and what to the defendant.—On the other hand, the defendant, on being sworn, said he was an architect, and resided at Sherborne. Swatridge called at his office several times early in 1857, requesting that he might supply some of the chimney-pieces at the rectory. He told him that he was in communication with a marble company, and showed him a book of designs, with list of prices, and a letter offering 15 per cent. commission on orders.

His Honour: Is that usual? I don't ask whether it is usual for architects to accept what they can get, but it is usual for companies to do that?

Witness: I don't think it is usual, but in this case it was done, however, I did not accept it.

His Honour: The defendant said he could not supply chimney-pieces at so low a price, and voluntarily offered me 5 per cent. commission. I told plaintiff on one occasion the nominee of the Green Anne's company.—The Rectory was erected by Cockworthy, was the owner, and the contractor Mr. Gale, then living at Portland. Plaintiff inquired what I knew of Gale as to his responsibility, and I read him letters from Mr. Gale referring to that Mr. John Trust and Mr. David James, of Stoke, were his sureties. On the 3rd of May, having obtained the consent of the contractor that Mr. Swatridge should be employed, I delivered plaintiff tracings, and drawings from which the chimney-pieces were executed and erected, under my instruction.

In November last I requested Mr. Swatridge to supply me with a memorandum of the cost, and other items, to enable me to measure for and make out my bill of extras. I left him the memorandum, which he has produced, and he sent me an account. I made out the bill of extras in the usual manner, allowing the contractor the amount of 6*l.* 13*s.* 2*d.* for the extra value of chimney-pieces, beyond the amounts named in the specification. The plaintiff has seen that bill of extras; and in December last the nominee attended, and settled the balance due to the contractor, and tradesman who had also been employed under my instructions, attended, and were paid the accounts by Mr. Gale. Most likely if Mr. Swatridge

had attended the settlement, he would also have been paid, as Gale received a very considerable balance.

Plaintiff: But you promised to write to me and say whether you would be bound to pay him.

His Honour: That shows where you expected to get your money.

Defendant said he had witnesses to call who had been similarly employed by him.

His Honour, however, did not think that necessary, and in delivering his judgment said there was no doubt that Gale was the contractor for the works. It was one of those unfortunate cases in which the person really liable had become insolvent. It must be very strong evidence that would make him believe that the case was one out of the ordinary run of business by which an architect made himself personally liable instead of merely giving directions. They had been told that before the work was done the plaintiff was informed of the name of the rector and the contractor, and that he offered 5 per cent. on any commissions defendant could obtain for him. If that was so it was conclusive, and it had not been contradicted; and it seemed that the plaintiff had also inquired as to the means of Gale, in reply to which the defendant had read several letters as to his character, and had informed him of his sureties. All that was perfectly inconsistent with the assertion that he looked upon the defendant as making himself personally liable, and nothing having been made out to his satisfaction that the verdict should be against the defendant, he should give it for him, with his personal expenses.

THE COST OF IMPROVING PARIS.

The reports of the tribunals which have adjudicated the sums received by tradesmen for leaving their places of business just now in the Rue de la Paix and its immediate vicinity facing the new Opera House, say:—

"The expropriations for the opening of the new street, the Rue Réaumur, are actively going on. The jury who estimate the sums to be paid for this relinquished property are now engaged upon the section between the Rue du Port Mahon and the Rue de Choiseul. Three of these purchases alone have cost each of them more than a million of francs. [The reader will bear in mind that a million of francs is 40,000*l.*, and 100,000, 4,000*l.*] For the house No. 25, in Rue Augustin, 1,200,000*fr.* has been paid for No. 7, Rue de Grammont, 1,025,000*fr.*; for No. 3, Rue de Choiseul, 1,000,000*fr.* In one house alone in the Rue Neuve St. Augustin the indemnity paid for loss of trade exceeded half a million; a florist obtained 240,000*fr.* for an unexpired term of his lease of six years; a dealer in lace, 160,000*fr.*; and the Restaurateur Bignon, whose cellars were in Rue de la Mochodere, No. 8, received 200,000*fr.* A question presented itself as to the claims of the Athletic Union Club, established in the Rue de Choiseul, the question being, whether the members of a club constituted a society properly so called, and whether they could claim as such? The question has been determined in their favour, M. De Barthélemy, who appeared for the club, having obtained 800,000*fr.* The total purchases made in the present series of awards exceeds 15,000,000*fr.* The jury has since proceeded to sever other awards for buildings required to be taken down in pursuance of the improvements everywhere going on in the city of Paris. In the Rue Louis le Grand, No. 38, the proprietor demanded 1,000,000*fr.* for his interest, and was paid 800,000*fr.* In the case of the proprietor of No. 39, Rue de la Paix, he demanded 1,500,000*fr.*, and obtained 1,320,000*fr.*; one of the shops belonging to this house is occupied by Madame Lucy Hoquet, a modiste, and to whom has been awarded 300,000*fr.*; 100,000*fr.* to a Glover, and 230,000*fr.* to a jeweller in the same house. The total amount of indemnities paid for several houses reached 800,000*fr.* The total amount of the sum amounts to 7,000,000*fr.* The gross total is somewhere about 26,000,000*fr.*, or 1,040,000*l.* For the short term from the Rue Louis le Grand to the angle of the boulevard the indemnity amounts to 60,000,000*fr.* The figures here given, it will be understood, are sums paid for expropriation and to the landlords. After this expenditure the new houses have to be built.

SANITARY MATTERS.

Surveyor's Reports on Newcastle-upon-Tyne.—Reports by Mr. Bryson for 1865-6-7, have been printed by order of the Newcastle Town Improvement Committee, showing the progress made during the last three years in sewerage and drainage, street improvement, &c. On the subject of the public health of the borough, the surveyor says:—

"It is a matter of serious concern that, notwithstanding the strenuous efforts made by the committee to improve the sanitary condition of the borough, a high rate of mortality still prevails.

In connection with those questions, underlying that of public health, which come within the range of my department, I may remark that, although a great deal has been done in the way of sewerage and house drainage, still much remains to be done in the ventilation of sewers, and in the paving and surface drainage of the extended parts of the town, especially in the neighbourhood of Scotswood-road and other places.

While, however, these improvements are all good as far as they go, still it is considered that a better accommodation be provided for the working class, the death-rate will not be very materially reduced. So long as the old houses in the overcrowded parts of the town are permitted to remain above ground, they will find inmates; and I would like the liberty of suggesting that, if some of those schemes of street improvement through Pandon and the lower parts of the town were carried out, they would be of immense service in this respect, and, in addition to opening out sites for such a purpose, would afford great relief to the commerce of the quay.

Another and most important problem which has yet to be solved relates to the disposal of the town sewage. At present it is, as you are aware, by the system of water-closets and sewers now in use, discharged into the river,—a system which is a great improvement upon the former

objectionable use of cesspools; but, looking at the matter in an economical point of view, a great inconsistency is observed: while, on the one hand, we send thousands of miles, at a great cost, for the excreta called guano; on the other, we not only throw away that we already possess, but render it worse than useless by converting it into an element of disease. But, whatever might be the benefit in pecuniary result of utilizing the sewage, the benefit of ridding the town of it is an advantage in point of health beyond money value."

CHURCH-BUILDING NEWS.

Brooklands (Manchester).—The church of St. John the Divine, at Brooklands, built and endowed at the cost of the late Mr. Sam Brooks, has been formally consecrated by the Bishop of Chester. The building, which was commenced in 1864, has only just been completed. It is situated on the west side of the road running through the Brooklands estate, due south from the South Junction Railway. The church is in style Gothic, and as evidenced by its most distinctive feature, such as sections of moldings, proportions of arches, and carving, of a simple type, belonging, perhaps, to the earlier period of French work, rather than to that of England. The materials of which it is built are, externally, Yorkshire shoddies of a warm tint, with dressed work of Halifax stone; whilst, internally, the walls are lined with fire-bricks, cream and brown, in bands and diaper-work. The plan is a nave of six bays, 90 ft. long by 33 ft. wide, without clearstory, roofed in one span, having transepts north and south, taking up the two easternmost bays, divided from the nave by arcades of two arches. The extreme width across the nave is 68 ft. Reached by a broad flight of steps are a choir and chancel, 32 ft. long by 20 ft. wide, with organ-chamber to the south, and on the north a small door leading to the sacristy. The building is entered at three doorways,—one in the west front, a porch on the north-west, and a porch at the angle of the sacristy and north-west transept. The chief façades of the building are the west and east. Right and left of the canopied western doorway the wall-space is broken up with a simple arcade, above which, and occupying nearly the whole of the gable, rises an arch, filled in with a pair of three-light windows, with traceried heads of three plain circles, a piece subdivided by geometrical iron glazing grilles. The sill of these windows is kept up a considerable height from the ground, and between it and the sub-sill of the main arch, under which the windows are grouped, are two large circular medallions, one on either hand of the door canopy, filled with highly relieved sculpture. The subjects are the Gall of St. John from his fishing-net to become a "fisher of men," and his writing of "the things he saw in the isle called Patmos." At the east is a rose window, of seven circles; all but the centre are cusped and uncanopied. Below the window is an arched panel, containing, in relief, the evangelist's symbol, the eagle. The reredos, painted in wax-colour, covers a space of 13 ft. wide by 5 ft. 6 in. high; it is divided into three compartments, the central subject being our Lord in Glory, with, on either hand, angels in postures of adoration, and at the four corners of the central panel are cherubs. The background of the work is filled in with plants of wheat and vine conventionally treated. Above the reredos, in the spandrels below the rose window, are two medallions, filled with Caen stone heads of the Virgin Mary and St. John, with gilded aureoles. The choir and chancel-floor and walls, to a height of 4 ft. 6 in., are laid with encaustic tiles. The whole of the windows are glazed with two tints of green glass, with the geometric forms in tracery picked out with touches of brilliant colour. The church is at present towerless, having but a slight headed wood-hell-tache rising from the nave-ridge, and supported by the roof-trusses. The building is arranged to accommodate at least 500 people, and a large proportion of the seats are free.

Gloucester.—St. Catherine's new Church has been consecrated. The edifice consists of nave, transepts, and chancel, with circular apse. The nave is 68 ft. long and 28 ft. wide; the transepts are each 20 ft. by 13 ft.; and the chancel 22 ft. by 22 feet. There is a vestry on the north side and an organ-chamber on the south side of the chancel. The church is of Early French character. The chancel is lighted by five windows; the transepts by three lancet windows with trefoil heads, and a pierced Catherine-wheel window of seven lights, with plate tracery; the west end by two double-lancet windows, and a

Catherine-wheel window of nine lights, with plate tracery. There are also double-lancet windows on each side of the nave. Severn-side bricks form the chief material used. Outside, the walls are relieved by bands and devices in black and white Staffordshire bricks, and by stone-dressings. Inside, the walls are lined to the height of the window-sills with red bricks, with an arcading in black bricks; above the sills the walls are lined with white Staffordshire bricks, relieved by bands and ornamentations in red and black bricks, pointed with white cement. The roof timbers are all stained and varnished, and the spaces between the rafters are plastered. Hereafter the panels of the chancel will probably be decorated with colour. The fittings throughout are of deal, stained and varnished. The system of warming is that by Porrett's underground stove. The roof is covered with red and blue Broseley tiles, arranged in ornamental patterns. At the west end a bell-cot has been erected of brick and stone, surmounted by a stone cross; at the east end, over the chancel, there is an iron finial, painted in chocolate, relieved with gilding. The porch is at the north-west corner of the nave, and is surmounted with a light iron finial. The whole of the floor of the nave is laid with tiles, blue, red, and white, arranged in patterns. The floor of the chancel has been laid with tiles by Godwin, of Lugwardine. The chancel-arch is of red and white stone, and rests on corbels, on which are carved angels. The corbels in the chancel are carved with the cross and crown, and the emblems of our Lord's passion. There is a credence on the north side of the altar. The five windows of the chancel are filled with stained glass by Messrs. Clayton & Bell. The subjects are,—Our Lord as the Good Shepherd in the centre, and the four Evangelists, two on either side. Beneath the figures, which are all in standing attitudes, are placed in quatrefoils the emblems of our Lord and the Evangelists,—the Agnus Dei, the Angel, the Lion, the Ox, and the Eagle. An organ of six stops has been placed in the church. It was built by Messrs. Bryceson, Brothers, of London, and was shown at the Paris Exhibition last year. The whole of the iron-work and gas-fittings were made by Mr. Cornell, of Cheltenham; the seats and roof have been stained by Mr. Barnes, of Gloucester; and the church has been erected, under the personal superintendence of Mr. Henry Medland, by Messrs. King & Godwin, of this city. The outlay has exceeded 2,000l.

Rushall.—The church here has been re-opened after alterations and repairs. In the alterations the style has been adhered to, but by an addition of a spire a new appearance has been given to the building. The nave has been enlarged 33 ft., and so 104 new sittings have been obtained. The whole building has been repaired and renovated, and the work has been done by Mr. Highway, builder, Walsall, from designs by Mr. Cranston, architect, Birmingham. The cost of the whole is about 2,000l., which has been defrayed by Mr. W. Mellish, Q.C., one of the patrons of the church.

DISSENTING CHURCH-BUILDING NEWS.

Liverpool.—The new Welsh Presbyterian Chapel in Prince's-road has been opened for divine service. We are indebted to the local *Journal*, which gives a description of the edifice, accompanied with an engraving, for the following particulars. The chapel, with its two lecture-rooms, two vestries, keeper's house, &c., occupies an open site at the corner of Upper Hill-street and Prince's-road, the principal façade being towards the latter. The chapel proper is built of stone throughout, yellow sandstone being used for all the finishings and ornamental portions, and grey-tinted Yorkshire shoddies for the general wall surfaces. The style of architecture is Gothic, with a strong bias towards the Early French school in all the details. In plan the chapel is in the form of a T, although not perfectly so, for the nave is continued eastward of the transepts about 5 ft., forming a recess for the reception of the pulpit and its accessories. The ground-floor is seated for about 800 persons, and is free from all obstructions to sight, except two slender marble columns which support the centre of the transept galleries. The two columns supporting the end gallery are so placed as to be out of the line of vision of any sitting behind them. The three galleries are seated for about 300 per-

sons. At the north-east corner of the chapel rises the tower and spire to about the height of 200 ft. This feature is described as being the finest in this district. The lower portion of the tower forms the principal porch. The upper stage of the tower is pierced with eight deeply-recessed and shafted heltry-lights. At this stage the eight great buttresses of the tower terminate against the base of the angle pinnacles in open tabernacles, supported on red columns. Above the parapet, in the base of the spire, are four lofty lucarne lights with pinnacled canopies supported on long detached red columns. The tower is attached to the body of the chapel by a vestibule, in which are placed the stairs to the end gallery of the nave. The main gable to Prince's-road contains a group of three deeply-recessed and traceried windows, the centre one being about 40 ft. high. A projecting porch is placed on the south side of the nave opposite the tower vestibule. The side windows of the nave and transepts are large, and the transept gables are pierced with triplets of lofty traceried windows. The west gable, over the pulpit, has a large rose window of plate tracery. The whole of the windows throughout the chapel are glazed by Messrs. Edmondson & Son, of Manchester. The whole of the woodwork of the interior, with the exception of the pulpit, is of selected pitch pine. The seating is open, and furnished with crimson cushions. The gallery fronts are arcaded with moulded arches, supported on black shafts, and bracketed from the beams. The latter are supported on wall corbels and columns of green marble with carved capitals. The pulpit (not quite finished) is constructed of oak, relieved with rosewood, teak, ebony, and boxwood. The chief feature of the interior is the ceiling. It is plastered between transverse and horizontal wood ribs, and is in shape a pointed cradle roof. The curved transverse ribs are supported on wall columns with carved capitals of various designs. The chapel is lighted by gas-fittings in wrought iron and brass, designed by the architects, and manufactured by Messrs. Charles Smith & Sons, of Birmingham, who also supplied the whole ornamental ironwork and ironmongery about the buildings. The cast railing of the boundary-walls was made by Messrs. Harrison & Son, of Liverpool. To the west of the chapel are large and convenient buildings in ornamental brick-work, containing two lecture-rooms, two vestries, and keeper's house, with other conveniences. The masonry was executed by the late Mr. Stirling and Mr. Edwards, of Liverpool. The woodwork has been executed by Mr. James Robbers. The plastering, &c., was done by Mr. vanishes by Mr. A. Lillyman, painter and planter. The architects from whose designs, and under whose superintendence the whole of the works have been executed, are Messrs. W. & G. Andsley, of Liverpool.

SCHOOL-BUILDING NEWS.

Liverpool.—The chief stone of St. Titus's National Schools, Portland-street, has been laid. It was estimated that about 4,000l. would be required, and towards raising this amount the Government and the National Society promised 700l., and the Liverpool Church and School Extension Society 1,000l. A space of ground was obtained on the right-hand side of Portland-street, and the schools will be erected nearly opposite to the church. The building will be a very plain and substantial one, and executed in grey bricks, with stone dressings. There will be three floors, each having a school-room 56 ft. 6 in. long by 18 ft. wide, with class-rooms 24 ft. long by 15 ft. 6 in. wide. Stone staircases will lead to each floor. There will be a spacious playground attached to the schools, which are estimated to accommodate 500 children. The architects are Messrs. Culshaw & Summers, and the contractors Messrs. J. Burroughs & Sons.

Sursey.—A contract has been signed with Messrs. Mansfield, Price, & Co., for 15,000l., for the county school buildings, to accommodate 300 boys. This contract includes a chapel, which is the gift of Mr. W. H. Peck, of Wimbledon House. The new buildings are to be completed in twelve months.

Stockport.—The foundation-stone of St. Paul's New Schools, Portwood, was to be laid on Wednesday. The schools are to accommodate 500 children. They are to be fitted with separate lavatories for boys and girls, and to be warmed with Haden's heating apparatus. The architect

is Mr. Medland Taylor, of Manchester; and Mr. W. H. Brown is the contractor.

Wakefield.—The foundation-stone of new National and Sunday Schools to be built in Zealand-street, in connexion with the Wakefield Parish Church, has been laid. The buildings, which are of Gothic design, and are intended to afford accommodation for 500 children, consist of boys' school-room, 60 ft. by 20 ft.; girls' room, 66 ft. by 20 ft.; infants' room, 52 ft. by 21 ft.; and two class-rooms, each 16 ft. by 16 ft. Cloak-rooms and lavatories will also be fitted up adjoining the entrances. The boys' and girls' rooms are so arranged that they can be thrown into one. The external faces of the walls will be of pitched-faced stone from quarries in the neighbourhood, with tooled dressings. Internally the rooms will be plastered, also ceiled at the rafters, and the roofs being high-pitched and open-timbered, wrought, stained, and varnished. The whole of the inside wood-work will be stained and varnished. The roofs will be covered with blue and purple slates in hands, unroofed by red ridge tiles. The contracts for the various works have been let to Mr. Geo. Fawcett (brick and stone), Mr. J. P. Hill (slating), Mr. C. Driver (plastering), Mr. J. B. Goldthorp (carpenters' and joiners' work), Mr. Drake (plumbing and glazing work), Mr. Thomas Hudson (ironwork), and Messrs. Hodgson & Son (painting and staining). The cost of the buildings will be about 1,800l., and they will be carried out from the designs and under the superintendence of Mr. William Watson, of this town, architect.

Miscellaneous.

HOUSES OF THE PEOPLE IN EDINBURGH.—Sir J. Y. Simpson states that in the old town of Edinburgh there are 13,000 families, consisting of 60,000 individuals, living in one-roomed houses; and that 1,500 rooms are the shoddy, day and night, of from 5 to 15 persons. About 120 have no windows, and 900 of them are cellars.

THE ARCHAEOLOGICAL SOCIETY OF MALTA.—At a recent meeting of this Society, Colonel Collinson, R.E., and Deputy-Adjutant Commissary-General Furse presented a plan of the Phœnician ruins at Hagiar Kim, near Crendi, about six miles distant from Valetta. A lecture was delivered in illustration of the plan by Mr. Furse, which gave the audience some idea not only of the ruins themselves, but of who are to be considered, according to the description of ancient authors, and the generally received tradition, the first inhabitants of these islands and the architects and builders of Hagiar Kim.

SELF-FEEDING PENHOLDERS.—A renewed attempt has been made to form a self-feeding penholder on improved principles. Mr. F. F. Benvenuti, principal of the Swansea Training School and Literary Institute, is the inventor. The *Cambrian* states that he has given the pen a thoroughly practical trial, and readily acknowledges its advantages over others. Ink can be kept in the holder for several days together—always at hand when wanted; whilst in writing, blots, which accompany other self-feeding holders, are almost impossible. Messrs. George Rowney & Co., of London, his agents, add our authority, recently received a testimonial from Mr. Redgrave, the principal of the Science and Art Department of the South Kensington Museum recommending it as a drawing-pen, and a valuable acquisition to the architect.

VALUE OF ILLUSTRATED BOOKS.—The *Publishers' Circular* mentions an incident at the sale of the library of the late Mr. Windus, of Tottenham, as showing the increasing value of choice books. One of the gems of the collection was a copy, on large paper, of Dr. J. T. Dibdin's "Bibliographical, Antiquarian, and Picturesque Tour in France and Germany," illustrated with etchings, India proof engravings, private plates, original drawings by Lewis, Pugin, and others, extending the three volumes to six. The copy was formed by Mr. Eyton, and at the sale of his library twenty years ago it was purchased for 63s. by Mr. Lilly, who disposed of it for 100l. The same book to Mr. Harvey, of St. James's-street, the next bidder being again Mr. Lilly, its former possessor. This sale afforded many other exemplifications of the same fact, which is, indeed, obvious to any one who takes an interest in literature.

ARCHITECTURAL EXHIBITION SOCIETY.—The private view of the Exhibition will take place on Wednesday, the 29th inst. A *Conversazione* will be held on the 5th of May.

THE NEW ST. THOMAS'S HOSPITAL.—Her Majesty has named Wednesday, the 13th of May, half-past eleven o'clock, for the ceremony of laying the first stone of the new St. Thomas's hospital.

OPENING OF THE NOTTINGHAM FREE LIBRARY.—The Mayor has opened the Free Library in the presence of a large number of gentlemen. It contains 3,500 vols. of voyages and travels, biography, and history; 5,000 of poetry, novels, & miscellaneous works; 1,200 of the sciences, philosophy, &c.; 600 of theology and ecclesiastical history; and 400 politics, law, economy, &c. A reading-room, a museum, and a reference-library, are also shortly to be added.

MEMORIAL TO SERGEANT BRETT.—A stone tablet, in memory of the victim of the Fenian outrage, has just been erected in St. Barnabas's church, Manchester. The inscription is as follows:—Erected by the minister and congregation, in memory of Charles Brett, police sergeant, of this city, who for many years worshipped in this church, until he fell at his post of duty, a victim of the violence of sedition, on the 18th September, 1867. A faithful man. Though offered life, he chose a cruel death rather than betray his trust.

FINSBURY AND ALEXANDRA PARKS.—The fencing and laying out of the grounds of Finsbury Park, formed on the site of Hornsey Wood and its extensive grounds, is advancing favourably. The fencing around the extensive and picturesque tract of land for Alexandra Park, situated between Muswell-hill and Woodgreen, Tottenham, is now completed, and the planting of flowering shrubs, herbaceous plants, and flowers along the borders of the flower-beds and grass-plots progresses rapidly, many of the earlier descriptions being in bloom. The entrance carriage-drives through the park are finished, and the large trees on the Muswell-hill side are left standing.

TINNING THE INTERIOR OF LEAD PIPES.—A method of tinning the interior of lead pipes has been patented by Mr. Peter Naylor, of New York, U.S. The invention consists in a mode of applying to the interior of the pipe a flux that protects the lead from oxidation, and insures a perfect coating of tin when the tin is poured through the pipe, or the pipe is dipped into the bath of tin. After the lead pipe has been made, place the same in a vertical or nearly vertical position, and pass down through the same a strong cord, to which a weight is attached to draw the cord through the pipe, and at or near the other end of the cord a sponge, or piece of very porous elastic material is attached, of a size to fill the pipe, and of any desired length, say 6 in., more or less. The flux employed is either grease or muriate of zinc, but any other wax may be used. The sponge or porous wad, being saturated with this flux, is drawn through the pipe, and by its length insures the covering of the entire surface of the inside of said pipe with the flux, so that the melted tin, subsequently applied, will adhere to all parts with uniformity and firmness.

OPENING OF ANOTHER TUMULUS IN NORTH WILTSHIRE.—The Rev. Canon Greenwell, of Marlborough, has commenced the examination for scientific purposes of the large tumulus situated at the western scarp of the Yorkshire Wolds, at an altitude of about 750 ft. on the Kirby Underdale estates of Viscount Halifax. A week's digging on the southern side of the barrow has produced an unexampled number of burials, all Anglo-Saxon and secondary interments, so that very little progress has been made towards reaching the primary. With the remains of men have been found bronze and iron swords and knives, and with women headdresses, brooches, &c., and various beads. The strange feature has been that the bodies have many of them been interred in the doubled-up way, hitherto thought to pertain only to the ancient Britons; but some were at full length, and when so were east and west. The results so far are enigmatical, presenting the first samples of contracted Anglo-Saxon burials. The full examination will stand over till summer, when several of the leading archaeologists will attend. It is believed the Anglo-Saxon burials surround the mound, which will contain the earlier British ones in the centre.

GAS.—The Sheffield Gaslight Company have declared a dividend of 10 per cent. for the last year.—The Colnbrook Gas Company, under new management, have reduced the price of their gas another shilling per 1,000. The price is now 6s.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—Mr. Hyde Clarke, D.C.L., at the last meeting, gave a lecture on "Ephesus," when the collection of photographs by Mr. Sochoda were exhibited in the rooms of the society. Mr. F. Y. Hnrstone, V.P., and Pres. S.B.A., was in the chair. The lecturer, briefly alluding to the prehistoric period of Ephesus, with its caves and rock pictures, regretted that such a mine of artistic and archaeological wealth had not met with more explorers; and next reverting to the historic period, remarked that within a circle whose radius was 30 miles were concentrated the schools of art of great cities, to which artists then resorted as to the galleries of Europe at the present day. Mr. Falkener, like Professor Donaldson, was only a few days on the spot, and had therefore but little time to examine the monuments, the unhealthiness of the district hindering further investigation. In the discussion that followed, Mr. A. A. Fry said that he hoped the facilities now afforded in travelling would induce the educated classes of England and France to visit the cities of Asia Minor, and explore localities of such surpassing interest.

VOICES TO SCIENCE AND ART DEPARTMENT.—The estimates propose a vote this session of 239,290, for the Science and Art Department, an increase of 29,567, over the vote of last session. The increase is chiefly in the grants in aid to schools of science and art—10,300, in the payments to teachers on results, and 15,750, in the payments to managers under the Minutes of 1865. The number of persons under instruction in science in May, 1867, was 10,230, an increase of no less than 3,388 over the number in May, 1866. The students taught drawing in schools of art and in night classes, day schools for the poor, &c., were 104,668 in 1866. The vote for purchase, circulation, and loan of objects of art shows a large increase. A vote of 10,000, is proposed, in part of 20,000, for the removal of the iron building at South Kensington to a site offered at Bethnal-green, with a view to the establishment of an auxiliary Museum of Science and Art in the East of London. The vote for the National Portrait Exhibition is 3,000, and the receipts for admission are estimated at a like sum of 3,000; the expenditure in 1866 amounted to 3,882. The accounts for 1867 were not closed when the estimates were prepared for this session. The vote for the permanent buildings at South Kensington this year will again be 32,500, on further account of 195,000.

THE POST-OFFICE AND THE TELEGRAPH.—The report of Mr. Scudamore to Lord Stanley of Alderley, upon the advisability of working the electric telegraphs by the Post-office has just been published. It is prefaced by a letter from the late Postmaster-General, in which he states that for some years he had been in favour of uniting the managements of the telegraphs and the post. In the report itself Mr. Scudamore compares at some length the results of the Belgian and Swiss systems with the English. In 1869, in Belgium, the proportion of telegrams to letters sent was 1 to 218. The Government reduced the price from 15d. to 10d., and immediately the proportion rose to 1 telegram to 114 letters. A further reduction to 5d. has raised the proportion still further. It was in 1865, 1 to 48. In Switzerland, too, a low rate,—1 fr. for 20 words,—prevails. In 1865 the proportion was 1 telegram to 69 letters; while in the United Kingdom the proportion, which in 1863 was 1 to 197, had only risen in 1865 to 1 to 151. Mr. Scudamore then passes on to consider the objection that the subordinate agents of the Post-office department in the small provincial towns are incompetent to control the telegraph. He answers that there is nothing peculiarly disqualifying in a postmaster, and that an increased pay would bring greater efficiency to the work. He thinks that the whole of the companies' properties and rights might be bought for 2,400,000, and as much as 2,500,000, would be required to start the scheme. If we got the same proportion of telegrams to letters as Belgium, and set the average of product of each telegram to 1s. 2d., deducting all charges, there would be, Mr. Scudamore shows, a net produce of something over 500,000.

SOUTH KENSINGTON MUSEUM.—During Easter week, free, the visitors numbered 31,500; and there went to the National Portrait Exhibition, by payment, 3,441.

ARCHAEOLOGICAL REMAINS IN THE SOUTH AMERICAN HIGHLANDS.—Some remarkable remains of the aborigines have been discovered in Chili, on the summit of the Cordillera of Dona Ana.

INFECTIOUS DISEASES.—The committee of the University College Hospital have, through the Hospital Carriage Fund, been placed in the possession of a carriage for the convenience of persons suffering from infectious diseases. The committee have determined that persons requiring it, and who reside within a three-mile radius of the hospital, may obtain it upon application to the clerk at the hospital, and paying the actual expenses of hire.

THE LEEDS SEWERAGE.—A report, by the borough surveyor, Mr. A. M. Fowler, to the Streets and Sewerage Committee of the town council, upon forming a drainage district for the south-west portion of the borough of Leeds, and the effectual sewerage of the same, has been printed by authority of the council. The cost of draining the district, including storm outlets and contingencies, is estimated at 40,500. The question how the borough sewerage can best be ventilated is at present referred to a sub-committee.

ROYAL MICROSCOPICAL SOCIETY.—At the annual *soiree* of this society, held at King's College, on Wednesday evening last, the 22nd inst., a large number of the scientific novelties of the day were presented in a very attractive form. Amongst the most remarkable, we may mention a preparation showing the decomposition of water, and two solid pieces of plate-glass, an inch and a half thick, pierced by the electric spark. Under the microscopes were shown sections of the human tongue and brain, and the usual number of living beings from the invisible world. Amongst the works of art were exhibited a large collection of highly-finished drawings of botanical, physiological, and zoological subjects; a number of handsome bronzes, by F. Sparrell; and a collection of flower-vases and *repoussés* salvers in beaten metal, by Richardson, Slade, & Elton.

"THE WALL OF ANTONINUS."—The *Edinburgh Courier* says, in the course of some improvements on the property of Mr. Cadell, of Grange, the workmen turned up a large stone, which at first was thrown aside as an ordinary boulder, and for a time was allowed to lie on the surface. An examination afterwards made, however, showed that the reverse of the stone contained an inscription which seemed to identify it with the wall of Antoninus (commonly known in that quarter as "Craham's Dyke"), built during the Roman occupation of Lollius Urbicus, for the purpose of shutting off the wild tribes to the north, and which was supposed to extend from the Forth to the Clyde. From the inscription it is conjectured that this stone was intended to commemorate the finishing of the wall; and, if so, it will prove a valuable aid to antiquarian research, as showing how far the work actually did extend eastward. It is to be hoped *this* will not be sold to go to America.

FROSTING IN COLOURS, AND ON PAPER AND COTTON FABRICS.—A curious discovery has recently been made by M. Auguste Bertsch, and turned to practical account by M. Kuhlmann, the celebrated chemist. The beautifully symmetrical and yet fantastic figures of leaves and flowers depicted on the window panes of a room on a frosty morning have been closely imitated, according to *Galvani's*, by means of Epsom salts (sulphate of magnesia) dissolved in beer, together with a small quantity of dextrine (artificial gum), and in this state applied to a pane of glass with a sponge or brush. The liquid may receive any colour whatever, at the option of the operator. M. Kuhlmann, on being apprised of the fact, conceived the idea of transferring those fairy-like creations to stuffs and paper. For this purpose he first got the crystallizations on sheets of iron, on which he afterwards laid one of lead. By means of a powerful hydraulic press the minutest details of the figures in question were directly imprinted on the soft metal, and a copy of them in relief was then obtained by galvanoplastics. In impressing cotton stuffs the patterns must be continuous. This obstacle has been overcome by effecting the crystallization on the cylindrical surface of a roller.

AN ENGLISH CHURCH IN DRESDEN.—The foundation-stone of an English church has been laid here, an English lady having generously subscribed the sum of 4,000*l.* towards the execution of the project. The design for the structure is by an English architect. The new building is to bear the name of All Saints' Church.

SALISBURY CATHEDRAL.—The Dean of Salisbury has received a cheque for 500*l.* from the Rev. C. B. Bicknell, rector of Stanton, for the purpose of placing twelve statues in the west front of Salisbury Cathedral, in addition to the forty which have been ordered by the dean and chapter. Fourteen statues have already been placed in niches.

MEMORIAL CHURCH IN CLERKENWELL.—A church is about to be erected in the St. John-street-road, for the new district of St. Peter's, in the parish of St. James, Clerkenwell, upon the site secured as the nearest available to the scene of the Smithfield martyrdoms. The total cost, including schools and parsonage adjoining, is not to exceed 10,000*l.*

THE DRINKING FOUNTAIN IN MARYLEBONE-LANE, OXFORD-STREET.—We regret to learn that this fountain is being allowed to fall into a state of dilapidation. The malicious acts of drunken varlets fresh from beer-shops only show how desirable it is to place drinking-water within reach of thirsty wayfarers, and we hope the authorities will not be disheartened by repeated acts of this description, but that they will set watch for the depredators, and hand them over to the police-courts, where they will meet with their deserts.

GUN-COOTS AND ITS SAFETY.—Mr. James Wilson (of the North-Eastern Goods Manager's office) has reported upon experiments undertaken for the purpose of investigating the risks incurred in the conveyance of compressed gun-cotton charges upon the North-Eastern Railway. The experiments were conducted by Mr. Prentice, of the Gun-cotton Company. The results of the experiments are said to have been convincing, and enabled Mr. Wilson to report that the railway company might safely carry gun-cotton along with other goods in ordinary wagons, adopting the same rules as now apply to the conveyance of cartridges.

THE MANCHESTER NEW STOCK EXCHANGE.—On Tuesday last, the members of the Manchester Stock Exchange assembled for the first time in their new room, in Commercial Buildings, Cross-street. The Exchange-room forms a part of a large structure which has been erected by the Commercial Buildings Company, and is now fast approaching completion. The front will be occupied by shops and offices; and there is a separate entrance in Newmarket-street to the Stock Exchange, which is upon the first floor, and is reached by two flights of steps. The Exchange-room is 66 ft. in length, by 46½ ft. in breadth. There is accommodation for about 120 members; and opposite to the main entrance are a reading-room, and offices for each of the telegraph companies. Messrs. Walters, Barker, & Ellis, of Manchester, are the architects, and the entire contract for the building has been executed by Mr. Wm. Southern.

UTILIZATION OF WASTE.—The refuse ore which formerly used to obstruct the entrance to some German mines has become highly valuable since it was discovered that it contains metals so important as nickel and cobalt. The lignor which the manufacturers of soap formerly allowed to run off as useless is the source from which we derive glycerine. The sulphuric acid which used to poison the atmosphere and to destroy vegetation in the neighbourhood of works for roasting sulphurets, is now carefully saved and converted into sulphuric acid. The "soda waste," which was permitted to accumulate in mountains in factories, is now made to yield quite a number of useful products, such as sulphur, hyposulphite of soda, and others. In many instances still, products, solid, liquid, and gaseous, are wasted, permitted to escape with the atmosphere, to fill the sewers, or to decay out of doors, which would yield a rich reward to the man who would turn them to serve some useful purpose. Nothing ought to be thought too insignificant for consideration. Who knows, says the *Scientific American*, but what even the carbonic gas which we are now glad enough to get rid of by our chimneys may hereafter be conveniently rendered useful in the economy of our households.

BEQUESTS TO BRITISH MUSEUM.—The late Mr. Felix Slade, of Lambeth, has left to the British Museum his collection of glass, consisting of vases and other objects illustrative of the art of glassmaking from the earliest period to the end of the seventeenth century. He has likewise bequeathed to the Museum his extensive collection of engravings; also the sum of 45,000*l.* to be applied to the endowment of fine arts professorships at Oxford and Cambridge, and at University College, London, where some exhibitions also are to be founded. The fine collection of Venetian glass belonging to Mr. E. W. Cooke, R.A., is about to be sent to the South Kensington Museum on loan for a year.

REFORM OF THE PATENT LAWS.—On Thursday last the Hon. Anneton Herbert, B.C.L., presided at a Second Conference on the Reform of the Patent Laws, at the Inventors' Institute. The secretary of the Institute, Mr. R. Marden Latham, read the report of the proceedings of the committee nominated a month ago, and composed of members of the council, together with representatives of various public bodies. From this document it appeared that arrangements are in progress for an effective agitation in the interest of inventors, and that already Mr. A. H. Layard, D.C.L., M.P., has consented to preside at a public meeting to be shortly held in London. The chairman moved the adoption of the report; and in doing so expressed his thorough appreciation of the important steps which were being taken. A petition was then submitted, and having been unanimously approved of, was ordered to be signed by the chairman in the name of the meeting.

THE EDUCATION GRANT.—The vote proposed for public education in Great Britain for the year ending with March, 1869, is 842,554*l.*, an increase of 136,689*l.* over the vote for the fiscal year just expired. The calculation based upon the number of scholars in average attendance in schools inspected in the last school year in England, with the percentage added for the ordinary increase, gives 985,200 as the estimated average attendance in 1868; but an addition of 45,000 is made for half-timers under the Workshops Act, and of 16,000 for scholars in Congregational and other schools newly admitted to aid, raising the estimated number of day scholars to 1,046,200. Briefly, the vote for Great Britain to be proposed this session stands thus:—Office in London, 29,482*l.*; inspection, 64,103*l.*; normal schools, 74,250*l.*; building grants, 45,000*l.*; annual grants, England and Wales, 549,639*l.*; grants to teachers in Scotland, 79,500*l.*; unexpired pensions, 580*l.* Total, 842,554*l.*

ARCHAEOLOGICAL DISCOVERY AT BERWICK.—While trenching ground for a garden at a recently-erected villa, in the Inner Cow-close, on the corporation property, the gardener, being compelled to go deep, came upon the skeletons of several human beings in different parts of the ground. On each side of three of the bodies were slabs of undressed stone, with rude stone coverings. On one was an incised cross, with a rose in the centre; and on another, the crest of a child, was a Latin cross. The place was probably at one time a burial-ground, but at what time it is impossible to say. At another part of the ground there was discovered a tower-like structure, in front of which is a wall 4 ft. thick, and running in a transverse direction into a portion of the adjoining land. Permission was obtained to trace the wall into the adjoining land, and it has been ascertained that the wall is 94 ft. long, by 43 ft. in width; the solid masonry is 23 ft. square, and between the wall and the building is a space of 20 ft. From a small piece of architectural moulding which was found, it is presumed that the building belonged to the Norman period.

TENDERS.

For alterations and additions to Thorpe Rectory, near Norwich, exclusive of old materials. Mr. R. M. Phipson, architect:—	
Hood	£2,336 0 0
Brookes	2,310 0 0
Leary	2,299 0 0
Bell	2,270 4 0
Dowling	2,210 0 0
Newell (accepted)	1,854 0 0
For restoring Stoke Ash Church, Suffolk, exclusive of old materials. Mr. R. M. Phipson, architect:—	
Burrell	£87 15 6
Rednall & Vane	69 12 6
Bishop	57 5 0
Cornish (accepted)	58 0 0

For new shop-front, &c., at No. 5, Esmont-street, Clerkenwell. Mr. Wm. Smith, architect:—

Dove, Bros. (accepted)	£495 0 0
For alterations, Messrs. Coates & Co.'s, Whitechapel, Mr. J. L. Linnell, architect. Quantities supplied:—	
Messrs. Leeming & Nicol and Mr. C. A. Gould:—	
Browne & Robinson	£819 0 0
Webb & Sons	815 0 0
Asby & Sons	810 0 0
Asby & Horner	796 0 0
Hill & Keddell	787 0 0
Little (accepted)	783 0 0

For Hemel Hempstead Church, Messrs. Drury Lovejoy, architects. Quantities supplied by Messrs. Curtis & Son and Bales & Rowell:—

	A seats.	B seats.
Cook	£3,722 0 0	23,705 0 0
Humphreys	3,325 0 0	3,325 0 0
Chappel	3,175 13 0	3,289 3 0
Wood	3,170 0 0	3,240 0 0
Nightingale	3,138 0 0	3,178 0 0
Harris	3,025 0 0	3,050 0 0
Webb	2,925 0 0	2,965 0 0
Watkins	2,602 0 0	2,882 0 0
Gibson (accepted)	2,500 0 0	2,864 0 0

For a chapel at the Grissenhall Union, Norfolk, exclusive of stone. Mr. R. M. Phipson, architect:—

Harold	£687 10 0
Skinner	564 0 0
Perkins	530 0 0
Lerner (accepted)	527 0 0
Nelson	425 0 0

For St. Paul's District Schools, Stratford, Essex. Mr. Ong, architect. Quantities supplied:—

Hedges	£2,834 0 0
Wood	2,831 0 0
Mortimer	2,817 0 0
Manfield	2,810 0 0
Chelton	2,636 0 0
Bivett	2,493 0 0

For chapel, Victoria Docks, for Mr. Duncan, Marshall, architect. Quantities supplied:—

Cheffins	£1,566 0 0
Weston	1,500 0 0
Manly & Rogers	1,470 0 0
Engles	1,788 0 0
Sherrin	1,648 0 0
Cutbush, Bros.	1,570 0 0
Rivett	1,537 0 0
Perry & Co.	1,516 0 0
Mortimer	1,497 0 0
Ennor	1,480 0 0
Clubb & Co. (accepted)	1,350 0 0

For alterations at the Church of St. Francis, Xaverius, Liverpool. Messrs. Pictor, Chambers, & Bradley, architects. Quantities supplied:—

Huish & Co.	£5,350 0 0
Weston	4,898 0 0
Mallen	4,790 0 0
Urmon	4,654 0 0
Jones & Son	4,640 0 0
Engles	4,600 0 0
Callie	4,510 0 0
Bowe (accepted)	4,414 0 0

For house and offices, Sutton Oak, near St. Helen's, Messrs. Jno. Marsh & Co. Messrs. Pictor, Chambers, Bradley, architects. Quantities supplied:—

Westham	£320 0 0
Harrierson	316 15 0
Harris (accepted)	797 10 0

For alterations, &c., at 21, Aldersgate-street. Mr. R. Campbell, architect:—

Myles	£1,057 0 0
King & Sons	763 0 0
Anderson	740 0 0
Carter	737 0 0
Sewell	730 0 0

For rebuilding warehouse, No. 21, Crutched Friars, Messrs. Hy. Bucknell & Sons. Mr. Arthur E. Pictor, architect. Quantities supplied by Mr. Joseph Clevier:—

Thompson	£3,223 0 0
Higgs	3,114 0 0
Rider & Son	2,883 0 0
Kilby	2,769 0 0
Browne & Robinson	2,720 0 0
Ennor	2,718 0 0
Conder	2,650 0 0
Henshaw	2,675 0 0
Mortier (accepted)	2,643 0 0

For the erection of a village residence at Grays, Essex, for Messrs. Sturgeon & Sons. Mr. D. A. Cobbett, architect. Quantities supplied by Mr. Geo. Mortimer:—

Harris	£3,626 0 0
Rivett	2,630 0 0
Crabb & Vaughan	2,465 0 0
Hell	2,347 0 0
Forrest	2,260 0 0
Blake (accepted)	2,285 0 0

For the erection of a villa residence near Severndroog Castle, Shropshire, Hill, Mr. C. F. Barrow, architect. Quantities supplied by Mr. Geo. Mortimer.

Newman & Man (accepted)	£6,226 0 0
-------------------------------	------------

For new workhouse for St. Mary's, Ilminster, to be erected in St. John's-road, Upper Holloway. Mr. R. H. Bondon, architect:—

Nutt & Co. (accepted)	£84,200 0 0
For Nottingham County Court, Mr. Thos. C. Sarby, architect. Quantities supplied by Mr. J. Scott:—	
Hell	£6,280 0 0
Barkie	6,280 0 0
Huddleston	6,188 0 0
Simpson & Co.	6,078 0 0
Marriott & Co.	5,980 0 0
Dennett	5,879 0 0
Bell & Co.	5,839 10 0
Stephenson & Co.	5,698 0 0
Johnson	5,650 0 0

for the erection of a Congregational church at More-
 mington, Devon. Mr. John Tarring, architect:—
 Briggs & Dyer £1,325 0 0
 Pillar 1,091 0 0
 Beam & Mervin 1,098 0 0
 Tarring & Avery 1,099 0 4
 Luscombe 891 10 0

for rebuilding wharf and warehouse for Messrs. Nash,
 & Nash, at Pickle Herring Lower Wharf, exclusive
 of wall and foundation. Mr. S. Brookes, architect,
 assisted by Messrs. Curtis & Son:—
 Piper & Wheeler £8,350 0 0
 Perry & Co. 6,005 0 0
 Cowland 5,990 0 0
 Gilbert & Wisbey 5,300 0 0
 Wells 2,467 0 0
 Willis 5,409 0 0
 Newman & Mason 5,368 0 0
 J. & P. Coleman 5,333 0 0

 Architects who are unwilling (as we are) that their names
 should accompany lists of tenders with which they are concerned
 prevent the omission by sending lists themselves. We cannot
 do so on the ground of such omission.
 As we are compelled to decline pointing out books and giving
 statements of facts, lists of Tenders, &c., must be accompanied
 by the name and address of the sender, not necessarily for
 publication. The responsibility of signed articles, and papers read
 at meetings, rests, of course, with the authors.

Advertisements cannot be received for the current
 issue later than THREE o'clock p.m.
 THURSDAY.

The Publisher cannot be responsible for ORIGINAL
 TESTIMONIALS left at the Office in reply to
 advertisements, and strongly recommends that
 ARTICLES ONLY should be sent.

NOTICE.—All Communications respecting
 Advertisements, Subscriptions, &c., should be
 addressed to "The Builder,"
 1, York-street, Covent Garden. All other
 communications should be addressed to the
 Editor, and NOT to the "Publisher."

[ADVERTISEMENTS.]

NOTICE.—Her Majesty's Commissioners of
 Works, the Royal Engineers, the War-Office, the
 Ordnance, the Commons, the Metropolitan Board of
 Works, and all leading Architects, Engineers,
 Contractors, &c., patronize Chappuis' Patent
 Light Reflectors to supersede Gas in Daytime.
 They are manufactured of various materials, at
 per square foot and upwards.
 Messrs. Chappuis & Co., of 69, Fleet-street,
 London, are the sole Patentees and Makers.
 They also manufacture special Reflectors for
 scientific purposes, and for the new Lights,
 Argand, Argand, Lime, Electric, &c., and the Street-
 Light Reflectors now generally adopted at
 all-ends houses.

MONOGRAMS of every conceivable design,
 Armorial Bearings, &c., in gold or
 enameled with enamel and gems, have been intro-
 duced as decorations for J. W. BENSON'S Watches,
 appointment to the Prince of Wales. Old
 Broad-street; Westhorne-grove; and Lindgate.
 See Price-list.

NEW DESIGNS from the Paris Exhibition
 have been introduced into all branches of the
 Clock Department at J. W. BENSON'S, Watch
 & Clock Maker to the Prince of Wales. Old
 Broad-street; Westhorne-grove; and Lindgate.
 See Price-list.

ADVERTISEMENTS.

A CLUE TO RAILWAY COMPENSATION
 For Property and Person, compulsory sale under special Acts,
 the nature and value of estates, prescriptive windows, rights,
 easements, and the principles of parol assessment. With
 Notes, and equipment founded on recent authorities. By THOMAS
 MOULTON, Architect. Avo and Ed. 3s. 6d. With Estimates of
 DILAPIDATIONS, ECCLESIASTICAL and
 GENERAL; their nature, and the principles of assessment succinctly
 demonstrated. With an Appendix on party-walls and statutory
 regulations. 8s. 6d.
 London: SIMPKIN, MARSHALL, & CO.

ARCHITECTURE IN SPAIN.
 With 26 large Plans and 100 illustrations, royal 8vo. 5s.
 THE GOTHIC ARCHITECTURE of
 SPAIN: from its origin to its decline. Observations made during several
 Journeys through that Country.
 By G. E. STEPH, F.R.S., Author of the "Brick and Marble
 Architecture of Italy."
 "Mr. Steph has not only explored and sketched the most impor-
 tant ecclesiastical buildings in Spain, but has also made a series of sketches
 but he has gone very far into the learning of the subject. Every part of
 the work presents evidence of the labour and deep interest with
 which he pursued his investigations, and the result is one of the
 most copious and valuable architectural works which we have
 received for some time past."
 "A most valuable work. It deserves to stand side by side with
 the best of Mr. Pugin's contributions to the Gothic Revival, while in
 some respects it is superior, and deserves, as we doubt not it will re-
 ceive, a careful study by professional architects."—*Littell's Review*.
 "This handsome volume merits the highest praise. It is well
 written and well illustrated; it is also well timed, and will certainly
 have the effect of calling the attention of travellers to this country
 for their tour of discovery."
 A valuable contribution to the history of Gothic architecture.
 With the exception of the great works of Wit and Knorr,
 we have no publication which throws so much light on the archi-
 tectural monuments of Spain."—*Edinburgh Review*.
 JOHN MURRAY, Albemarle-street.

A CARD.
 MR. E. W. SHAW, C. E.
 CONSULTING ENGINEER,
 ARCHITECT, AND SURVEYOR,

WANTED, a RE-ENGAGEMENT as General Foreman. Twelve years' practical experience as such. Well up in all the branches of the building trade. Address 29, Joiner by trade. Address, 825, Office of "The Builder."

TO CONTRACTORS AND OTHERS. WANTED, EMPLOYMENT, by a practical Man, who thoroughly understands the appertaining veyor, Croydun, Surrey. - Address, Mr. GAID, Road Bur-

TO BUILDERS, &c. WANTED, a RE-ENGAGEMENT, by a BUILDER'S CLERK, well up in measuring, bookkeeping, and the usual duties of an office. Good references. Address, H. B. care of Mr. Jones, 7, Great Charlotte-street, Blackfriars, S.W.

TO ARCHITECTS AND SURVEYORS. WANTED, by the Advertiser, who has

WANTED, a RE-ENGAGEMENT as General Foreman. Twelve years' practical experience as such. Well up in all the branches of the building trade. Address 29, Joiner by trade. Address, 825, Office of "The Builder."

WANTED, by the Advertiser, a RE-ENGAGEMENT in an Architect, Surveyor's, or Builder's Office. Has had considerable experience, and is willing to make himself generally useful. Address, Messrs. Malby & Co. The Merchants, corner of Tottenham-square, Finsbury, E.C.

TO BUILDERS, CONTRACTORS, and DECORATORS. - A first-class WRITER, GRAINER, PAINTER, &c. desires a permanent SITUATION. Has been accustomed to take the entire charge of painters' work in general. Good references can be given as to ability, experience, &c. Address, Z. 3, Clifton-square, Hammersmith, W.

TO CONTRACTORS, ENGINEERS, AND BUILDERS. THE Advertiser, experienced in the construction of public works, railways, docks, sewage works, &c. as accurate leveler, clerk at setting out, measuring up, estimating a good draughtsman and accountant, seeks an ENGAGEMENT. Has been much abroad and speaks several languages. Terms moderate. Address, C. R. Leo Cottage, Cowley-road, Islington.

TO BUILDERS or MASTER PLUMBERS. THE Advertiser, a good PLUMBER, is open for an ENGAGEMENT. Two years' reference from present employer. No objection to the country, on a job. Good wages required. - Address, H. B. 14, Post-office, Manchester-square, London

TO ARCHITECTS AND JOINERS. THE Advertiser WANTS a SITUATION, as above. Has some knowledge of lines and setting out work. Wages moderate. Address, 891 Office of "The Builder."

TO ARCHITECTS AND SURVEYORS, &c. THE Advertiser seeks a SITUATION. Is a good draughtsman and estimator, competent to undertake working and drawing drawings, measuring, &c. - Address, K. 9, Great-street, Plymouth, Devon.

TO BUILDERS, PLUMBERS, PAINTERS, &c. THE Advertiser seeks a Permanency as WORKING FOREMAN of Three-branch Head. I quite conversant with general and particular work of a good building shop. I will do pump and closet work, and quite capable of managing a branch concern. - Address, W. S. No. 1, Post-office-lane, Notting-hill Gate.

TO NOBLEMEN, GENTLEMEN, AND BUILDERS. THE SUPERINTENDENT of WORKS on an Estate will shortly be discharged, and wishes a similar ENGAGEMENT; or would take charge of Works for a Builder. Is thoroughly practical and preserving. Wages moderate. Age 45. Good references. - Address, D. 149, Pentonville-road North, London.

TO ARCHITECTS, &c. THE Advertiser, having just served his articles with an Architect and Surveyor in the country, and having been employed in a similar office in London, is now desirous of entering a LONDON OFFICE, at a small remuneration in the first instance. Is a fair draughtsman. Address, A. B. 20, Post-office, Newchurch, Rossendale, Manchester.

TO ARCHITECTS AND OTHERS. THE Advertiser is open to an ENGAGEMENT. Many years with last employer (an architect, &c.) Undertakes management of household property. Good references and security if required. - Address, X. Y. Z. 43, Dagmar-road, South Hackney, N.E.

TO ARCHITECTS AND CIVIL ENGINEERS. THE Draughtsman, who is a first-class general draughtsman, desires an ENGAGEMENT. Forms set prepared. Has just completed a three years' apprenticeship in Egypt. Address, A. Z. B. 74, Oxford-road, Brompton, N.

REQUIRED, a SITUATION, as FOREMAN of PLUMBERS and PAINTERS. Testimonials, W. W. Post-office, Shaftesbury.

CARPENTER and JOINER, good Workman, wishes EMPLOYMENT. Town or country. Day or piece. Wages 75s per hour. Address, G. R. 81, Borough-road.

TO ARCHITECTS. AN experienced DRAUGHTSMAN desires a RE-ENGAGEMENT in town. Qualifications - Design (both exterior and interior), and construction of a superior class. Eleven years in the profession. Two years outdoor experience. References. An estimate of work. Terms moderate. Address, BARKLEY'S, 4, Crutchein-street, Hamstead-road, N.W.

TO DIRECTORS OF WATER WORKS, TOWN CORPORATIONS, and LOCAL BOARDS OF HEALTH. A GENTLEMAN, having had great experience in the designing, construction, and management of water works, wishes to be open to an ENGAGEMENT as RESIDENT ENGINEER; also understands sewage and gas works. Address, 54, Office of "The Builder."

TO BUILDERS. A RESPECTABLE YOUTH (aged 17), who has some knowledge of Bookbinding, wishes for a SITUATION where he will LEARN the Business. Is well acquainted with architectural drawing and measurement. Wages not so much an object as a suitable situation. Address, J. T. M. 170, Drury-lane, W.C.

TO MARBLER and STONE CARVERS. An age, wishes to be apprenticed to learn either of the above. Address, F. W. 14, Upper Park-place, Dorset-square, N.W.

TO ARCHITECTS. AN ASSISTANT desires a RE-ENGAGEMENT in town. Is competent to prepare finished working drawings, and will fill up in general other work; understands perspective. Address, 816, Office of "The Builder."

TO LAND AGENTS, LAND SURVEYORS, AND OTHERS. A GOOD practical LAND SURVEYOR and neat DRAUGHTSMAN wishes an ENGAGEMENT in town or country. Salary moderate. Address, 855, Office of "The Builder."

TO ARCHITECTS AND SURVEYORS. A JUNIOR ASSISTANT, aged 19, is desirous of an ENGAGEMENT. Writes an excellent hand, and has been four years with a District Surveyor. Address, D. B. G. 20, Clarendon-road, Bow, E.

TO ARCHITECTS, BUILDERS, &c. A RE-ENGAGEMENT as General Foreman or Clerk of Works. Is offered by a thoroughly competent Man. Joiner by trade. Address 37. For more than three years foreman to one of the largest firms in London, leaving only an account of duties of an office. Good references. Address, 45, care of Mr. Palmer, 39, Harrison-street, Gray's-inn-road, London, W.C.

A BUILDER'S ESTIMATING and MEASURING CLERK of good practical experience is open to an ENGAGEMENT. Will fill up office work, making out accounts, &c. Good testimonials. Address, G. F. M. Thomas's, Tea Dealer, 5, Kingland-green, N.E.

TO ARCHITECTS AND SURVEYORS. A JUNIOR ASSISTANT, aged 19, is desirous of an ENGAGEMENT. Writes an excellent hand, and has been four years with a District Surveyor. Address, D. B. G. 20, Clarendon-road, Bow, E.

TO ARCHITECTS, BUILDERS, &c. A RE-ENGAGEMENT as General Foreman or Clerk of Works. Is offered by a thoroughly competent Man. Joiner by trade. Address 37. For more than three years foreman to one of the largest firms in London, leaving only an account of duties of an office. Good references. Address, 45, care of Mr. Palmer, 39, Harrison-street, Gray's-inn-road, London, W.C.

The Builder.

VOL. XXVI.—No. 1317.

Meeting of the Art-Union of London.

BEFORE the hour appointed for the meeting of this association on Tuesday last, for the reception of the annual report and the distribution of the funds subscribed for the purchase of works of art, the new Adelphi Theatre was well filled with an elegant and attentive audience, and the stage almost inconspicuously so. Amongst the members of the council present were Mr. Antrobus, F.S.A.; Mr. Bennoch, F.S.A.; Mr. Butterworth, F.S.A.; Sir Thos. Gabriel, bart.; Mr. Chas. Hill, F.S.A.; Mr. R. Hudson, F.R.S.; Mr. Chas. Mayhew; Mr. L. Pocock, F.S.A.; Mr. Zouch Troughton; Professor Westmacott, R.A.; and others; and amongst the visitors were Mr. W. E. Frost, A.R.A.; Mr. Maclean, F.S.A.; Mr. Jas. Pahey, and other well-known artists. In the absence from England of the president, Lord Houghton,—

Professor Westmacott was called to the chair, and having explained the circumstances under which he took it,—

Mr. Godwin, F.R.S., read the following

REPORT.

The Council are glad to be able to commence the thirty-second annual Report of the proceedings of the Art-Union of London with an announcement of its continued prosperity. The subscriptions for the present year amount to the sum of 13,622 14s. 6d. The engraving to which each subscriber is entitled, "The Play Scene in Hamlet" (after Maclean), has been received on all sides with the greatest approbation, and the periodical press have echoed the good opinion of the public. It could scarcely be otherwise. The cost of such a print under ordinary circumstances would be at least two guineas, and a large part of each subscriber's guinea will nevertheless come back to the body of members in the shape of prizes.

Various other engravings of great importance are in the hands of the Society already known; and in addition to these Mr. W. Holl, who engraved the "Mortyrmagny," has been commissioned to produce a plate in his best manner after the picture "Rebeckah," by Mr. F. Goodill, R.A.

Mr. Vincent Brooks has made for the Society a chromolithograph from a charming picture by Mr. Birket Foster, called "The Kites," examples of which, framed, will form part of the present distribution.

The Council have in hand for next year a copy in chromolithography of Mulready's well-known picture "Choosing the Wedding-Gown," one of the most attractive paintings in the South Kensington Museum. "I had scarcely taken orders a year," says Goldsmith's immortal "Maiden," "before I began to think seriously of matrimony, and chose my wife as she did her wedding gown,—not for its glossy surface, but such qualities as would wear well." On this observation the picture is founded. Mulready's works depend so greatly on colour and light, that they are peculiarly suited for production in chromolithography. If real artistic feeling and careful manipulation are brought to bear on such a work, there will be no danger of its inducing a feeling against this mode of reproduction. The Art-Union may, however, point to the "Young England," after Frapp, examples which none but those constantly in the habit of examining such works are able to distinguish from the originals. In the case of Mulready's picture above mentioned, there will be many colours, and the great care and skill required in "registering" may be imagined, since, of course, the deviation, but by a hair's breadth, in placing one colour over another would be as fatal to the whole work, and render useless all the previous paintings. Turning to another department,—

Mr. Leonard Wyon has successfully completed for the Society dies for a medal of the late Sir Richard Westmacott, R.A., sculptor, impressions from which will be allotted on the present occasion.

Mr. W. F. Woodington, one of the artists engaged to model the bas-reliefs on the base of the Nelson column, has prepared an exact copy of this monument on a scale of 1-7th in. to the foot; and copies in bronze, executed by Messrs. Franchi, will form part of the prizes.

A vacancy in the council, caused, soon after the last meeting by the lamented death of Edward Hawkins, esq., late of the British Museum, was filled by the election of the Right Hon. Sir Thomas Gabriel, bart., then Lord Mayor of London. Mr. Hawkins was a member of the executive council of the Society, and gave constant and valuable assistance for many years.

The Right Hon. T. Moncell, and Peter Graham, esq., have been elected members of the council in place of Philip Hardwick, esq., R.A., and Chas. Leaf, esq., who retired in accordance with our by-laws.

The following is an outline of the receipts and expenditures.

Detailed account, duly audited, will be printed hereafter, as usual.	
Amount of subscriptions.....	£13,612 14 6
Cost of engraving and printing "Hamlet," exhibition, and reserve of 25 per cent.	25,155 11 0
Agents' commission, rent, salaries, postage, &c.....	2,232 2 0
Expended in pictures, bronzes, parian, &c.....	6,285 0 0
Total.....	£13,612 14 6

The amount available for the purchase of works of art from the public galleries by the prizeholders themselves will be divided in the following manner:—

22 works at.....	£10 each.
20 ".....	15 "
14 ".....	25 "
12 ".....	30 "
12 ".....	35 "
10 ".....	40 "
6 ".....	45 "
6 ".....	50 "
8 ".....	60 "
6 ".....	75 "
3 ".....	100 "
1 work at.....	150 "

There will also be distributed,—

- 25 Bronzes of the Nelson Column.
- 20 Medallion Bronze Inkstands.
- 100 Statuettes, "The Wood-nymph."
- 250 Chromos, "The Kites."
- 30 Silver Medals, commemorative of Sir R. Westmacott, R.A.

There will therefore be, with the parian busts, given to all who have subscribed for ten years consentively without gaining a prize, 758 prizes, in addition to the engraving received by every member.

On the plan followed on other occasions, the smaller prizes will be allotted by numbers drawn from the wheel, in the same manner as the picture prizes; but as the drawing of these would occupy more time than the business of the theatre would allow, the drawing will take place at the office to-morrow morning, at eleven o'clock, when any members desirous of being present are invited to attend.

The reserved fund now amounts to £14,478.

One of the galleries from which prizeholders have been allowed to select—that of "The British Institution for Promoting the Fine Arts"—is no longer open. The casual intimation that has reached the public, that this Institution, which was founded in 1806, has ceased to exist, is felt to be unsatisfactory. The British Institution has done good service, as well by bringing artists and the public together, and by the rewards bestowed on painting men, as in its periodical gatherings, and exhibitions of the works of the old masters which are scattered over the kingdom, and are not thought to be seen; and the art-loving public had a right to expect an authoritative statement of the position of the Institution, and the opportunity to assist in preventing its disappearance.

The painters of past times still live in the memory of the present generation cannot afford to give up the study of them. A moderate acquaintance with the wondrous masterpieces of former times, should teach us humility, and how is it that the works of Raphael and Leonardo da Vinci remain unapproached,—seem still unapproachable? And who could estimate the debt that humanity owes to these men? What steps should a nation take to secure the best chance of developing similar powers? This is an inquiry worth making,—and at some cost, too.

It has been contended again and again in the reports annually made to you, and at a time when it was needed, that slavish copying, alone, of Nature (the power of drawing having once been acquired) is not the course that will produce great artists. Every really great work of art is ideal; it sets forth the ideas of the producer, the mind of the workman,—a striving after the best,—as well as the material objects sought to be represented. The sentiments and feelings of the human mind are the subjects the artist must deal with who would leave behind him works that will move, enthral, and influence human kind.

Following the course adopted at intervals on previous occasions, and which assisted in bringing before the public, early in their several careers, Mr. F. R. Pickersill, R.A., Mr. Henry Selous, Sir J. Noel Paton, Mr. John Tenniel, Mr. W. Cave Thomas, Miss Pistrucchi, R.A., and other artists, who have been and will be in the hands of the public, the Council in September last invited a competition in designs. The sum of 500 guineas, with a further sum of 100 guineas, if a production of very high character were submitted, was offered for a series of drawings, illustrating some poetical or historical work of a British author, or events in British history; the series selected for the premium to become the absolute property of the Art-Union, with copyright. In response thirty-five sets of drawings have been received, several of them being works of great merit. With the obliging permission of the Committee of Privy Council for the Department of Art, the whole of these designs will be exhibited to the public in the South Kensington Museum in the course of next month, and the decision will then be announced.

With reference to a previous set of illustrations issued

to the members, "The Ancient Mariner," the Council have assented to the request of a photographer for the permission to produce photographs from those plates, for the purpose of illustrating by the magic lantern a reading of the poem about to be given in various country places, and to compose his successful cantata, "The Ancient Mariner," first produced at the Birmingham Musical Festival, by turning over our illustrations of the poem which made its capabilities apparent to him.

It is a matter of last year your Council, as representatives of the Society, were entertained at the Mansion House, by the then Lord Mayor, Sir Thomas Gabriel, an incident that should scarcely go unrecorded. In proposing as a toast the success of the Art-Union of London, and aiding artists, he maintained, could enable us, as the Lord Mayor dwelt effectively on the part that had been played by the Society in ministering to the gratification and advantage of the community,—in improving the labour of this Society were necessary, they were so at this time; for nothing, he maintained, could enable us, as a nation, to keep our place among the manufacturing countries of the world but a thorough education, and training of the people in all that belongs to the arts. A love for the beautiful was innate in human nature, and the savage would prefer a decorated and well-proportioned tool or instrument to a rough, ugly article; but, if this were true in that class of manufacture, how much more so was it with reference to all those productions of various classes required to meet the luxurious taste of the day incident on the vastly increasing wealth of every country. We might therefore depend upon it that if we wished to avoid seeing ourselves altogether distanced in the manufacturing of all articles in which anything like taste could be introduced, and left as the manufacturers of only coarser works, we must diligently do all that tends to improve and raise the taste of our people.

One of the Honorary Secretaries, in replying to the Lord Mayor, referred to the eventual career of the Society, and claimed that when the history of the progress of art in this country should be fully written, it would be found that the Association had played no unimportant part. The early progression of it was remarkable. When Mr. Henry Hayward, Mr. Lewis Pocock, Mr. Bent Gabriel, and himself, the only four of the founders remaining, the Council had sat down at a small table in a small room to organize it they had hardly expected such a result as had followed. Scarcely able to obtain a subscription of 500*l.* in the first year, it soon became 1,000*l.*, then 2,000*l.*, 5,000*l.*, 12,000*l.*, 14,000*l.*, and so mounted to nearly 16,000*l.*, after which it subsided to a comparatively steady income of from 13,000*l.* to 14,000*l.* a year. About 350,000*l.* had been raised by its means, the whole of which large sum, with the exception of the necessary expenses for room, printing, and so forth, had been devoted to the encouragement of artists, and the dissemination of works of art. All over the kingdom, in every colony, wherever, indeed, English men and women were to be found, whether China, India, Barbary, Egypt, Russia, Turkey, New Zealand, or the gold diggings of Australia, the Art-Union had a colleague engaged in the dissemination of works of art. It was surely no small thing thus to have spread over the world an associated brotherhood interested in the progress of the arts that ennoble and refine. Looking round the hall in which they were assembled, the speaker said, he was reminded of a member of their council, the late City architect, through whose endeavours mainly the corporation had been led to aid nobly the sculptors of the country, by filling the niches of that apartment with their works. It was to be hoped that before long their exertions would be led to call in the aid of the sister-art, painting. Strange to say, there was not a single picture in that Mansion House of the richest city in the world. He hoped he might not be thought impertinent for mentioning it; at any rate, it was a fact not to be proud of, and ought to be remembered. For many years the reports of the Art-Union have urged the desirability of placing works of art on the walls of public meeting-places, and where they might delight, appeal to, and improve the multitude. Public galleries of works of art in our provincial towns were greatly needed. In most French towns, as at Rouen, Caen, Lyons, Lille, Bordeaux, there are galleries of art to which the public have free access; it is surely not creditable to us,—it is not even commercially, that, with the exception of those in the three capitals, no such collections are to be found in England. Liverpool, prompted by a right spirit, determined some time ago to erect a building and found a public gallery of works of art. An examination was made of the best galleries at home and abroad, and plans were prepared. It appears, however, that on the ground of commercial depression the development of this excellent determination has been postponed for a time. It is to be hoped this time will be very short. The appropriation to such a purpose of some part of the immense revenues of Liverpool will be a most profitable, important, and praiseworthy step.

The Corporation of Manchester have recently determined on the erection of a new Town-hall at the cost of more than a quarter of a million of money, and, assisted at different stages of the selection by the advice of two members of your Council, have fixed on a design which promises to result in a building of great magnificence. The expression of a hope that sculpture and painting of the highest excellence obtainable will be enlisted for its adornment, may not be thrown away.

It is a subject for congratulation that sculpture to a considerable extent is to be introduced in the external adornment of the new building for the University of London, Burlington Gardens; though as much can scarcely be said in regard to the whole proceedings of this fine site. Instead of three separate buildings without congruity, under three different architects (one of the buildings—namely, that for the Royal Academy—tacked on to an existing structure), a noble and harmonious pile might have been erected that would have done something more than amply fill the wants of the various bodies that are to be lodged there.

The Thames Embankment now approaching completion not merely affords good opportunity for the introduction of high-class sculpture, but absolutely demands it. Let artists, then, prepare themselves for coming tasks. Statues have recently been set up in Westminster Hall, and there seems to be a disposition elsewhere to employ sculpture to a larger extent than heretofore. Some works of this art have been going in hand. Many years have elapsed since the country voted a sum of money for a monument in St. Paul's to our great commander, the Duke of Wellington, and as yet even the model is unknown. With whom rests the fault, with the

well worth careful study, as they show the different stages through which the design passed before the final drawings were commenced.

Secondly, the designs submitted for the ultimate competition for the New Town-hall, Manchester, are, most of them, on the walls; amongst them the successful design of Mr. Waterhouse. Those of the profession who were not so fortunate as to see the complete collection in the Rooms of the Corporation in Manchester, will be glad of this opportunity of observing the principal positions. In addition to some of those submitted in the first competition for the same Town-hall, there are also many beautiful drawings by eminent French architects, which were to be seen at the late Paris Exhibition, and were highly spoken of at the time. They have been kindly lent for the present occasion. These drawings were brought over from Paris at the cost of the Society, and have to be returned to their owners, free of expense.

A new phase in the existence of this Society is, that instead of being short of material where-with to fill all the wall-space at its command, they now exhibit about 100 designs more than on any other former occasion, while many have been rejected for want of hanging-room.

Valuing highly as we do drawings as proofs of artistic power, we yet heartily welcome the presence of numerous photographs showing portions of buildings, as they represent more faithfully than any drawing can the result of the architect's labour, and the manner in which the workman has succeeded in carrying out his intention. Photographs of this sort are also invaluable as representing the status of our art-workmen,—a class whose interest has ever been the care of the *Builder*.

We again call upon the profession to make, without delay, such return for the disinterestedness and energy of this Society as lies in their power. Let them enrol themselves as contributors, and for the future be more careful in supplying them with the best subjects at their command. Were these annual exhibitions discontinued for a few years, architects would find how much they suffered by the suspension of the Society's efforts, and be glad to have a renewal of their good offices at any price. It is, in short, the great arena in which the architect may try his strength with brother athletes, and he has the satisfaction of knowing that his place in the struggle will be assigned to him by judges. The drawings and photographs now on view in this Exhibition number about 700 or 800 separate subjects in some 450 frames. The series commences in the large room near the entrance, and after passing round the apartment is continued in the first or smaller room, and from thence to the screens. We will now approach the drawings, and examine them in consecutive order, referring, however, only to such as we consider deserving of special notice, either for their virtues or faults. Mr. John Croft exhibits some clever interior views of different parts of Westminster Abbey. The detail and perspective are well attended to, and the colouring (with the exception of his peculiar weakness for grass-green tint on some portions of the building) is pleasing and harmonious. Mr. Edward P'Anson contributes six views of different buildings in Russia and parts of Germany; amongst them are a tower from Dantzio, with bulbous-headed cupola in two stages; the St. Isaac Cathedral, St. Petersburg, showing the central and clustering domes; a tower in the wall of the Kremlin, Moscow; the town-hall, Breslau, and others. The sketches are outlined in ink, and slightly tinted. Many drawings, by Mr. E. J. Talbot, are to be found on the walls; one of them is No. 9, called "A Study from the Roof of St. Mary's Hall, Coventry." It is a water-colour drawing, and includes the church spires and their surroundings.

No. 6. View of the Church of St. Jacques, Antwerp;" and No. 12, "View in the Church of Notre Dame, Lambader, Brittany," both by Mr. E. S. Cole, are well worthy of examination. In the first, the view is taken from the south aisle of the nave, showing the junction of the chancel and south aisle with the choir and south transept. The whole length of the south aisle to chancel is given, with a portion of the clear-story and groining to chancel, the part under that being occupied by the Renaissance chancel screen, with its side altar, at which Mass is being celebrated. The picture is finished on the left-hand side by one of the circular pillars of the nave arcade.

No. 5. "Interior view of S. Andrew's Church, Oshensfurth, Bavaria; and No. 10, "Sketch of Ancient Synagogue" at Worms, by Mr. H. W. Brewer, an engraving from which we have published, are for sale. The detail and architectural character are well preserved. No. 5 shows an apsidal end, with four lofty and narrow two-light windows; then flamboyant traceried heads, finishing close up under the groining of the chancel roof, which springs from carved corbels. The side wall space is very bare for want of shafts or impost. The chancel arch is of *low pitch*, and composed of nothing more than the continuation of the shallow pilaster of its joints, the whole having a very weak effect. The altarpiece is very lofty, and of the local phase of Renaissance. It is in three stages, and contains in the lowest compartments carvings in high relief, richly gilt, of the three crosses on Calvary, with figures of SS. Mary and John, in niches on either side. In the second state is the "Resurrection," and in the uppermost the "Coronation of the Blessed Virgin."

No. 14. "Exterior view of Manchester Cathedral," by R. H. Bentham, from the south-east. Until within the last twenty years this building was the old parish church, and is now one of the smallest cathedrals in England. The roof over the nave is coloured, with carved angels on the hammer beams, and with richly carved choir stalls, good examples of the period. The drawing shows the late restorations, and the new tower erected by Mr. Holden.

No. 16. A window and part of a bay from the ruined Abbey at Kirkham, near York, by J. H. Leonard. The beauty of the rich mouldings, shafts, and caps of this graceful lancet-window are very well shown, and the colour of the stonework is pleasing and true. Nos. 18, 20, and 21 contain eight coloured sketches by the Rev. J. L. Petit, taken from buildings on the Continent, with the one exception of that at Peel, in the Isle of Man. Mr. Petit has a true eye for colour, and had he chosen art as his profession, would have achieved a good position amongst the fraternity.

No. 24. "View of the Great Temple of Edfoin," and No. 35. "Capitals, drawn to a large scale, from the temple of Esneh," both in Egypt, are by Mr. R. Phend Spiers, who contributes many other valuable drawings to the collection. No. 24 is a very bold and crisp drawing, slightly coloured, but well conveying the effect of solemn grandeur invariably connected with the best work of the Egyptians. No. 35 is very carefully drawn and delicately coloured, and is altogether a valuable drawing. No. 28, "Laborare est Orare," by F. P. Cockerell. A masterly composition delicately treated. It is an old friend, and having been alluded to in a previous number of this journal, we will pass on to No. 33, "Hotel de Ville and Church, Berque, near Dunkirk," by Ernest George; a valuable study, showing two very fine towers. Both the sketching and colouring are spirited. No. 39. "Competition Design for Church at Hemel Hempstead. Interior View," by Mr. Henry Hall, marked "*Palnans qui meruit ferat*," rather a dangerous motto, we think, to attach to this composition.

No. 40. With the exception of the perspective of some of the arches, this is a very careful and refined coloured drawing of the Interior (looking east) of S. Charles Borromeo, Ogle-street, Marylebone, by Messrs. Wilson & Nicholl. The roof over the nave looks very bare, which rather damages the look of the drawing.

No. 46. A pen and ink drawing of the Interior, looking east, of the Church of St. John, Torquay, Devon, now in course of erection, by Mr. G. E. Street, A.R.A. It is rather scratchy and confused in parts; but the general correctness of the perspective and accuracy of detail, in conjunction with the architectural merits of the composition, render it a very valuable addition to the exhibition. The chancel is shown to be square on plan, having in the east gable a fine window of five lights, with an octagonally-treated wheel-light over the same. The roof is groined in three bays, and lighted by a clear-story reaching to the crown of the groining. On the south side are two arches, supported on clustered columns, and occupied by a metal screen giving access to a south aisle. Three steps and a gate in the chancel-wall lead into the nave. On the north of this wall, and at the junction of the nave and chancel piers, is a circular stone pulpit, having a small arcade with circles over running round the whole.

We shall continue our notice next week.

ON BUILDINGS FOR EUROPEAN OCCUPATION IN TROPICAL CLIMATES, ESPECIALLY INDIA.*

THERE exists nothing of a physical nature which causes such an entire revolution in our feelings and habits, in ourselves and in our surroundings, as the addition or withdrawal of a few degrees of heat. Even within the limits of our own temperate climate, we know no contrast so strong as that between a sweltering harvest heat, and the cold of a keen black frost,—the sunny life of a brilliant summer day, and the bound-up torpor of a deep winter snow-storm; and when we carry our inquiries to the climates which lie at the extreme limits of human endurance, either of heat or cold, we find almost every condition of life reversed. The food, the dress, the dwellings, and the habits of the Esquimaux have hardly a single thing in common with those of the Hindoo, and both differ widely from our own.

Many of the countries where the heat of the sun is far greater than in England, and especially the East Indies, are so connected with us by commerce or colonization that, from time to time, English architects are called on to design buildings to be erected within their limits. Not fewer than eight Fellows of this Institute and four or five other architects practising here have been, within my own knowledge, lately called on to prepare designs for proposed buildings in Bombay. Two others, Messrs. Owen Jones and Digby Wyatt, have, within the same time, been called on to act as advisers respecting a large proposed building for the same city, the plans of which I had to prepare; and they, in that capacity, rendered me cordial and most invaluable assistance, which I am happy to seize this opportunity of publicly acknowledging. Some five or six English architects also are, or lately were, residing and practising in that one city,—facts which show that buildings for such countries as India may be fairly considered as not too remote from our own possible practice to be treated here. If, then, the conditions of life in a tropical climate are very far removed from those with which we are here conversant, it cannot be that many differences will exist between the buildings with which we are familiar as suiting our climate and such buildings as will suit the tropics; and it will be our business to-night to consider a few of these differences. First we shall take note of some of the essential requirements for European life in a tropical climate, such as that of India; afterwards we shall consider a few of the peculiarities which will affect the actual erection of the buildings, and the most obvious of the difficulties to be apprehended. Throughout I must be understood as referring to buildings for the use and occupation of Europeans only: my time is too short, and my information on the point too imperfect and fragmentary, for me to say anything on the interesting though less important subject of such buildings as are occasionally put up in tropical countries for the use of natives. In each of the two heads of this inquiry we shall be naturally led, as we go on, to notice such expedients and methods as may be best employed, or as have been actually found efficacious in meeting the needs which we shall discover. My own justification for bringing forward this subject is, that I have been obliged to make myself acquainted with the requirements and circumstances of, at least, one tropical climate, that of Bombay. The Government of Bombay proposed, in 1864, to erect the European Hospital in that city, from designs which I had submitted in competition. This led to my visiting Bombay at the end of that year, and to my being associated with Mr. Trubshawe, the consulting architect to the Bombay Government, in the preparation of working drawings for several public and other buildings of importance; I can, therefore, offer you the results of some little practical experience; and I hold it as almost a bounden duty of any member of this body, whose practice has led him to acquire information not readily accessible, and likely to prove of some use, that he should come forward here, and contribute it to the common stock.

It may provoke a smile to say that the great peculiarity of a tropical climate is, that it is very hot there; but, nevertheless, that is the great peculiarity, and the one point an architect must never forget, remembering that even what is called the cold season is far hotter than our

* By Mr. T. Roger Smith. Read at the ordinary general meeting of the Royal Institute of British Architects, held on the 27th of April, Mr. W. Tite, M.P., president, in the chair.

summer. It is also very light in such a climate; at some period of the year it is further very wet, the rain falling at times in torrents, and the air being saturated with moisture; but in the fine season it is ordinarily uninterrupted fine, remaining so for long stretches of time. Climatic disturbances, however, when they come, are violent; wind-storms, dust-storms, thunder-storms, with driving rains—perhaps earthquakes—must be expected occasionally; and such disturbances are more sudden in their visits, and more violent in their force, than in our climate.

Insect and reptile life are far more prominent within the tropics than here. Household pests there include such formidable enemies as the cobra, the scorpion, and the white ant. The white ant is an enemy of the most destructive powers. It eats almost all kinds of woods, and if the timber with which a house is built be such as it will devour, it will be not unlikely that all the woodwork of the house will be hollowed out and eaten away. The essential oils of one or two woods, such as teak and blackwood, seem to protect against them, but all ordinary wood is liable to be eaten by this ant. The damp of the monsoon time is a second powerful destructive agent; any unpainted or ungalvanized surface of iron would be found oxidized to a remarkable extent; and whether it be this, or the saline particles of the air, or an extra dose of actinic power in the sunlight, I know not, but the climate of Bombay, though free from frost, appears to act almost as destructively on building-stone as that of London.

The people, again, who will be about you in the tropics, are essentially different from Europeans. They will be all, or nearly all, natives; and if in India, all of various castes. The number of servants will be very great; they will dispense with most things that an European wants, but, on the other hand, they will require some things which in Europe would not be thought of. No English gentleman, for example, would think of planting all round his private house, a sort of hamlet of little cabins for the wives and children of his servants, any more than he would dream of his valet being willing, under any emergency, to sleep on a mat outside his bedroom door, as a personal retainer might have done here in feudal times. In India both would seem very reasonable things. The people engaged on the work will also differ altogether in their notions of workmanship, and especially of accuracy and finish, from the European artisans for whom we are accustomed to make drawings. Their setting out will be defective, and their finish, to an European eye, faulty; but, on the other hand, if the right sort of men be found out, and employed in the right way, their ornamental work, obtainable in India even now, after long disuse has caused the higher branches of the art of building to languish, will be very beautiful, and much of the workmanship excellent. The joinery and cabinet-work especially, executed with very rough tools, and put together without glue, will surpass most English work for solidity and durability.

To return, however, to the heat and light. Where the sun's heat is so powerful that nothing but English pluck prevents the attempt to work being altogether given up, and between sunrise and sunset it is almost impossible for an European to expose himself safely to his rays—where walking a few hundred yards, at midday, even under an umbrella, would be an exhausting and imprudent exertion for an European—where fresh air is the greatest essential of comfort, almost of life—where the glare of light is so intense, that the smallest unshaded opening seems, in the hours of sunshine, to admit more brightness than is compatible with comfort—and where the main walls require to be screened, both from the pelting heat of the sun in the fine season, and the driving rains of the wet season, it is almost self-evident that rooms should be large and airy, windows and doors so open as to admit every breeze that blows, yet so shaded as to keep out as much of the light as possible; and that walls should be far thicker than here, is necessary, and sheltered by some outer screen.

Outside all the external walls, or, at any rate, on all sides open to the sun's rays, a screen called a verandah is essential; and it becomes, in fact, the leading feature of buildings for the tropics. This may be best described as something like an external cloister, ordinarily about 10 ft. wide, the roof usually running over it in a continuous line, and overhanging it. The verandah is, of course, often constructed of slighter materials than the main wall, but,

where practicable, it is better to be of masonry. It is, of course, desirable to have it as many stories in height as the building, and covering most or all of the wall, but it admits of many variations, corbellings, projections, breaks, &c. The floors of the verandah should be water-tight, and should slope away from the building. Towards the quarter of the wet winds, it will be well to provide means of partly or entirely closing the openings; this is usually effected by temporary matting, and some permanent contrivance for the purpose is rather a desideratum. In the day time the floor of the verandah, as indeed that of the rooms, is often sprinkled with water for coolness. These roomy appendages are not all lost space, advantage is taken of them when in shade, or catching the passing breeze, and then they serve as workrooms for native workpeople, or for lounging, smoking, walking, and even dining and sleeping in; little studied, compared with comfort. The verandah, with its unglazed openings, its deep shadow behind them, and its overhanging roof, affords the chief, and a remarkably fine opportunity, for external architectural treatment in more artistic native houses, it is beautifully treated in carved wood. As an example of the treatment of it in masonry, I may refer to the Mahomedan buildings at Ahmedabad, shown in Mr. Hope's photographs, or to the fine design of Mr. Burges, for the Bombay School of Art, which exemplifies excellently this as well as many other points of the proper treatment for a building for the tropics. Allied to the verandah are corbelled balconies, and open oriels thrown out to catch the breeze and afford a cool evening walk; such features occur in the best Mahomedan work, and afford an excellent opportunity for picturesque treatment.

Behind the shelter of the verandah, the doors and windows should be spacious. The building should, if possible, be made to point so as to catch the prevalent breeze; for in the tropics winds often blow with a wonderful regularity from the same quarter for months together. And the building should, if possible, be so arranged, with rooms *en suite* from side to side, and having openings opposite to openings, that the wind may blow quite through it, windows opening down to the floor, and doors placed opposite the windows, and both made wide and high. The necessity for a thorough draught, and the use as a thoroughfare all round the building of the verandah, have combined to exclude the corridors almost entirely from dwelling-houses; and your life in an Indian bungalow (or house) is public to a degree that would here seem strange, and would, in fact, be unsuitable to a temperate climate.

The general plan of all buildings for the tropics ought to be, as will have been already understood, very simple, and at once compact and roomy. All servants reside apart, and few stores are kept in any house; consequently, buildings intended for residence are relieved from almost all that gives rise to great complication in Europe. The external verandah will be found to swell the bulk of the building extraordinarily, but then it is constantly used for every sort of purpose to which room space might have been appropriated; and it is also so capable of furnishing here and there an odd corner to be architect to reduce greatly the number of parts into which the block of his building is divided, and so to render the form as simple as possible.

Over this simple mass a simple roof should be thrown. If not a terrace, its pitch should be flat and its eaves overhanging, so as to give most shadow, and throw the heavy tropical rains well off the foot of the walls. In many, perhaps in most hot countries, however, flat roofs are the rule, their comfort during the hot part of the year being felt to overbalance their inferiority in the rainy season. The dome also forms a leading feature of many Oriental styles of building.

In one or two good Mahomedan domestic buildings which I visited, I found the stories but low. This, however, would not at all satisfy any European resident, or I think be suitable to our great need, in a sultry climate, of all the air we can get. The ordinary height of a story is about 13 ft. or 20 ft.; and stairs being a serious fatigue in a hot climate, buildings of many stories are not common. An underground basement is not usual; it would become a harbour for vermin and filth, and would be flooded or damp in the monsoon (or wet) season. The ground-floor is usually not less than from 2 ft. to 3 ft. above the

level of the surrounding earth, and raised on a solid terrace. This height is, I believe, chiefly given as a protection against moisture, and hollow floors are avoided because vermin and snakes would be sure to get into them. Many residences, where ground is plentiful, are only one story in height, and few buildings could conveniently have more than three stories. I may here suggest that the frequent use in hot climates of timber-built houses, of only one story high, may be in part accounted for by their being safer than any other in times of earthquake. This can hardly, however, be the reason of their use in Bombay. Between the ceiling of the top story and the roof there should be a space well ventilated and unoccupied, to keep the top story cool, a precaution often neglected.

It may be almost unnecessary to remark that no fireplaces or chimneys are ordinarily required, and that kitchens ought to be, where practicable, an outbuilding apart.

Coming now to the openings for doors and windows, they will rarely require to be filled, inside the building or out, with a solid door or shutter. The ordinary window is a large casement hung folding, and each fold in two flaps; the flaps are divided into several heights, and filled with louvres, like those of a Venetian blind, only finer, and capable of being set close or open; the ordinary internal door is of the same character. Internal openings are often, however, not even fitted with doors of this sort, but left as arches, to be closed occasionally by the use of silk or open black wood screens, often of beautiful design, reaching only to the spring of the arch, and with a space of a foot in depth left open underneath, to admit a current of air along the floor. This substitution of some sort of pierced work for panels, I may observe, is carried out in many directions. In some of the beautiful Mahomedan buildings the panels of pierced brass-work and pierced stone which occur in the openings form the most beautiful decorative feature conceivable. These have been elaborated in such a case as the window in the mosque of Seedein Soyed, at Ahmedabad, to a point which challenges comparison with our most complete tracery. Other modes of filling openings may be used; for example, in Cairo and many other Eastern cities the most effective grilles for filling windows are formed of small turned wooden spokes, fitted together in a simple effective way. In the Egyptian Okei, in the park of the Paris Exhibition, this was well shown, as were other peculiarities of structures suited for hot climates.

It occurs, sometimes, in most or all tropical climates, that from external openings it is necessary to keep out the wet, and sometimes even the heat. I believe even, that in some very hot inland regions, away from sea breezes, the air is so hot during the sunshining hours that it is customary to keep it out instead of letting it in. Here, of course, external openings are made capable of being thoroughly closed, and comparatively small. It is also necessary in some districts to be able to shut out night fogs, or sea fogs, or some other injurious state of the air, and even cold winds; and in Bombay, which is on the sea-shore, I found that it was necessary to be provided with the means of closing external openings against the humidity of the monsoon or wet season, and even against driving dust; accordingly there all window-frames have two sets of folding casements, one with the Venetian louvres already described, the other glazed, and left folded back out of the way, except in the wet season. I am not aware that our sash-windows have ever been attempted to be employed, and they are just such a contrivance as I should expect would be ill carried out by native workmen. Casements in solid frames are preferable, and those frames that I have seen, internal doors as well as windows, are always framed with a cill, which in doorways you have to step over.

It is not, I think, usually requisite to make provision for strongly protecting any building for European occupation against robbery. It is usual to have watchmen patrolling round even private houses all the night, and more reliance is placed on them for protection than on fastenings or doors. Notwithstanding the general simplicity upon which I have insisted, one or two points, in the arrangement of buildings where Europeans are to reside, in India, at least, often cause some perplexity to the architect; but these it is imperative he should attend to. For instance, the bedroom of any European entitled to the smallest comfort must have appended to it a bath-room, in which stands, on a

large cement platform with a raised ledge, a large sponging bath: this has to be daily filled by a water-bearer: often it is so placed as to be filled through a pipe; but however this may be, the arrangement is not that water is laid on as in England, but that it is brought daily in a skin on a man's shoulder to the outside, if not the inside of the room. For this purpose, consequently, access must be reserved for the bees-tee (or water-carrier). But this is not all. In or adjoining each dressing-room is a convenience taking the place of a water-closet. The system of water conservancy is not established, and may probably never be found available in India; while even the more suitable system of Mr. Mount and his earth-closets would not obviate the necessity of removing, more or less frequently, fecal matter by hand. This is at present done twice daily, and the persons whose business it is to do this work (and who are termed sweepers) must not, both on account of the offensive nature of their work, and on account of their lowness of caste, come into the building so as to risk their contact with higher caste servants. Hence it becomes necessary to provide a sweeper's staircase, and often several such (which are very frequently external staircases, more or less open), with means of access along verandahs or otherwise to the external wall of each dressing-room, and to form at each convenience a small doorway through the wall. In a complicated building this necessity for a dressing-room to each bed-room, and for a secluded and external access to each dressing-room for the water-carrier and the sweeper, makes no inconsiderable demand on the ingenuity of the architect, and even on the space at his command. I may add that as regards bath water a regular system of drain-pipes to carry it off does not seem usual. Provision is made for discharging it by some simple outlet to the exterior of the building, where it flows over the surface of the ground, and soon sinks in, or is evaporated by the sun's heat. Here it may be fitting to add, by-the-by, that eaves-gutters and down-pipes, and means of storing rainwater, do not seem to be in use.

Another peculiarity of tropical life is that, as every European who can afford it must ride to his business, and about his business or his pleasure, every building requires a carriage porch, sheltered from the wet of the monsoon and the heat of the other seasons. Every house and most public buildings will also require stabling and coach-houses. These are very much ruder than our own, but must be spacious.

Special attention must be paid to the great value of one aspect as compared with another—the breezy and the shady sides of a building are preferable to the other aspects in a very great degree, but the difficulty of securing a good aspect for as many rooms as possible in a building being not unknown in England, I will not enlarge upon it.

Wherever practicable, an Indian building is placed within an ample walled enclosure, called a compound, which is a kind of compromise between a meadow, an orchard, and a garden; and in this compound, when a number of attendants are required, nestles a cluster of huts where they and their families live, and other huts, such as the cook-house, where the household work is mainly done. In city buildings it is usual to give up the whole or some part of the ground floor to the servants, though in some buildings lately erected in the city of Bombay they, and the kitchen (called cook-room), have been provided for in the topmost story. The number of attendants required is very great. As a rule in all tropical countries native labour is cheap and plentiful; each individual does not do much, and the subdivision of labour is carried out to a perplexing extent. It is worth taking a good deal of trouble to arrange the stables and these servants' dwellings, so that they shall not come to the windward of the building they belong to,—that is, if the prevalent direction of the wind is known. Various bad odours are likely to arise there, and even the fuel burned in cooking in these places, being cakes of dried cow-dung, gives forth an unpleasant smell, and this or any other bad smell is peculiarly offensive in a hot climate.

Having now said something upon the arrangements and features desirable in a building intended for a tropical climate, we are next to consider some other peculiarities which may have to be provided for in preparing to execute such a building. The difficulties attendant upon the actual carrying out of any building in a

tropical country are often serious. They are of two classes; those of a structural nature,—as difficulties relative to materials, to labour, to modes of working, &c., and those of what may be termed an administrative nature, that is to say, those affected by the peculiarity, or arrangements, or want of arrangements, for getting building work done. It is not sufficient to prepare plans for a building which would be a good-looking and suitable one if it were built. It is also necessary that the plans and arrangements should be fitted as nearly as possible to the material and moral circumstances of the case. This necessity is too often overlooked, ignored, or at best inadequately met; and in consequence works well designed in this country have often been ill carried out, abandoned, or modified in a destructive sense abroad. There may be many things that would prove good if done, which yet cannot be done, and others which could be done, but which people cannot be got to do.*

ON THE UTILIZATION OF SEWAGE BY IRRIGATION.†

Norwood.—At Norwood the results of irrigation have proved equally remunerative, the land being, as has already been stated, on a clay formation distinct from that of Croydon. The arrangements for the purification of the water are most elaborate. By gravitation the sewage is conducted from the outfall, through a covered straining tank, whence the solid refuse is pumped by hand, with moveable apparatus. The covering of this tank is questionable policy. It simply effects the concentration of the sulphuretted hydrogen, which if exposed to the atmosphere, could do little offence, and renders the cleansing a duty of tenfold danger. From this point, the sewage is passed in conduits, covered and open, and flows through the soil three several times ere it is finally discharged. The natural conformation of the ground is admirably adapted for this, and the purification is perfect. The quantity irrigated is about 37 acres. Prior to the application of sewage to the land at South Norwood, it was considered a very poor soil indeed; but recently the present tenant, Mr. Cousins, has offered 16l. per acre per annum for a twelve years' lease.‡

Edinburgh.—It is recorded by various authorities that town sewage has been here applied to the same land for a period of at least 200 years. The value of this fact is great, for in it we find a decisive proof that the land is not exhausted by this method of cultivation, even after the lapse of generations, but that exceeding fertility continues to be its characteristic. The soil upon which the utilization is mainly effected cannot be said to have ever been abundant of the elements of fertility, being simply the pure sea-sand. An additional valuable fact is, that throughout this long period of cultivation, conducted in a very rude and imperfect manner, there exists no record of injury to the health of the vicinity having been sustained therefrom. These considerations, taken in conjunction with the enormous rents that have long been paid for the irrigated land, give Edinburgh a prominent position as an exponent of the vast manorial wealth which lies hid in the form of common town sewage. The late Mr. Smith, of Deanshouse, in reporting upon the application of sewage to the purposes of agriculture, gives the following description of the irrigation works at Edinburgh:—"The sewer-water, coming from a section of the Old Town, is discharged into a natural channel or brook at the base of the sloping site of the town, at sufficient height above a large tract of ground to admit of its being flowed by gravitation over a surface of several hundred acres. The water as it comes from the sewers is received into ponds, where it is allowed to settle and deposit the gross and less buoyant matter which is carried along by the water, whilst it flows on a steep descent. From these tanks or settling ponds the sewer-water flows off at the surface at the opposite end to its entrance. The water so flowing off still holds in suspension a large quantity of light flocculent matter, together with the more minute débris of the various matters falling into the sewers, chiefly of vegetable or animal origin. The water is made to flow over plots or plateaux of ground, formed of even surface, so that the

water shall flow as equally as possible over the whole, with various declinations, according to circumstances; and it is found in practice, that the flow of the water can easily be adjusted to suit the declination." The report goes on to say: "The practical result of this application of sewer-water is, that land which let formerly at from 40s. to 6l. per Scotch acre is now actually let at from 30l. to 40l.; and that poor sandy land upon the sea-shore, which might be worth 2s. 6d. per acre, lots at an annual rent of from 15l. to 20l.," a veritable mine of wealth. This land produces from four to five crops of Italian ryegrass per annum: and as much as eighty tons per Scotch acre have been taken off in a single year. Yet so little alive are the rate-payers of Edinburgh to their own interests, that, glad to be rid of this valuable commodity, they make a free gift of it to their farmers, or rather to their landlords; who, on their part, find no better occupation than in turning its rich fertilizing ingredients into gold. The consequence of this disregard of public interest, so little creditable to the practical genius with which the Scotch are supposed to be gifted, is, that instead of being applied in a careful judicious manner, so as to make the most of it, the sewage is allowed to flood the land with wasteful prodigality, by reason of which a very considerable portion of it escapes without effecting the slightest good. It may be a necessary policy, during the infancy of irrigation experiments, to grant concessions of sewage at a nominal or pepper-corn rent; but after men have grown grey in the experience of its value, it is simply neglect to suffer a few private individuals to reap the advantage which should accrue to those whose sole property it is, to wit, the rate-payers.

Rugby.—The works at Rugby, like those at Croydon in their earlier stages, may be said to have been of excellent service in demonstrating what is to be avoided in sewage irrigation; and we cannot do better, in viewing this side of the question, than attentively study both these examples, and profit by their errors. In 1853, Mr. G. H. Walker took a lease of the sewage of Rugby, at an annual rent of 50l., with the twofold object of procuring the River Avon from pollution, and at the same time fertilizing his own land. He constructed a tank capable of holding 150,000 gallons, and erected a steam-engine of 12-horse power. He then laid down six miles of iron pipes, in five radiating main branches, with subsidiary branches. Through these pipes the sewage was pumped from the tank into gutta-percha hose affixed to hydrants, and so distributed over the land. The hose and jet system proved a failure, and was exchanged for open carriers, necessitating great additional expense. Other costly mistakes were discovered. The outfall, instead of being so low as to require steam-power to raise the sewage on to the land, might have been so constructed as to have admitted of its flowing over the ground by gravitation only, whereby the cost of engine and pumping apparatus, with their annual working expenses, might have been saved. The six miles of iron piping, of far too large a section for their original purpose, as well as of too great a lineal extent, were, on the adoption of open carriers, rendered useless, being abandoned by the lessee.* The land upon which the sewage was applied, instead of undergoing a special preparation for a special crop, was old farrowed pasture of the ordinary kind, covered with a strong stubborn turf, entirely unsuited for treatment by irrigation. The system of application was also injudicious, and it is not surprising, after Mr. Walker's catalogue of errors, Rugby should stand forth as a signal exception to the usual success of the utilization of sewage by irrigation. Yet, although the Rugby experiment has proved a failure so far as the enterprise of the lessee is concerned, it has by no means affected the estimation of sewage manure. Mr. Walker has stated in evidence that, under proper management, the money returned by the sewage disposal expense, even with the existing arrangements; and he considers the Rugby farm to be more valuable and productive since the application of sewage.† Nowwithstanding, then, the untoward circumstances which have attended the works at Rugby, they cannot justly be looked upon as a failure in demonstrating the value of sewage but rather as a proof that mismanagement will bring the most promising enterprise to a disastrous end. Rugby was the scene of Mr. Lawes's experiments.

Milan.—The drainage of Milan, which receives little or nothing of the solid excrement of the population, is received into two conduits, which make the inner and outer circle of the city, and unite in a natural channel called the Vettabbia, at the southern outskirts. The Vettabbia flows ten miles, and during its course to the Lambro, wherein it falls, distributes the sewage thus diluted over a considerable area of level meadow. The irrigation is carried on by the system of submersion, and is very successful, four crops of grass and three of hay being cut in the year. Professor Way adverted to the sewage of Milan in his report to the Commission,* and stated that although it was so dilute as hardly to be distinguished by the senses from ordinary stream water, yet it conferred upon the land to which it was applied, an increased value of from 4l. to 5l. per statute acre per annum above that obtained for land irrigated by streams containing no sewage.

The National Advantages of Sewage Irrigation.

It is not within the scope of the present crude statement of facts to enter into anything like a minute consideration of the manifold and widely-extended benefits which may be expected to accrue from the realisation of success in utilising the contents of our sewers. It will, however, be to the purpose to summarize the most prominent of them.

In the first place, it will be the means of effecting a sanitary reform unrivalled in the history of cities; and this may be submitted as the primary object to be attained. It is well if our impure refuse can be converted into gold; but it is better that it should first be rendered harmless to the public health. By this method, then, we not only obtain perfect facility for drainage, but we divert it from those abundant sources of water supply which hitherto it has perennially defiled; so that besides effectually banishing the noisome stenches and putrid epidemics which hover over the shores of he-fouled rivers, we render these latter once more to the beneficent purposes of nature, and swell the diminishing bulk of our present water supply by immense volumes of the purest and most wholesome water. Secondly, in placing the sewage upon the land, the country will become possessed of a permanent revenue, derived from a solid basis—a welcome relief to a heavily-taxed community. Thirdly, in thus developing the national resources, by multiplying the productive power of extensive districts, and enriching soils at present barren or impoverished, an important law in political economy will be carried out, and that dependence upon foreign supplies done away with, which is an ominous and almost unique feature in the commerce of this country. Lastly, the development of a large field for manual labour tends to a wholesome reduction of the evils of over-population.

The following is a tabulated statement of the value of London sewage per head of the population. The calculations are based upon its estimated worth per ton, taken with the net quantity of sewage discharged, the population roundly numbered at 2,500,000.—

Net weight of sewage, Tons.	Price per ton.	Population	Value per head.
155,544,000 (Mr. Bassigette) ...	0s. 2d. 0 11 0 1	2,500,000	£0 10 4½ 0 7 9 0 5 2½
215,762,000 (Capt. Galton)	0 2 0 1½ 0 1	"	0 14 4½ 0 10 9½ 0 7 2½
266,000,000 (Mr. Ellis)	0 2 0 1½ 0 1	"	0 17 9 0 13 3½ 0 8 10
			9½ 15 7
Average value per head			£0 10 7½

Thus we find that the average estimated value of London sewage per head of the population is about 10s. 7½d.; and if we roughly estimate the whole population of England and Wales at 20,000,000 souls, it will be found that our drainage refuse represents a gross annual value of 10,625,000l. sterling. Of this, say that not more than three-fourths can be rendered fully available, and there is still left the sum of 7,968,750l., a fact worthy of the attention of political economists. It may, nevertheless, with truth be alleged that a very considerable portion of the drier and more solid parts of sewage are not at present wasted, being applied to the soil. But the privies and cesspools of our most populous

* Rep. Met. Sewage, 1861: 4721.

towns, which chiefly contribute to this imperfect utilization, are already under condemnation upon the strongest sanitary grounds, and will sooner or later yield to the substitution of water-closets. It must not be forgotten also that under the existing state of things, immense sums are being annually paid from borough rates for riddance of this valuable commodity. At Manchester 6,600l. per annum is paid for the removal of the contents of cesspits,* an expense which more or less is universal throughout the country. At Aldershot it has already been said that 500l. or 600l. was annually paid for this purpose before the introduction of main-drainage. The population was then six or seven thousand: the cost therefore would amount to nearly 2l. per head. It is truly to be hoped that the fact of this extraordinary waste of national wealth will not long have to be recorded against those numerous and powerful corporate bodies in whose hands the administration of sanitary government is centred.

"All our advances in arts and sciences," says Liebig,† "are of no avail in increasing the conditions of human existence; and although a small fraction of society may by their means be gainers in material and intellectual enjoyment, the load of misery weighing upon the great mass of the people remains the same. A hungry man cares not for preaching, and a child that is to learn anything at school must not be sent there with an empty stomach.

"Every step in advance, however, made by agriculture serves to alleviate the sufferings and troubles of mankind, and to make the human mind susceptible and capable of appreciating the good and the beautiful that art and science present to us. Improvements in agriculture constitute the only solid foundation for further progress in all other branches of knowledge."‡

M. P.

NEW TRENT BRIDGE FOR NOTTINGHAM.

THE town council have resolved to erect a new bridge in place of the old Trent bridge from a design by their surveyor, Mr. Tarbotton, at a cost of 31,000l. The site will be a little lower down the river than that of the old bridge. The structural part of the bridge will be allied in its mechanical details to the modern bridges over the Seine and the Thames. The material for the abutments and piers below the lowest water mark as also for the hearing of the same will be of the best brickwork. The exposed surfaces of the abutments and piers will be formed of rock-faced Derbyshire or Yorkshire grit-stone, with the more ornamental parts of red sandstone, magnesian limestone, and granite. The arches will be of cast-iron, as being most suitable to resist the strains pertaining to the condition of the ribs employed. The upper platform to support the roadway will consist of wrought-iron girders supporting wrought-iron buckled plates as used on Westminster and on the largest railway bridges, or similar material. The surface of the roadway will be of Yorkshire landings for the footpaths, bituminized concrete and macadam for the carriage-road, and cast-iron channels, similar to those used by Mr. Tarbotton in building the Navigation Bridge, for the gutters. The parapets will be of cast-iron, with geometric ornamental open work, containing medallions composed of lilies and other water flowers and leaves, made of cast-iron and conventionally treated. These are intended to be gilded, and the rest of the ironwork painted. The width of the bridge clear of the parapets will be 40 ft., containing footpaths 8 ft. 6 in. wide, and a roadway capable of accommodating three lines of carriages with ease and safety.

IMPROVED DWELLINGS FOR SALFORD.—At a meeting convened by the mayor, it has been resolved that a company be formed under the provisions of the Companies Act, 1862, to be called "The Salford Improved Industrial Dwellings Company, Limited," with a capital of 25,000l., in 1,000 shares of 25l. each, and that a subscription list for shares be opened, and so soon as the list amounts to 8,000l., the mayor will convene a meeting of the members for the purpose of electing directors and other officers of the company. Subscriptions amounting to upwards of 6,000l. were at once put down.

LUDUS PATRONYMICUS.*

DR. CHARNOCK has made a collection of upwards of 3,000 peculiar surnames, and prefaced them with an etymological scrutiny into the real meaning and derivation of a large number of the most curious of them. The volume containing the result of his examination might well be entitled "The Consolations of Etymology," but he has preferred to call it "Ludus Patronymicus." Although some of our peculiar surnames are nicknames, most of them are corruptions from onomastic appellations; and the supposition that the owners of names that are disagreeable in their present form would be glad to return to the original or proper orthography, instead of changing them for new ones, has been the main-spring that has directed our author's labours. The familiar instance of the abasement of St. Anby into Stubbs is not more startling than scores of similar degradations. Modern usage, with its tendency to abbreviations in all words, has reduced Fenwick to Phoenix, and thence to Spinks; in other words, in the course of generations the Plantagenet Squire Fenwick and his Tador moustrooping descendants have lapsed into police-constable Spinks. Some of the De Veres are now Wires and Weirs. The Seymours, or St. Mans, are Simmers. Some of the Luceys are Lace. The Traceys have contracted to Tress. Sir William de Sevenoake is represented by Snooks. The Tremaynes have degenerated into Trimmings; the d'Aubignies into Twopennys; the Fitz-Paynes into Phippens. "Few," says Dr. Charnock, "would probably change their name from Buggin or Simper to Smith, if they thought they were justified in writing Bacon and St. Pierre. The same might be said of such names as Death, Dearth, and Diaper, from d'Aeth, d'Arth, and d'Ypres respectively." Everybody, we must warn, who owns a peculiar name is not certain of improving it by tracing it to its source. To be stripped into Evans after having been Havens would scarcely be so satisfactory a return to a starting point as the instances just quoted. But the rule is in favour of the investigation.

The amount of research expended upon the perfection of Dr. Charnock's work may be realised when we scan the list of authorities he has consulted, some seven-and-twenty in number, including the works of the most esteemed German and Danish philologists. Some of his verbal explorations are, indeed, polished pieces of scholarship. We will quote a few of our best-known eccentric names, beginning with Cubitt. This Jamieson gives as a probable abbreviation of Cuthbert; but our author thinks that, with Cupit, Cupett, and Cobbett, it may be a diminutive of Cohl, Copp, Cope, the old German Cohlho, Coppo, Cuppa, whence the patronymics Cobbing, Copping, &c.; "from A. S. *cop*, O. H. G. *kop*, Mod. G. *kopf*, D. *kop*, the head; O. Fr. *coppe*, *coppeau*, *coppe*, *coupeau*, *cime* *sommet*, *pedage*. Cob is also a name for the sea-fowl, the sea-cock; and in some parts of England for a spider; from O. D. *kop* or *koppo*, retained in *koppessin*, *spinnokop*, a spider. *Cob* is also a close-built strong kind of pony; and *cob*, *cop*, is still used for the top or head." Telford, formerly written Telfer, is from the Norman name Taillefer, cut iron, in recognition of a feat performed by William, Count of Angouleme, who with one stroke of his sword Darissime, cut in two the body and cuirass of King Storrin. In Scotland, in the sixteenth century, it was written Taitzfer. The celebrated engineer, our author thinks, could not have been aware of this origin when he changed his name to Telford. Sheepshanks has been supposed to refer, like Cruikshanks, to mal-formed legs, but our author has given another possible origin. There is a narrow lane in Canterbury, called Sheep-Shank, which he thinks must have referred to some tavern, such as the Sheep or Ship Tavern, from the G. *schenke*, a drinking-house, or ale-house. The surnames Schenck and Schenck signify a publican or vintner; hence Sheepshank may be a combination of the tradesman and his sign. Going on to less remarkable names, we come to further singular deviations. Dolman was perhaps a man from Dol in Bretagne; Farthing was Fardan, in the days "Domesday" was compiled. Pennythorn belongs to the family of names starting from the Welsh *pen*, head, chief, end, which includes Pennycook, Manypenny, Turpenney, &c.

* "Ludus Patronymicus; or, The Etymology of Curious Surnames." By Richard Stephen Charnock, Ph. D., F.S.A., F.R.G.S., &c. London: Trübner & Co., No. 60, Paternoster-row, 1865.

† "Natural Laws of Husbandry," p. 226.

‡ To be continued.

Front is a corruption of Provost. Smiles is more properly Smellie, from *smeech leag*, smooth pasture. Tite is the French form of Titus; Trenchit, corrupted from Tyrwhitt, has been Tyrell, and was perhaps the diminutive of *turris*, a tower. Virtue, with less transformation, is from the French town on the Loire, Vertou; Wiggs can look back for consolation to the ancestry of Cerdic, king of the West Saxons, and can write themselves Wiga, as in "Domesday." The still more objectionably named Willgoose can likewise refer to the genealogy of Anglo-Saxon Kings, for, as Wilgis, his occurs in those of Northumbria. The well-known name Speke, written Spink in a Devonshire map, Dr. Charnock refers to Bramford Speke in that county. He remarks, "Lower says the Spokes of Somersetshire descend from Richard le Espeke, who lived in the reign of Henry II., but that he is unable to explain Le Espeke. A correspondent of *Notes and Queries*, thinks 'Willi le Espece' may be a misreading for 'Willi le Espece,' that is, William the Swordsman, or William of the Sword; another thinks *espece* may mean a *syder*, who was formerly something between a grocer and a chemist, and he quotes Riquetfort, 'Espece, epicier, drogoniste, apothecaire; de species, specierum.' The O. Fr. *spec* is an inspector."

A curiosity in Dr. Charnock's volume is an autobiographical sketch written almost exclusively in surnames. It purports to be written by Aretchid Kooez. We give a short sample of this mastery of patronymic language:

"I've Been a Great Traveller, and Such a Walker! I've Traded Many Lands, And Was Once a Pilgrim to Calvary, Galilee, Nazareth, Jordan, Jerusalem, And Gath, without Kirman Nor Pass Port. By Jove! the Weather Does Not Stop Me: It's His Ain the Same; I've Washed, I've Washed, Merrywash, Ever Foun weather. I Delight In Tempest, Snow, Storm, Rain, Shower, Hail, Thaw, Sleet, Frost, Dew Wind, Fog, Mist, Gale, . . . I Once Went to Church; and the Parson, in His Sermon, Said, 'If One Was Just, Had Faith And Trust In the Gospel, And Was a True Man, in the Coming World—i.e., Paradise, Nor Kingdom of Heaven—One Might Be a Perfect Man (Wart Blas!); Butt, if One Was a Badman, after Getting Off Our Mortal Coil, Thayer Was a Good Chance of Going to the Devil. Cant Say Him a Croker, Butt Death, Collins, Churchyard, Graves, Tombs, And Monuments Air By Noe Means Pleasant Things."

These who contend the human race is dwarfing and degenerating instead of developing might use for an argument some of the etymological facts newly arrayed before us. The kingly Canute, they might say, has shrunk to Mr. Nntt in our hands. Pele has been clipped and rolled into Pili; the Humphrey of former days is a mere Pili in ours. But it is, as we have said before, the consolations it administers that will form one of the chief sources of popularity of the volume. How consoling to Mr. Shovel to know that he is in reality Ceely; for Mr. Shovel to know that his ancestors were Escovilles; for a Smallbone to reflect that his forefathers were Seabornes (seabears); for a Slumber to believe one member of his family has been a St. Lambert, if, as our author inquires, there ever was such a saint or sinner; for Slow to return to Do la Slo; for the Sextys and Sixtys to know there was a Sacristan in their family in former times; for the Slippers to know they were once sword-grinders, having slipped downwards from the Tent. Schwerdt-Scheiffer; for the Gammles to be able to plume themselves upon having been Fitz-gamels as well as Gamhoils (from the gund-hold—bold in war); or for the Gins to know that scholars trace their name to the root of *Plantagonista*, accident also having made the difference. The Painters, Panters, Pantlings, have had at some time in their generations the post of breadkeeper or *panetarius* either in a monastic or other large establishment; and Paradise, unlikely as it appears to be, also bears within itself the hedge of former servitude from the O. G. *paradous*, a servant. But, to return to our string of instances in which it is consoling to look backward: the Sands, on the contrary, numerous and unpretending as we should suppose them, have probably been sent forth, in former times, as envoys or princely messengers, if we may take the etymological evidence of five languages as an index of their origin. Leaf, seemingly, so valueless, is a corruption of Léof, beloved, precious. Muffin is a contraction of Morfin, a sea-brink. Our author traces Gotobed to Gottedah, pray to God. Deadman should be Debenham, from a place of that name in Suffolk, much to its gain; and Scaredevil may likewise take the name of a town for its origin, this time, perhaps, Ecardenville, Normandy. Snch, when given in full, is Ashby-de-la-Zouche. There is a curious evidence of the departure of a name from its original meaning preserved in the parish

register of Brenchley, in Kent, where an entry states that in 1612 "John Diamond, son of John du Mont, the Frenchman, was baptized."

Interspersed with the mass of etymological facts there are not a few smart puns upon names introduced, which, however, we must record are not profanely made by Dr. Charnock, but quoted from the American writer, Bowditch, and other sources. Thus, against the name Deed, Deeds, we read, "Doubtless for Daid, Daids; from David, Davids. There is also a Deedy. The Messrs. Deed, of Toronto and of Philadelphia (says Bowditch), may be regarded as the representatives of conveyancing." Again, the same writer says, Abraham Shurt, of Pemaquid (near Bristol, M.E.), took an acknowledgement of an Indian deed in 1826, twenty years before any enactment on that subject, and he dedicates his work "To the memory of A. Shurt, the Father of American Conveyancing, whose Name is associated alike with my Daily Toilet and my Daily Occupation." Against the name Vowell there is another quotation from the same humourist. "Our newspapers mention that a friend informed Mr. Barton that Mr. Vowell was dead. He said 'Vowell dead? O! how glad I am that it is not 'v or t!'" On another page we read that the *Boston Courier*, in June, 1859, mentioned that Mr. Slim had a narrow escape from drowning.

Against the name Smoker, which Mr. Ferguson thinks may be derived from the Anglo-Saxon *smoce*, elegant, polished,—but which our author deems more likely to be derived from the Danish *smok*, fair, handsome, fine,—there occurs a note to the effect that before the Reform Bill of 1832 was passed, every person at Preston, who had a cottage with a chimney, and used the latter, had a vote, and was called a *smoker*. We can give, however, but one more sample of this phase of the work. It occurs with reference to the name Wisdom. "Mathew Hele, of Holwell, Devon, was high-sheriff of the county the year of Charles II.'s restoration, 1660, and so numerous and influential were the family, that he was enabled to assemble a grand jury, *all of his own name and blood*, gentlemen of estate and quality, which made the judge observe, when he heard Hele of Wisdom, esq., called,—a gentill seat in the parish of Cornwall,—that he thought they must all be descended from Wisdom, in that they had acquired such considerable fortunes." A curious combination occurred at the Liverpool Police-court once, when "the witnesses and solicitor in two cases bore the ominous names of Death, Debt, and Daggers." Our author does not attempt to account for the two last-mentioned. These samples of the anecdotes illustrating some names must not lead to the inference that entertainment is the aim of the writer. These are but as the leaves to the leaf, the work being, in reality, a serious, industrious, instructive series of suggestions, inquiries, and conclusions. As the author remarks, some of the suggestions are but guesses, but, we must add, they are made with the assistance of the discrimination that complete acquaintance with the subject ensures. Indeed, if we consider the difference of opinions held by etymologists over the probable radicals of hundreds of words, concerning which there was no doubt, there is little more than that can be said for nine derivations out of ten. Take the famous name of Shakespeare with its variations Shakespeare, Shakespere, Shakesper, Shaxper, and Chackesper. "Concerning its etymology there can be no doubt," says Lower, as he assigns the ordinary practice of vibrating a spear to ascertain its strength before using it as its origin, and calls Homer to witness; nevertheless, Dr. Charnock sees considerable doubt about the correctness of this view, and suggests that the name of our great poet may be a corruption of Sigisbert, renowned for victory, while Mr. Ferguson thinks that Scisper, or victorious bear, is more likely to have been the etymon: finally, our author abandons his first conviction, in favour of the supposition that *Jacques Pierre* is the true solution of the riddle; and who shall say which is right? Seeing that the differences of etymologists rival those with which doctors are solely accredited, it is, perhaps, sufficient to remark that the erudition of the author before us, and the continuity of his philological labours, entitle his opinions to consideration, if not to acceptance. Some curious names he accounts for as the result of a tendency he has observed them to possess of drawing towards a meaning, as in Sweetsir, which is evi-

dently merely a slight departure in sound from the German Schweitzer, a Swiss; or Broadlock, which must have been Bradford; or Wedlock, which must be but a derivation from Wedlake. Gem, from James, with the aid, perhaps, of an intermediate Jim; Giddy, from Gideon; Gird, from Carle, are samples of surnames with English meanings made out of Christian names by force of this tendency. More attractive than these in the brimming volume we here recommend to all interested in the pleasing study of etymology, are the names which the old Scandinavian heroes left among us, among which Rùm is a curiosity. This is supposed to have once been *rum*, a giant, one who, we agree with our author, would, in all ages, have been considered "a rum customer."

THE NEW WATERWORKS AT SWANSEA.

THESE works, just now completed, were designed and carried out by Mr. R. Rawlinson, C.B., assisted by Mr. Edward Consins, the borough surveyor. The Act of Parliament giving powers to the local board of health to construct reservoirs on the Llan, Lliw, and Blaenmant ddw streams was obtained, after a good deal of opposition, in 1860. The Board, determining to proceed in the first instance with the construction of the Lliw reservoir and the necessary conduit, tenders were invited; and, in 1861, that of Mr. Wm. Williams, of Swansea, was accepted. In March, 1862, Mr. Williams commenced work, and in the month of June following the first pipe was laid for the conduit. Tenders were afterwards received for cast-iron pipes, valves, hydrants, and for laying and jointing cast-iron pipes; and contracts were entered into with Messrs. D. Y. Stewart & Co., of Glasgow; Messrs. Gaest & Chirnes, of Rotherham; and Mr. Thomas Crump, of Derby, for these works. The conduit and cast-iron main from Morriston to Swansea were vigorously pushed forward; and in June, 1863, or about twelve months after the commencement of the works, they had so far progressed as to admit a supply of spring-water found on the line of conduit being taken to the town, and, on the 8th of November, water flowed to Swansea from the river Lliw, and has done so since. The reservoir was filled to overflowing for the first time on the 24th of October, 1867. From daily gaugings taken in 1867, it was found that 1,000,000 gallons of water passed into the conduit from the Lliw reservoir for the supply of the town during the year, being an average of 2,765,000 gallons per day. The estimated quantity of water supplied to the town during the progress of the works is 3,000,000 gallons, which, at 2d. per 1,000 gallons, would represent a money value of 25,000l. The period has been about four years and a half, so that the benefit to the town of this mode of working has been at the rate of 5.540l. per year. The greatest observed daily volume of water in the river Lliw, was on the 13th of January, 1866, when about 143 million gallons flowed down the stream in twenty-four hours. The lowest recorded flow was on the 19th October, 1865, when the volume was about 322,000 gallons in twenty-four hours. All the permanent works of the reservoir, as valves hie-wash, waste weir, &c., are competent to remove safely upwards of 100 millions of gallons of water per day. The drainage area of the Lliw valley above the reservoir embankment, is about 1,860 statute acres, 1 in. of rainfall over which would be 42,077,217 gallons. The area of top water of the reservoir is about 32 acres, the depth of available storage, 64 ft., and the storage capacity about 300,000,000 gallons. The works, as contracted for by Mr. Williams, were for a reservoir to contain only 200,000,000 gallons, and having an embankment 70 ft. in height, the cost of such being 28,071l. 10s. 6d.; but in August, 1864, in consequence of the very strong recommendations of Mr. Rawlinson, the enlargement of the reservoir was determined upon by the Local Board of Health, and the embankment raised 12 ft. above contract level, by which means storage for an additional 100,000,000 gallons were obtained. The cost of this additional storage has been about 4,000l. The embankment is formed principally of sandy and stony material, with a small portion of gravel, nearly the whole of which was excavated above top water from adjoining land. The embankment is 650 ft. long, and 403 ft. wide in the widest part. It is 82 ft. high in the deepest part above the original surface of the ground, the puddle trench being carried 18 ft.

below this level, or 100 ft. below finished top bank. The embankment is 12 ft. wide at the top, the outer slope 2½ ft. to 1 ft., and the inner slope 3 ft. to 1 ft. in the lower portion, and 2 ft. to 1 ft. in the upper portion. The puddle is 20 ft. thick at the original surface, and 9 ft. thick at the top bank. The puddle wall is supported on both sides by selected material, and the loose, rocky material is placed to add support to its height. There are two outlet culverts,—lower and mid-level. The lower outlet culvert is 8 ft. diameter, and the mid-level outlet culvert 6 ft. diameter, with valves, &c. The two valves in the lower culvert are 6½ ft. below top water, and therefore it will not be necessary to work any valve in connexion with the outlet works under a greater pressure of water than 29 ft.—the difference between 35 ft. and 6½ ft. The overflow is 46 ft. in length, and is so constructed that at a slight cost arrangements may be made for increasing the depth of water by fixing stop-planks on the top of the coping; an increased depth of 18 in. will give about 20,000,000 gallons of additional storage, which, filled three times a year, the service capacity of the reservoir will be increased some 60,000,000 gallons. The wastewater channel, which is 8 ft. broad, is formed of steps varying from 7 ft. 6 in. to 37 ft. 6 in. long, and having a vertical fall of from about 2 ft. to 4 ft. 6 in. To insure at all times a body of water on each step, and form a fish-ladder, a cast-iron girder or plate 6 in. in depth has been fixed on the edge of each step, and the steps have a fall inwards of about 12 in. The total fall from the top water-line of the reservoir to the river below is 85 ft.; but the velocity and force with which the greatest flood can enter the river from the bye-wash will very little exceed that due to the last fall of about 4 ft. The materials used and work executed in connexion with the Embankment and outlet arrangement are as follow:—

Shipping and trimming surfaces	47,798 square yards.
Soiling slopes	12,698 "
Pitching inner slope	2,291 "
Metalling road	1,065 "
Flagging	156 "
Earthwork in Embankment	179,150 cubic yards.
Excavation in earth	11,739 "
Ditto in rock	5,074 "
Puddle	23,443 "
Dry rubble work	311 "
Masonry in mortar	5,276 "
Ashtar and coping	12,022 "
Ashtar pitching	6,191 "

The conduit between the Lillw reservoir and Morrington is 7 miles 339 yards in length, contouring the intervening district, the principal portion being formed of stoneware pipes 2 ft. in diameter. The lengths of the different descriptions of conduit are—stoneware pipes, 6 miles 283 yards; brick culvert, 1,438 yards; cast-iron pipes, 378 yards. Upwards of 4,000,000 gallons of water have passed through the conduit for the supply of the town in twenty-four hours. There are on the line of conduit sixty-three man-holes, with moveable covers and ventilators, ten tunnel-shafts and seven wash-outs, or one man-hole to each 173 yards. There are also 122 gates on the line of conduit. The cost of the conduit and the works at Morrington has been 20,837l. 7s. 10d. The main from the well at Morrington to the town commences with a pipe of 24 inches diameter, diminishing to 18 inches, of which size it continues to the town. The highest part of the town will have to be supplied from a small service reservoir, proposed to be constructed at an elevation of about 575 ft. above the sea, and into which the water must be pumped either by steam power or by a turbine worked by water from the main flowing into Cwm Donkin reservoir. The highest district at present in operation is supplied from the well at Morrington, the height of which is 291 ft. above ordnance datum, and the greatest pressure is on the pipes under the river Tawe, which are 301 ft. below the Morrington tank. The cast-iron pipes, valves, and works were supplied and executed under contracts entered into with Messrs. D. Y. Stewart & Co. of Glasgow, for pipes, and Messrs. Guest & Chrimmes, of Rotherham, for sluice-valves. Mr. Thomas Crump, of Derby, executed the laying of the pipes. The amounts of the several statements are: Messrs. Stewart & Co., cast-iron pipes, 10,885l. 18s. 5d.; Messrs. Guest & Chrimmes, for valves and hydrants, 1,123l. 6s.; Mr. Thomas Crump, for excavating, laying, and jointing, 4,567l. 16s. 5d.; total, 16,580l. 0s. 10d. Upwards of 2,005 tons of cast-iron pipes were supplied by Messrs. Stewart for these works. Summarising the total cost of the works, we find that the contract with Mr. William Williams,

for work in connexion with Lillw reservoir, was 32,071l. 10s. 6d.; ditto, for conduit to Morrington, and works in connexion therewith, 20,837l. 7s. 10d.; allowed for completing conduit before specified time, 500l.; ditto, for works in connexion with temporary water-supply, cast-iron clips, and stone-ware pipes, 366l. 15s. 3d.; total of Mr. Wm. Williams's contracts, 53,775l. 12s. 10d. Contract with Messrs. D. Y. Stewart & Co., 10,885l. 18s. 5d.; contract with Messrs. Guest & Chrimmes, for sluice-valves, &c., 1,123l. 6s.; contract with Mr. Thomas Crump, for laying pipes, 4,567l. 16s. 5d. The money for cost of works, 70,355l. 13s. 8d. The money has been borrowed from the Public Works Loan Commissioners, the repayment being extended over a period of thirty years.

ALEXANDRA PARK, MUSWELL HILL.

On the 30th of June and the 1st of July next, races will first be run in Alexandra Park. The Grand Stand is finished, the course is all in order, and, on Saturday last, a large number of gentlemen interested in such matters, and others connected with literature, science, and art, were invited to go over the grounds and the Palace, and were afterwards hospitably entertained by the directors, Mr. William Haves presiding, and efficiently making known the objects of the undertaking.

The Park race-course is formed on slightly undulating ground, commencing near the Wood-green railway station, and extending along the south side of the Palace. It has been drained and levelled throughout, and the turf taken up and carefully relaid on a bed of ballast, to improve its elasticity. The T.Y.C., or 5-furlong course, is 30 yards in width, and nearly straight. The 1½-mile course commences near the Grand Stand, and joins the 5-furlong course by an easy curve.

The Grand Stand is situated at the west end of the 5-furlong course, and on the edge of the rising ground leading up to the Palace. It is approached by a wide road from Hornsey as well as from the Wood-green station.

The general character of the architecture of the exterior is Italian, with a frontage of steps from the lawn to within the whole length and width of the building. The ground-plan consists of an entrance-hall, 40 ft. by 18 ft., adjoining which are two towers containing the stairs leading to the Grand Stand room and lead flat. On this plan are also first and second class refreshment-rooms, together with entrance to the lawn. The Grand Stand room, 130 ft. by 25 ft., is on the first-floor, and divided into private boxes and stewards' compartment. Adjoining these are the ladies' refreshment-rooms, &c.

Above the Grand Stand room is a graduated lead roof 130 ft. by 25 ft. It struck us that, if the stand had faced a little more towards the east, a greater number of the occupants would have seen the whole race.

The main building is situated on the highest part of the park, commanding all sides beautiful views of the surrounding country. It is erected partly from the material of the late Exhibition building at Kensington, altered to make it appropriate to its new situation and purposes. The general plan consists of a nave 900 ft. long and 85 ft. wide, a centre transept 190 ft. long and the same width as the nave, and two shorter transepts, each 320 ft. long, the same width also as the nave, and intersecting at a short distance from each end. There are, therefore, three points of intersection of the nave and transepts. The centre has erected over it a great dome, which is 170 ft. in diameter and 220 ft. high in the interior, appropriately panelled and decorated, light being admitted near the top and by lunette windows at the sides. At the intersections of the shorter transepts with the nave there are pendentive octagon cupolas supported on slender columns, lighted by windows in the sides. The ends of the nave and three transepts are terminated with large circular windows, decorated with stained glass.

On each side of the nave and transept are erected buildings about 50 ft. wide and two stories in height; these have brick external walls, with arched openings and windows, and form extensive galleries next the nave and transept. The ground-floor on the south-east side will be almost entirely devoted to refreshment and dining rooms, opening by French windows to

a verandah overlooking the terrace beyond; and in the basement beneath are extensive and complete cellar and kitchen arrangements.

Other arrangements, such as news, reading, writing, and coffee-rooms, library, museums, picture-galleries, sculpture, plants, and flowers, &c., are all considered, together with many things tending to the entertainment and comfort of the public, and a great organ will form the centre of an orchestra for musical performances on a grand scale. The building will be lighted by gas in an ornamental manner, for evening promenades.

The organ, now in course of erection in the north transept, is of gigantic proportions. It is constructed by Mr. Henry Willis, the builder of the organ in St. George's Hall, at Liverpool. It possesses five claviers, four for the hands and one for the feet, and there are 101 stops, eighty-seven of which are sounding stops. The wind is supplied by two steam-engines, placed in the basement, and remote from the organ itself. The instrument is governed by various contrivances for varying its powers and qualities of tone. Amongst these are the pneumatic pistons for the hands, each clavier possessing six. There is also a complete system of combination pedals, acting precisely as those in the grand organs recently erected in the cathedral at Notre Dame and the church of St. Sulpice at Paris. The cost will be about 6,000l.

The interior is elegantly decorated throughout in coloured ornamentation, and is to be filled with objects of beauty and interest arranged in spaces so as not to interfere with the grand avenues for promenade.

Externally, the end of the nave and transepts present eight façades flanked by supporting incrusts, containing the large windows and entrances. These façades are united by the walls of the lower buildings, two stories in height, and by the clearstory walls and roof of the nave and transepts, and the whole is terminated by bold cornices and ornamental parapets.

The general character of the architecture of the exterior is Italian, and consists principally of brickwork in colours, with stone dressings and ornamentations. Above the roofs in the centre of the building rises a bold tambour, pierced with windows, from which springs a great dome, terminated at the top by a single balustraded parapet, and a standard mast 50 ft. high. This dome and the octagon cupolas at the smaller intersections are decorated with moulded ribs and panelling in bold relief.

On all sides of the building are spacious terraces, on which, and the ornamental slopes adjoining them, stand many large and handsome trees, giving relief and effect to the building. The terrace on the north-west side, which will be 1,000 ft. long and 160 ft. wide, supported by Italian arcades, will cover a railway-station, from which access will be had directly to the building at the ends of the three transepts, and to which station all the railways of London will ultimately be brought.

At present, however, the nearest railway station is some quarter of a mile from the building, and this has led to a determination, which seems to us to be regrettable, to postpone the opening of the building till the 1st of May next year. The decorations, very light and elegant, and the gilding of the ironwork, are all done, and must suffer, we should fear, during that time. The loss of interest, too, on capital will be considerable. Doubtless, however, the directors have carefully weighed the pros. and cons. Messrs. Lucas & Kelk have erected the building, and contributed a large portion of the capital. For the architectural design and details Mr. John Johnson is responsible, and for the construction and engineering, Mr. A. Meason. The decorations of the interior were executed by Mr. C. H. Schmidt, from Mr. Johnson's designs.

A CURIOUS CLOCK.—A clock of singular workmanship, designed by Raingo the Elder, and of the period of the First Empire, is now on view at M. de Boos's, 20, Down-street, Piccadilly, and the base is a musical box, which plays every hour. The front dial has, in addition to the usual index of time, a record of the days of the week. The signs of the zodiac and days of the month are also registered, and in connexion with these is a mechanical arrangement, exhibiting from day to day the relative positions of the moon, earth, and sun. The whole of this mechanism is worked by three springs.

SELECTED DESIGN FOR THE
MANCHESTER TOWN-HALL.

We illustrate in our present number the design by Mr. Waterhouse for the proposed Town-hall in Manchester, which has been selected by the Corporation of that city. Our view, being taken at the angle, shows the Entrance or Albert-square front, and the Princess-street front. The plan we give is of the one pair or main floor. In a previous number we reviewed the design at some length. On the present occasion we shall confine ourselves to a *resumé* of the designer's own statements, as best calculated to set forth his intentions.

The ground-floor is raised a few steps from the street, thereby gaining a cartway from Lloyd-street into the courtyards on the basement level.

Most of the business rooms look towards the street; the corridors and staircases, on the other hand, are lighted from the internal courts.

The corridors have a minimum width of 10 ft. along the Cooper-street, and Lloyd-street sides, and 12 ft. 6 in. along the Albert-square front. They open out at intervals into wider spaces, convenient for consultations, and which break the monotonous effect of long corridors of uniform width.

A porch and groined entrance-hall (in the centre of Albert-square front), with porter's offices on either hand, lead into the grand staircase hall, 52 ft. by 35 ft. Out of this the main staircases are carried up, by double flights, one on either side, each of them 10 ft. wide, to a similar hall on the main floor, which gives access, on the one hand, to the public hall in the centre of the building, and on the other to the suite of reception rooms. On the ground-floor the principal hall is lighted by the staircase windows on either side.

In addition to the main entrance in Albert-square there are three other principal entrances to the building; one in the centre of the Cooper-street front, another near the corner of Albert-square and Princess-street, and a third near the corner of Albert-square and Lloyd-street.

Each entrance has its porter's office, double-swing doors, one within the other, and close to it one of the three principal staircases placed in the angles of the corridors, which staircases ascend to the uppermost story in the building, and descend to the basement, thus giving direct access to the various stories from the street.

These three principal staircases are circular on plan, and average 21 ft. internal diameter. An open well has been placed in the centre, thus making the steps at their narrow end not less than 11 in. or 12 in. on the tread, with a rise of 5½ in.

There are, in addition to the grand staircase and the three principal business staircases, two secondary flights in the middle of the Princess-street and Lloyd-street corridors, rising up to the third floor. They are united together by a hall or corridor on each floor, thus giving inter-communication between the centres of the Princess-street and Lloyd-street fronts.

The private entrance for the mayor adjoins the public entrance in Princess-street, and is placed there in order that the same porter may command the two. It gives separate access not only to the mayor's private rooms, but to that portion of the Albert-square corridor which runs behind and communicates with the reception rooms.

The public hall is placed in the centre of the building. It would be approached by the public from Albert-square by the grand staircases through a large hall on the main floor, forming a sort of anteroom to it, and adding about one-third more available standing space on the occasion of a crowded town's meeting. The hall is lit on either side by two-light windows. The roof, though of hammer-beam construction, has a ceiling of an average height of only 42 ft. (to render successful the acoustic properties of the room).

In order to prevent onward thrust at so great a height from the ground, the roof is tied across. The walls of the central hall will be of stone, the lower part panelled in oak, with seats in the window recesses. At the farther extremity of the hall are two entrances, with retiring-rooms attached, which communicate with the two secondary central staircases, and the Lloyd-street and Princess-street corridors. Above these retiring-rooms is a gallery for an organ and orchestra, or capable of seating sixty people.

It will be observed that the hall is on the same level as the reception-rooms.

The mayor's reception-rooms front Albert-square; the large committee-room and the council chamber being placed in a line with them, so as to make one magnificent suite of entertaining rooms, 300 ft. in length, and occupying the whole of the principal front of the building on the main floor. These rooms are 23 ft. in height. The space over the main entrance is occupied by the anteroom, which can be approached either by the grand staircases or by the mayor's private staircase.

One one side of the dining-room is a serving-room and butler's pantry, with a staircase and hoist from the kitchen. From this staircase another flight, for servants, leads to the higher portion of the mayor's staircase, and so to his private rooms.

The mayor's private room is in easy communication with the town clerk's.

The cloak-room is placed so as to be easily accessible either from the grand staircase or from the mayor's private staircase.

Above the serving-room, in a mezzanine, are placed lavatories and other conveniences.

The mayor's suite of apartments is placed wholly on the second floor, looking for the most part towards Albert-square. In addition to this suite there is an extra sitting-room over the mayor's business-room, on a rather lower level, approached like the rest of these rooms by the mayor's private staircase.

Below the reception-rooms are placed the kitchens and servants' apartments.

Adjoining the anteroom on the main floor is placed the principal committee-room, so as to be in immediate connexion with the reception-rooms, and only separated from the public hall by the Albert-square corridor.

Annexed is a small serving-room, with staircase and lift down to basement, so that this principal committee-room might be made use of as a supper-room, if required.

Beyond the committee-room comes the anteroom of the council-chamber.

The council-chamber itself will be a well-lighted apartment, with a retiring-room on one side. It is planned so as to be approached by members either from the anteroom or the retiring-room, or, if needful, direct from the corridor. Above the retiring-room is a gallery capable of seating 113 people, with a separate staircase from the principal Lloyd-street entrance.

The other three general committee-rooms are in the centre of the Lloyd-street front, with the committee clerk midway between them and the town clerk and assistant town clerk's rooms.

The town clerk's rooms, connected together by a private corridor, face Princess-street.

The assistant town clerk's rooms adjoin and are brought into close contiguity with the committee-rooms, by a corridor running across the centre of the building.

The clerk of prosecutions is placed immediately over the assistant town clerk, with the Princess-street staircase connecting the rooms.

The treasurer's offices look into Albert-square, and are so placed as to be contiguous to the two entrances nearest the centre of the town, so that persons receiving cheques from other departments could pass the treasurer's offices on their way out of the building.

The surveyor occupies a portion of the main floor looking towards Princess-street, adjacent to the assistant town clerk. His offices have a north light and a private staircase to the room on the second floor.

The Chief Constable is placed in the centre of the building under the public hall, so as to be reached with facility from all the public entrances.

The Lloyd-street staircase leads direct from this department to the committee-rooms on the main floor in the centre of the building. The department is still more contiguous to the committee-rooms on either side of the main entrance.

The water department is placed at the Cooper-street end of the building. On the ground-floor the rooms look into Princess-street, and on the main floor into Lloyd-street. The two floors are connected by a book-lift and by the Cooper-street staircase. From the ground-floor rooms a private staircase descends to the stores in the basement.

The gas offices occupy the centre of the building, chiefly on the Lloyd-street side, and would be approached with equal facility from Lloyd-street and Cooper-street entrances. The

rooms on the ground-floor and main floors are connected together by a private staircase and paper-lift.

The building, sanitary and nuisance, and hackney carriage departments are placed on the southern half of the Albert-square side. Doors have been placed across the corridors, cutting off these and the scavenging departments from the rest of the building, and so admitting of the corridors adjoining the departments being used as waiting-halls if desirable.

The scavenging department is on the Lloyd-street side.

The workshops for the weights and measures department are in the Lloyd-street front towards the Cooper-street end, and have a recess for carts to unload.

The markets and paving and highway departments are placed on the Princess-street side of the building.

The court of record is on the ground-floor adjoining the Cooper-street entrance.

The muniment-rooms are in the basement. They intercommunicate and have a separate staircase.

The lamps' department, though in the basement, has a ready approach from the street by the cart entrance.

Large cellars have been provided for coal stores in a central position accessible by the cart entrance, with lifts to the upper floors on either side.

Housemaids' closets have been placed on the different floors.

In addition to the private water-closets, lavatories, &c., connected immediately with the principal officers' rooms, are groups of retiring rooms, in close connexion with all the three staircases in the basement, and on the second floor with the staircases on the Lloyd-street side of the building.

The head porter's rooms are on the third floor, approached from Lloyd-street by a separate entrance and staircase. His rooms are in connexion with a large dining-room in the centre of Lloyd-street front.

With regard to the warming of the building, it is proposed to place in a large sub-basement, three hot-water boilers, two of them for ordinary use, the third as a reserve for use while either of the others was under repair. The smoke from the furnaces will pass through two wrought-iron smoke flues, enclosed in brickwork, between which and the iron flues will be an intervening space for extracting vitiated air, as hereafter described. From these boilers hot-water pipes will traverse the main corridors, in channels below the floors, everywhere on the window side. These lines of hot-water pipes will form the mains from which coils of pipes, wherever wanted, would be fed.

The prisoners' cells will also be warmed by hot water.

For the extraction of the vitiated air, it is proposed, in the case of the public hall, to have a horizontal air shaft above the ceiling with numerous openings into it, communicating with the two vertical extraction shafts before alluded to. These shafts would be warmed by the boiler fires in the winter and by special means in the summer.

The clock tower and the Cooper-street tower will form convenient means for the extraction of vitiated air from the other portions of the building. Horizontal air flues, carried behind the cornices, will lead to vertical shafts in the angles of the towers, accelerating power being provided as required for summer ventilation, or whenever the reception-rooms happened to be crowded.

The whole of the building will be fireproof, constructed, where practicable, on the principle of the Dennett arch. The internal areas will be lined with light glazed tiles, and ceramic ware will be largely introduced against the walls of the corridors, staircases, and the principal rooms.

The clock tower in the centre of the Albert-square front will be 235 ft. high to the gilded globe at its summit, and 155 ft. to the illuminated clock dial, which is shown, 15 ft. wide.

At the other end of the building there is a secondary tower, and there is a staircase tower in the Princess-street front, so as to give variety of sky-line.

With regard to cost, the building is designed not to exceed the 250,000*l.* mentioned as the sum the Corporation are prepared to spend.

The building contains, above the ground-floor, exclusive of towers and chimneys, 3,956,815 cubic feet; and below the ground-floor line, 956,518 cubic feet.

MANCHESTER NEW TOWN HALL: SELECTED DESIGN.—MR. ALFRED WATERHOUSE, ARCHITECT.

INSTITUTE OF PAINTERS IN WATER-COLOURS.

The thirty-fourth exhibition by this society, now open, consists of 316 pictures. The society have strengthened their ranks by the election of a certain number of "honorary members," four of whom, Mlle. Rosa Bonheur, M. Louis Gallait, Mr. F. Goodall, R.A., and Mr. Millais, R.A., have sent works. Mr. Goodall's "The Arab Messenger" (30), and "Rachel" (205), are important contributions. Mr. E. H. Corbould has a powerful piece of colour, "Salome Dancing before Herod" (53), in which all the light is brought to bear on the figure of Salome. The action depicted is so momentary that the wreath thrown to the dancer has not yet fallen, but rests partly in air, a condition that fatigues. Mr. Louis Haghe has several drawings, of which we prefer No. 62, "A Tribunal of the Holy Inquisition in the Low Countries." Two unpleasant-looking familiars are taking a child to the torture, apparently with a view to work on the parents, who are also present. The general result is less impressive than might be desired. Mr. H. Tidey maintains his position with "Jennie Morrison" (displaying much feeling), and 225, "The Woman of Samaria." Mr. C. Green's picture, "The First Bouquet" (36), will hold the observant visitor some time. It represents "Behind the Scenes," during the performance of a pantomime; a little girl, apparently the clown's daughter, has come off with a bouquet. Various characters are introduced, an ineane dandy talking to one of the ballet-girls, and a poor, snarly old man, who holds under his arm the jolly rubicund mask he has worn before the public, not less truthful than many a face of flesh. "Seven A.M." (76), G. G. Kilburne; "Lady and Child" (130), E. H. Webber; "A Gipsy Forge at Seville" (163), Mrs. E. Murray; "Happy Hours" (196), Guido Bach; "Bombay Fruit Sellers" (242), Henry Warren; are amongst the other figure subjects that will obtain attention. "The Children of the Forest" (244) is the largest and most important work sent by Mr. Edmund G. Warren, and is a fine specimen of his manner. A smaller work of his, however, "An English Cornfield" (131), in the back room, gives us even more pleasure. "Mont St. Michel" (20), John Mogford, is an excellent seascape. At sight of "Crossing the Channel" (65), we notice an involuntary "Good Lord, deliver us!" If Mr. W. Bennett got his materials on the spot, he must needs be a good sailor and a brave man. 49, by George Shalders:—

"Then homeward through the twilight shadows stray,
Sauntering and slow;"

"Watford, Herts" (277), Mrs. W. Oliver, and some landscapes by Mr. Fahey, Mr. Chas. Vacher (especially the Palace of Rameses III., with the ruins of Luxor in the distance), W. W. Deane, H. G. Hine, R. Beavis, Reed, John Chase, B. R. Green, who continues to increase his collection of architectural subjects, Whynper, Telbin, and others, ought not to escape praise. Mr. Carl Werner's interiors include figure subjects, and have singular merit. "Hareth Ben Herraddin the Notary's House in Cairo" (137), and "The Mufti of the Hafenites at Damascus, sitting near the prayer niche in the Great Mosque" (218), have all the minute fidelity of photographs with breadth and colour superadded.

The sales, we hear, on the private view day, were above the average: so is the collection.

IRRIGATION IN INDIA AND SPAIN.

INSTITUTE OF CIVIL ENGINEERS.

On April 21st, the first paper read was "On Irrigation in India," by Mr. Allan Wilson. The value of artificial means of irrigation, for increasing the fertility of the soil, was recognized in India at an early date. In the Punjab, canals for this purpose, as well as for navigation, were constructed as far back as the middle of the fourteenth century. But it was in the southern parts of India, where the rainfall was more precarious, and the river supplies were less easily available, that the most extensive works were to be found. It had been estimated that, prior to the establishment of British rule, there were, in fourteen of the principal irrigated districts of the Madras Presidency, upwards of 43,000 tanks and channels in repair, besides about 10,000 out of repair, having, probably, 30,000 miles of embankments, and 800,000 separate masonry works. Some of these tanks and

reservoirs were on an immense scale, for irrigating many thousand acres, while there were smaller tanks, wells, and springs which watered only a few acres. It was remarkable that the Government should have allowed so many fine works gradually to fall into decay, without replacing them by others; as great natural facilities existed for storing water, and for forming canals to lead it on to the land. The irrigation works on the Godavary and Krishna rivers, in the northern Circars, and on the Coleroon, in Tanjore, had only recently been completed; but many large rivers were still allowed to flow into the ocean, almost unused for agricultural purposes.

With regard to the most general and least expensive mode of irrigation by means of artificial reservoirs, and to the methods adopted in forming such reservoirs, it was stated that in selecting a site it was essential to ascertain in the first place that the foundation was suitable; the next point to be determined was the extent of land to be irrigated, and the quantity of water necessary for such irrigation. The area of the drainage or gathering grounds could be estimated from the trigonometrical survey maps of India, and the quantity of water that would pass into the tank during floods should be calculated according to the known rainfall, due allowance being made for absorption and evaporation. With these data, the dimensions of the different works could be fixed. It should, however, be borne in mind, that depth of water was of greater importance than a large surface area, as the evaporation would be less in the former case. An examination should also be made of the valleys in the vicinity of the proposed reservoir, with a view to ascertain whether the surplus water flowing through the tank during floods could not be carried across intervening ridges, and be stored in natural basins at a small outlay, so as to fill a chain of tanks. It was explained that a tank was simply a reservoir formed by throwing an embankment, or bund, as it was called in India, across a valley to dam up the drainage. The most simple description of bund was constructed entirely of earth, which was generally dug from the bed of the intended reservoir. The breadth at the top was usually about 12 ft. The inner slope was 3 to 1, and this was faced with a pitching of loose stone, while the slope of the land side varied from 2 to 1 to 1 to 1. Puddle was seldom, if ever, used; indeed it was not required, as, owing to the lodgment of silt, a tank would puddle itself as soon as it had been once filled. In illustration of this fact it was mentioned, that Major-general Sir Arthur Cotton had stated that in a channel cut through loose sand, within a yard of the water's edge to a depth of 5 ft., not the least moisture was found in the excavation; the lining of silt having rendered it completely watertight. In addition to this embankment, some of the large Hindoo works had a massive retaining wall of masonry in front. Many of these walls were built of dressed stone, close-jointed, backed with rubble and a rough description of concrete; and flights of steps of cut stone were constructed down to the edge of the water.

To obviate the danger of an excessive influx of water during floods, most tanks were provided at one end, and not infrequently at both ends, of the embankment, with a waste weir (known in India as a calingulah), to allow the surplus water to escape after the tank had been filled. In constructing a tank, the discharge capacity of the calingulah was an essential feature. It was a safe rule to allow one-fourth more than the dimensions obtained by calculation, so that the water might have a free passage in the event of an excessive flood, as otherwise the earthwork might be entirely destroyed. The author had found that many of the tanks which were now useless had been breached from no other apparent cause than the want of sufficient outlet to carry off the surplus water during floods.

With a view of showing how favourable some parts of India were for forming reservoirs of large capacity, attention was directed to a design for a large artificial lake, which it was proposed to construct by damming up the gorge of a valley. This reservoir would be capable of storing sufficient water to irrigate 200,000 acres of land,—an area equal to the county of Buckingham, allowing the usual average of 500 acres to the square mile as being under cultivation. Taking 170,000 acres as the extent of land to be irrigated for a single crop, this would require provision to be made for the discharge of 170,000

cubic yards of water per hour at each end of the tank; and discussion was invited as to the best description of sluice for discharging such a vast volume of water.

A paper was read "On Irrigation in Spain, chiefly in reference to the Construction of the Henares and the Esla Canals in that Country," by Mr. G. Higgin.

It was stated that, of all the countries in the world, there was perhaps none that so much required irrigation as Spain, nor one which so gratefully repaid the labour expended upon it, by rich and valuable results. The climate of the south and east of Spain was suitable for the production of crops of almost all kinds. Productions of the torrid and temperate zones here grow together. In the gardens of Murcia and Valencia might be seen wheat, barley, corn, maize, the orange, the lemon, the date palm, the olive, the citron, the peach, the pear, the apple, rice, pepper. In Malaga and Seville, in addition to these were the sugar-cane, the cotton-plant, the prickly pear, and, in sheltered spots, the plantain, which was seldom found out of the tropics. The soil of most of the river plains was a rich alluvial deposit, from 3 ft. to 10 ft. in depth. Nothing was wanting but water; and this might frequently be seen a few yards off running to the sea, useless and unproductive. A few charts of comparative rainfall and temperature had been prepared, which showed that, with the exception of Oran, Spain was by far the driest country.

The earliest, and, indeed, almost all the irrigation works in Spain, were constructed about A.D. 800 or A.D. 900, when that country was under the dominion of the Moors. Perhaps the system of irrigation and the whole administration of the waters in Valencia and Murcia were as perfect as well could be, and the results were very surprising. It was not possible, however, within the limits of this paper, to give more than a cursory notice of these works; but such data were collected as would assist in the description of the new canals now in course of construction by the Iberian Irrigation Company. The areas of the several large irrigated districts in Spain were then detailed, amounting together to 680 square miles. According to the published Government returns the total amount of irrigated ground in Spain was 4,439 square miles, so that it would seem that there was an area of 3,759 square miles irrigated from water-wheels, small canals, tanks, &c.,—a quantity which was believed to be excessive. Admitting, however, that the returns were correct, then only 44 per cent. of the whole cultivated land was irrigated. While the rate of population in all Spain was only eighty-one to the square mile, in the irrigated garden of Murcia there were 1,681 inhabitants to the square mile, and in Oriuela 767 inhabitants per square mile. The effect of irrigation was to raise the value of land ten, fifteen, or twenty times. Several illustrations of this were cited, and it was stated that, as a rule, all over Spain, good land in the valleys when unirrigated might be bought at an average price of from 6*l.* to 10*l.* per acre, while irrigated ground fetched from 80*l.* to 120*l.* per acre. In proportion to the value of the ground was the value of the water. Colonel Baird Smith gave the value of a cubic foot of water per second in Piedmont at 16*l.* per annum, and in Lombardy at about 15*l.* per annum. In most of the old systems of Spanish irrigation the water was attached to the land, and was sold with it, and the value of the water could not, therefore, be ascertained. But, perhaps, the fair average value of a cubic foot of water per second in Spain might be taken to be that fixed by the Government for the Henares Canal, viz., 375*l.* per annum, which was not considered a high price.

The projects for irrigating the Henares and the Esla valleys were of very old date; but it was only during 1859 that the concessions were granted, and in 1863 that a company was formed in London to carry out the works. The river Henares rose amongst the mountains of the Somosierra; its course was extremely steep, and very rapid; the total fall of the river, from the weir of the new canal to Alcalá, a distance of thirty-six miles, being 407 ft., giving a mean fall of 11.3 ft. per mile. The total length of the new canal was twenty-eight miles. It received its water from the river at a point sixteen miles above Gnadálajara, just below the junction of the Sorbe and Henares, and ended at Alcalá. The area of ground capable of irrigation in this valley, after deducting that due to roads, streams, towns, &c., was 27,170 acres. For this purpose the volume of water conceded by the Govern-

ment was 175 cubic feet per second for the nine months from October to June inclusive, and 105 cubic feet per second for the remaining three months. From accurate measurements made near the new weir since the commencement of the works, it appeared that during the months of July, August, and September, the average quantity of water carried by the weir was 210 cubic feet per second, the lowest point which it had touched being 140 cubic feet per second. During the remainder of the year it carried an average of 300 or 400 cubic feet per second; but it was liable to enormous floods, and some came during the progress of the works, which were estimated to amount to 8,000 cubic feet per second. The weir, it was calculated, would discharge 20,000 cubic feet per second.

The most difficult portion of the works was comprised in the first division—involving a rock cutting, 16 ft. in depth, immediately after leaving the river; then a tunnel 3,171 yards in length through a high limestone cliff, followed by a deep cutting in gravel. At the ninth kilometre the canal crossed the Madrid and Saragossa Railway; and at the tenth kilometre, a wide torrent bed. These were the ruling points in this section, and it was with reference to them that the actual height of the new weir was fixed. At the site chosen for the weir, the bed of the river was composed of compact clay rock, very impermeable, mixed with strata of excessively hard conglomerate. The front wall was built of rubble in hydraulic mortar, the foundation being hatched into the rock. The main body of the weir was of hydraulic concrete; but in order to guard against filtration, a continuous line of cut stone was let into the rock in the centre of the concrete, all the stones being bedded in pure cement. The apron was entirely of cut stone, and from the top of the rubble wall to the crest, the weir was also of cut stone. The water for the canal was drawn off by five sluices, set in masonry arches, built of large blocks of rock-faced ashlar. At the entrance of the canal three sluices were fixed, for the purpose of scouring out any deposits which might accumulate in front of the gates. Immediately inside the head sluices, and forming a portion of the head works, there was an overflow weir, to provide for the discharge of any water which a sudden flood might admit into the canal during the absence of the guard. The weir was 130 yards long between the abutments, and its total cost, including all the head works and the waste weir, had been 17,343l., or 2l. 10s. per cubic yard, as the mean price of the total cubical contents. Details were given of the prices paid for different classes of work, and of the materials employed. One flood, which came down when the weir was unfinished, tried it severely. The water rose 4 ft. over the crest of the finished portion, completely filling up the gap, and pouring with great force on the exposed concrete bearing of the unfinished end. This flood was estimated to have a volume of more than 9,000 cubic feet per second, yet not a single stone was displaced.

The Esla Canal, as regarded ease of construction, was perhaps one of the best in Spain. The whole estimated cost of the works, including a weir 191 yards long, was a little under 100,000l., and for this amount 32,140 acres would be perfectly irrigated at a cost of 3l. 2s. per acre, while the cost per acre of the Henares Canal was 7l. 7s. The land in the Esla Valley was exceptionally rich; it was very thickly populated, and the only objection that could be made to it was its distance from any seaport.

One of the most interesting questions in the construction of an irrigation canal was the acreage which could be irrigated with a certain disposable quantity of water. Opinions varied very much upon this point. The amount supplied in different districts was given, and it was stated that in Spain the usual dotation for rice-crops was considered to be 24 litres per second per hectare. It had been found, by M. Ribera, from a series of experiments made near Madrid, that the quantity of water consumed in the irrigation of a nursery garden was 0.35 litre per second per hectare, and for a market garden 0.47 litre per second; in both cases the water being supplied without stint. The author had found, by experiment based on the quantity of water actually employed by cultivators also near Madrid, that 1/2 litre per second would irrigate one hectare every twelve days. This, it was thought, was quite sufficient for the cultivation of almost any crop except rice; and taking into account the fact that, in a large valley, such as

the Henares, there must always be a great variety of crops, many of which would only require irrigation every twenty or thirty days, it was evident that half a litre per second was a good dotation for a canal. This, in English measure, amounted to 1 cubic foot per second for every 140 acres. The quantity allowed in India varied, it was believed, from 120 to 200 acres per cubic foot per second. The canon fixed by Government for the Henares Canal was equivalent to 3s. 9d. per irrigation of 450 cubic metres, and for the Esla Canal, 2s. 9d. for the same quantity; the lower price in the latter case being due to the less expensive character of the works. Some particulars of the price of water in Spain were then furnished.

ON THE WATER-SUPPLY OF LONDON.

PROFESSOR FRANKLAND, F.R.S., has been lecturing at the Royal Institution "On the Water Supply of London."

The Professor said that out of every thousand people upon this globe at least three live in London, which fact alone shows the importance of the subject of the water supply of the English metropolis. The water at present supplied to London, he continued, is greatly contaminated with sewage, and it is of hard quality, the first of these characteristics being bad for health and the second bad for washing. A year ago he had brought under the notice of the Royal Institution five or six schemes which had been set afloat for supplying London with better water, and since that date the quality of the water from two of the proposed sources, namely, that of the sources of the Severn in the neighbourhoods of Pimlico and Cader Idris, and that of the Cumberland lakes, had been tested by Dr. Odling and himself. The results of those tests he intended then to make known; also two curious facts discovered in the course of the analyses, one revealing the peculiar effect of the detritus from lead mines upon water, and the other the conditions which determine the action or non-action of water upon lead. The samples of water from the sources of the Severn were collected at Cader Idris and Pimlico. The projectors of both schemes propose the construction of an aqueduct to carry the water. The one from Cader Idris would be the shortest, but the other would supply many large towns on its way to London. These schemes are not intended to endanger the present large water companies, arrangements to buy them up being included in the estimates; in short, the only effect upon them would be to abolish a certain number of hoards of directors. Both plans are very costly. The Welsh scheme is estimated to cost 10,850,000l., and the Cumberland scheme, 13,500,000l. These enormous sums, however, need not trouble the ratepayers, the only question for them being how much they will have to pay for the water when one of the plans is carried out. From the calculations of the engineers it appears that after constructing the works and compensating the companies, London will be supplied at a less cost than at present. Now we pay 1s. 5d. in the pound. On the completion of the Welsh scheme it is estimated that the payments will be 10d. in the pound, supplemented by a public rate of 2d. in the pound. The payment for Cumberland water would be 1s. 1d. in the pound. Of course he could not speak as to the entire accuracy of the foregoing estimates, but the figures given show that the enormous capital required need not stagger the Londoners or prevent them from taking the schemes into serious consideration. Where the saving is effected is evident when it is considered that every gallon of water now used in London has first to be pumped up by magnificent steam machinery to a height of from 150 ft. to 200 ft., and even then the supply is intermittent. In the Welsh and Cumberland schemes gravitation will do the work of steam. Why should water be pumped up by these fine engines when the sun is willing to do all the work for us gratis? The sun flings the water up to the tops of our mountains daily, and we in our imbecility let it fall, and go through the work of raising it again by steam. Coal would be saved by economising the power of the sun as proposed, and this is worth consideration when the exhaustion of our mine is a matter for serious thought, even though the saving thus effected would very slightly alter the figures given by Mr. Jevons.

The quality of the proposed waters is also a subject of interest, and in this respect, as shown

by tables exhibited by the lecturer, they are much better than the water now supplied to London. The present water supply, he observed, is largely contaminated with sewage, and the fact that this is somewhat oxidised is no guarantee that its noxious properties as regards health are removed. Some of the companies, especially those on the south side of the Thames, supply badly filtered water, and the quality of the water supplied to London is worse than that supplied to any other town whose water he had tested. The specimen of muddy water supplied to Lambeth, which he now placed on the table before them, would show what kind of water could filter through an Act of Parliament. The Lambeth, Vauxhall, and Chelsea Companies had long been supplying badly-filtered water, much worse than that of the New River Company, which delivers the best in London.

Again, the organic matter in water may be of animal or vegetable origin, and may be judged of to some extent by the proportions of carbon and nitrogen it contains. Nitrogen comes principally from vegetables, and on examination of the tables it would be seen that there is in this respect a vast difference between the Welsh and Cumberland, as compared with the London waters, for the organic matter in the last comes principally from animals.

In the course of the analyses a very curious effect of the detritus of lead mines upon water had been discovered. Water collected near these mines contained very little nitrogen or organic matter, and though full of mineral matter is nearly colourless. The fact is that the finely-divided quartz from the mines has the power of destroying organic matter nearly to the same extent as animal charcoal. It was likewise pointed out that lead would not contaminate the Welsh or Cumberland waters in the supply-pipes. Pure water acts violently upon lead, but it had been discovered in the course of the recent investigations that the presence of a very minute proportion of phosphoric acid in water entirely prevents its action upon lead.

Two of the tables referred to we append.

THE FOOD RESOURCES OF THE PEOPLE.

Some interesting information in regard to the food resources of the United Kingdom was given in a paper recently read by Mr. Caird before the Statistical Society, and since reprinted as a pamphlet. The yield of wheat in England, he had estimated eighteen years ago at 264 bushels per statute acre, and he believes from careful inquiries and observations it would not be safe to take credit now for a greater increase than 1½ bushel; this will bring the present rate of yield up to 28 bushels. The domestic demand for bread-corn in 1863 was satisfied by an expenditure of 40,000,000*l.*, about one-seventh of this sum, 6,000,000*l.*, being paid for foreign grain. Last year, according to Mr. Caird, the necessary supply cost 70,000,000*l.*, and nearly half—i. e., 33,500,000*l.*—was spent for imports. The cost in 1867, as compared with 1863, was therefore raised 30,000,000*l.* against the consumer, but nearly the whole increased payment went out of the country, since we took in value 27,400,000*l.* worth of foreign wheat beyond the imports of the earlier year.

Good and bad harvest years run in cycles of varying length: 1866 and 1867 were both "bad," the former two bushels and the latter six bushels under the average.

For our requirements, till the harvest of 1868 is garnered, Mr. Caird computes that we must depend upon the foreign supply of wheat to the extent of 9,600,000 quarters. A table prepared by Mr. Caird exhibits the results of some rather elaborate calculations to ascertain the average value of the principal agricultural products consumed as food in the United Kingdom.

	Home Production.	Foreign Supply.
Corn	484,769,000	£25,000,000
Beef and Mutton	475,000,000	6,500,000
Butter and Cheese	31,100,000	5,400,000
Potatoes	18,000,000	200,000
Total	£180,000,000	£10,100,000

Another table compares the value of British with Irish agricultural produce. On the aggregate value, for 100*l.* worth raised in Great Britain 26*l.* was produced in Ireland, the Irish percentage for corn being 14; for cattle, 27; for potatoes, 66; and for flax, 100 (since the growth of this fibre is restricted to the sister Isle), on the respective British values.

An interesting experiment in meat preservation, indicating the possibility of utilising for our own benefit the enormous supplies of animal food in far off countries, has just been completed in America. On March 2nd, a dinner was given at Everett House, New York, for the purpose of eating mutton which was furnished by the carcasses of sheep killed and subsequently preserved in England one, two, three, and four months previously by Professor Gamgee, by means chiefly of sulphurous acid. The *Tribune*, speaking of the dinner, remarks that the "meat dishes were pronounced to be excellent, and even far superior to the mutton usually eaten on this side of the Atlantic." Judge Paschal, of Texas, in the course of the evening, remarked that he had often, encountering the great herds of beef which roam over the 270,000 square miles of his own state, asked Bulwer's question, "What will we do with it?" He thought the interrogation answered. Mr. Richardson detailed numerous ways in which he had tested the character of the preserved meat, and gave it as his opinion that the best beef "would soon be sold in New York for four cents a pound." [Mutton, by the way, was sold not long ago in Melbourne, it is said, at 1*d.* a pound.] The mode employed by Professor Gamgee, in the preservative process, and in which the whole body of the animal is kept entire, is as follows:—

"The beast is made to breathe carbonic oxide gas, by which it is suffocated. It is then bled, killed, and dressed as usual. The carcass is now placed in an air-tight receiver, from which the air is exhausted. The vacuum is filled up by carbonic oxide gas, and a communication is opened between the chamber in which the meat is placed and another containing charcoal charged with sulphurous acid. By this means the meat is impregnated by the gas in such a manner that it may be hung up, and will remain unchanged for, it is said, months."

One way of turning large quantities of foreign or colonial beef and mutton into good wholesome and tasty food for consumption in the country, would be to convert it into the well known and esteemed form of spiced beef and mutton, sometimes, though not quite correctly, called beef and mutton ham.

In a report just published on the subject, Mr. F. T. Buckland states that the salmon fisheries of England and Wales are on the increase, and a hope is held out that by-and-by this descrip-

tion of food will be placed within the reach of those who have hitherto been unable, through its high price, to obtain it. M. Agassiz, in a recent lecture on artificial fish culture, declared, contrary to the accepted opinion, that of all animal substances fish is the best adapted for food for those engaged in mental labour, and is the most nutritious in repairing the wear and tear of the human brain. This is no doubt on account of fish containing much phosphorus. The shining of fish in the dark while decomposing is an ocular manifestation of its richness in phosphorescent material; and, on the other hand, the human brain requires more phosphorus in its composition than any other organ.

The Paris correspondent of the *Post* remarks that the high price of food and the general stagnation of commerce are continually bringing from various parts of Europe distressing accounts of the condition of the working classes. The privations to which the working classes in Italy are exposed are very severe, especially at Turin, where the winters are extremely cold. If provisions are cheaper in Turin than in the large towns of France wages are not so high. For instance, a mason or a carpenter is paid scarcely 2 fr. a day. Most of the carriers receive only 1 fr. 60 c. for a day's work; and the men employed in the manufacture of arms and in the arsenal have little more. The most essential commodities at Turin are very dear; bread is at a higher price than in Paris; salt in Italy is three times dearer than in the French capital. Wine is cheaper; but the workmen scarcely ever drink it except on Sundays. The labouring population are ill-provided with domestic comforts, two-thirds of them sleeping usually, not upon good mattresses, but on maize straw. The misery of these poor people, says a letter from Turin, is augmented by the indolence and idleness of the women. In this important particular the difference between Turin and Paris is very marked; for, in the latter, a variety of businesses give employment to the women. An idea may be formed of the trifling earnings of the Turin workpeople, from the fact that there are very many instances of a family of four persons living upon 1 fr. 60 c. a day (1*s.* 4*d.*).

AGED AND INFIRM WARDS FOR MARYLEBONE.

SOME new wards have been erected for the purpose of relieving the over-crowded state of the house, and providing more suitable accommodation for that class of persons to whom only a workhouse should he made attractive. The Guardians of St. Marylebone are anxious that their aged poor should be made as comfortable as the rules of a workhouse will permit.

The building is erected at the south-east angle of the workhouse ground, and occupies the site of the old bakehouse and laundry.

The wards, six in number, are each 40 ft. wide, 60 ft. long, 13 ft. high, and give 780 cubic feet of air space to each occupant. The beds are ranged down either side of the room, and a double row of beds occupies the centre of the room, which is divided longitudinally by a partition 5 ft. 6 in. high. The western ends of the rooms are formed as large double hay windows, and constitute the day rooms. The skirting at the back of the beds forms a box 9 in. square, with a perforated zinc front; below these boxes are channels containing hot-water pipes; at the ends of these channels, and in the front and back walls, are large openings through which, by raising a damper, is admitted the external air. By this means the fresh air will be first warmed by passing over the hot-water pipes, and then rising upwards he emitted through the perforated front of the skirting boxes into the wards immediately under the beds. The foul air is carried off through wide channels in the ceilings, which communicate with large flues running up the side walls, and terminating just above the level of the eaves of the roof; each opening into a flue is provided with a door that is under the control of the nurses only.

The upper wards are somewhat differently constructed from those of the lower wards, inasmuch as the ceilings follow the line of the sloping sides of the roof, which are supported at intervals on semi-elliptic cast-iron ribs. The emission of foul air in these wards is provided for by a channel in the apex of the ceiling, running the whole length of the room, and has zinc flues at intervals open to the air.

The walls are plastered throughout, the lower portion being finished with Portland cement; they are coloured with varied and pleasing tints, which give them an appearance as cheerful and homely as they are unlike the bare, lime-washed, vault-like brickwork of an ordinary workhouse ward. The basement of the building contains store-rooms, heating-furnaces, coal stores, and other offices.

The total cost of the building as finished for occupation, including every description of fitting, gas-lighting, architect's commission, and all other contingencies, was about 6,400*l.*; and this being for the accommodation of 240 inmates, is at the rate of 27*l.* per bed.

The architect is Mr. H. Saxon Snell; Messrs. Manley & Rogers are the builders; Messrs. Potter & Sons executed the heating, ventilating, and sanitary works; and Messrs. Abercrombie the gas-lighting apparatus.

MURAL PICTURES FOR THE HOUSES OF PARLIAMENT.

MR. E. M. WARD, R.A., has completed three more of the Illustrations of English History confided to him, and has lately shown them to some of his friends in the trumpery shed which an appreciative Government provides, adjoining Victoria Tower, for distinguished artists. The subjects are,—*"The Acquittal of the Seven Bishops," "General Monk Writing to the Parliament,"* and *"William and Mary receiving the Lords and Commons in the Banqueting House."* They are painted with all the careful attention to truth and research as to detail that distinguish Mr. Ward's works. The heads are portraits, and King William look somewhat insignificant, and Monk short-necked and gouty, it is because these were characteristics of the men. We need scarcely say that they are all works of high character.

They may be described at present as simply water-colour pictures on plaster. The question how shall they be made permanent remains to be settled. The artist, we understand, would not object to fixing them as they are and protecting them with a glass, but this is scarcely the right solution of the question. It might, however, be adopted temporarily, pending further inquiry and experiments.

KEBLE COLLEGE, OXFORD.

THE foundation-stone of a new college, dedicated to the memory of the Rev. John Keble, was laid, in Oxford, by the Archbishop of Canterbury, on the 25th ult. The site is almost facing the new museum, and lies between the new park laid out by the university authorities and St. Giles's Church, where hitherto there have been only a few tumble-down houses and half-wasted gardens. Here will be built rooms for 100 students, in wings forming three sides of a quadrangle. The material will be red, white, and grey brick, with stone dressings, and the style will be Early Decorated. Mr. Butterfield is the architect. When additional funds are obtained, the plan will be completed by the erection of a chapel and hall, an entrance gateway, and some additional rooms.

The whole of the spectators afterwards went to the Sheldonian Theatre, which was soon crammed, and various addresses were made. About 35,000*l.* have been subscribed to carry out the idea.

NEW COTTAGE HOSPITALS.

THE memorial stone of one has just been laid by the Countess of Bradford at Walsall. The site consists of about one acre and three-quarters, at the junction of the Wednesbury-road, Bradford-street, and Dudley-street, above which it rises to a considerable height. The soil is sand and gravel. The building is the premises called The Mount, formerly used as a school, and in making the alteration advantage has been taken to utilise and convert every part that could actually be brought into use, with a view to the strictest economy. The main block of buildings now form the administration department. The school room and the dormitory have been converted into two spacious wards, and the stable buildings have been converted for the washhouse and laundry. The new buildings comprise the

entrance of the kitchen and culinary department, in-patients' department, and out-patients' department. The general arrangement of the building externally is not very pleasing in effect; the architect evidently having brought his judgment to bear upon utility and convenience for the internal arrangement and management, guided by the strictest economy, in which the comfort of the patients, however, has been the prevailing element. The two new wards are designed for eight beds each, giving 1,120 cubic feet to each patient; at the end of each ward are semi-detached buildings forming the bath-rooms and lavatories, the closets and urinals; the architect carrying out the pavilion principle. On the upper floor is a nurse's room, having a command of the upper wards. There are four wards—two on the ground floor and two on the upper floor, the whole arranged to accommodate thirty patients. On the upper floor there is an operating room. The buildings have been carried out from designs, and under the superintendence, of Mr. G. B. Nichols, of West Bromwich and London, architect; Mr. Adkins, of Walsall, being the builder.

The committee recently appointed under the presidency of the Hon. and Rev. K. H. Digby, of Titchshall, have determined to make such preparations as will enable a Cottage Hospital to be opened at Litcham on the 1st of July.

WEST LONDON SCHOOL OF ART.

The committee of the West London School of Art, Great Portland-street, have issued a statement of the extent and success of the school's work, and its financial position, with the view of obtaining subscriptions to pay off existing liabilities to the amount of 400l. One of the strong grounds on which they appeal to the public is that the establishment is essentially an artisan school, and, though the latest established of the ten metropolitan schools of art, this school is teaching more than a fourth of the entire number of artisans (1,750) taught in the whole of the ten London schools; and an analysis of the occupations of those attending the school during 1867 suggests in a general way the advantage gradually being derived by a great number of local industries. The Examiners' Report on Schools of Art for 1867 shows that, among the ten London schools; and an analysis of the occupations of those attending the school during 1867 suggests in a general way the advantage gradually being derived by a great number of local industries. The Examiners' Report on Schools of Art for 1867 shows that, among the 100 existing schools in the kingdom, only five schools had a greater number of students under instruction; only five had a greater number of students examined; and only three sent up sets of works for examination from a greater number of students during the year.

This school obtained the greatest number of prizes taken by any school in 1866, the National Art Training School at South Kensington alone excepted. The Examiners' Report for 1867 also shows that only two schools passed a greater number of students in the personal examination; and only two schools obtained a greater number of prizes upon the sets of works sent up for examination during that year.

THE NUT FOR PROFESSIONS TO CRACK.

II. PAYMENT OF ENGINEERS.

SIR,—Though I have long ago stated in the *Builder*, more than once or twice, my solution of the standing "nut" that "A Country Gentleman" has once more brought before you as regards architects—(I did so last in 1865, October 25th, p. 829),—and have never met with or elicited any objection to it, I cannot learn of any engineer having applied similar principles to the regulation of his claims, and will therefore ask for a column to suggest what appears to me the parallel method for most of the work now special to that profession.

In a healthy state of morals and education these would not be two professions. The engineer's, which is the mother profession, and bears the older, indeed the sole indigenous English name—for "Elias the Engineer" was the name and style of the artist of this empire's grandest work of art, Salisbury Cathedral—this original profession would have continued in such culture as never to require supplementing with the offshoot, or rival school of pedantic tatomongers, begun by Inigo Jones, and dubbing themselves with the affected classic euphuism of "architect," which of course is only barbarised Greek for the native term "engineer." It is quite right, therefore, that these dilettanti should be con-

signed, as they are, to one part (and the smaller that part the better) of the practice of the engineer (or real *apixiretos* of the ancients); while this latter, of course, includes, and must always include, all the modern "architect's" province, and much besides.

As far, then, as the engineer does what is called a modern architect's work,—that is habitable buildings of any kind,—I assume his basis of charge to be the same as mine, the area of internal floor space. I have explained (if so simple a thing really needs explanation) why there must be no cubing, but only squaring of dimensions, and why they must be internal. Of course, too, the engineer can get, as I do, for all unnecessarily varied detail, its market value,—that is, if there are twenty features of the same position, dimensions, and use, I lay before my employer as many sketches for one as I think suitable, be they two or a hundred, with a price on each; and he pays without demur invariably my prices for such of them as he likes to have carried out, be they the twenty dearest or only the one cheapest. For the mere charge per square of floors I only hold myself strictly bound (though I should never, perhaps, do so little) to make the details all alike, even on different stories, which (though the most impudent thing a shameless percentage can possibly do) does not hinder the Record Office in Patterlane from being, *on the whole*, to my taste, the least offensive modern work I know in the whole Isle of Great-Britain.

As for different prices per floor-square, I really do not believe any single artist need have more than one. A lower price would, doubtless, be fair for warehouses, and perhaps the larger sort of workshops and mills. But in aught else there seems a kind of compensation between utilitarian design and artistic. To make an exterior plain and good may as often be harder as easier than to make it rich and good; and if a church needs more artistic study, height, proportion, and better construction than a house, so it does less division and contrived arrangement. The addition I once reckoned by the exposed girth of each story is really a needless refinement. Architect's work will be best done when paid *only* on the two bases above described.

But now, coming to the wider provinces of work rightly held peculiar to the engineer, we shall find by far the largest of them, indeed their vast majority at present, fall under the general head of *ways*, always the kind second only to shelters in importance. Under "ways" of course I mean to include ways for any and everything, trains, ships, barges, carriages, foot passengers, letter-bags, water, fire, gas, or electricity. Now, it is common to all such ways to unite two given termini, and to be at a more or less variable height, or depth above or below (or both above and below) the natural surface. Moreover, in the parts that are raised above that natural ground-line, certain areas of void require to be left for snarrows, culverts, &c. For each of these classes of ways, then, I would let the engineer's pay be composed of two parts; one based on the area of longitudinal section of the whole line of work, as included between the natural ground-line and the finished way,—the other similarly reckoned on the area of all snarrows openings. I would have no extra for snarrows over the sunk parts of the line, because their need and their dimensions are created by the engineer's own design, and the numbers of them to be expected being always practically uniform, they should be included in his general price as things of course. Moreover, observe that the area of longitudinal section of the whole line must always be reduced in the ratio that the direct distance of the termini bears to the line's length. This will not, as might at first appear, give the engineer much interest in taking you straight rather than roundabout, but rather make length of detour indifferent to him (which would otherwise be advantageous). For, suppose two points fifteen miles apart are, joined by one road of sixteen miles, and another of twenty miles. If, as is probable, their longitudinal section-areas were in about the same ratio, say 16,000,000 and 20,000,000 square feet, both being reduced by this rule to 15,000,000, would pay their engineers the very same fee.

You will observe that *width does not enter my equation*. I think it fair that a work of a given class and given longitudinal section should invariably pay its engineer the same fee, whether it be 10 ft. wide or 100 ft. Take a bridge, for instance, as the class of work to be charged on the highest scale (but all bridges, without exception, on the same scale). Had Westminster

Bridge been required only for a footway, or an aqueduct, on the other hand, of double its present width, I do not see, in either case, what part of the engineer's duty would have been *materially* lessened or increased. Hence I exclude *width* from the bases of the way-engineer's charge, as I do *height* from those of the shelter-engineer (or "architect").

Among those few engineering works that come not under the head of Ways, I think all docks ought to pay by a uniform scale on their cube water-space; but for reservoirs of water (or gas, &c.), as the merit and utility of the work is greater the less ground it occupies, the cube contents ought to be divided by the square root of the outside area occupied by the work and all its necessary adjuncts. You must not divide by the area, but only by its square root; otherwise a great and small reservoir, of the same average height, would pay the same, which is not intended.

I may beg space for a word or two on this "Nut," as regards some other trades and professions. EDWARD L. GARBETT.

CURE FOR A SMOKY CHIMNEY.

I OFTEN see in your journal remarks on what is called "the Smoky Chimney question," and complaints are constantly made against architects and builders for smoky rooms; therefore I suppose you will not object to make public a cheap, simple, and sure remedy for eight out of every ten bad chimneys, without the requirement of unsightly chimney-pots. I find from experience that, by the use of fine wire gauze, of from 36 to 40 wires to the inch, as a screen, blower, or guard, judiciously applied to register stoves, ranges, or stove doors, little if any smoke will come into a room. The atmospheric pressure prevents the smoke entering the room through the gauze; and if applied immediately to the front of the fire, more smoke will be consumed than by any other means. In that case the wire should be kept 2 in. from immediate contact with the hot fire.

Any respectable ironmonger will readily supply both cheap and ornamental screens of this kind, either as permanent or movable. I. O. U.

RECREATION AND WORK.

SIR,—I have but just now seen the letter in your impression of the 28th of March, commenting upon a remark made in my paper read before the Society of Arts on Technical Education. The writer takes exception to the passage in which I stated that I looked upon the pursuit of geology in my case as a recreation merely. He says he is of opinion that "it ought not to be looked upon as merely recreative; neither does it prove so." Our friend appears to have a great dread of recreation as others would have of work. Why, sir, work and recreation are relative terms, and if one can convert what another is right down hard work into recreation or the means of it, so much the better. It depends much upon circumstances, and upon the light in which it is viewed, together with its results, whether a pursuit is recreative or not. Work with me is not irksome. I stand to it and am dependent upon it, and my wages are equal to any in the same manufactory. I also find time to write for the press what brings handsome addition to my income; and, would your correspondent rather than from the profit derive therefrom. But with respect to geology, I regard my pursuits in that line as having been eminently *recreative*. Geology with me has converted this earth, which some sordid individuals persist in regarding as "a desert," and "a bowling wilderness" into a very paradise full of good and beautiful things, which it is source of great gratification to me to become familiar with. It brings me face to face with nature, takes me down into deep dingles, and up to the summit of great hills; and whilst it stores my mind, and supplies that food for which it craves, it has a *re-creative* effect upon an entire system, imparting vigour to the body and elasticity to the spirit.

But your correspondent, I have no doubt, will see that he has mistaken my meaning altogether, when he comes to look again at the passage he quotes and its connexion. My argument was that if a working man could gain the distinct

of being elected a Fellow of the Geological Society of England in consequence of studies in a science which had been pursued merely as a recreation, why should there not be some means whereby similar distinctions could be awarded "to men who devoted their energies to the attainment of excellence in their own particular business"? The passage occurs at the close of the discussion, in urging the necessity of district colleges, which should have the power of conferring such distinctions, and is as follows:

"If thought it would be well, if these district colleges should be established, that they had the power of conferring honorary distinctions upon such persons as showed themselves worthy of them in their particular calling. He had seen made a Fellow of the Geological Society in consequence of his studies in that science, which he looked upon merely as a recreation; and if some similar distinction were awarded to men who devoted their energies to the attainment of excellence in their particular business, it would be very likely to have a very beneficial effect, especially on the rising generation."

JOHN RANDALL, F.G.S.

TEMPLE BAR AND OLD ARCHWAYS.

HAVING long outlived its period, it is difficult to imagine wherefore this ancient gateway is suffered to obstruct the traffic of the most central and crowded City thoroughfare: there is barely room for two vehicles to pass together under the arch, and the footway on either side will only admit of two pedestrians abreast; whereas, by the removal of the crazy old structure, the roadway in this, the narrowest strait of the whole line, would freely admit three carriages, and the footway four persons on either side.

The line of Fleet-street westward from St. Dunstan's Church gradually narrows towards the Bar, as it does also from Clement's Dances eastward; so that, to make the width of roadway at all equable or adapted to the route of this great and leading thoroughfare, the whole line from Chancery-lane to the space cleared for the new Law Courts should be opened, and the frontages withdrawn at least 10 ft. in a graduated line.

There are impediments in the way, for one side of the arch is occupied as a barber's shop and cutting-room; and the other, together with the small chamber above the arch, has been the appanage of Child's Bank, time out of mind, probably for the amusement of children to see Lord Mayors' shows.

If there exists a corporate veneration for their ancient relique of the Bar, can they not find out a favorable location for it somewhere? But let them not reconstruct it over any great leading thoroughfare, where it must cause an arterial constriction, or an aneurism in the heart of commerce.

Another ancient gateway, possessing architectural pretensions of a higher order, which formerly opened its portals to royal processions, now seems to sink unheeded into the slime of the Thames; it is buried to the top of its pilasters in heaped rubbish, and must be taken down, but it must be reconstructed.

QUONDAM.

THE TENDERS FOR THE HORNCASTLE SEWERAGE.

See.—The list of tenders for the sewerage of Horn-castle given in the *Builder* for April 25th, is followed by some remarks conveying a false impression; and as my name is given in connection with the statements there made, it seems due to myself and the Board to set ourselves right with your readers.

Mr. Young did not put in an error, nor was he allowed to make any private proposal to the Board, nor did he ask to be allowed to do so; nor was he allowed to alter one figure in his tender as regarded the works for which the other parties tendered. Compared with the others, item by item, he was all along the lowest. What really occurred was this: the applications for copies of the specifications were so numerous that when Mr. Young applied the specification was out of print, and only the bill of quantities was sent to him. In the bill of quantities mentioned was made certain castings, which the specification showed the contractor was only to fix; but Mr. Y., not having the specification, included the cost price of the other castings. This cost price was not included in any other bids, and therefore was very properly struck out of Mr. Young's, to put him on a level with the rest; which being done, he was the lowest, and his tender was accepted.

I hope Mr. Frow was not one of those who assented to the erroneous statement, because he was in possession of the real facts of the case, as the following extracts from our minutes will show.

"Board Room, Horn-castle, 9th April, 1868. A letter from Mr. Frow was read, complaining of the non-acceptance of his tender, when the clerk was directed to reply that Mr. Frow was not allowed to lower any item for which Mr. Frow had tendered; and so far as they had tendered for the same works, Mr. Young was all along the lowest; and, moreover, the Board never bound themselves to accept the lowest or any tender."

W. H. MILNER.

MODELLING.

See.—Will some one inform me what is the material to model in which does not shrink or crack in drying?

I have modelled a good deal, as an amateur, in clay, and made my warts and pieces moulds; but this is too much trouble for the sake of one copy; and, besides, the modelling I now allude to is not suited to this method of casting, but must remain in the modelling material: I mean those pet animals from life, and figures elaborately under-cut and delicately light and gauzy in the drapery. I have seen many such objects from Italy, and I thought the material was an earth found there; but I have since been informed that it is a composition resembling modelling-clay made in England, though I have not yet been able to get any of it.

FUZZOLANA.

"THE IRON MOP."

See.—Will you kindly get an answer to a query arising out of the excellent letter which you lately inserted from the pen of a Canadian lady?

What is the "Iron Mop" that is to supersede the labours of our housemaids? Where can it be produced? and how does it perform its functions?

A well-cranked deck, with convenient scupper-holes, may indeed be scrubbed and sluiced at arm's length; but how can we remove dirt and superfluous water from an ordinary floor (without damage to ceiling beams), unless by the deprecated process of "going down upon our knees"?

A reply will greatly benefit many old housekeepers, besides a constant reader of the *Builder* and

Your humble servant,

DOLLY.

* * * The floors alluded to by our Canadian correspondent had evidently no ceilings beneath.

PROVINCIAL NEWS.

Stockport.—The workmen and others engaged in the erection of the bridge connecting St. Peter's Gate with the Market-place, to the number of about forty, have been entertained at supper, at the Egerton Arms, in celebration of the completion of the work. The chair was taken by Mr. James Whitaker, one of the assignees appointed by the corporation to carry out Mr. Pierce's contract; and the vice-chairs were occupied by Mr. George Roy (the other assignee), Mr. John Whitaker, jun., and Mr. Simpson, assistants to Mr. Brierley, C.E., by whom the plans were made, and who has personally superintended the work.

Kingston (Sussex).—It having been found by the guardians during the severest part of the winter that additional accommodation was necessary for inmates, the subject was discussed and a committee appointed to consider the question. The committee unanimously recommended the Board to increase the buildings of the house, so as to accommodate 200 additional inmates, and they approved of Mr. Luck's plans for the proposed alteration. The Board of Guardians, however, by a vote of eight to four, have decided that the alteration of the house, which was estimated to cost about 10,000*l.*, should be deferred at all events till the new infirmary is completed, as it was thought by some that the new infirmary would relieve the house of some cases, and so afford a certain amount of room.

Cambridge.—The market committee are considering the question of a new corn-exchange. The council had referred the matter to the committee, and a report has been drawn up strongly recommending the building of a new corn exchange. Three sites have been considered, but the most eligible one is said to be in Wheeler-street, upon property known as Parson's-court.

Rochdale.—At a meeting of the estate committee of the corporation, after a lengthened discussion, it has been decided to commence the proposed alterations and improvements in the Guildhall of this city forthwith, from the plans proposed by Mr. H. Andrews, the city surveyor. The alterations to be effected will include improvements in the portion of the Guildhall devoted to the magistrates, and a renovation of the interior of the old hall.

Worcester.—The three slaughter-houses ordered by the Town Council to be erected at the north-west end of the Cattle-market approach completion. They have been built according to the plans of Mr. Rowe, city architect. The houses are lofty and have ventilating cupolas. At the rear of each house are fasting pens, from which the beasts are brought for slaughter. There are in addition a boiling-house and other requisite offices for obtaining water, &c. The whole is well drained.

Wigan.—At the next quarter sessions of the peace for the county, the following resolution is to be moved.—"That a plot of land containing 340 square yards, or thereabouts, situated at Ince, in the division of Wigan, be taken on lease for the term of 999 years, at a yearly rent of

5*l.* 13*s.* 4*d.*, and that a police-station and strong rooms for the temporary confinement of prisoners be erected thereon; and that for this purpose a sum not exceeding 890*l.* be granted out of the police rates of the division of Wigan."

Stratford.—The chief stone of the new Town-hall has been laid. The building will be in brick, with stone facings, and will comprise extensive cellarage on the basement floor, and above this will be the board-room of the Board of Health, with clerks' rooms, and suitable offices; board-room for the meetings of the Board of Guardians, offices, &c.; and the plans also provide a justice-room for the magistrates of the division. The architects are Messrs. Angell & Giles. Mr. Thomas Ennor is the contractor, and the amount of the contract, exclusive of four or five hundred pounds for cellarage, which was forgotten at the outset, was 10,239*l.*

CHURCH-BUILDING NEWS.

Louth (Lincolnshire).—Leigh-on-ear Church has been re-opened. For some months past it has been undergoing restoration. In the nave, chancel, and aisles, nothing of the old church remains, except the stonework of the walls, arches, and windows. The woodwork of the roof is new. The old lead has been re-cast. New seats and flooring have taken the place of the old pews and decayed floor. There is a new organ (by Messrs. Foster & Andrews, Hull), new pulpit, lectern, and reading-desk. In the stonework of the nave arches and the windows the mouldings are of a simple character, and there is no carving in stone. The carved oak screen which formerly occupied the chancel arch has been restored and replaced there by Mr. J. L. Fytche. Two chapels are formed at the east end of each aisle by carved oak screens. The nave and aisles are filled with open seats of pine. The fittings of the chancel correspond with those of the nave as to design. The stonework of the exterior has been repaired, and where it had been previously repaired with brick the brickwork has been removed and stone inserted. The architects employed were Messrs. Rogers & Marsden; and the builder, was Mr. M. J. Thompson, Louth.

Wilcote.—The parish church has been re-opened for Divine service, after having been closed since last September, for the purpose of undergoing a restoration, under the superintendence of Mr. A. W. Blomfield, of London, architect. It was found that only the walls of the old church were in a condition to be left up, so that the restoration comprises, besides a new porch, new roofs, floors, doors, windows, and fittings. All the wood-work is oak. The roof of the nave has a deep cornice on the wall-plates, moulded principals and purlins, the circular ribs carved in the spandrels, and the space above the collar-beam filled in with cusped tracery. The roof is covered at the backs of the rafters with oak boarding. The chancel-roof is boarded, and divided into panels by moulded ribs, with carved bosses at the intersections. The seats in the nave have tracery in the panels of the bench ends, and the fronts of the book-boards. The pulpit and prayer-desk are moulded, and have open tracery work in front, with a considerable amount of carved work. The font is in stone, with oak top and ornamental iron-work. The altar is of oak, with carved panels in front, and the altar-rail is supported on pillars, carved and moulded. The floor (except under the seats, being there of wood) is laid with tiles and pieces of stone alternately, some of the tiles glazed and some plain. The masonry has all been restored, and a bell-turret added to the west gable,—the old turret having been gone for many years. The east window has been made somewhat larger, and filled in with stained glass, the subject being the parable of the "Good Seed," executed by Messrs. Heaton, Butler, & Bayne, of London, who also supplied the mosaic-work over the altar. The other windows are filled in with cathedral glass in small quarries, with a narrow ruby border, the two quatrefoils of the west windows being occupied with the arms of the Pickering family. This restoration has been carried out at the sole cost of Mr. Leonard Pickering, of Wilcote Grove. Mr. Joseph Castle, builder, of Oxford, executed the works, and the carving was done by Mr. Chapman.

Blackheath (Worcestershire).—The memorial stone of a new church at Blackheath, Rowley, has been laid by the Countess of Dudley. The

intended church has been designed by Mr. Hopkins, architect, to the Worcester Archdiocesan Church Building Society, and the building will be erected by Mr. Wilson, of Birmingham. The estimated cost is 6,400*l.*, of which 5,071*l.* (including 2,000*l.* from the Earl of Dudley and 2,000*l.* from "Delta") have been collected. The church will, when completed, accommodate 850 persons, and contain a nave, north and south aisles, vestry, organ-chamber, and children's chapel. The church is to be built of bricks. The nave is 80 ft. in length, 29 ft. wide, and 54 ft. high.

Liverpool.—The chief stone of St. Saviour's New Church, Breckfield-road North, Everton, has been laid. It will accommodate a congregation of 900; and the style of architecture is that of the end of the thirteenth century. According to the plans, it will consist of a nave with two aisles, and of a chancel with two chantries. The length of the nave and chancel will be 109 ft. The nave will have a clearstory, and its walls will reach to a height of 47 ft., the height to the ridge of the roof being about 70 ft. The church will have three entrances from Breckfield-road North,—one with the centre of the nave, and the other two by porches, one of the latter being intended to serve as a base for a tower and spire, which it is hoped will be raised at a future time. The roof will be an open one, and that portion over the aisle will be supported by cross arches of masonry, instead of by timber framings. The chancel-window will have five lights; it will contain 230 ft. of glass. At the opposite end of the building will be another large window, having four lights, with tracery in the head, and a rose-window over. The arches at the side of the nave will be of 21 ft. span, 17 ft. to the spring, and the height will be 27 ft. There will be three of those arches at each side, and the arrangement is such that the chancel and chantry arches will spring at the same level. The material to be used is principally the native red sandstone. The walls are already 5 ft. above the floor. Wrought stone is used throughout. In the chancel, and for the main part of the dressings, white Stonor stone is being used, and the pillars and other portions of the erection, which will have to support a heavy weight, will be of Cefn stone, with red Mansfield stone in the smaller shafts. The pavement will be of Staffordshire tiles, with stone borders, except in the chancel, where Minton's tiles will be used. The roofs will be covered with green slate, from Wales. The seats will be of pitch-pine, and there will be no gallery; but one-half of the fittings will be free. The entire cost of the building itself will be about 6,400*l.*, and the cost of the site is 1,600*l.*, of which 1,000*l.* have been contributed by Mr. F. A. Hamilton, and the remainder by the Church Extension Society, who have also given 3,000*l.* towards the building of the church. The architect is Mr. Gordon M. Hills, of London; the contractor, Mr. Tomkinson, of Liverpool; and the clerk of works, Mr. James Howea.

DISSENTING CHURCH-BUILDING NEWS.

Parkgate, near Rotherham.—A new chapel, erected by the members of the United Methodist Free Church, has been opened at Parkgate. The new building is of stone, in the Early English style of architecture, and surmounted by a tower and spire. In the basement below the chapel is a schoolroom. The total cost of the erection has been 2,600*l.* Messrs. Blackmoor & Mitchell-Withers, of Rotherham, have been the architects; and Messrs. Askew, Brothers, of Parkgate, the builders.

Birkenhead.—A new church, to be called "The Hamilton English Presbyterian Church," has just been commenced in Laird-street. It is intended to accommodate 620 persons. The contract is being carried out by Messrs. R. Anderson & Sons, of Liverpool, for the sum of 2,200*l.* Mr. James N. Crofts, of Liverpool, is the architect. The lecture-hall, which does not form part of the contract, will not be commenced at present. It will be placed at the back of the church.

Shipley.—A new Moravian chapel has recently been erected at Baildon. The style is Gothic, and in size the edifice is capable of accommodating between 600 or 700 people. All the fittings are to be free. The cost of the erection is 1,400*l.*, towards which about 1,000*l.* have been subscribed. Mr. Samuel Jackson, of Bradford, is the architect.

Chipping-Norton.—The new Wesleyan Chapel

has been opened. This chapel is situated in one of the principal thoroughfares of the town. It is built in the Italian style of architecture, from designs by Mr. W. Peachey, of Darlington, the builder being Mr. C. Young; it will accommodate upwards of 500 persons.

Kidderminster.—The new chapel which the Baptists have been erecting in a central part of the town has been opened. The building stands in Church-street. It has a Gothic front, and two flights of steps lead up from the entrance part to the doors giving access to the interior. The area of the chapel is 72 ft. by 40 ft., and it will seat about 600. Underneath the chapel are a large school-room and four class-rooms, and they will accommodate about 400 scholars. The work has been carried out by Messrs. Scholes & Warrington, from the designs of Mr. Bidlake, of Wolverhampton. The total cost, including site, will be about 2,400*l.*

Farsley.—The foundation-stone of a new Baptist chapel has been laid at Farsley. The edifice, which is to be built from the designs of Mr. John Simpson, of Leeds, will be 90 ft. by 45 ft., inside measurement, and 40 ft. from the floor to the crown of the segmental ceiling. The walls will be built of Horsforth stone, lined on the inside with brick. The style of architecture will be the Italian, with a bold stone cornice and rusticated quoins at the angles, and moulded dressings to the whole of the windows. The principal entrance will be a portico, with rectangular rusticated piers, surmounted by an entablature and ornamental vases. The edifice will seat 1,100 persons; and the total cost of it, including fencing, lighting, and warming, will be 3,500*l.*, towards which at least 2,000*l.* have been already obtained.

Bowdon.—The Congregational Church on Bowdon Downs has been re-opened for divine service. The nave or body of the building has been prolonged westward as far as the site would permit, and transepts have been added on both north and south sides. Each transept is divided from the body of the church by two arches supported by double columns. These columns are in two tiers, the lower portion connected together by curved capitals, carrying the principal support of galleries, the upper portion supporting the arches having similar capitals. There are galleries provided in each transept, the separate means of access to each being well arranged. There are also two new vestries. The style of architecture is the enlargement of the Gothic of the Early Perpendicular period, the old portion of the building being also Perpendicular, but of a debased character. The new west end and each of the transepts have large wheel-windows in the gables of different and original designs, and two windows of two-lights each under, the heads of the windows being filled with tracing of the Perpendicular type. The wheel-windows in the transepts lighting the galleries is the same. The gables are surmounted by crosses. There is additional accommodation provided for about 530 persons. The works have been carried out from the designs and under the superintendence of Mr. Ernest Bates, architect, Manchester, and we believe it is in contemplation further to improve the building, particularly the part facing the Downs.

STAINED GLASS.

Congregational Church, Ramsbottom.—A large stained glass window has been placed in the west end of the new Congregational Church, Stubbin's Vale, near Ramsbottom, co. Lancaster, in memory of the late wife of Mr. Joshua Townsend. The window is composed of five openings and tracery. In these openings are figures, life size, of our Lord in the centre, with the four Evangelists, two on each side, beneath canopies. Under these, and forming the base of the window, are smaller canopies, the central being occupied by a figure of David, king and prophet; and the side canopies are filled with the emblems of Evangelists, bearing scrolls, on which are inscribed the beginning verse of each Gospel. The tracery is filled with inscribed scrolls, monograms, and foliated works. In addition to this window the whole of the glass in the church is of an ornamental character, consisting of geometric work in different tints of cathedral glass and colored borders. The windows are from the establishment of Messrs. R. B. Edmondson & Son, of Manchester.

Church Preen.—This little parish church has lately received an additional adornment in the form of a large stained-glass window, placed in

the chancel by Mr. Arthur Sparrow (the patron), as a memorial of his father, the late Mr. William Haubury Sparrow, of Penn, in the county of Stafford, and lord of the manor of Church Preen, by whose liberality the restoration of the church was principally effected two years ago. The figures on the window represent nine events in the life of our Saviour, viz.—Magi, Presentation, Christ with the Doctors, Baptism, Temptation, Agony, Crucifixion, Resurrection, and Ascension. It was executed and supplied by Mr. Frederick Preedy, London.

St. Stephen's Church, Carlisle.—Miss Burdett Coutts has filled with stained glass the windows of the west end of this church, at a cost of about 300*l.* Messrs. John Scott & Son, Dickergate, Carlisle, furnished designs for the windows, the firm having already filled with stained glass for Miss Coutts the east windows of the edifice. The main window is composed of four lights; and the history of Stephen having been chosen as the subject for illustration, each of the four lights is devoted to an incident in the martyr's life. Each group is under a crocketed canopy, and in the tracery above these canopies a demi-figure of Christ is placed; while the cinquefoil on each side of this central circle is filled with angels playing upon harps. The groundwork of the window is ruby glass, upon which is a scroll pattern, and the predominating colours are ruby and gold, an effect having been produced by the introduction of a good deal of white. The general style of the groundwork is floriated. The five small single lights below the main window have been filled with a geometric pattern. The new windows are much lighter in their effect than those in the apse, where greater masses of deep colour have been used.

SCHOOL-BUILDING NEWS.

Edgeley, near Stockport.—New schools for girls and infants are being built at the Roman Catholic church here. The foundation stone was laid on Easter Monday, by Mr. E. W. Walker, M.P., with the usual formalities. The estimated cost, including fittings, will be 1,600*l.* The architects are Messrs. M. E. Hadfield & Son, of Sheffield; and the builder is Mr. J. Paul, of Kutsford. The exterior is of brick, with stone facings, and some slight admixture of tiles, strings, &c. The entrance and staircase are at one end of the building through a dome gabled, and surmounted by a cross. There are spacious play-grounds, and the site is cheerful and open. The schools are in all respects planned to suit the requirements of the Privy Council aided by a building grant. The schools will accommodate 500 children, and it is expected they will be completed by the end of September.

Masbro (Rotherham).—New schools for boys and girls are being erected near the church of St. Bede, Masbro, by Messrs. Hadfield, architects. The group of building is composed of two schools, 55 ft. by 20 ft., placed at right angles so as to communicate or be thrown together, with spacious class-rooms and porches. The design is a simple broad treatment of brick architecture, of the twelfth century, with stone facings, the face of the wall being secured by bands of pressed brick; the roofs are covered with slate. There are play-grounds separate for boys and girls. The roofs are of open tracery timber. Mr. J. Ripley, of Masbro, is the builder. The estimate, with fittings, is 950*l.*

Brinkworth.—The new school here has been opened. It stands on the hill-side, about a stone's throw from the church. It has been erected from the designs of Mr. Darley, of Chippenham; and is a brick building with free stone dressings. It is in the Gothic style, though very moderate in this respect with regard to windows, which have been altered to suit a suggestion from the Privy Council. The main room is 57 ft. 3 in. long by 18 ft., and there is a class-room 20 ft. by 14 ft. Both rooms are 17 ft. in height from floor to ceiling. The schoolroom has a vaulted roof of stained deal. There are two entrances to the building, one on the north side and the other on the south-west side, over which a bell-turret stands. At the end of the school is the schoolmaster's house, which is a new building, and in character with the school. The total cost has been about 1,200*l.* Mr. Milhaud, builder, had the contract.

Denholme.—The foundation-stone of an Independent Sunday school has been laid here in

connexion with the chapel erected in 1844. The new building will accommodate 300 children. Its cost will be about 8000. The building will be 66 ft. long by 36 ft. wide; inside dimensions, 18 ft. high in the centre, and 14 ft. high at the walls. It is to be entered from the front, facing the road, by two doorways, with large three-light, ornamental window over them. The front will be gabled and surmounted by a moulded pediment cornice. Six semicircular-headed windows at each side and two at the front, in addition to the window over the door, will give light to the interior. The roof is intended to be supported by two rows of cast-iron ornamental pillars, which, being braced longitudinally by timber arches, will give the interior somewhat of the effect of nave and aisles. There will be two class-rooms at the end, which will be connected with the large room by sliding doors. These class-rooms will have fireplaces, and the large room will be warmed by hot-water and lighted by gas. The style of architecture is Italian. The plans have been designed by Mr. T. C. Hope, architect, Bradford. The works have been let to Messrs. Robinson & Ibbotson, masons, Thornton; Messrs. Thresh & Illingworth, joiners, Bradford; Mr. Thomas Walton, plumber, Bradford; Mr. Joshua Taylor, plasterer, Denholme; Mr. B. Hill, slater, Denholme; Mr. W. Atkinson, painter, Denholme.

Rotherham.—The foundation-stone of a new school building, in connexion with the Rotherham Congregational Church, has been laid. The total cost of the new building will be 6000, and it will provide accommodation for 500 children. It will be erected of stone, similar in quality and appearance to that of the church, and in the same style of architecture; and it will have a chapel-keeper's house adjoining. It will contain one large room, 60 ft. by 33 ft., with an infants' room, 19 ft. by 16 ft., and several class-rooms. Mr. Masterton, of Rotherham, is the architect; and the contractors being Mr. Harper and Mr. Woodhouse.

Beccles.—The new National School-rooms in this town, which were commenced building nearly twelve months since, have now been opened by the bishop of the diocese. The building, which is situated in Ravensmere, is a large structure, in red brick, having Gothic windows with stone mullions, and a slate roof ornamented and surmounted by a bell-turret. It has been built by Mr. R. A. King, of this place, from the plans of Messrs. Hayley & Dawes, of Manchester, at an entire cost of about 2,000. It will contain 150 boys, 100 girls, and 150 infants. There are convenient class-rooms attached to the boys' and girls' school-rooms, and also lavatories for each school.

Books Received.

The *Quarterly Review* for April contains a good paper "On the Use of Refuse," which, though the subject is not new, has many points of interest and importance, some of them no doubt new for the first time collected together, and the whole forming one of the best papers in the number.—"A Shilling's worth of the United States of America," compiled by Belding, Keith, & Co., and published by Cassell, Petter, & Galpin, London and New York. Messrs. Belding, Keith, & Co., have prepared this epitome of the finances, railroads, trade, laws, population, &c., of the United States, with a business purpose, as American bankers and merchants who offer their services for the transaction of business; but the compilation is a very useful one, containing an immense amount of tabular and other information.

Miscellaneous.

THE THAMES EMBANKMENT AND THE DISTRICT RAILWAY.—The Metropolitan Board of Works has considered a proposition received from the Metropolitan District Railway Company that the Thames Embankment from the Temple Gardens to Blackfriars Bridge should be a solid embankment, and that the question of liability to pay compensation be referred to an arbitrator. An answer was ordered to be returned accepting the proposition on certain terms,—that each party should deposit half the estimated amount of compensation, and the railway company pay forthwith to the Board the 200,000, referred to in their Act of Parliament; an answer to be returned in seven days.

HER MAJESTY'S THEATRE.—We are able to state that the rebuilding of Her Majesty's Theatre will be commenced in about a fortnight's time, the site being nearly cleared. The designs, prepared by Mr. Charles Lee, of Whitehall-place, have been approved by Her Majesty's Commissioners of Woods and Forests, the site being Crown property.

UNCOVERING OF A STATUE OF THE PRINCE CONSORT IN BIRMINGHAM.—The Mayor of Birmingham has performed the ceremony of unveiling a statue of the Prince Consort in the Art Gallery of the Midland Institute. The statue, which is of white marble, is the work of Mr. Foley, R.A. It stands on a pedestal as near as possible to the spot where the Prince Consort stood when he laid the foundation-stone of the Midland Institute. The cost of the statue is 1,100, which has been raised by public subscription.

A LANDLORD AND HIS POOR TENANTS.—At an inquest held at the Sessions House, Broad Sanctuary, relative to the death of Elizabeth Nutts, aged 70, who fell from a dangerous staircase at 16, New Peter-street, and so met her death, it was stated in evidence that the house in question is let out in single rooms, the deceased occupying the first-floor back. In order to get to her room she had to walk along a narrow piece of board, placed over a well-staircase. From that board she fell, and sustained a compound fracture of the leg, from which she died. Several of the lodgers spoke as to the decayed and broken-down stairs, and their ineffectual complaints to get them repaired. All the landlord or his agents thought of was to collect the rents, and leave the positively dangerous stairs unrepaired. The jury found a verdict of accidental death, and expressed their opinion that the landlord should at once have the stairs repaired, and not allow them to remain unprotected and in a dangerous condition.

VENEERS FOR WALLS.—According to the *Boston Transcript*, a man in Cambridge, Mass., has made an invention by which wood hangings will take the place of paper. "A very delicate, simple, and beautiful machine has been constructed, which will take a portion of a tree, after it has been cut the right length and width, and shave it up into thin ribbons as wide as a roll of house-paper, making 150 to the inch. These rolls of wood are placed on the walls by paperhangers with paste and brush, precisely in the same manner with paper. The wood is wet when used, and really works easier than paper, because it is much more tough and pliable. In these days, when variety is sought for, one can finish the walls of his house in different woods to suit his taste. One room can be finished in bird's-eye maple, another in chestnut, another in cherry, another whitewood, and so on. Thus he has no limitation, but the real genuine article upon his walls." Something similar, we believe, has been done in England for some time past.

THE PRISONS OF LONDON AND MIDDLESEX.—The Howard Association have issued another tractate, treating especially on this subject. They state in it that two at least of the metropolitan prisons (that of Holloway, belonging to the City, and Coldbath-fields, belonging to the county) have, under the able management of their present governors, displayed in a noteworthy degree the practicability of a great and advantageous increase in the adoption of remunerative and reformatory labour in gaols. Whereas the average cost of each English prisoner is 34s., and the average earnings of each only 2s. (in many prisons only one, or two farthings per day), the inmates of Holloway Prison (most of whom are committed for a month or less) have earned upwards of 900. Clear annual profit on their labour, in addition to a specially large amount of useful economic service rendered within the walls. Some of the long-time prisoners almost earn their own cost. It is of importance that the industrial reformation of criminals should continue to be promoted in the London prisons, and there is room for much further advance even in this direction. But just at present the subject of prison dietary claims the attention of the Association. Prisoners, however, should certainly not be placed in a condition even equal to that of the honest outside or workhouse poor; but the chief deterrent, and at the same time the most reformatory and economic treatment, should consist in a rigorous enforcement of an ample quantum of task-work. Real hard work, and the enforcement of it (but without semi-starvation), is a condition most useful and most hateful to the generality of criminals.

LADY DE ROTHSCHILD'S INDUSTRIAL EXHIBITION.—It is announced that the industrial exhibition to be held at Hulton, Bucks, under the patronage of Lady de Rothschild, will be opened with much ceremony on Whit Monday by Mr. Disraeli. An influential assemblage will be present.

NEW ENGLISH CHAPEL AT CHANTILLY.—A new Wesleyan chapel was opened at Chantilly for divine worship on the 21st ult. It was announced that the chapel was all paid for, and that there only remained a comparatively small amount to be raised for the surroundings of the building.

STEAM RAISED BY GAS.—A machine on Jackson's Patent, at Lyon's-wharf, one of the granaries near Queenhithe, is exciting attention. The principle is the substitution of gas for coal, but in such a form that power can be obtained in a small space. The machinery which illustrates the working of the process was erected by Middleton, engineer, of Southwark, and in a space of about 6 ft. by 5 ft. the power is supplied for raising sacks of grain from the barges in the river at four different places at once. The boiler will generate steam from cold water in twenty minutes after the gas is lighted, and when once generated steam can be kept up by one burner at trifling cost. It is proposed to apply it only where small power is needed.

THE PROPOSED NEW WATER WORKS FOR LIANELLY.—At a recent meeting of the Local Board of Health, tenders for haulage and laying pipes in connexion with the new water works were opened. There were twelve tenders sent in for contract No. 3, the lowest by Messrs. Bewicke & Lambert, being 1,421l. 13s. 4d., and the highest by Messrs. Griffiths & Thomas, 1,918l. The number of tenders for contract No. 4 was the same. The lowest was by Mr. T. Jesson, 282l. The next highest was by Messrs. Bewicke & Lambert, 295l. 15s., and the highest was that of Messrs. W. & T. Thomas, 663l. 6s. 8d. After some discussion the tenders of Messrs. Bewicke & Lambert for both contracts were accepted, subject to the usual inquiries.

INAUGURATION OF THE SHAKESPEARE MEMORIAL LIBRARY AT BIRMINGHAM.—The Shakespeare Memorial Library at Birmingham has been formally opened in the presence of the mayor, several members of the town council, and a large number of the donors. The library, which contains upwards of 1,000 works in English and foreign literature, together with a number of portraits of the great poet and pictures illustrating his writings, &c., has been incorporated with the free libraries of the town, and made over to the town council under certain conditions for its proper maintenance. A handsome room has been fitted up for the reception of the collection. The furnishings of this room, which are of a quaint and Shakspearian character, have cost the corporation 600l.

GREEN GLASS FOR PLANT GROWTH.—Mr. William Thompson, of Dalkeith, in speaking of a visit to Belvoir, says:—"Descending to the large kitchen-garden in the vale beneath the castle, we saw a long span-pit full of greenhouse plants, including azaleas, epacris, and such like, and which had all the glass shaded green, by being washed inside with what painters call green distemper powder mixed with butter-milk, except two sashes. The plants, when placed in this pit some months before to make their summer growth, were all in the same general state as to health and vigour. They got the same treatment as to water, ventilation, &c., the only difference being that those in the two lights referred to were under the clear glass, the others under that which was shaded green; and had we not seen the plants with our own eyes, we could not have believed that there could have been such a difference in their health, growth, and general appearance, and all in favour of those under the green glass. Nor was this growth at the expense of maturity, for we examined the azaleas minutely, and found them well set, with fine hard flower-buds. The shade of green was but a light one, yet such was its effect in this case: and we beg to call the attention of physiologists to the fact, in which there may be something of great importance to horticulture. If such a shade is found to be permanently beneficial to vegetation, glass of the colour could easily be made. If beneficial in summer only, then Mr. Ingram's colouring can be made available for the summer, and be washed off in autumn."

IMPROVEMENT OF EDINBURGH INFIRMARY.—A movement has been set on foot to raise a fund for the rebuilding of the medical hospital of the Royal Infirmary of Edinburgh. The estimated cost of the work is about 100,000l. Nine subscriptions of 100l. each, and several of 500l., have been announced.

THE PAXTON MEMORIAL MUSEUM.—There has just been held a large meeting of working men at Leighton Buzzard, in promotion of a movement set afoot by the Working Men's Institute there, for the erection of a museum in that town in honour of Sir Joseph Paxton, who spent his earlier days in the vicinity. Funds are flowing in, and Lord Charles Russell is expected to lay the first stone on an early day.

AN AGREEABLE MEETING OF WORKMEN AND MASTERS.—The employes of Messrs. Pictor & Sons, Bath stone merchants, Box and Corsham, Wilt., with a few of Messrs. Pictor's friends, upwards of 300, recently met at dinner in the new workshops of the firm, which were decorated with evergreens, &c. The feast was given to celebrate the coming of age of Mr. W. S. Pictor, and his accession to the firm. There were many present who had been employed by the firm upwards of thirty years. The men continued to enjoy themselves with singing, &c., until late in the evening, when they broke up, well pleased with their entertainment, notwithstanding the arrangements had been conducted in strict accordance with the principles advocated by the firm, viz., "total abstinence from all intoxicating liquors." The workmen employed at Messrs. Pictor & Son's depot at Paddington were entertained at a supper, and so participated in the general rejoicing of employers and employed.

THE ALBERT MEMORIAL MUSEUM AT EXETER. This structure, of the selected design for which, by Mr. Haward, we gave a view and plan in our volume for 1864, page 415, has been formally opened. The edifice has been erected at a cost of 12,000l. A grand fancy fair was held, besides a host of festivities, during a whole week, in commemoration of the event. It was soon after the death of the Prince Consort that Sir Stafford Northcote suggested, at a meeting of the Exeter School of Arts, that a memorial should be erected in honour of his Royal Highness. The idea was warmly taken up, and it was agreed that the memorial should take the shape of a museum, school of art, and free library. At a public meeting, 1,800l. were subscribed towards the object, and the late member for the city, Mr. R. E. Gard, gave the site, which is worth 2,000l. The foundation stone was laid October 30, 1866. In the interior the main architectural feature is the staircase leading from the ground-floor. The stairs commences in the centre of the floor, and at the top of the first flight is a niche filled by a statue of the Prince Consort, which has been executed by Mr. Stephens, a local sculptor.

TENDERS.

For Mr. Southcott's new premises, Commercial-road, Finsbury. Mr. P. Sullivan, architect. Quantities supplied by Mr. Parker: Jackson £1,605 0 0 Keeble 1,298 0 0 Piper & Wheeler 1,207 0 0 Ring & Son 1,280 0 0 Richards 1,266 0 0 Lacy & Flexman 1,240 0 0 Saunders 1,090 0 0 Manspratt 983 0 0 Richardson 835 0 0

For works at Cowfold, Sussex. Messrs. E. Habershon, Brock, & Webb, architects:— Keys £3,365 0 0 Manley & Rogers 2,790 0 0 Simpson 2,675 0 0 Halton 2,523 0 0 Wilcox & Spragg 2,395 0 0 Bland 2,349 0 0 Bish 2,277 0 0 Nightingale 2,207 0 0 Fencoe 2,247 0 0 Hall 2,245 0 0

For erecting premises at Bermondsey, for Mr. Wallace. Mr. J. Gale, architect:— Epps & Gates £830 0 0 Wells 584 0 0 Meiers 563 0 0 Nightingale 553 0 0 Wood 507 0 0 Sheppard 495 0 0

For alterations at premises, Millstreet, Bermondsey, for Messrs. Roberts, Adlard, & Co. Mr. Elkington, architect:— Coleman £195 0 0 Eustace 183 0 0 Wills 177 0 0 Wale 174 0 0 Preston (accepted) 162 0 0

For a pair of semi-detached houses to be erected on the Godstone-road, Caterham, Surrey. Mr. Geo. Robson, architect:— With attics. Without attics. Ward £985 0 0 £015 0 0 Ellis 894 0 0 843 0 0 Baldwin 900 0 0 890 0 0 * Accepted, subject to reductions.

For new bathing establishment at Folkestone. Mr. Joseph Gardner, architect. Quantities by Messrs. Pain & Clark:— For Building. Prebble £9,085 0 0 Bowley 7,987 0 0 Denton 7,125 0 0 Head 6,980 0 0 Holdron 6,980 0 0 Unwin 6,911 0 0

For Machinery. Gwyns 2,982 0 0 Wails 1,800 0 0 Hayward 1,665 0 0 Deane 1,585 0 0 Aley 1,568 0 0 Smythe 1,449 0 0 Hoad 1,440 0 0 Francis 1,248 0 0

For erecting a new chapel for the Welsh Presbyterians, Newcastle-Emlyn, South Wales. Rev. T. Thomas, Swansea, architect. Materials fit for the new fabric of chapel to be taken by contractor at the architect's valuation, and the sum deducted from amount of tender:— Woodward & Davies £1,401 17 10 Jones & Thomas 1,370 0 0 Jones & Williams 1,350 13 6 Lloyd & Evans (withdrawn) 1,192 7 8 Edwards & Evans (accepted) 1,180 0 0

For new Wesleyan chapel, Alsager, Cheshire. Mr. Geo. B. Ford, architect:— Strenger £2,522 0 0 Booth 2,440 0 0 Keen 2,230 0 0

For three houses at Wokstanton, near Barslem, for Mr. Clement N. Nash. Mr. Geo. B. Ford, architect:— Estlin £2,878 14 0 Woolrich 2,822 4 3 Bennet & Cooke 2,765 0 0 Brimley & Critchlow 2,660 0 0 Blackhurst 2,483 0 0 Bowden 2,432 0 0 Newton 2,020 0 0

For St. Paul's church, Addiscombe, Croydon. Mr. E. B. Lamb, architect. Quantities supplied by the architect:— Cook £6,610 0 0 Patman & Co. 6,910 0 0 Carter & Son 5,979 0 0 Claxton & Hoys 5,839 0 0 Fish 5,630 0 0 Gammon & Son 5,773 0 0 Key 5,500 0 0 Staines & Son 5,468 0 0 Wardle & Baker 5,400 0 0 Mundy & Hutchinson 5,250 0 0 Hallidge 5,240 0 0 Knight 4,888 0 0 Lacey & Flaxman 4,880 0 0 Wright 4,846 0 0 Hatton 4,643 0 0

For house on Prospect Hill Estate, Walthamstow. Mr. W. A. Longmore, architect. Quantities not supplied:— Munday & Hutchinson £750 0 0 Palmer 745 0 0 Bailey 695 0 0 Elms (accepted) 680 0 0

For twenty-seven houses in the Old Kent-road. Mr. W. Smith, architect:— Fitcher £9,611 0 0 Monday 8,284 0 0 Watkins 7,875 0 0 Welsh 7,749 0 0 Brown 7,734 0 0 Lewis 7,570 0 0 Crabbe & Vaughan 7,500 0 0 Sabey 7,300 0 0 Forster 7,272 0 0 Hearle 7,247 0 0 Bowler 7,215 0 0 Johnson 7,149 0 0 Davis 6,840 0 0 Schofield 7,000 0 0 Blackmore & Morley 6,937 0 0 Blacore 6,096 0 0 West 6,473 0 0 Sherrinur 6,390 0 0 Ellis 6,182 0 0 Smith & Simmonds 6,158 0 0 Wigmore 6,100 0 0 Manspratt 5,631 0 0

For erecting a new Congregational chapel at Cannington, near Bridgewater, Somerset, for the Rev. B. Hurman and the Committee. Messrs. Habershon, Brock, & Webb, architects:— Shortney £910 0 0 Kitch, Brothers 790 10 0 Paddon 767 10 0 Hartree 750 0 0

For building new Baptist chapel and school, Coventry. Mr. John D. Webster, architect. Quantities supplied:— Hewitt £2,560 0 0 Wolf & Kendall 2,400 0 0 Marriott 2,378 0 0 Norwood 2,289 0 0 Trow & Sons 2,210 0 0 Malspeace 2,158 0 0 Claridge 2,079 0 0 Bennett 2,063 0 0 Hayward 2,000 0 0 Wilson 1,900 0 0 Halsall & Co. 1,820 0 0 * Accepted, with slight modification.

For additions and alterations at No. 36, Golden-square, for Mr. A. Gagnier. Mr. Elkington, architect:— Kendall £1,980 0 0 Gammon & Son 1,807 0 0 Little 1,829 0 0 Coleman 1,787 0 0 Conder (accepted) 1,756 0 0

For houses, cottages, &c., for Mr. John B. Soper, Basingstoke. Mr. Charles Smith, Reading, architect:— Barnicott £2,190 0 0 Barnicott 2,158 0 0 Thorne 2,003 7 0 Musselwhite 1,997 0 0 Pool 1,931 0 0 Matthews 1,951 0 0 Stevens 1,830 0 0 Dover 1,827 0 0 Grover 1,816 0 0 Bland 1,678 3 7 Alway (accepted) 1,630 0 0

For constructing sewer in the Crown-road, Fulham, for the Board of Works for the Fulham district:— Reddin £3,120 0 0 Wilson 2,890 0 0 Chamberlain 2,800 0 0 Chamberlain 2,900 0 0 Bloomfield 2,858 0 0 Moxon 2,840 0 0 Floyd 2,410 0 0 Goodair 2,128 0 0 Hirst & Co. 2,059 0 0 Whitlock 2,040 0 0 Wainwright 2,000 0 0 Williams & Co. 1,950 0 0 Wigmore (accepted) 1,990 0 0 Porter 1,350 0 0

For constructing sewer in the Fulham-road, Fulham, for the Board of Works for the Fulham district:— Reddin £3,967 0 0 Wilson 3,420 0 0 Keeble 3,410 0 0 Chamberlain 3,200 0 0 Goodair 3,068 0 0 Whitlock 2,950 0 0 Williams & Co. 2,940 0 0 Chamberlain 2,820 0 0 Bloomfield 2,818 0 0 Moxon 2,750 0 0 Floyd 2,718 0 0 Porter 2,250 0 0 Wainwright 2,200 0 0 Wigmore (accepted) 2,190 10 0

For both of the above:— Porter £240 0 0 Nicholson 5,100 0 0

For constructing the King's Scholars Pond sewers, St. John's-road, for the Metropolitan Board of Works:— Scott & Co. £11,333 0 0 Hill & Keddell 13,800 0 0 Ferguson 12,499 0 0 J. & S. Williams 11,800 0 0 Wigmore 11,900 0 0 Smith & Co. 10,300 0 0 Crockett 9,300 0 0 Nicholson 8,350 0 0 Morris & Bloomfield 9,140 0 0 Hirst & Co. 8,849 0 0

For finishing public-house and shop adjoining at Leyton Essex, for Mr. W. Richardson. Mr. J. M. Dean, architect:— Smith £853 0 0 Davey 650 0 0 Mansfield 489 0 0 Harris (accepted) 467 0 0

For a wing to Beaumont-lodge, Winchmore-hill, Middlesex. Mr. J. H. Rowley, architect. Quantities by T. Green:— Crabb & Vaughan £1,854 0 0 Field & Sons 1,280 0 0 Rivett 1,213 0 0 Bayes 1,191 0 0 Shepherd 1,129 0 0 Patman 1,064 0 0 Rig & Sons 1,071 0 0 Sharpington & Coles 1,048 0 0

NOTE.—Architects who are unwilling (as we are) that their name should not accompany lists of tenders with which they are concerned may prevent the omission by sending lists themselves. We can repeat lists on the ground of such omission.

We are compelled to decline pointing out books and gifts addressed to us.

All statements of facts, lists of Tenders, &c., must be accompanied by the name and address of the sender, not necessarily a publication.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

Advertisements cannot be received for the current week's issue later than THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for ORIGINAL TESTIMONIALS left at the Office in reply to Advertisements, and strongly recommends that COPIES ONLY should be sent.

NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the Builder," No. 1, York-street, Covent Garden. All other Communications should be addressed to the "Editor," and not to the "Publisher."

The Builder.

VOL. XXVI.—No. 1318.

Idling at
Amiens Cathedral.

N idle tourist has a complacent senso of conscientiousness as he concludes a short day's travelling by rail from Hazebrouk at Amiens. Would not an opportunity of revisiting the cathedral justify the pains of even a hurried traveller? This, perhaps, is the French cathedral that is more familiar to Englishmen than any other, except Notre Dame, in Paris; and by delineation, description, and occasional reference, it comes under the notice of lovers of architecture with a frequency

that would make the very mention of any less interesting structure an annoyance. We visit it again and again, however, with confident expectation of renewed pleasure, and we renew notes of observation upon it with the calmest reliance on the tolerance of those who are not so fortunate as to be again upon the spot. The notes are but those of an idler, yet even these are set down without apology, for they rather ask for sympathy with enjoyment than make any pretence of novelty or particular instructiveness.

The west front of the cathedral seems at present as falsely presented as that of Cologne, facing, as it does, an aggregation of insignificant and base structures in irreverent proximity; but we have only to pass through the intersecting streets to perceive that encroachments have covered up the ground that, originally open, sloped upwards to the grand portales, and afforded the façade its noblest aspect.

Noble and effective as this façade must always remain, it is impossible, after a fair appreciation of the interior, not to regret that it was not to be the completed work of the genius to whom we owe the body and choir of the cathedral. The westward interior terminations of aisles and naves of cathedrals generally are apt to be ineffective,—to afflict us like the hithos of a grand intention,—and Amiens is not the exception. This was the portion of the structure usually left to the last, and here the master-mind of the original designer was more likely, where growth of art so largely extended beyond ordinary limits of life, to be withdrawn from the work. Even at Cologne, uniform as the entire ancient work at first appears, the signs of degradation in intersecting and vanishing mouldings are palpably apparent in the western pier-arches.

At Amiens the influence of a modified design is as visible in the western details within as in the façade, which is as absolutely secondary to the main structure as that of Reims. Reims, however, with a general analogy of design, is incomparably superior in respect of breadth,—the more wonderful as it is as pure an application to a completed front as if such a front as

that of Amiens were now to be attached to the existing façade of Notre Dame at Paris. But breadth most exquisitely distributed, and most forcibly felt, is the noble characteristic of the interior of Amiens. Gothic architecture here has attained its majority,—has completed its emancipation,—has sealed its independence and originality. Proud as we have every right to be of the bold originality of Salisbury, it is impossible to compare it with the most genuine part of the design of Amiens, and not to feel that, in holding on to the indulgence of the horizontal story instead of breaking boldly with established lines and giving predominance to the vertical compartment, the especial privilege of loftiness which is the appanage of the style, its grand chance of most distinctive character, was missed,—missed the more unfortunately as it received such magnificent expression in the spire without, and the graduated heights of transepts and nave. Salisbury, however, he it said in passing, has an excellence, though only in rudimentary form, that the style of Amiens has passed by to reach at once a simple and more speedy finish. The eye is but ill satisfied with the nestle contours of the English compound roll-mouldings; but they introduce the combinations of multiple archivolts that were soon to be drawn more decisively and contrasted with a knowledge of light and shade and instinct for subordination that give the Early English style at its heat a high place amongst the very highest.

The predominance of the compartment is effected at Amiens, in the simplest but perfectly effective way. The ranged supports of the columniated nave are still not entirely obliterated, but shafts attached to the cylindrical piers rise from their bases, and proceed upward with well-defined prominence, and uninterruptedly to bear the transverse arch of the quadripartite vaulting. The comparatively close spacing of these shafts, and the happiness of their proportion, albeit extended to the very extreme of permissible loftiness, give to the nave the noble expression of a continuous arcade that passes by no sudden break, but in natural development, into the wide span of the central crossing. A secondary effect of the same kind was obtained by the vaulting shafts attached at the back of the piers, and responsive to wall shaft, while two intermediate shafts completing four about the vast central cylinder, and of well-subordinated diameter, bear the archivolts of the arches between aisle and nave. The shafts which carry the diagonal ribs of the nave rise from bases which nest in nooks upon the abacus of the nave pier; those which bear the arch mouldings of the clearstory rise from nooks upon the triforium band or string course. The tendency of such a successive augmentation of the group of shafts is, no doubt, to introduce an appearance of incongruous widening of the pier from below upwards,—a disadvantage that was afterwards sought to be counteracted by giving to each and all independent and conjoint origin at the very base of the nave pier.

Howbeit, it does not appear to an idle and might not even to a more concentrated observer, that the disadvantage has declared itself in the order of Amiens. The whole is a question, not of absolute propriety and strict law of style, but of propriety and style as conciliated by proportion. The proportions appear to be so harmoniously arranged here that style fairly makes a pause and asserts the sufficiency of its resources, even at this stage of development, to realize well-balanced beauty. The next stage will be one of transition,—that is, of that intermediate disturbance of balance which it will be for a new genius again to subdue and regulate by new adjustments; but in the mean time,—fairly enough even for all time,—the design of a bay of Amiens Cathedral remains a completed triumph of architecture.

This simple bay is relieved and varied by the most graceful differentiations of span in aisle and crossing, and choir and aisles of choir, and reaching the most pleasing and most marked contrast in the closer spacings at the turn of the apse behind the altar. The compound piers of the choir aisles and the graceful treatment of the vaulting of the crossing, are developed naturally from the same combination, and must command admiration, even when space warns that detailed exposition may be superfluous.

There is at least a seeming divergence from verticality,—an inward how,—in the great shafts of the arch at the crossing; but whether more than seeming is not easy to decide; the seeming effect might result easily from optical contrast with the bow of the arch: the real effect has a *vera causa* at hand in the pressure of aisle arcuation; the lamps of the nave are suspended by wire of such rigidity as to be useless for the service of a plumb-line. The bow is probably too true a reality, although the eye can detect none of the openings and faults of joints that should be its necessary consequence. The piers of the choir of St. Paul's seem really affected in the same unfortunate way; and yet Wren, as we have it under his hand, was quite aware of the liability in cathedral building. Be it how it may—a reality or a seeming—the mere appearance is a blemish and lamentable drawback.

It is among the glories of Amiens, as an early model of a perfected style of Gothic, that the clearstory windows, with their mouldings, accurately and entirely fill the groined openings,—the entire plane up to the proper vaulting. The clearness—cleanness of articulation—thus achieved has all the value in architecture that a Greek ascribed to the freedom from superfluous fat and idle muscle and overgrowth of bone in a well-formed athletic frame, that had had all the advantage of persistent and able exercise and training.

The terminations of the transepts, like that of the western nave, are of later date and design than the ever-to-be-exalted nave and choir, but they are true to the original principle in this respect, and their enormous windows fill, with no excessive margin of moulding, the vertical plane from spring of archivolt to apex. The design of the transept windows, again, however later, adheres generally to the leading distributions of the original windows. In these a circle, almost as large as the head of the pointed arch will admit, rests upon the points of arches of two sblights below, divided by a central pillar. The transept window is but such another on an enormous scale, with the differences that are enforced and suggested by scale: a circle of such diameter would have but inadequate bearing on a pair of arches, and their numbers are necessarily increased on this account, as well as for further subdivision of wide spaces.

Precisely the same principle is observable in the transept windows at Sens Cathedral. The heads of these are each filled with one large circle, having its centre on a line with the spring of the arch; the interval under the apex is filled with symmetrical but insignificant foiled circles; and the grand circle rests on the points of five sblights of varied height, the smaller in the middle, the mouldings of the side-lights being confluent with the great circle at the points of contact and interference.

So we may trace the origin of that important feature of French architecture—the great rose-window, of elaborate design and exquisite mouldings,—thus most directly, though, as in the case of so many other developments, it is the concurrence of influences that ultimately induce decision. At Sens and at Amiens we see the great rose-window, rudimentary in smaller lights, ready to detach itself from its adjuncts, from ogival opening and supporting awnlight, and yet the last detaching process might never

have taken place,—nay, the development might never have advanced so far, if the Lombard architect had never set an example and never been followed by the Norman.

The rose of the north window at Amiens seemed to the observer,—idle eyes,—much the finest, the southern in the second place, and lastly the western, of which the designer seemed to have had more consideration for the external effect of his moldings and pattern than for susceptibility of illuminated effect,—certainly, than for receptiveness of a storied design, as seen from within.

The cathedral has received an extension that is very considerable but was never contemplated by the original designing genius, in the chapels which now open out of the side aisles, and fill up the spaces between the buttresses. It is not alone that the inferior and, indeed, often very wretched, tracery of the windows betrays the later date,—the marks are palpable in groove and attachment, where the windows were originally inserted, filling the arch which now gives entrance, through wall broken down to the ground, to these supplementary chapels. Their effect upon the exterior is not happy, as they aid very much a certain inflated and boneless look that makes the structure unattractive, if not ungainly, from without. This, however, might be condoned,—the questionable value of the deep buttress-walls being taken into account,—if the interior really receives from them an accession of value. This is at least very doubtful. They certainly give a degree of expansion to the nave that detracts from the gradation of effect with which the choir, with its additional aisles, most formerly have been so advantageously approached. Moreover, it can scarcely be overlooked that a series of windows of such magnitude filled with coloured glass must have added an effect to both aisle and nave much surpassing the remoter borrowed reflections from a multitude of smaller openings.

In this respect then, as in others,—in the secondary transepts and western front,—there seems cause for regret that we have lost a portion of the original conception of the first great architect: thankful, however, all must ever be who have either idled or studied at Amiens, that we have left to us in uniform simplicity and consistent grandeur so large a proportion realized in the existing fabric of one of the very grandest imaginations that man has ever dared to hope to carry into execution.

DEFRAUDED DEBENTURE HOLDERS.

HAVING on more than one previous occasion called the attention of our readers to the calamitous story of the London, Chatham, and Dover Railway Company, we should not now revert to the lengthened proceedings which are slowly unveiling such a serpentine train under the mild patience of Mr. Commissioner Winslow, were it not for the appearance of new and striking features in a case which might have been accounted, two months ago, very noticeable in the list of *causes célèbres*.

So intimately is the present waning phase in the history of the public works of this country connected with the operation of the principles, or (to coin a word) the unprinciples, now illustrated, that it is of extreme importance to all those in any way connected with the engineering profession, or with the shrewdness of the builder or of the contractor, to understand the actual course by which sums so enormous, as matter of figures, have evaporated into figures alone. The long and careful reports published by the daily papers are necessarily extremely condensed, and it requires some considerable amount of independently acquired knowledge of the case to be able fully to understand them. In addition to this circumstance, it must be regretted that the investigation now taking place is carried on before a court almost entirely unchecked and unassisted by the presence of a bar. The conduct of a case by a solicitor, however eminent, is almost necessarily less satisfactory than the more rapid but more practised manner in which a leading barrister pounces upon the salient points. In the present case, too, there has been the additional misfortune of the absence of any such opening speech as should lead those who watch the important inquiry to see always distinctly the point at which the examiner was aiming. Time, on one or two occasions, was, if not sheerly thrown away, yet dealt with as if it were one of the most valueless of commodities;

and the result of a personal attendance on several occasions, with the sole object of watching the proceedings, was the conviction that the accuser had lost his way, that the personal discredit of the bankrupt was his only aim, and that the case of the directors of the London, Chatham, and Dover Railway was only rendered more and more obscure—morally, not intellectually, obscure—by every fact elicited by their advocate.

The two last examinations have modified this opinion. First, we come to the nonobscuring conclusion that, however tedious the proceedings, and however exorbitant the consumption of the time of commissioner, attorneys, and witnesses, the public is unquestionably the gainer by that full exposure of an almost incredible course of action, which, perhaps, could not have been attained by any other machinery.

Secondly, we think that a point which has been present to the mind of the examiner, and lost sight of by others, is the question of the official identity of the present directors of the London, Chatham, and Dover Railway with their predecessors. The former can be regarded in no other light than as principals in any irregularities in which the contractors—their servants and agents in law, though their masters in wit, such as it was—were, after all, only accessories. It is in this respect that the heavy blows planted by the solicitor on the face of the honourable baronet tied to the stake seemed so roughly to shake the platform of the attack. But if the case had assumed, or could be made to assume, the aspect of a claim on behalf of the plundered and misled shareholders to restitution from those who had induced them to subscribe their money on pretences now shown to be absolutely untrue; then, and then only, every effort of the solicitor for the Company would have been deserving of entire approval.

We have already referred to the fact, as proved in the earlier sittings, that the actual result of the several agreements between the old directors and their contractors was, that out of the original parliamentary capital of 2,200,000l., the sum of 1,375,000l. was actually subscribed and paid by the public in hard cash, while the nominal sum of 825,000l., represented by the "A. Shares" the nest-egg of the whole proceeding, was handed over to the contractors, for no other consideration whatever except the fact that they had induced certain brokers to induce the public to subscribe. Nor was this all; for, in addition to the shares, which of course would have no actual intrinsic value except in so far as they represented a claim to dividend out of the working of the railway, the sum of 34,375l. *in cash* was further handed over to the contractors under the same unusual condition. The whole of this extraordinary proceeding was invested with as much regularity as the exchange of clear and precise letters, the passing of resolutions by the Board, and the aid of the legal advisers of the several parties (the joint-advisers of the several parties) could impart to it. The brokers, indeed, may be thought to have secured the lion's share of the spoil, as five per cent. on the amount of the contract, and half the commission or rebate at which the shares and bonds were taken by the contractors from the Company (that is to say, half of 859,375l., plus five per cent. on the amount of the contract) was claimed by these persons for putting their hands into the pockets—not, as it turned out, of their own garments, but of those of the public. Very near half a million of money,—in cash and shares,—ran down this sink-trap.

The new feature which the examinations held during the month of April have disclosed was indeed indicated on the 11th of March. A certificate was then read to the effect that the capital of 1,650,000l. for the construction of the Western Extension had been subscribed, and the examination was directed to establish the fact that this certificate, which was rendered necessary to comply with the provisions of the Companies Clauses Consolidation Act, had been obtained by false evidence. The difference of opinion, the discussion of which occupied no inconsiderable portion of one day's hearing, was this:—Mr. Linklater insisted that a subscription (a nominal subscription) of 618,750l., or 825,000l. less the "rebate" of 25 per cent., was not a subscription of 825,000l., as sworn in order to obtain the certificate. Sir Morton Peto saw an essential difference between a subscription of only 75 per cent. of the nominal capital, which he denied that he had arranged for, and a subscription of 100 per cent., with an agreement for the return of a rebate of 25 per cent., which he admitted.

The court handsly allowed the disputants to elucidate this important difference, each in his own way. It is to be hoped that the distinction was fully satisfactory to the conscience of Sir Morton, which, indeed, appeared to be the case.

The precise amount of cooking, however, or in any way making pleasant the steps taken to obtain the colourable fulfilment of the requirements of the law, in this instance, are so trifling in comparison with what followed, that they excite interest merely on account of their tentative and experimental character. This first certificate was merely the pilot balloon, sent up to test the currents in the upper regions to which the Great Nassau monster was about to be elevated. If a subscription with a "rebate" was a subscription according to Act of Parliament, the amount of the rebate was a mere matter of detail. If 25 per cent. was legal, who should say that 50, that 75, that 100, would be illegal? So by-and-by capital was subscribed for under a discount of all per cent.

Even the formality of exchanging cheques was abandoned. The simpler process of exchanging receipts was had recourse to for "carrying out the transaction without paying the cheques through the bankers: they were not, in fact, signed. He (Sir Morton Peto) was informed that Mr. Newman had said that he should prefer that receipts were given in lieu of the cheques."

The London, Chatham, and Dover Railway Company, in their report, for the information of the shareholders, on the accounts between this Company and the contractors, admit the receipt by the Company from the public of the sum of 533,000l. under the title of "Debtentures, 1864." In authorising railway companies to raise money on debtentures the Legislature has stipulated that a proportionate share-capital shall have been previously not only supplied, but in part paid up. The intention of this very proper provision is, that those who advance money under a mortgage shall have some tangible security. 100l. subscribed, and 50l. of it spent, has been regarded as the least admissible margin on which 33l. could be safely borrowed. This is the object and the purport of the law. The manner in which the "financiers" of the London, Chatham, and Dover Railway Company, under the advice of their legal officers, proceeded to fulfil the intentions of the Legislature was as follows.

In April, 1864, Messrs. Peto & Co. applied to the finance committee for some 200,000l. debtenture-bonds and debtentures, in order to deposit with the Imperial Mercantile Company. Sir Morton knew, at the time that this application was "accepted," that the Company was not authorised to issue the securities, and that half the amount of capital had not been paid up. He was likely to be fully informed on the subject, as he had contracted with the Company to "subscribe" for rather more than a million of the 1,600,000l. capital known as "A. Shares, 1864," on the security of which these debtentures were to be legalised, "at 40 per 100." That is, at a discount of 60 per cent., a great improvement on the hezzyry 25 per cent. of the "rebates" on the "A. Shares" of 1860. Towards this parliamentary capital "a nominee of witness" subscribed the trifling amount of a quarter of a million sterling. John Harvey, "a clerk to the firm," subscribed 100,000l.; Mr. Trevelthick "in the employment of the firm," subscribed 100,000l.; Mr. Christian, "the manager," subscribed 130,000l.; Mr. Miller, "a broker's clerk," subscribed 65,630l. "The shares for which the firm did not sign they had agreed to take," and the shares for which the above capitalists had signed "for the firm" were afterwards handed over to the latter commercial entity. But when the firm obtained the debtentures, the legality of the issue of which depended on the *bonâ fide* subscription, and half payment-up, of the sums in question, it had "paid nothing in respect of the 1,600,000l." It seems, therefore, to have been almost a superfluous piece of candour for Sir S. M. Peto to write, on the 3rd of November, 1864, "We feel no delicacy in asking you to allow me to have the remainder of the Metropolitan Extension stock." The only curiosity excusable on the matter is, as to what edition of the "Complete Letter-Writer," or other repository of enthusiastic English terms, Sir Morton could have resorted to obtain the singularly happy expression, "delicacy." A man of less genius would have been content with a simpler word.

The 1,600,000l. shares, then, were handed over to Sir M. Peto. Some were "given away" the rest he held in May, 1865. In February, 1866,

the holder attended the half-yearly meeting of the Company, when the shareholders were informed that 804,000*l.* had been paid up on those shares! The Credit Fancier Company succeeded in selling nearly the whole of these shares to the public at 52*l.* 10*s.* for the 100*l.* share (the contractors having taken them at 40*l.*, which was to be paid "in works"), with interest at 6 per cent. guaranteed for two years and a half. Afterwards the firm repurchased three-fourths of this stock, at a premium of 3 per cent., "in order to make a market." It was a fortunate event for the sellers.

Subscription by subscribers who represented other persons, not any of whom had any idea of paying except to the amount of two-fifths of the nominal amount, at some indefinite time, "in works" was not, however, quite sufficient to keep all parties within the four corners of the Act of Parliament. But, as extremely eminent lawyers advised them all, it was thought as well to attempt some colourable compliance with the letter of the law. The person who designed the method of doing this deserves a brighter immortality, a more wide-spread fame, than even the inventor of "Lloyd's bonds." No living writer can hope to do justice to that fertile invention. The pen of the writer of the "Provincial Letters" alone could have been relied on for that purpose. And amid all the casuistry dissected by Pascal we miss the great novel doctrine of "anticipation." Subscriptions were paid by anticipation, works were done by anticipation, were as naturally paid for by anticipation. So it came to pass that the public took the debentures on anticipation, only this latter anticipation had an element in it which was absent in the former instances; it was the element of actual payment of cash invested in anticipation of even the most shadowy security. It was a triumphant application of a new law.

On the 22nd of April, 1864, Mr. Christian signed a receipt for 429,700*l.*, as "part of the arrangement by which the firm was to provide one-half the capital of 850,000*l.*" (This appears to be a reversion to an imaginary arrangement prior to the bargain to take the whole 1,600,000*l.* at 40*l.*) In exchange for that receipt, Mr. Johnson, the secretary of the Company, handed to Mr. Christian two receipts, one for 214,000*l.* in deposit, and in anticipation of Metropolitan Extension A. Shares, and the other for 215,000*l.* in respect of Metropolitan Extension B. Shares. By the exchange of these three pieces of paper, which it is to be hoped were duly stamped, all difficulties were triumphantly surmounted, under the guidance of Messrs. Froehfield & Newman. Sir M. Peto "knows very little about it."

It seems as unnecessary as it might prove tedious to go into any more detail. The next hearing of the case is adjourned till the 27th of May, and no doubt there are further disclosures forthcoming. But enough is as good as a feast. And if it be not enough to the grown-up and educated men, peers and members of the House of Commons, stockbrokers and contractors, directors, clerks, and agents, engaged, under the advice of men of the highest repute as solicitors, in the deliberate evasion of the law, and the patient and skilful construction of a trap for the money of the public, it is hard to say what is enough. People must be uncommonly hungry who ask for more.

As to the direct object of the gentleman conducting the examination, as we remarked before, we feel somewhat in the dark. On the case as far as it has gone at present we do not see any justification whatever for the claim made by the directors of the London, Chatham, and Dover Railway Company against the estate of Messrs. Peto, Betts, & Crampton. We do not see how the directors of 1868 can repudiate the regularly recorded official acts of the directors of 1864. The case of the shareholders as individuals, on the other hand, appears to us to be clear and simple. It is liable to the remark that "it is ill taking the brooks off a Highlander;" and probably the sooner the attention of the sufferers is turned to some mode of replacing their loss by industry not connected with "l'exploitation de l'homme par l'homme," the better for them. Still it is extremely desirable that the whole case should be brought out into full daylight. Nor does it seem less desirable that such a judgment should be pronounced on the matter as shall mark with judicial reprobation all the parties to this great fraud. If they have nothing to pay, it does not follow that the injured should freely forgive them all. Especially does it seem appro-

priate that those persons who occupy positions of what may be called public confidence should be duly noted and branded for their complicity. Any explanation they have to offer should, of course, be patiently listened to, but unless forgery be added to the imputations thrown upon those who already have enough to answer for, there seems but little available ground for defence. The law speaks of what it calls conspiracy in the harshest and most peremptory tones. The mere accusation of men as conspirators is an offence, unless it be judicially justifiable. But what other term in the English language is applicable to the series of "arrangements" by which the hoodwinked public were induced to subscribe 638,000*l.* for "Debentures, 1864"?

THE ARCHITECTURAL DRAWINGS IN THE ROYAL ACADEMY EXHIBITION.

In the year 1768 the Royal Academy of Arts was founded (the Exhibition was opened January, 1769), and on Monday last the public were admitted, for the first time, to view the one hundredth exhibition held under its auspices. The walls of the different rooms are covered with pictures of average merit. The number of paintings sent for exhibition was, we understand, very much in excess of the number submitted last year; the wall-space remains the same, and the consequence of course is that the number of the rejected and discontented has proportionately increased. The "Eldest Sister of the Arts" has fared but poorly at the hands of the Council. It is to be desired that next year may see the Academy occupying their new home in Burlington-gardens, as, judging by the way in which the space allotted to architecture has been gradually curtailed, and their having already elbowed the art into the corner of an ante-room, we might expect, at the same rate of progression, to see it, in another season or so, kicked down the steps, and out of the building altogether. The few drawings hanging there are not fair specimens, and do not represent the capabilities of architects of the present day.

In the new building, painting will have a glorious opportunity to make amends to her injured relative for many years of cruelty. The advancement of architecture was one of the primary objects for which the Academy was founded, but this particular clause in the charter seems to be overlooked. Why are there so few architects amongst the body of academicians?

To guard against the probability of any of our readers being unable to find the small collection of architectural drawings, we may mention that the right-hand side of the south room—the first entered by the visitor—is thus appropriated. Let us see what is to be found there.

No. 831, "Brambletye, near East Grinstead," now erecting for Mr. Donald Larach, on designs, and under the superintendence of Mr. T. Roger Smith. This is a quiet and unpretending domestic group, in which each part of the building honestly expresses the purpose for which it was designed. The entrance-porch, hall, and tower are well accentuated by a richer treatment of detail and dignity of parts. The colouring is bold and harmonious, and some parts of the drawing are really charming pieces of landscape painting. The well-known ruins of Brambletye House remaining, it seems to be a mistake to give this name to a new building.

No. 832, "Holyrood Chapel, Edinburgh," T. Cafe, jun. The sketch of this fine old ruin has the merit of appearing to have been worked out on the spot. The colouring is dull; but this may be intentional, to keep the drawing more in harmony with the shattered fortunes of the place.

No. 842, "Mausoleum (of Sicilian marble and granite) erected from the designs and under the direction of J. Gibson." The upper is the best portion of this design, but it is too depressed to produce a pleasing outline in execution.

No. 843, "Design for a Mansion, proposed to be erected at Encombe, Dorsetshire, for the Right Hon. the Earl of Eldon," by David Brandon. The style adopted is Late Tudor, and it is altogether a very good example of what such a residence should be. The house is shown to be charmingly situated at the foot of some well-wooded hills, having ornamental water in front of it.

No. 845, "Chartres Cathedral," E. George. The sketching is clever and spirited, and the glow and tone of the colouring highly satisfactory.

No. 846, "The Sanatorium at Harrow School," C. F. Hayward. The open porch and pyramidal roof (with its *niche* termination placed over the staircase) is well-considered and effective. The materials employed in the building are red and blue bricks, with cut stone for mullions, &c., having coloured tiles for the roofs.

No. 849, "The Convent of Santa Maria della Salute," F. W. Scholander. The drawing of the domes is very commendable, and the climatic effect well indicated in the colouring. This drawing repays close examination.

No. 850, "View of the Quadrangle of Miss Burdett Coutts's Market in Bethnal-green," now approaching completion, from the designs and under the superintendence of H. A. Darbishire. We have already published an illustration of this building. The tower is the least satisfactory part of the design.

No. 851, "Exterior of the Convent of Saint Margaret, East Grinstead, Sussex," erected from the design of G. E. Street, A.R.A. A pen-and-ink drawing of a very severe design. The gable to the left side of the group is good, and the spire looks better in execution than it does in the drawing.

No. 852, "St. John's College, Cambridge: View of the New Chapel," now nearly completed, from the designs of Professor G. G. Scott, R.A., by J. D. Wyatt. This is a pretty drawing, delicately treated. The east end is apsidal and well arranged, the north chapel or transept resembling one of the old monastic rooms of an abbey, with its blank arcade corresponding to the main windows of the chapel, and its isolated hipped roof seems to have little connexion with the rest of the building. A good opportunity for raising a graceful spire appears to have been missed.

No. 853, "Silk-mercers' Bazaar, Cairo," by R. P. Spiers, has a cool and refreshing appearance. The shade thrown upon the street is pleasantly varied by the rich costumes of the merchants and their customers. This is a good specimen of Mr. Spiers's appreciation of form and colour.

No. 854, "New Church for Taunton," B. Ferrey. The tower, with its low spire of tiles, placed over the junction of the nave and transepts, is dignified. The chancel seems too short to balance the length of the nave. The windows to the aisles are too small in proportion to those forming the clerestory of the nave.

No. 855, "Design for a Town-hall, to which the Soane Medalion for 1867 was awarded by the Royal Institute of British Architects, G. Vials. The tower is fair in outline, but on far too large a scale for the rest of the main facade. The extremities of this principal front are not sufficiently imposing and lofty to balance the central tower. As the design of a young man it is highly creditable.

No. 859, "Mechanics' Institute," J. P. Jones. An unfortunate column of the same diameter as the rest in the main arcade, has to support one half of a lofty angle tower in addition to the full allowance of upper story!

No. 861, "Interior of a Church," by H. Conybeare, is a highly-finished coloured drawing of a building by the author, already illustrated in the *Builder*.

No. 863, "Crews Hall Restored, with Additions," E. M. Barry, A.R.A. The materials used are red brick, black brick for the diagonal patterns, and cut-stone dressings. The style is Elizabethan, similar to that of the old hall not long since burnt down. The roof of the tower might wisely be raised, on account of the depressing effect which the angle chimneys will exercise over it.

Mr. Waterhouse's design for the Manchester Town-hall has been so recently described and illustrated in those pages that we may pass over No. 865.

No. 869, "Mansion at Possingworth, Sussex," by M. D. Wyatt, is a very varied and effective group in the Tudor style. The material used throughout is cut stone. The conservatory is handsome. Mr. Wyatt also exhibits his India Office Court.

No. 870, "Interior, looking east, of the Crimean Memorial Church, Pera, Constantinople," just completed from the designs of G. E. Street, A.R.A. This view is quietly coloured, and for the most part well drawn. The chancel is groined, clustered columns marking the separation of the sanctuary from the choir. A rose window of pleasing design is placed over the altar. The clerestory to the nave is finely composed.

No. 873, "Design for a National Gallery upon

the present site," being an adaptation of a design submitted for the gold medal of the Royal Academy in the year 1849, H. S. Legg. A rather pleasing Classic composition. The central dome is too low to be equal to its position, and the circular features flanking the main façade are not sufficiently imposing.

No. 875, "Houze, Coombe Lammas, Esher," F. Wallen. An original group. The finish of the bay window is suggestive, and would be improved by its roof being carried up in a pyramidal form above the gables of the dormer windows.

No. 876, "Alley's College, Dulwich," by C. Barry, we propose to illustrate shortly in our pages.

Nos. 884 and 885 are coloured sketches, by E. George: one of "Lansanne Cathedral," and the other showing the "Churches of Notre Dame and S. Pierre, Caen." The sun of Academic favour evidently shines upon this artist, judging from the number of his works exhibited.

No. 887, "New Mansions, Bayswater-road," now in course of erection, by R. W. Edis. The extremities of these groups are well accentuated by bold pavilion roofs, and the most is made of the broad stack of chimneys on the outer wall. The bow-windows and balconies are calculated to look well in execution.

No. 889, "Premiated Design for the Bristol Assize Courts," E. W. Godwin & Crisp. This is a handsome and manly composition. The lower story is quiet and massive, all the architectural enrichment being reserved for the principal story. Over the windows on the main floor are crocketed hood gables, springing from corbels supporting staves under canopies. Above is a rich cornice abutting against small circular angle turrets. The dormer windows are remindful of those of the Hôtel de Cluny. The clock-tower is original and pleasing in design.

No. 891, "Holy Trinity Church, Shaw, near Oldham," by R. W. Drew, is a most clumsy affair altogether, and it should never have been submitted by the author, much less hung by the committee.

No. 896, "The Reredos now in progress for Chiochester Cathedral," Slater & Carpenter, is noticeable for the amount and size of the sculpture introduced.

THE ARCHITECTURAL EXHIBITION, CONDUIT-STREET.*

No. 52. "New Roman Catholic Church, now erecting in Kensington," by George Goldie. This coloured drawing represents an imposing interior, one calculated to look better in execution than in the view given. The columns to the nave arches are pleasing, but the soffits of the arches themselves are bare and flat, being of the full thickness of the wall, and relieved by nothing more than a plain angle bead. The roof is somewhat low in effect; it is trefoil in shape, having the purlins forming the angles of the cusp supported by shafts resting on carved tie-beams. The chancel is groined with the ribs springing from angle-shafts. The eye painfully feels the want of a ridge-rib. No. 53, "New Cemetery Chapels, Diss, Norfolk," J. W. Muskett, is interesting solely from being an architectural perspective view treated in oil-colours. The trees and sky are, however, the most pleasing part of the picture. No. 60, "New Church at Great Yarmouth," J. T. Bottle. The treatment of the upper part of the tower is suggestive. The spire, however, requires further consideration. No. 67, "Sketch of Sideboard," by B. J. Talbot. Substantial and quaint in design, delicately drawn and coloured. No. 75, "Pencil-sketch of a Drawing-room," by the same architect, showing a complete set of furniture as well as general decorations, carefully worked out.

Nos. 80 and 82. "Design for the Bristol Assize Courts," to which Mr. A. Waterhouse awarded the premiums, are hold and manly in feeling. No. 91, "Design for a Clock-tower, Leicester," J. Johnson, is in the Neo-Grec style. The outline is pleasing, but the portion above the clock is quite capable of improvement. The perspective of the circular finish, as well as of the clock-dials, is faulty. Red and yellow courses alternating are shown in the main portion of the tower. No. 97, A Gothic version, in a free treatment of the Early French style, of the same subject, and by the same

architect, is also good on the whole. The transition, however, from the square balcony over the clocks to the octagonal lantern which finishes the composition is by no means happy, for the space between the angle pinnacles and the side of the octagon is excessive. There is also a want of buttresses at the base of the tower.

No. 105, "Town Hall, Luton," T. T. Smith. An imposing design, well-considered in outline and detail. The colouring and finish of the drawing are worthy of careful examination. Nos. 106 and 107, "St. Swithin's Church, Lincoln," Messrs. Spiers and Drury. The tower and spire are decidedly fine, but the canopies resting on the brackets of the spire should be re-considered. The shafts to these canopies, being above vertical in the drawing, bave, from their proximity to the raking lines of the spire, the unpleasant appearance of tumbling forward. To avoid this damaging effect, the shafts should, in reality, incline slightly towards the spire. The treatment of the groining to the square-ended chancel is peculiar.

Nos. 115 and 116, Two frames containing ten sketches, principally from France and Germany, by Mr. T. H. Watson, who gained the Soane Medallion or Travelling Studentship of the Institute. The drawings are very valuable, from the number of measured details amongst them, and the crisp and decided manner in which they are executed. Nos. 120 and 121 contain twenty sketches from Italy and Venice, by George Patrick, and form a useful collection.

No. 152, "Sketch of the Bath-haus at Cologne," by H. W. Brewer. An oil-painting, showing in the foreground the grand portal of two stages, with ogee-shaped roof, and behind it the tower of the same building. The colouring is rich and varied, yet natural, and the detail and perspective of the different parts are carefully preserved. The grand portal is the only portion in high light,—an arrangement that assists greatly in the successful composition of the picture. No. 153 is the already known design for the Royal Exchange, by the late C. R. Cockerell, R.A.

No. 176 is the plan of the Pompeian house of H. H. Prince Napoleon, Avenue Montaigne, Paris, by M. Normand. Five other drawings, with the addition of some photographs from the building itself, illustrate this design, to which the Gold Medal of the Paris Exhibition, 1867, was awarded. On plan the porte-cochère is approached from the road by a carriage-way, enclosing a parterre, containing an ornamental water-basin, having a bronze group on a marble pedestal in the centre. On the right and left of this parterre are gates for ingress and egress, and beyond them porters' lodges. This porch gives access to an outer vestibule, which is but partially separated from an inner one by a flight of three steps, having a low balustrade on either side. The staircase leading to the upper story will be found to the right of this vestibule. In addition to this entrance-hall, two small reception-rooms, an office with private side-entrance for business purposes, and a room for archives, occupy the main front on the ground-floor. In the centre of the building is an atrium or hypæthral court. The shed-roofs are supported by four columns at the corners of the central water-basin, which is lined with ornamental tiles, to correspond with the surrounding pavements. The portion over this basin is open to the sky. The upper part of the roofs to this atrium is formed into a terrace, having doors leading on to it from the chamber floor. To the left, again, is the library, and on the right the dining-room, and below are the kitchen offices and heating-room. Beyond the atrium lies the state-room, which leads into the *salon privé*, an apsidal-ended room, supplied with a dais, and used for concerts. A bedroom and dressing-room, with small staircase leading to the upper floor, are placed on each side of the state-room, and on the left of the music-hall will be found the workshop, pinacothèque, swimming-bath, and hot-room. On the opposite side is the boudoir, and between them lies the flower-garden. The coach houses and stables, giving accommodation for more than forty horses, occupy the remainder of the site to the right of the residence. These buildings can be entered either from the Avenue Montaigne or the Rue Jean Gonjon. Illustrations of this building will be found in a previous volume of the *Builder*.

Nos. 174, 177, 179, and 180 are sections of different portions of the same building, drawn to a large scale, and showing the coloured decorations on the walls of the different apartments.

The beauty and delicacy of the drawings and richness of the coloured decorations render them very good examples of the style in favour at the Ecole des Beaux-Arts. In the whole of this series, and, indeed, in all the French drawings exhibited, the sectional portions are left white, instead of being heavily coloured in a manner similar to the walls of a plan, according to our usual custom.

Ten frames, containing nearly twenty drawings, illustrate a design by M. Charles Lamire for the interior decoration of a church, founded upon the Apocryphes of St. John. To this series a gold medal was awarded by the Commissioners of the late Paris Exhibition.

No. 192, "Perspective View of the Chevet and of the Triumphal Arch in this Church." In the centre of the vault over the choir, which has a bluish-green ground, and represents the Sea of Glass, is the Lamb with seven horns, resting on the hook with the seven seals, and pressing down the lid of the phial of the wrath of God, accompanied by the four beasts symbolical of the Evangelists. On the diagonal groining ribs, which spring from arched pendentives containing the four Greater Prophets, are angels holding captive the four winds of heaven, viz., Boreas, Eurus, Notus, and Zephyrus. On the arches above the cornice, enclosing the dome-lights, are placed the twenty-four elders, and on the spandrels below, the altar of God, and the horses with their riders that went forth of Jerusalem to execute the judgments contained in the great book. On the piers are placed the twelve Apostles.

No. 194 contains a Perspective View of the Porch. The doors are divided by two piers, having carved on their front face the Apostles St. Peter and St. Paul, the pillars of the Church. Above, in the tympanum of the arch, are the symbols of the Evangelists corroborating the truths of the Gospel. On the domed roof of this porch is a mounted angel, clothed with the dalmatic, raising the triumphant labarum. Below, over the angle piers, are colossal beads of the four divinities that Christianity has conquered, viz., Jupiter as Europe, Buddha as Asia, Isis as Africa, and Huitzilopochtli as America. All the figures are wrought in yellow bronze, and the artistic treatment and power of conception displayed upon them are very great.

No. 198, "Section of Nave, Choir, Sanctuary, and Apse." Each bay of the nave is occupied by two semicircular arches springing from a square cap of Byzantine design, the style adopted in this building. Above this a triforium occurs having four openings in each bay, divided by piers with semi-detached columns; on these rest moulded corbels supporting square lintels. The space between the triforium and main cornice is occupied by frescoes representing the invasion of the Barbarians and the Empire of Byzantium, the Merovingians and Carolingians, the houses of Valois and the Bourbon and Napoleon dynasties. The clearstory windows, one in each bay, have semicircular heads, and are covered into the arched ceiling. This ceiling has a bluish-grey ground, and angels with red wings and gold and green vestments worked upon it. The triforium is continued round the apse, but the openings differ from those in the nave, from their heads being semicircular. The domed ceiling has a gold ground, with white figures outlined in red representing the Word of God seated upon a horse standing on the vanquished dragon, and accompanied by the noble army of martyrs. Around the apse and behind the altar are nineteen seats for the choir, somewhat similar in arrangement to the ancient church at Torcello, near Venice. Stalls are placed on the north and south sides of the sanctuary. Those are amongst the most complete and carefully worked-out set of decorative drawings that we have ever seen. The architecture of the church is very tame, and some portions of the colouring might be objected to, but as a finished work the whole is very praiseworthy.

No. 201, "Design for Museum and Library at Grenoble, France" (gold medal, Paris Exhibition, 1867), by M. Charles Questel. The interior view of library exhibits three tiers of light wooden galleries, with ornamental railings, supported by metal brackets and bronze hands encircling coupled columns, separated from the wall by the width of the gallery. From the entablature over these columns spring flat segmental arches, bearing shallow domes glazed in the centre. The effect of these low arches is very depressing. As a drawing this approaches nearer to the English style than any of the other French designs exhibited.

* See p. 310, ante.

CONVERSAZIONE OF THE ARCHITECTURAL EXHIBITION SOCIETY.

ON Tuesday evening last the opening of the annual Exhibition of this Society was inaugurated by a *soirée* held in the rooms, in Conduit-street. In an opening address, Mr. Bevesford Hope, M.P., as President of the Society, said he thought the Exhibition of this year was the best that the Society had ever succeeded in collecting. He would not attempt to give any opinion of the drawings separately, as that was the pleasing duty that every one present had to perform for himself; nor would he enter into a detailed history of the progress of the movement: he would address himself to other topics. He considered that the conduct of the Royal Academy towards architecture had compelled architects in self-defence to commence an exhibition of their works under their own control. He called the attention of the meeting to the presence, upon some of the screens, of Sir Charles Barry's designs for the Houses of Parliament. These drawings, he considered, marked the most important epoch in the history of modern architecture. Before that time architecture was understood and enjoyed only by the favoured few, whereas now she was the welcomed guest of every educated gentleman, from the country parson to the highest in the land. The President next touched upon the subject of competition, which he viewed as a useful system if judiciously and honourably employed. He regretted to say, however, that the people who composed building committees were seldom conversant with the subject upon which they were expected to adjudicate impartially and successfully. He praised highly the system adopted in the late Manchester Town Hall competition, where architects were asked, in the first instance, for the smallest number of drawings capable of embodying their ideas. The drawings by the French architects were afterwards commented upon. Mr. Hope hailed with pleasure the increased use of mural decorations in our churches, which he considered should be composed of votive offerings from all the arts.

After a lengthened speech, the President resumed his chair. No one responding to his invitation to address the meeting, the formal proceedings terminated.

JOTTINGS FROM PARIS.

THERE seems at present to be somewhat of a lull in the bugle building operations which have so transformed modern Paris. There is, however, plenty of activity, according to English notions, but so many large works have been completed that Baron Hansmann must sigh for fresh worlds to conquer. Could we not tempt him to the banks of the Thames? He might take up, as preliminary trifles, to keep his band in, the Thames Embankment, the Metropolitan District Railway, the new National Gallery, and the new Law Courts. The new Opera House approaches but slowly its completion, but, as the exterior is now exposed to view, a judgment can be formed of its ultimate effect. This can scarcely be pronounced satisfactory. The use of coloured materials and gilding, though profuse enough in parts, is nevertheless so partially applied that unity of general effect appears to be sacrificed to an exuberance of ornaments and decoration, producing an effect which may almost be termed meretricious. A new street is about to be formed in front of the Opera House, leading directly from it to the Tuileries, and crossing diagonally the top of the Rue de la Paix, many houses in which will be destroyed. These are now being cleared out, preparatory to their demolition. When the new street leading directly to the Opera House has been made the want of an adequate central feature in the design of the latter will, we think, be apparent. It is true that there is to be a very depressed domical roof over the auditorium, but this will only be visible at a distance, and will not be prominent enough to possess much importance. It seems to us that the architect would do well to re-consider this portion of his design. It would be very easy so to develop the feature referred to as to confer on it the requisite importance, and the space gained by raising the roof would be useful for many purposes in connexion with such an establishment as the Académie de Musique. The building is grandly placed, with ample thoroughfares all round it. As regards the latter, a word of warn-

ing occurs to us for those who are responsible for laying out our streets at home. Nothing can be more dangerous than the wide crossings used here, especially when approached by carriages at an oblique angle, as in the case of the Place Vendôme. If wide crossings be required, they should be subdivided into narrower spaces by refuges for foot-passengers. They should not be wide enough to tempt coachmen to cross them at an oblique angle to cut off a corner. It is impossible to be fully on guard against carriages approaching from all quarters at once. For similar reasons, the mode in which the corners of the foot-pavements are cut off at the corners of streets is not to be recommended.

Many persons who admire the cheerful cleanliness of the fronts of Paris houses are not aware that this is not more due to the purity of the air than to enforcement by law of the periodical cleansing of every house. We saw a large building on the boulevards being cleaned by steam. A steam-boiler on wheels is placed in the road in front of the house, and flexible steam-pipes convey the steam to platforms suspended at various heights. Each pipe ends with a nozzle and steam-cock, and a workman holding the latter directs the steam against the stonework. Another workman, with a scraper or hard brush, rubs off the dirt as fast as the steam is applied. The latter issues with considerable velocity, and the work appears to be very rapidly and efficiently done. The workmen wear waterproof clothing, similar in appearance to the dress of our divers. We mentioned the application of the process to St. Paul's, Covent-garden, not long ago.

The builders appear to be still kept at bay on the confines of the Luxembourg gardens, and it would seem to be inexcusable to destroy this charming place of recreation for the children and others of that part of Paris who now enjoy it daily. It is very pleasant to see the rising generation playing about by the side of fountains and flower-beds, and sailing their toy-boats in the ornamental basins. By the way, when will English nursemaids emulate the simplicity of costume of the French *bonnes*, with their high white caps? The open squares in many parts of Paris suggest some thoughts of comparison not wholly to our advantage. In London the "squares" are private, reserved for the few, forbidden to the many; in Paris they are open to all, and charmingly kept up at the public expense. A single guardian preserves order, and there are plenty of chairs for the use of weary pedestrians. How is it that you may walk from one end of London to the other without the possibility of a rest, except by entering a house?

ARCHITECTURAL ASSOCIATION.

CONSTRUCTION OF HOSPITALS.

THE usual meeting of members was held at the House, Conduit-street, on Friday evening (the 24th ult.). There was a good attendance. The topic of discussion for the evening was "Hospitals," on which a paper was read by Mr. T. R. Smith.

Mr. Hayward, in moving a vote of thanks to Mr. Smith, observed that one thing in the paper which struck him particularly was the general adoption in modern hospitals of the plan of having the beds placed between the windows,—the only notable exception to this rule, in these modern hospitals, being in the case of St. Thomas's Hospital. It struck him as being at once remarkable and satisfactory that doctors should have arrived at so general an agreement upon this question. In some of the old hospitals with which he was acquainted the arrangement was different. Referring to cottage-hospitals, and their advantages with respect to cheerfulness and comfort, and pointing to the excessive death-rate in our large London hospitals, he said it became a question whether the professional spirit was not carrying us too far with regard to these large institutions. It occurred to him that some of these large institutions might, some years hence, come to be regarded as being far too elaborate to be worked satisfactorily,—far too large, not only for the neighbourhoods in which they are situated, but for their practical and perfect working in a pecuniary point of view. These were institutions generally founded upon a certain amount of endowment, as well as dependent upon voluntary assistance to carry them on; and if the public should come to be of opinion that they were too large, and that they

No. 205, "Design for a School of Architecture," sent in competition to the Ecole des Beaux-Arts, of which the author, Mons. Adolphe Coquet, was the senior pupil of the first department. Some parts are very chaste, and the tinting and general finish are most laborious. Although colour has been washed over the pencil lines, their strength appears to have been little affected by the process.

No. 239, "Study of a Design for the Manchester Town Hall," by T. Roger Smith. An effective group. The body of the tower, although we like to see some plain, honest masonry in a building, is too bare and unbroken, and the angle of main building in the centre of Princess-street wants finish.

No. 242, a drawing by Mr. B. J. Talbert for the same competition is a good specimen of pen-and-ink drawing. The treatment of the light and dark portions is very varied and artistic.

No. 249, 250, and 251 show a design for the same subject by Thomas Allom. The drawings are effective and sparkling. It is worth while to compare these drawings with those in the adjoining room by French architects. We can conceive no greater contrast.

No. 267, "Design for Clock-tower, Leicester," Medland & Edmeston. Decidedly good on the whole, and showing considerable knowledge of Gothic detail. The perspective drawing is done in hold firm lines, but looks hurried. We scarcely like the treatment of the angle canopies over the statues.

No. 271, "Design for a Town Hall," by H. L. Florence; obtained the second prize in the Soane Medallion competition. It is got up in the French style, and we believe was executed in one of the ateliers of Paris. The central tower is graceful, but the roofs over the angle pavilions are a joke.

No. 278, "Premiated Design for the London Orphan Asylum," T. H. Watson. The dining-hall is a manly and successful composition. No. 288, "Design for Stratford Town Hall," J. Johnson. The drawing is very French in style. The central block is novel and good.

No. 291, "Brooks's Bank and Offices in course of erection at Manchester," G. Truefitt. We may have another opportunity to speak of this.

Having so lately reviewed the designs of Messrs. Speakman & Charlesworth, Lee, Salomons, Wortington, & Waterhouse, which will be found in this Exhibition, we may proceed without further comment to examine the remaining drawings.

No. 383, Design in competition for a Church at Yarmouth, by Messrs. Giles & Robinson. Coloured principally in sepia, and drawn in a clear and spirited manner. The chancel arches or screen are peculiarly treated. A lofty central arch of wide span has, on either side, smaller arches with pierced quatrefoils in circles over them. Over these passes an enriched parapet with weathered coping. From this parapet rises a roof-principal with massive curved braces, forming a horse-shoe arch. The roofs over the nave and chancel are of the same altitude, and the principal before alluded to is of the same canting as the others, thus showing that the arches below have no adequate duty to perform—at least, more than what walls, posts, and corbels would have been equal to. The triplet windows in the east gable are very successful, and the tower and spire refined and graceful.

Both sides of two screens are devoted to Sir Charles Barry's drawings for Houses of Parliament, and are most interesting as designs, and as showing the amount of study that each portion of that important building received at his hands.

Numerous sketches, prepared by members of the Architectural Association, session 1866-67, are exhibited. Conspicuous amongst the contributors to this collection are Messrs. Vials, Ewll, Lonsdale, Jones, and Spiers. Some of the conceptions are very vigorous and original.

Photographs of some very capital sculpture by Mr. J. Forsyth will be found on one of the screens.

No. 401 is a photograph of a clever design for the head of a crozier, designed by Mr. W. Burges, in the style of the thirteenth century. Photographs of domestic furniture are exhibited by the same architect.

We cannot conclude our remarks upon this very interesting and instructive collection without expressing a hope that we have succeeded in inducing many of our readers to determine on visiting the Exhibition and examining the drawings for themselves. The rooms of the Society will be open daily till the 13th of July.

were made rather in consideration of the profession than for the cure of the bodily illness of the patients, he was afraid they might find themselves in difficulties. Mr. Hayward next alluded to a sanitarium which he had built for Harrow School, and a view of which had been sent to the Academy Exhibition. It was a peculiar institution, adapted to the requirements of the school. It was not usual for a school of 500 to require anything like a hospital; but there were occasions when great sickness occurred, and it was important then that there should be a hospital of some kind for the patients. In case of infectious disease, or where a patient was seriously ill and required to be kept quiet, it was necessary that there should be beds in separate rooms; but otherwise it was thought best to have the beds together for the sake of cheerfulness, which was a matter of the highest consideration, both as to the internal arrangements and as to the site. Altogether, he thought the plan to which he referred would be found simple and to work well; and it appeared to have met with the approval of the *Lancet*.

Mr. Blasill remarked that a hospital was only a particular and very special form of house. A house, ordinarily speaking, was intended for people under all circumstances of life, a hospital only for people under circumstances special and disagreeable. There were none of these hospitals in the olden times; it was only as the science of medicine advanced that it was thought better to have a large number of sick-rooms together. The leading idea which seemed to have influenced the whole of modern improvement in hospitals was greater ventilation and cleanliness. It seemed rather remarkable that, after all the ideas which had been put forth in old writings on the subject of cleanliness, it was not just in modern times we were beginning to act exclusively upon them. He had often heard people talking of our modern ideas of cleanliness, but they were by no means modern ideas; for in old writings, including the Scriptures, they were to be found in a remarkable degree. People were apt to sneer at these modern improvements, but it was not too late to open one's eyes to their importance, and help them forward. Mr. Blasill went on to say, with reference to Mr. Hayward's remarks as to hospital windows, that he should like to ask Mr. Smith as to the effect on patients of the large amount of window surface and the whitewashing upon the walls. Again, one of the most essential requisites with people when ill was quiet. Not only man, but all animals required quiet particularly, and not too much light, to induce sleep. It seemed to him that modern practice possibly went too far in increasing the ventilation and the light, and that there was not afforded, perhaps, that amount of quiet which was necessary.

Mr. Lundy said that, with regard to the effect of windows on each side of the beds, the light could be, and was, regulated as might be thought necessary by means of curtains, hung so as to keep the light away from the heads of the patients.

Mr. Ridge referred to the Lariboisiere, and observed that, although it had been generally taken as a model for construction, it had been found practically to be not a model in working; for he had read that the deaths there were equally numerous in proportion with the deaths which occurred in the old Medieval buildings used as hospitals in Paris. It was bountifully supplied with windows, but it appeared they were never open, the French doctors thinking it best to depend upon artificial ventilation, which they had ingeniously introduced, and which no doubt was all very good in theory, but which, it appeared, was attended with the unfortunate result that people did not live very well under it. With regard to ventilation, Mr. Ridge went on to argue that if, from their arrangement, the air around one bed was not infected by the air from the bed next to it—which seemed to be admitted—it was impossible that the infection could be such as to infect a bed in the next story, and that therefore if they had air enough for each space. Medieval hospitals, which were better than those of a later period, and came nearer to those of modern times, were extremely high, and well ventilated in the roof. With reference to Mr. Hayward's objection to large or elaborately constructed hospitals, he (Mr. Ridge) thought if they could afford to build such large structures they could also maintain them. At the same time, they ought honestly to keep in view, as was done at St. Thomas's Hospital, that they were building

so many distinct hospitals, with the view of treating the sick for their good, and not with a view to architectural effect.

After a few remarks by Mr. Matthews and others,

Mr. Smith replied to some of the observations. Mr. Hayward had referred to the tendency to build large institutions, and questioned whether they were not getting too elaborate. Perhaps there was a danger of that, but at any rate it was the temper of the present day, and to some extent it was no use going against the tide. Small hospitals might be as useful as complex ones, but the appliances hitherto brought to bear in these large institutions had generally been found conducive to some good end. As to that on the whole a large amount of light was rather beneficial than otherwise; and, as had been shown, it could be modified by means of the curtains, when the patients required shading. On the whole, medical men considered that the balance of advantage was considerably in favour of having the wards well lighted and cheerful. With regard to the whitewashing of the walls, it would of course be more advantageous if the walls could be covered, as was proposed to be done in some of our London hospitals, with pictures. He believed there was a good deal of truth in what had been said as to artificial ventilation in connexion with the Lariboisiere, where it had been resorted to, he believed, almost exclusively. What he advocated was a judicious mixture of artificial with natural ventilation, according as circumstances might require it; but artificial ventilation, for introducing fresh and throwing off vitiated air, was indispensable.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ACCORDING to the report of the council, which was read at the annual meeting, held May 4th, the Institute now consists of 623 members—viz., 262 fellows, 14 honorary fellows, 10 honorary members, 78 honorary and corresponding members, 236 associates, 11 contributing visitors, 10 students, and 2 temporary students.

The report referred to the re-election of Mr. W. Tite, M.P., as president, after an interval of four years since he held the same office.

"The council regret that his state of health has deprived them and the Institute generally of the benefit which on former occasions was frequently derived from his personal presence and supervision, and which, no doubt, all the other members had anticipated from the able and zealous co-operation he has hitherto afforded in all matters concerning the interests of the profession. They have, however, thankfully to acknowledge that, notwithstanding his absence, they have received most gratifying and practical evidences of his good will and thoughtful liberality. The contents of the library of the Institute are now being enriched by means of a munificent donation of £500, a special vote of thanks was accorded to him by a general meeting of the members."

"There can be little doubt that the collection of architectural works of the Institute promises to surpass any of the kind which exists, and will form a library of reference for the members of the highest value and utility, thus affording a privilege of which it is to be hoped they will avail themselves."

The board of examiners of candidates for certificates of competency to act as district surveyors have, since the last annual report was issued, held three meetings, at which sixteen candidates have been examined, ten of whom, having been recommended to the council by the board, have received certificates of competency.

"The council regret that their efforts to establish voluntary architectural examinations meet with scarcely any response from the younger members and students of the profession, only one candidate having come forward for the ensuing examination. In accordance with the recommendation of the revising examiners, it is intended to hold the examination notwithstanding, it is intended that thanks are justly due to those members who have kindly promised their services as examiners, and moderators, but it is to be regretted that so much zeal and energy should be expended for so inadequate a result. It is advanced thus offered be evinced, it will be impossible to continue the machinery that has been established for the purpose by the Institute with so much care. It may be, therefore, worth reconsideration whether the granting of some certificate would be desirable, in order to attract a greater number of applicants."

DESTRUCTION OF GREYSTOKE CASTLE.—The seat of Mr. Henry Howard, near Ullswater, has been destroyed by fire. The main building is gutted, and many valuable paintings of the Howard and Norfolk family have been destroyed. Some valuable art-treasures have been saved.

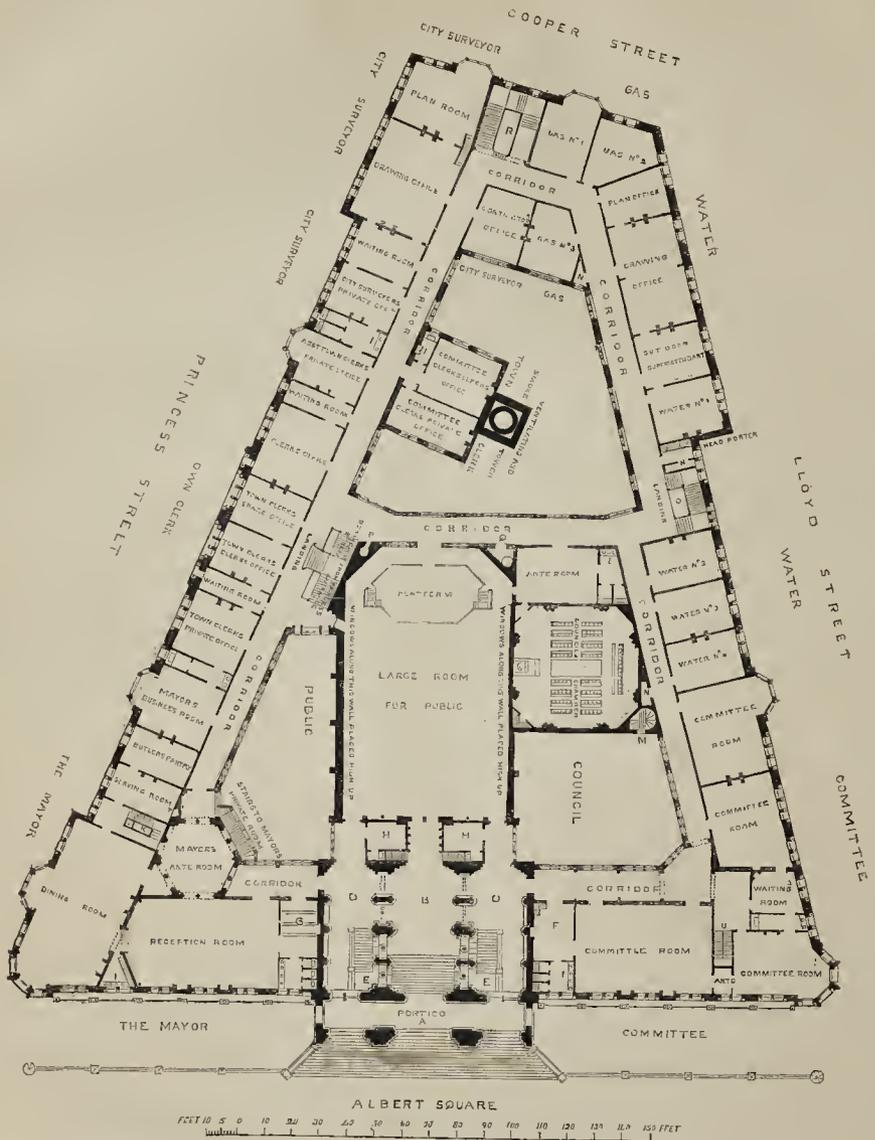

WORKMEN'S READING-ROOMS AS AN AID TO SANITARY IMPROVEMENT.

In a communication on the relative immorality in town and country by a correspondent from Carlisle, the workmen's reading-rooms of that city are set forth as an example for imitation, with the view of promoting sanitary disclosures in towns. After quoting Dr. French's disclosures as to overcrowding and its impurities in Liverpool, the writer says,—"The question naturally divides itself into two others,—firstly, how may popular education in large towns be most readily accomplished? and, secondly, of what shall it consist, so as to be at once acceptable to the recipients and effective for the great object in view—our national welfare, based on the great individual comfort and prosperity? . . . Is Carlisle not in a position to give practical lessons in this matter to much larger towns? May we not with gratification resulting from a twenty years' experience point to our Working Men's Reading Rooms, as by far the most satisfactory solution of this vexed question which has ever yet been afforded? . . . Let Liverpool take the hint we now kindly offer; there is no great difficulty in the way. Let every town in the kingdom adopt the plan so admirably worked out by the working classes in Carlisle. . . . The original Mechanics' Institute founded by Dr. Birkbeck at Glasgow some sixty years ago remained unimitated for twenty years; and having then been copied in Edinburgh, and subsequently in London, whither Dr. Birkbeck had removed, these invaluable societies spread and multiplied rapidly in all directions. But experience having proved that, however great the public benefit is which they have conferred (and this is very great indeed), they nevertheless had unexpectedly and signally failed to do the good intended, the want not supplied being more than ever felt; something was still longed for; and that something did, in 1843, turn up in our Border city. Twenty years have confirmed the good opinion formed, and now we shall be glad to hear that these invaluable libraries and news-rooms for the labouring classes are shortly to be sown broadcast over the land."

A tractate on working men's reading-rooms, by Dr. R. Elliot, of Carlisle, printed at the Victoria Press, Great Cornam-street, London, treats of the principles of, and the benefits derived from, the Workmen's Reading Rooms in Carlisle.

THE TRADES MOVEMENT.

Liverpool.—The Bricklayers' Union has caused a strike at the works of Messrs. Holme & Nicol, builders and contractors, the grounds of dispute being understood to be the refusal of Messrs. Holme & Nicol's foreman to pay a penalty of 5l. towards the expenses of a former strike, and an opposition to a new code of rules of which the master builders had given notice. The Master Builders' Association have intimated that, unless the strike against Messrs. Holme and Nicol be immediately withdrawn, steps will be taken to protect that firm, and that, after the 4th of May the master bricklayers will only employ men who are willing to work under the new code of rules. It is hoped that the men will yield, and that a general strike, which would throw about 4,000 men out of employment, will be averted. In regard to the new rules, the bricklayers contend that no proper notice was given, and that as no mutual discussion of new rules took place, the notice was informal. The masters, on the other hand, say that when the new rules were drawn up the bricklayers were invited to meet the Masters' Association Committee, and refused; that the six months' notice having expired, the Masters' Association determined that the new code of rules should come into force on the 4th of May next. As opposed to this statement, Mr. Loe-Nham, on behalf of the bricklayers, asserts that after an abortive interview in October, the subject lay in abeyance until the society received a note from the masters, dated the 22nd of Jan. next, accompanied by a code of rules drawn up for the consideration of the men; but the masters gave no notice when their rules were to come into effect, and Mr. Lachman emphatically denies that the employers ever sent the society a note regarding "a second interview." He contends that the only "definite notice" given by the masters to the men was dated only the 17th of April, and comes into operation on the 4th of May, which is "quite opposed to the agreement" settled upon.

DESIGN FOR MANCHESTER TOWN HALL.—Plan of Principal Floor.

MANCHESTER TOWN-HALL.

We illustrate in our present number the design for Manchester Town-hall submitted by Messrs. Speakman & Charlesworth, and to which the first place for architecture was assigned by the professional referees.* We have already expressed our opinion of its merits, and described

* See p. 261, ante.

its main features. We add the following references to the plan.

REFERENCES.

- A. Portico. Floor paved with glass and carriage-drive beneath.
- B. Staircase for public from portico.
- C. Staircase from public carriage entrance.
- D. Staircase from mayor's carriage entrance: the three capable of being used as a grand staircase.
- E. Covered carriage entrance.
- F. Gentlemen's retiring-room.

- G. Hat and cloak room.
- H. Ladies' retiring-room.
- I. Lavatory.
- K. Back stairs.
- L. Hoist.
- M. Stairs to gallery.
- N. Housekeeper's closet.
- O. Stairs from Lloyd-street entrance.
- P. Dust shaft.
- Q. Coal shaft.
- R. Staircase from Cooper street entrance.
- S. Stairs to second floor.
- T. Stairs for coals.
- U. Stairs from detective department.

DESIGN SUBMITTED FOR MANCHESTER TOWN HALL.—By MESSRS. SPEAKMAN & CHARLESWORTH.

THE LIME AND PLATINUM LIGHTS.

A RENEWED endeavour to make the lime or Drummond light available for use instead of gas is being made. With that view improvements have been suggested. Arrangements are being made for supplying Perth barracks with the lime light. The jet of hydrogen being lighted, a separate jet of oxygen will be turned on so as to mix with it at the moment of combustion, when the flame impinges on the lime, which then emits the intense light for which it is noted when white hot. Various towns in Scotland are said to be adopting the light. Another light of an analogous description has been suggested by a Frenchman, M. Bourbouze, who uses common air instead of oxygen, and common gas instead of hydrogen, for the sake of economy. In this case the air and gas are admitted into one common tube; thence they pass through a sheet of metal, perforated with a great many holes, in order to be divided into many small jets: these are delivered through a gauze of platinum wire, when they are lighted. The metal, in being heated, soon becomes red, then white, and thus diffuses a dazzling light. If, as seems to be the case, the air and gas on this plan are previously mixed in the proportions proper for combustion, that is a dangerous element in the proposed light, because such a mixture is explosive. We would suggest, therefore, that the air should be supplied to the gas at the point of combustion. Otherwise, perhaps the platinum light would be less unsuitable for ordinary house illumination than the lime or magnesia light. Has lime ever been tried with a light from street-gas and common air instead of pure or mere hydrogen and oxygen, or gas and oxygen?

REPORT OF THE AMALGAMATED SOCIETY OF CARPENTERS AND JOINERS, 1867.

THE eighth annual report of this Society, by the General Secretary, Mr. Applegarth, has been issued. We have often spoken of the exemplary business-way in which these reports are made up, and of the very prosperous state of the Society, which is a highly important and influential one in the trades movement. The branches are upwards of 200 in number, comprising among them fully 8,000 members; and the accumulated funds of the union actually in hand already exceed 15,000. In 1860 its members were only 600, and its available balance, 320. The depression of trade last year has had its influence on the progress of the Society, but still it has been progressing. The income was 18,245, and the expenditure, 16,144; so that even an unprosperous season added upwards of 2,000 to its capital. Mr. Applegarth advocates "union not only among men against masters, but among masters and men together," and is sanguine as to the practicability of arbitration.

PRIZES FOR ART-WORKMEN.

THE council of the Society of Arts, having first referred the list of prizes to be offered to art-workmen to a committee, consisting of Mr. Hawes (chairman of council), Mr. Redgrave, R.A., Mr. Digby Wyatt, Mr. Godwin, and Mr. Le-Neve Foster (secretary), has issued an entirely fresh programme. It has for its special objects—1. To encourage the revival of the practice of dormant or rarely-used processes of handicraft, by which the field of art-industry may be extended, and art-workmen thereby be, in course of time, more adequately remunerated as a class; and, 2. To exercise the artisan in the practical application, in accordance with recognised principles of good taste, of the art-processes so to be revived, to objects of ordinary use, hitherto for the most part unadorned.

In considering the apportionment of the money prizes to the respective subjects, attention has been paid to the probable expense to which any art-workman must be put in each case who may enter upon the competition.

In the first division, "Specimens of art-workmanship in prescribed processes," the money prizes are in all cases of smaller amount than in the second division, "Specimens of the application to ordinary industry of prescribed art-processes."

The reason for this difference consists in the fact that the council look for minor specimens

in the one case, involving the workman in little expense beyond the risk of the loss of his own time, against which he should set the value of the improvement he may derive from making the effort under any circumstances; while in the other they expect to see a finished article of a more elaborate nature, fit for immediate use by any purchaser.

Art-workmen are earnestly recommended to pay due regard to simplicity and harmony, as well as richness and elaboration, in all their productions, since the judges will estimate no less highly purity of line and good balance of colour, or of plain and enriched surfaces, than they will any merits of mechanical execution.

The taste exercised in the selection of objects for ornamentation will be considered in the adjudication of the prizes.

All the prizes are open to male and female competitors on equal terms; and, in addition, special prizes, on the same scale as to amounts, will be awarded, at the discretion of the judges, among female competitors, although the specimens exhibited by females may not be as good as those exhibited by males, not deemed worthy of reward.

Two or more art-workmen may concur in the production of any article sent in for competition; but in that case the names of, and respective parts taken by, each must be specified when the article is sent in.

We shall hope to hear of a very full response on the part of art-workmen to the offers of the society.

FROM SCOTLAND.

Leith.—The new dock works are in a forward state. All within the entrance is completed, except a very small portion occupied by a line of rails for conveying building materials to the new harbour or basin in course of construction. The excavation is completed, and so are the quay walls, even to the placing of the copestones. At the entrance to the dock the works are in an advanced state. The masons' work, with the exception of the laying of the copestones, is finished, and workmen have begun to erect the gates. The only portion of the works uncompleted where any delay is likely to arise is at the outer harbour or basin, that will occupy a space equal to two superficial acres. There the excavation has been completed to within a short distance of the East Pier, and the builders of the quay walls are close on the excavators; but though this in the case, a tedious piece of work has to be accomplished by Mr. Scott, the contractor.

MODEL FARM BUILDINGS AT AUDLEM.

THE trustees of Lord Newry (the Hon. J. Knox and Lord Alfred Hervey) have recently invested considerable sums in the purchase of landed property in Cheshire and Shropshire, as nearly as may be, contiguous to the family estates. Among others the fine old half-timbered house, "Moss Hall," near Audlem, has fallen into their hands, with the surrounding farm, and on this estate the trustees have lately completed a range of farm buildings on improved principles.

The buildings comprise three sides of a square, with a projecting range on the north side. The range of buildings on the east consists of pig-house and two-stalled hacks' stable, with loft over; implement-house and cart-house (including loose box), with loft over. On the north are drift-house (enclosed with large doors), two loose boxes or hospitals, corn hay, barn, and straw bay; also large root-house, with chopping-room over, from which radiate, south and west, two donkey cow-houses open to the roof, and furnished with Musgrave's patent iron fittings as used in the Government model farms; one house containing forty cows, and the other twenty cows and twenty-two young stock, with houses for calves and yearlings. The ventilation of the cow-houses is by "bonnet" ridge at intervals, and louvre boards at the centre of each range, the centre one being surmounted by a vane with a "fox" indicator. Down the centre of each cow-house there runs a "gangway" for feeding purposes in direct communication with the root-house, straw bay, and an intended "Dutch" hay shed. In the angle formed by the two ranges of cow-houses there is a paved causeway all round, five yards wide, with sunk manure stead in the

centre, which receives the drainage from the cow-house, as also the refuse of the whole of the buildings. The paved yard is about 80 ft. square, with soft-water tank and pump in the centre, into which the rain-water of the building is carried, with watering trough attached.

The piggeries constitute a prominent feature at the area of the "old hall," and have outlets at front and back; the front outlets are divided with iron fence, the walls being of stone, with troughs of the same material. The yard at the back is to be fenced with wooden rails, and is intended for the deposit of straw and litter to be converted into manure.

The whole pile of buildings is of red brick, made on the site of the new building, with arches of blue bricks. The entire cost is about 2,000. The erections are from the designs and under the superintendence of Mr. John Myatt, of Congleton; the builder being Mr. Beckett.

THE INDIA AND FOREIGN OFFICES.

LORD REDESDALE, in the Commons, the other day, moved for a return of the cost of four statues erected against the pilasters at the south-west angle of the India Office, and the cost of the decorative paintings of the interior of the India and Foreign Offices, and asked whether it was intended to allow the east front to be completed on a line which would render the demolition of the front of the present Government offices necessary, or require it to be so constructed as to form a handsome elevation in connexion with those buildings.

In reply, the Earl of Malmesbury said that the cost of the statues of which Lord Redesdale disapproved was only 847. The report would very soon be laid before Parliament, when the whole plan would be announced and explained.

Lord Redesdale said that the statues were positively unsightly, and were contrary to every principle of architecture. He was glad to hear that the design for the buildings for the Whitehall front was to be carried out.

COMPETITION.

It having been decided to erect new schools at Gaddesby, near Leicester, a design by Mr. R. W. Johnson, architect, of Melton and Leicester, has been selected in a limited competition. The building, which will be of red brick with white stone dressings, will be commenced forthwith.

MIASMATIC EMANATIONS.

DR. JULES LEMAIRE, who, for many years past, has been examining the theory of miasma, ferments, virus, &c., according to which theory they are considered to be albuminoid substances modified by oxygen, has arrived at the conclusion that this is an erroneous view of the question, and that its author, Baron Liebig, confounds, under the generic name of ferment, agents of an essentially different nature; that his doctrine contains some contradictions, and is insufficient to explain various known facts, as well as certain new ones due to Dr. Lemaire. *Galignani* thus describes one of his experiments:—

"In one of the rooms in the barracks of the Fort de l'Est, near St. Denis, and inhabited by volunteers of the Garde Impériale, all young and vigorous men, he placed a frigoriferous apparatus of his on a table a metre in height, all the windows and doors being closed as soon as the soldiers were in bed, that is at nine p.m. A similar apparatus was placed in the open air at the same altitude, for the sake of comparison. At four a.m. the water collected in the open air had the taste of the pure element, and presented nothing extraordinary. That collected in the room had the smell of confined air, and the microscope revealed in it a considerable number of transparent spherical, ovoid, and cylindrical bodies, their dimensions in length and breadth varying between two and three thousandths of a millimetre. They were microphytes and microzoaria in a state of incipient development. Six hours after condensation their number was found to have increased; there were thousands of them in a single drop of liquid. There were various bacteria of the termo and punctum species, and numerous vibrios were moving about in every direction. There was also a mould described by Ehrenberg, and which Dr. Lemaire thinks might be the cause of typhus fever."

The importance of ventilation in a hygienic point of view is thus obvious, since these minute creatures, which are so easily generated, are, with some reason, believed to be the cause of many diseases, the origin of which remains otherwise unexplained. We may here add, that

we do not think the importance of certain agents which prevent the formation of microscopic life is fully appreciated. For example, paste, or moist dextrine, will very shortly develop such life, but if it be well spiced with oil of cloves it will keep for months without doing so, or in any way altering or decomposing. If certain diseases are caused by animalcules, the power of such agencies ought to be tested in these cases.

ACCIDENTS.

ST. PAUL'S CHURCH, Little Chester, Derby, has been struck by lightning, which completely shattered the minaret, 14 ft. or 15 ft. high. The stones were thrown in all directions on to the roof and into the churchyard and two neighbouring fields, some of them being carried to a great distance. The roof was damaged in a great many places by the falling of the stones. A portion of the stonework on the opposite side of the tower was torn away, and one of the three small pinnacles injured. Beyond the falling of the stones, the interior of the church has sustained no great injury.

While the workmen of Messrs. W. Beattie & Sons were engaged removing the roof of Morning-side Church, near Edinburgh, which sustained much damage during the gale of January last, another accident occurred to the building by a heavy gale, whereby a considerable portion of the roof was blown down. Happily, none of the men were injured.

By the fall of a gangway at Spittal-street, in the same city, three men have been injured at a house in course of erection. They were engaged in carrying a large stone, weighing some 8 cwt. or 10 cwt., up a gangway, in preparation for the masons commencing work. When they were about half-way up, the piles by which the gangway was retained at the bottom suddenly gave way, the gangway slipped, and the men, six in number, were precipitated to the ground from a height of 8 ft. or 10 ft.

A sad accident occurred at Chicago on Good Friday. The Roman Catholic Cathedral of St. Mary was filled with people, and the weight of the multitude caused a portion of the floor to give way, which, raising a great dust, led some one to cry, "Fire!" A terrible panic ensued, and in the rush that was made for the doors four women were crushed to death, and twenty or more persons were seriously injured, three of them having since died.

A terrible disaster is reported on Lake Michigan. The steamer *Sea Bird* caught fire when about thirty miles from Chicago, and in ten minutes was wrapped in flames. There were about 100 persons on board, all of whom, including the officers, perished, except two persons, who were saved by a schooner which was passing.

THE BELLS OF WESTMINSTER ABBEY.

The north-western tower of the Abbey Church of St. Peter, Westminster, contains a peal of six bells, and a saint's bell. The first and fourth of the peal were made by Thomas Lester in 1743; the second was evidently cast in the fifteenth century; the third and fifth respectively in 1583 and 1598, Gabriel Goodman being then dean. The sixth, or tenor, bears the following inscription:—

"Remember John Whitnell, Isabella his wife, and William Rus, who first gave this bell, 1430. New cast in July, 1599, and in April, 1738. Richard Phelps, T. Lester, fecit."

The comparatively small, or saint's bell, was also made by Thomas Lester.

I do not hesitate to say that the tenor, or largest bell of the peal, is an excellent one, remarkable for dignity and mellowness of tone, its weight being about 36 cwt., and its note D flat. It will be seen that this bell bears the names of Richard Phelps,—founder of the great bell at St. Paul's,—and Thomas Lester. According to the Whitechapel register of hirals, Phelps died in 1738; and I may state that Lester was his foreman and subsequent successor. This will account for both of their names appearing on the bell.

In an opening in the upper part of the gable of the south transept is another comparatively small bell, which was made by Thomas Lester in 1749.

I may here mention, in order to show when

and how the bells are sounded for calling the people to church, that divine service is performed daily in the Abbey at 10 a.m. and 3 p.m., and on Sundays during the summer there is a special service in the nave at 7 p.m.

Half an hour previously to each of these services the fourth and fifth bells of the peal commence chiming, and are continued until five minutes have elapsed, when, if a sermon is to be preached, the fine tenor bell is tolled for about three minutes. At fifteen minutes before 10 a.m. and 3 p.m. the small bell in the gable of the south transept is tolled, and this is continued until the clock in Poet's-corner proclaims the hour. For the special service in the nave on Sunday evening the small bell in the north-western tower is tolled during the last fifteen minutes.

On week days there is also an early service at 7.45, for which the small bell in the south gable is tolled, commencing at 7.30; and on Sundays Holy Communion at 8, for which the same bell is sounded at 7.45 a.m.

This bell is also rung daily at 8.45 and 1.30 for about three minutes, after which forty strokes are given on the tenor bell.

I have said that the tenor or great bell is a remarkably fine one; and I believe it is never tolled for deaths or funerals except for a member of the Royal family. It certainly was not used at the funeral of the late Lord Palmerston.

THOMAS WALESBY.

THE FROG AND LIZARD, ROME.

SIR,—In the *Builder* of the 15th ult. reference is made to the statement of Pliny that two Greek architects placed the figures of a frog and lizard upon the "bases" of the columns of the Portico of Octavia, at Rome, as emblems of their names, Sauros and Batrachos. In the basilica of San Lorenzo is the Ionic capital of a column, which has a lizard and frog in the "volutes," and which is said by Professor Nibby to have been brought from the above portico.

When at Rome a few years ago I sketched the capital, and have it now before me. Of course the above is only interesting as verifying Pliny's statement, the carving and design of the capital being very inferior.

ALFRED PERRY.

STORING RAIN-WATER.

I CAN bear ample testimony to the convenience of storing rain-water. I have an underground cistern containing about 1,500 gallons. It was made ten or twelve years ago, and it has never yet been entirely empty. The water it contains, which comes from a slate roof of a school-room and dwelling-house, is perfectly clear and fit for any domestic purpose.

True, after a heavy shower of rain, succeeding dry weather, it is somewhat discoloured, but that soon passes off. The water not being exposed to the action of light, there is no animal life developed therein, as is the case in tanks or cisterns exposed to light and air. This is the third cistern of the kind I have had made for myself in different houses, and though each house is supplied with water from the town water-works, I consider the rain-water far the more valuable of the two; and, what is more, I have no water-rate to pay for it. There is certainly the expense in the first instance, also the cost of a pump, but the additional comfort afforded far outweighs that.

J. B.

PROPOSED MUSEUM IN LEIGHTON BUZZARD.

It would seem from the following communication to us that the statements that have been made as to the foundation of a Paxton Memorial Institution at Leighton Buzzard, are a little premature. A plain account of the proposal and the steps already taken is as follows:—

In January last an Industrial Exhibition was held in this town, under the management of the "Working Men's Mutual Improvement Society." It was opened by Lord Charles J. Russell. In the course of his lordship's inaugural address, he made an suggestion to the effect that the exhibition should lead, eventually, to the establishment of a museum, to be associated with the name of Sir Joseph Paxton, as a native of this locality.

This idea has been taken up by the working men, and, at their annual meeting on the 15th ult., three resolutions were passed, one approving of Lord Charles Russell's proposal, another specifying in outline the kind of institution deemed desirable, and a third resolving that a memorial address be presented to his lordship, calling upon him, as the originator of the idea, to take the necessary first steps in order to ascertain the practicability of the proposed scheme. The memorial address now only awaits a convenient opportunity for presentation. We have advanced no further than this. It will, therefore, be evident that the statements in the paragraph referred to are premature. We are sanguine enough to hope that the scheme, when fairly before the public, will meet with support, and that the statements which we now feel bound to notice may, at no distant time, be substantially realized.

On behalf of the Working Men's Mutual Improvement Society,

EDWARD W. LEWIS, Treasurer,
WILLIAM ABRAHAM, Secretary.

COMPOUND CHURCHES AND HOUSES.

SIR,—The letter of your correspondent "Progress" induces me to bring forward somewhat similar ideas which I have long entertained.

I propose to group a number of churches of the same or of various denominations around a central dome which would form a grand vestibule to all of them. This arrangement would admit of many modifications. The simplest would consist of each forming a separate church, while the central dome would, if the structure belonged to the Established Church, be used as a baptistery and for the administration of the Holy Communion.

The arrangement may even be carried so far as to have two stories of churches, the lower ones with fireproof domed ceilings, and the upper ones domed. The central dome would, in this case, be surrounded by an arcade, and grand staircases on each side would give access to the upper churches.

A somewhat similar construction to that I propose for churches could, I believe, be adapted with advantage to private dwellings. In these days of Limited Liability Companies it is surely possible to buy a square mile of land, and upon this area to erect sixteen large blocks of buildings, each composed of from six to ten flats surrounding a spacious piazza? If the blocks were, on an average, six stories high, and contained twenty houses on each side of the piazza, the population per square mile would, reckoning five persons to every habitation, be 38,400, which would be swelled to more than 40,000 by the residents in hotels, keepers of public halls, &c.; space for which would be found in the angles of the building, where bath-rooms, washhouses, and public schools could also be located. The basement floor could be used for warehousing, and the ground floor for shops of various kinds.

The entrance to each block could be in the centre of each side; and the enclosed space could, if thought desirable, be in some instances roofed with iron and glass, and converted into a conservatory.

The unoccupied ground, which would be, at least, three-quarters of the whole (since the accommodation above mentioned would not, at most, require each block to be above 600 ft. square) could be laid out into broad streets or walks, bordered with trees and flowers, and adorned with fountains, while ample spaces could be still left, covered with greenward, for the athletic games of the youth of the town. Each block would form a spacious parib or ward, and should be bound to keep in order its own streets and open spaces. The churches might be grouped as above described.

A law built in this manner would afford ample scope for the architect and landscape-gardener to exert their highest powers, and noble results might be reasonably expected were the system to be tried.

W. N. T.

HOW IS THIS?

In the *Builder* of Saturday last there was an intimation from the Architectural Association that, on the same afternoon, "a visit will be paid to the New Smithfield Markets, at which place members are requested to assemble at three o'clock precisely." The notice was signed by both honorary secretaries, and no doubt many persons deemed that there was a treat in store for them. I, myself, was amongst the number, and, expecting to hear the opinions of distinguished people, put off a visit that I intended to the Southern Thames Embankment opening. Of the two affairs I chose what I considered the "superior article," and, at three, "military time," was let into the premises by the small boy in charge at the wicket. Once inside, I naturally looked about for such distinguished members of the engineering and building sciences as I counted upon, but, to my astonishment, I found myself the most distinguished person present. The only other people I could see were a couple of brace of labourers and a ganger; the latter asking me for my name, with all proper respect, adding that "it was Mr. Jones's special desire." I then walked from one end of the building to the other, and from side to side; and, thinking that the gentlemen might all be below, I made for the *facilis descensus* of the regions below, but found it strongly barricaded and covered in with tar-pastin. I listened for voices, but, alas! all was still, save the "Hi!" and the "Ho!" of the labourers, whose privilege it is to work on Saturdays three hours after everybody else has gone for the week!

I began to feel myself the victim of a "sell," and, as I deemed the public opinion of the five working men a matter of importance, I pulled out my "two foot" and began to do something.

Where were the "authorities" who were to receive the Association? Where was even the clerk of the works? Presently, two or three gentlemen came and, seeing me at work, they made up at once, thinking that I was an

official party. We asked one another questions, but could not give one another answers. We then spread ourselves out in skirmishing order to make a reconnaissance, but the country in front was entirely deserted. We were obliged to go back, and with similar results as before. At length, four o'clock having arrived, and no more company putting in an appearance, I thought that it was time to move off.

"How is this?" said one, and "How is this?" said another, before I left the building. I am, sir, but a plain man, and I love fair play, if it is only tossing for pious. I would, therefore, say, in plain terms, that "somebody" put up "sewer-covers" in the hole, and the secretaries have put us "in the hole," and— "How is this?" STYLUS.

"CONCRETE SEWERS."

Sir,—From the earliest times, all who have dared to earn their bread by abstract thought, or have tried to promote the health and comfort, or otherwise improve the condition of their fellow-men, have had to encounter an amount of ignorance, prejudice, and opposition that, when viewed by the light of science, is absolutely astounding.

As a rule, the inventor is ever before the age in which he lives, or rather exists; the offspring of his brain is unacknowledged, or received with indifference, but the *Builder* for the *Times* notices "Nobody's Child," fifty loving fathers claim him at once as their own.

In your impression of the 4th ult. you refer to the construction of concrete sewers at Sidmouth, and again, on the 5th, you publish a letter, written by Mr. John Phillips, on the same subject. This letter will be received as a lesson by many young engineers, and your publication of it will give confidence in the use of a material too long overlooked.

No one will now dare dispute the advantages consequent on good drainage. Not a sewer can be formed, or a pipe laid, without lessening the death-rate of the locality. Yet how many districts remain fever-stricken in consequence of the prohibitory cost of procuring the necessary bricks or large pipes from works far distant, when the very material necessary for good and perfect drainage is to be found under the feet of those whose duty it is to bring consideration to bear upon the appliances within their reach! Charles Swanke has it, "Flowers as sweet bloom at our feet, if we would stoop to find them." I hope in the future that surveyors and engineers will turn to profitable account materials hitherto rejected and carried away at considerable cost.

As one whose whole life has been devoted to experiment,—who has tried in his generation to be useful,—I would ask you in common fairness to record a fact—viz., that in December, 1852, her Majesty granted me Royal letters patent for constructing sewers of concrete. (Here I send you the official copy of the patent.) Sixteen years have passed, and the effort I then made has never been acknowledged, but the value of my conception at that date is proved by the fact of all the sewers and drains in connexion with the late Paris Exhibition being of beton or concrete, with many of which I had to form close acquaintance, but the works entrusted to my care, and in doing so I found them to be more like Portland stone than concrete. I hear also one of the engineers of the Metropolitan Board has, during the past week, been engaged to construct sewers, and Mr. Phillips asserts the sewers of Sidmouth are most satisfactory.

These facts, I think, prove my statement, that "as a rule, the inventor is ever before the age in which he lives, or rather exists;" but I am content if you record the fact that I sixteen years since suggested the use of "concrete for sewers and drains." GEORGE JANINUS.

HORNCASTLE TOWN SEWERAGE TENDERS.

Sir,—My attention has been directed to a letter in the *Builder* of last week, signed by the Rev. W. H. Milner, chairman of the Local Board. By the insertion of my name, the Rev. Mr. Milner indirectly calls upon me to reply to his assertions that the works intended for the subject contained "erroneous" statements; perhaps he does so from the circumstance that my tender was originally the lowest.

As you stated that more than one contractor had supplied information, I think the rev. gentleman somewhat unnecessarily introduces my name, and improperly writes as follows:—"I hope Mr. Frow was not one of those who supplied to you the erroneous statement, because he was in possession of the real facts of the case." Upon the first part of this sentence I wish, through you, to inform the Rev. W. H. Milner, that I was one of those who sent you list of tenders, but the notes at the head and foot were not of my writing. I sent a foot-note, but different from those used; consequently I suppose other of the contractors supplied those notes. However, I can readily to endorse them, and defend them from the charge of being erroneous; in doing so I fear that I shall prove, by extracts from the specification, that the rev. gentleman's statements of the facts of the case, with reference to the assumed mistake in the adopted tender.

The letter sent me by the Clerk of the Board, a copy of which Mr. Milner supplied you, did not reach me until some time after I had sent you a list of tenders, consequently did not influence me. It certainly gives a very plausible explanation of the circumstances alleged to have led the Board to accept an amended tender; but as I have no objection to the facts of the case, it did not change my views upon this case, of the impropriety of Boards admitting amended tenders after the opening day. In this case six of the contractors had been put to a second competition, being requested to supply sample pipes, to see who would supply the best at the proposed tender prices; and in this no preference could be gained by any one. Possibly some gentleman who takes an interest in town chat, who could tell his brother townsmen what was gained, and who galled by this step.

The Rev. Mr. Milner attempts to justify the acts of the Board by those of the Rev. Mr. Frow, in the bill of quantities made of certain castings (? where: not castings, only flings) which the specification showed; the contractor was only to fix, but Mr. Young, not having the specifications before him, introduced the price of the castings (? without having dimensions). Had this been a fact, it

would not have been a sufficient excuse for breaking through the secrecy of the seals of twenty other contractors to favour one; this act stillifies the principle—the very foundation—of contracting by tenders. In Mr. Young's tender several corrections in items are said to have been made; the greatest amount of corrections is admitted to have been under the head of manholes and ventilating shafts, which amounted up to about 20% in some tenders, but Mr. Young made it considerably more. I have been informed that the greatest error appeared at the bottom of these items. As the Rev. Mr. Milner implies, "fixing covers to manholes (what words could a plain man understand than these?) are in the bill of quantities. We do not hear of any other one of the twenty tenders mistaking the purpose of these works, fixing is not providing. However, a loose figure appeared in the adopted tender in this line, of considerable magnitude, whether by accident, or for a "call in" to explain, does not affect the question of culpability of Boards correcting tenders, or allowing corrections after prices have been published.

In the bill of quantities which Mr. Young and all other contractors had, the only reference to the title of castings is contained in the words, "fixing covers to manholes; ditto ventilating shafts." It may have been that Mr. Young did add the cost price of covers without having dimensions; but the error should have been corrected by notes previously to opening of tenders, or the item should have been taken as it stood. Every tender is open to corrections if the rule be allowable. CHARLES FROW.

PLAGUE STONES.

A CORRESPONDENT of the *Builder*, mentioning the discovery of a plague stone at Stockport, wishes for information about plague stones. Harveys his "History and Description of the Ancient City of York," 1818, vol. 1, p. 135, says,— "The plague, which the preceding year had carried off 30,573 persons in London, raged to such an alarming extent here, in 1604, that the markets within the city were prohibited, to prevent the contagion from spreading into the country; and stone crosses were erected in various parts of the vicinity of York, where the country people met the citizens, and sold their wares and commodities. Several of these crosses are yet remaining. The Lord President's Courts were adjourned to Ripon and Durham; many of the inhabitants left the city; the ministers and churchwardens, were both shut up; and the unfortunate subjects of infection were sent to Hob-moor and Horse Fair, where hoots of boards were erected to receive them. No fewer than 3,112 inhabitants of York fell victims to this pestilential disease; though by means of these precautions it was not of long continuance." Drake, in his "History of York," mentions,— "I have noted before that a uniform street once extended from Bootham-bar to a place called Burton Stone, where a stone cross formerly stood; the extent of the city's liberties on this side." p. 268. Now, this old stone called Burton-stone has several holes in its upper surface, evidently meant for the placing of vinegar in as described by your correspondent, or to fumigate. Hoping to see this question answered further, I have sent this as some contribution to the question. YORK.

BRICKWORK IN SWANSEA.

Sir,—Your correspondents "T. U. & J." complain that "all exposed brickwork in Swansea after a short time becomes covered with a white powder or efflorescence, which renders any attempt to produce coloured patterns in that material quite futile; and inquire how it can be prevented or removed."

The facts are not exactly as "T. U. & J." have stated. It is not "all exposed brickwork in these parts" (Swansea) which is so affected; nor is it any peculiarity in the climate which produces the mischief; but it is the fault of the bricks used, which are generally from Bridgwater, or those made on the spot from clay or sand impregnated with salt. C. E.

WORM-EATEN FURNITURE.

Sir,—I have two articles of furniture very much worm-eaten, and I am glad it is likely they will effect the other furniture in the room. Is there anything to prevent it? RICHARD JAMES.

VALUE OF REVERSIONS.

A SALE of absolute reversions, contingent reversions, reversionary life interests, annuities, policies of assurance, &c., the property of the late firm of Overyend, Garney, & Co., took place at the Auction Mart, Tokenhouse-yard, City, under the direction of Messrs. Chinnock, Galsworthy, & Chinnock. The following reversions were sold.—Lot 1. The absolute reversion to a sum of 20,000*l.* 4 per cent. debenture stock of the Great Eastern Railway Company, expectant on the decease of a lady aged sixty, invested in the names of reversionary trustees, subject to succession duty at 1 per cent.—3,150*l.* Lot 2. The life interest, in possession, to a sum of 20,000*l.* invested on mortgage at 4 per cent., thus producing an annuity of 800*l.* per annum, receivable during the life of a gentleman aged seventy-seven—3,610*l.* Lot 3. The life interest, in possession, of a gentleman aged forty-two, in the income arising from the sum of 8,000*l.* at present invested on mortgage at 4 per cent.—3,500*l.* Lot 4. The life interest, in possession of a gentleman aged forty-two, in the income of a 4,000*l.* which is invested partly in a freehold estate at Thorpe, near Norwich, and the remainder in Bank stock—1,810*l.* Lot 5. The life interest of a gentleman aged fifty-two in the sum of 6,874*l.* 19s. Consols, expectant on the decease of his wife, aged fifty-five—500*l.* Lot 6. The absolute reversion, expectant on the decease of a lady aged fifty-four, in a sum of 5,470*l.* 2s. 6d. Consols, and in the proceeds of an estate at Arley, in the county of Stafford, consisting of a residence, cottages, and 192 acres, producing a rental of 300*l.* per annum, a freehold of 5,830*l.* At the same time the Rocks estate, a freehold property in Gloucestershire, within five miles of Bath,

extending over 840 acres of arable, pasture, meadow, and wood land, divided into compact farms, the Elizabethan mansion, the Hunters' Hall public-house, and several cottages, the whole being of the actual rock rental of 1,700*l.* per annum, was sold for 51,000*l.*; the timber and fixtures at a valuation.

BANQUET AT THE ROYAL ACADEMY.

On Saturday last the anniversary dinner of the Royal Academy was held in their rooms in Trafalgar-square, where a numerous and distinguished company assembled.

The president presided, supported by the Prince of Wales, the Duke of Cambridge, Prince Christian, the Duke D'Aumale, the Prince of Teck, and Prince Edward of Saxe-Weimar.

The president, in the course of the evening, referred to the anxiety of the Academy to inaugurate the completion of the first century of the Corporation by holding their next exhibition in the new galleries at Burlington House.

"The Royal Academy (he said) would have no difficulty in getting their buildings suitably advanced for that purpose if they could get access through Burlington House. But I regret to say that the buildings for the learned societies are not yet commenced, in consequence of unforeseen difficulties that have occurred arising from their interfering in some degree with the lights of the Albany. I am glad, however, to learn from the noble lord the First Commissioner of Works that these difficulties are nearly, if not quite, removed. We are, therefore, sanguine in the hope that an object so very desirable not only to the Academy, but to the whole body of artists, to the trustees of the National Gallery, and to the public generally, may yet be accomplished. We even contemplate having an exhibition of a selection of the works of all the members of the Academy since its foundation to the present day, to be opened, if possible, on the 10th of December, to inaugurate the centenary. We feel assured that we shall receive the hearty co-operation of the noble lord the First Commissioner of Works, to whom we are already so much indebted. With regard to the Academy, I think I may say with confidence that it is in a flourishing condition. While we may point with some pride to the many distinguished artists who now belong to it, we recognise with infinite satisfaction the vast amount of rising talent, which leaves no doubt on our minds that the fame of the British school will be maintained, if not surpassed."

CHURCH-BUILDING NEWS.

Swinton (Lancashire).—The chief stone of a new church, dedicated to St. Peter, has been laid here. The edifice, which is now in course of erection, will consist of nave, north and south aisles, chancel and chancel aisles, with organ chamber at the north, and clergy and choir vestries at the south, together with a western tower. The height inside will be 150 ft., and the width about 60 ft. The style of the architecture is the early Decorated. The church will be entered at the west end by two porches, north and south; also by a small porch on the north side adjoining the vestries. The aisles will be lofty, and contain nine windows. There will be no clearstory, the roofs being all gabled. The interior will be open-timbered, and the walls will consist of Dunford-bridge pinnacles, while the walls of the exterior will be composed of dressed stone from Longridge. The whole of the interior will be of stone from the Hollington quarries, the fittings of pitch pine, and the doors of oak. The present contract is for the entire church and tower (the latter up to the open roof only), and amounts to about 10,500*l.* The edifice is to be completed by June, 1869. Its total length will be 144 ft., and the width 60 ft. The nave will seat 473 persons, the north and south aisles will seat 270, and the chancel 140. The height of the tower will be 105 ft. The architect is Mr. Street, of London; the contractor being Mr. Philip Horsman, of Wolverhampton; and the clerk of the works is Mr. J. Smith.

Alton.—The parish church of Alton has been re-opened. The alterations have been effected under the superintendence of Mr. Christian, of London, who has made available the space which in the old church was shut out by high pews and overbadowed by galleries. The pews, which are open, are all of lead wood, stained and varnished. The aisle is laid with Minton's tiles and iron gratings, while attention has been given to the warming of the church by means of hot-water pipes, the boiler being placed under the organ chamber. This chamber, erected on the north side, and given by Mr. W. Dyer and the Misses Dyer, is built on the outside of stone, while the interior consists of brick, leaving a cavity to render the chamber dry. It is roofed with tile, while the ceiling is circular, with moulded ribs, an arch of native stone being formed at its junction with the church. The roof of the church has been cleaned of accumulated coats of ybitewash, its timbers, which are

of oak, varnished, and the tower itself, at first looked upon as a hopeless obstruction, is now utilised as a baptistry, the font, in Caen stone, being placed in it. In the baptistry, Messrs. J. H. and E. Dyer have placed a stained-glass window, representing "Christ's Baptism," and "Blessing Little Children," the artist being Mr. Joseph Bell, of Bristol. The old Norman arches, on which the tower stands, are thrown open, the floor of the belfry having been raised 6 ft. or 7 ft. A turret, with spiral stone stairs, has been built outside the tower, to admit bell-ringers and others to the belfry without entering the church, and the roofs of the porch and vestry have been taken off and new ones substituted. The four Norman pillars and arches which support the tower and spire have been, until lately, almost hidden from observation. Care has been taken not to destroy the ancient character of any portion of the masonry. The east window, which was in a bad state, has been removed, and a new one substituted by Mr. C. Trimmer, at a cost of 75*l*. The lighting of the church is by means of Medieval pendants from the roof. The church will now seat about 1,000 persons, or a few over the number accommodated before the alteration.

Whitby.—A parish church for the suburb of Rnsward, containing 908 sittings, is about to be erected, from designs prepared by Mr. Charles Noel Arnfield, of Whitby, architect. The plan comprises nave, with south-west porch, two bays of a south aisle, semicircular apsidal chancel, and vestry under tower, which latter is on the south side, at the junction of nave and chancel. With the exception of the dressings to arches, windows, doors, &c., the whole of the walls will be plastered on the inside with Martin's fire-proof cement, to which it is proposed to apply a considerable amount of coloured decoration. The walls, which are to be built of brown Bosca Gill wall-stones, hammer-dressed, and fine white sandstone from Blue Bank, random-tooled, for the dressings, will be 2 ft. 3 in. thick, 22 ft. 6 in. high above floor of nave, having buttresses 2 ft. square at intervals of 12 ft., centre and centre. The tower rises to a height of 64 ft., which raises the belfry well above the roof ridges. A spire, 45 ft. high, finishes the tower, making a total height of 110 ft. The whole of the works, except decorative painting, have been let to Mr. Robinson, of Whitby, builder, for 1,846*l*. 16*s*. The architect's estimate was 1,871*l*.—A small mission-school church is shortly to be erected at Sandens, near Whitby, from designs by Mr. C. Noel Arnfield, of Whitby, architect. It will be of Middle Thirteenth-century Gothic, of a rural type, with low walls and high-pitched roof, and will contain 156 sittings, exclusive of choir and clergy; it will consist of a building of one uniform height, the chancel being defined on the exterior by ridge-cresting, and wall treatment slightly differing from that of the nave. In the interior the chancel will be strongly marked by a screen, by the arched principal of the roof, and by a polygonal boarded ceiling. The whole building will be plain, but substantial and ecclesiastical in appearance, both within and without.

Rowley.—The memorial stone of a new church at Blackheath, Rowley, has been laid by the Countess of Dudley, amidst a large assembly of the gentry and inhabitants of the neighbourhood. The intended church has been designed by Mr. Hopkins, architect to the Worcester Archidiaconal Church-building Society, and the building has been entrusted to Messrs. James Wilson & Son, of Birmingham, builders. The estimated cost is 6,400*l*, of which 5,701*l* (including 2,600*l* from the Earl of Dudley and 2,000*l* from "Delta") have been collected. The architect's description of the building shows that the church will, when completed, accommodate 850 persons, and contain a lofty nave, north and south aisles, vestry, organ-chamber, and children's chapel. The church is to be built of bricks. The nave is 80 ft. in length, 29 ft. wide, and 54 ft. high. The tower is very plain, and with buttresses up to the belfry stage, which rises freely above the ridge of the nave roof. The belfry stage has three large adjacent lancets, with louvre-boards on each side, and is surmounted by an octagonal-broached, shingled spire, banded at intervals.

Hailey.—The chief stone of the new church of St. John the Evangelist at Hailey, in the county of Oxford, has been laid by the Duchess of Marlborough. The new edifice will be erected in the style of Thirteenth-century Gothic, from the design of Mr. Clapton C. Rolf, the architect. The building is arranged with a chancel, to accommodate a small surpliced choir; a north aisle to

the nave, and a vestry at the west end of aisle. It will seat 250 persons, and the estimated outlay is about 2,000*l*. Mr. A. Groves is the builder employed.

East Raynham (Norfolk).—The Church of St. Mary, through the liberality of the Marquis of Townshend and the rector (the Rev. R. Phayre), has just been rebuilt and reseated, at a cost of upwards of 5,000*l*. The church, which was recently re-opened, is in the Perpendicular style, and consists of clear-story nave, with north and south aisles, chancel, tower, and north and south porches. The walls are faced with squared flints and Ancaster stone dressings. The chancel floor is of Ketton stone in 2-ft. squares, with Maw's glazed black tiles at intersections. The reredos also improves the general appearance of the building. The tower is lighted by a stained-glass window, the gift of Sir Arthur P. Phayre, C.B., K.C.S. The works have been carried out under the direction of Messrs. Clark & Holland, architects, Newmarket, by Mr. William Hubbard, contractor, East Dereham.

SCHOOL-BUILDING NEWS.

Redcar.—The foundation-stone of the Turner Free School has been laid at Coatham. The schools will be erected in the Gothic style, and will be 103 ft. 6 in. long, 52 ft. wide, and four stories high. There will be accommodation for a number of boarders. The main front of the building will face Coatham-road, and at the gable end there will be a tower. A large dining-ground-floor, immediately over which will be the school-room, with open timber roof, and classrooms in the rear to the south. There will also be a residence for the master. The entire cost of the building will be under 4,000*l*.

Minchinhampton.—These schools have been formally opened. They have been built by Mr. Edward Clayfield, of Horsley, builder, from the designs of Mr. Clissold, of Stroud, at a cost of 1,400*l*. The land was given by Mr. H. D. Ricardo, lord of the manor, who has also been a donor.

Nottingham.—The New Free Grammar School, situated on Nottingham Forest, between the Arboretum and Forest-road, has been formally opened. Mr. T. Simpson was the architect. The school and playground, according to the description in the *Nottingham Guardian*, from which we quote, occupy a piece of land at the back of the Arboretum, containing about 3½ acres, stretching from Arboretum-street to Forest-road. The building is in the Perpendicular style of the Lancastrian period. Its principal front extends east and west, facing Arboretum-street; its classrooms and other offices north and south. The school to the east, and English school to the west. Each is 60 ft. long and 30 ft. wide, and has open-timbered roofs, supported with hammer-beamed, circular-stayed principals, borne by angels bearing shields of the period. These rooms are 21 ft. high to the eave and 39 ft. high to the ridge. The two schools are entered separately by porches right and left of the rear, while the principal entrance is by steps from the terrace to the south. The schools are divided to the south by private rooms for the masters, and beyond, in the centre, by a visitors' room and library, 36 ft. 6 in. long and 10 ft. 2 in. wide, with slide doors at each end, so as to unite the schools with the library at pleasure, thus forming an unbroken vista of 160 ft. long. Leaving the visitors' waiting-room from the front, you pass into the entrance-hall of the schools, which is 28 ft. high and 15 ft. wide, lighted from the top through an open-timbered roof, supported from the walls by enriched corbels. From the entrance-hall stretching north is a covered corridor, 93 ft. long and 8 ft. wide, with an open-timbered roof, boarded right and left by a suite of nine class-rooms, each 17 ft. by 15 ft. To the hall, 44 ft. by 28 ft., and a covered passage leading to the grounds, which completes the contents of the ground-floor. The site of the school is divided north and south, the south portion taking the schools, terraces, and lawn, while the west of the corridor is devoted to play purposes, and is lowered to the level of Forest-road, leaving the school on a high terrace sheltered from the north by a belt of shrubs, the shelter being held by a tennis wall the whole length of the site. An archway under the terrace in the centre of the tennis wall leads by a passage-way to a

well-lighted play-room under the schools, 160 ft. long and 30 ft. wide, so that in the winter or inclement weather the boys may retreat from the playground to a sheltered room. Passing through an arcade to the right of the entrance ball on the ground-floor, a flight of steps leads to the gallery library over the visitors' waiting-room, 16 ft. by 36 ft., in the centre, and a committee-room over the south entrance, having terrace on the front overlooking the lawn, the town, and its suburbs. The gallery library is directed from the schools by traceried windows, from which may be seen the operations of a geometrical staircase leads to the museum and observatory on the third story, lighted on all sides, and surmounted by an octagonal flag-tower. The head-master's house, though detached, is in the same style as the principal block.

STAINED GLASS.

St. Silas's Church, Losells.—The east window of this church, which consists of three lancet-lights, has lately been filled with stained glass, to the memory of the late Rev. Daniel Nathaniel Walton, M.A., the first incumbent of the parish. The subjects chosen for illustration are—in the centre light, in the top group, St. Silas preaching; and in the lower portion, St. Paul and St. Silas being delivered from prison. In a small quatrefoil in the middle of this light, are depicted the emblems of the clerical office, viz.—the Chalice, Bible, and Book of Common Prayer. The two side-lights are filled with two medallions, containing figures of the Evangelists—St. Matthew and St. Mark, in the dexter light, and St. Luke and St. John in the sinister—with their respective emblems introduced at their feet, viz.—the angel, lion, bull, and eagle. The work has been designed and drawn in accordance with the early period of the architecture, viz., of the thirteenth century; and the work has been carried out by Messrs. Hardman & Co.

Church of St. Michael's and All Angels, Basingstoke.—A new stained east window has lately been erected in this church, at a cost of 552*l*, by Messrs. Lavers, Barratt, & Westlake, of Bloomsbury. The ministrations of angels are introduced in every subject. The lower row is taken from Scripture history, of times before our Saviour's birth, and is typical of those in the upper row. The upper part of the window represents the Saviour triumphant in Heaven.

Guildhall, York.—The Fox-Clark memorial window has been completed, and placed at the extreme corner, near to the entrance to the Council Chamber. In the highest light is introduced the White Swan, a favourite badge of King Edward III. In the compartment immediately below, to the left of the spectator, is the shield of the arms of the city of York, surmounted by the cap of maintenance, as in the windows already placed on the south side of the hall. In the corresponding compartment is the monogram on a shield, and the crest of the late alderman. The above and other lesser lights in the tracery are filled with a foliage of oak-leaves. The subject commemorated in this window is the marriage of Edward III. and Philippa of Hainault, in the cathedral at York, on the 24th of January, 1328. The subject occupies the principal portion of the four chief lights of the window.

Bucclerch-street Church, Edinburgh.—A memorial window, executed by Messrs. Ballantine & Son, has been presented by the Marquis of Bute to this church. It has been executed from sketches by the young marquis. There are three lights in the window, and the illustrations are from the 21st and 22nd chapters of the Revelation of St. John. In the central light at the top is the emblem of God the Father—a hand issuing from clouds, and surrounded by an aureole. Beneath this and within a vesica piscis shape, surrounded also by a vesica aureole, is a figure typifying the New Jerusalem descending as a bride adorned for her husband. In the base is a figure of our Lord standing on a mount, from which flows the river of the water of life. Over Christ's head are seen the Alpha and Omega. In the upper portions of side-lights are the figures of St. John and one of the seven angels holding a golden phial and reed; and beneath these, in devotional attitudes, looking towards the centre figure, are a number of Christian saints. The figures are all in white shining drapery. The groundwork is atmospheric blue, studded with silvery stars. Roses of different

shades of crimson mingle with white lilies behind the figures.

Acle Church.—This church has recently had an addition made to it, in the shape of a memorial window. The subject is the Ascension, and the style, in contradistinction to the Gothic, and the close imitation of the old school, Messrs. Boston, Butler, & Bayne, London, were the artists.

Miscellaneous.

RECREATION GROUNDS.—The *South London Press* states that the entire interest of the lord of the manor in Peckham-rye, Goose-green, and Nunhead-green has been purchased by the Camberwell vestry for 1,000*l.* The sale was made on the condition that the Rye and the two Greens should be legally dedicated as recreation grounds, to be kept open for ever, for the benefit of the parishioners, and effectually secured to their use. A space of forty acres has thus been obtained at a nominal cost.

OPENING OF THE THAMES SOUTHERN EMBANKMENT.—The first section of the Embankment was opened to the public on Saturday last. The foundation-stone of the work was laid on the 28th of July, 1866, by Mr. W. Tite, M.P.; Lord John Manners, the first commissioner of works, the Lord Mayor, and the members of the Board of Works being present. The works completed comprise a length of 2,200 ft. of river-wall, between Westminster and Lambeth Bridges, and there is to be a further length of 2,100 ft. from Lambeth Bridge to the site of the London Gas Works.

THE KIRBY UNDERDALE TUMULUS.—During last week the Rev. Canon Greenwell continued his investigations into this remarkable tumulus. The barrow proved to be a great cemetery of Anglo-Saxons, all (with few exceptions) being doubled up, a feature quite exceptional. With the burnt bones there was no relic, but in the soil not far distant was a greenstone axe, some parts of a British drinking-cup, and one flint scraper. The total number of bodies exhumed exceeds sixty, mostly with the heads to the west, only some six or eight being to the north. The chief relics found last week have been necklaces of glass beads, with silver and gold pendants; two bronze boxes, one having in it thread (quite distinct) used by the Anglo-Saxon lady with whom it was interred; several bronze huckles and other ornaments; a silver brooch, set with rubies (or garnets); a bronze bowl; a gold amulet; a variety of bronze and iron articles not easily described or named, and a great number of other relics. One lady wore three silver rings, a necklace of blue, white, and green glass beads with small silver amulet, three bronze rings, a knife, and two large iron articles, mostly resembling exaggerated picklocks, thought, in fact, to be a sort of key. The last named were found at the waist. With the burial was also a long comb of bone, cut remarkably well on both sides.

LANDLORDS AND TENANTS.—A case which came before the borough justices at Doncaster will interest both owners and tenants of houses. Mr. Bacchus appeared for the purpose of obtaining an ejectment warrant against a tenant named William Fletcher, occupying a house, No. 5, South St. James's-street, at a weekly rent, on whom he had served a notice to quit, but he had refused to go out. He then served a second notice on the 30th of March, at half-past eight in the morning, to either go out or appear at the court to explain why he had not left. As Fletcher had neither gone out nor appeared at the court, he asked that he might have a warrant for ejectment, as seven days of twenty-four hours had expired that morning since he gave the second notice. Mr. Fisher said the Act of Parliament required seven "clear" days to be given. The applicant contended that he had complied with the Tenements Act, and had given seven clear days' notice. Mr. Fisher then referred to the interpretation of the word "clear," and also to several cases bearing upon the point, which, on being read, clearly bore out the construction he put upon it, namely, that seven clear days meant seven days exclusive of the day of the service and the day of hearing. The application was accordingly refused, as really only five days had elapsed, and he would, therefore, have to give another notice, and then, if the tenant refused to go out, he might make his application.

CONVERSATION, SOCIETY OF ARTS.—The council have arranged for a *conversations* at the South Kensington Museum, on Wednesday, June 3rd.

STEAM ROAD ROLLER.—We are informed by Messrs. Aveling & Porter that the price of the roller illustrated by us recently (see p. 298, ante) was 750*l.*, not 900*l.*, as mentioned.

THE WHITWORTH SCHOLARSHIPS.—The council of the Institution of Civil Engineers have sent the following to Mr. Whitworth:—

"Resolved unanimously.—That this meeting desires to record, on its own behalf, and on that of the members of all classes of the Institution of Civil Engineers, its grateful recognition of this act of munificence, and its high appreciation of the services which have thereby been rendered to the cause of technical education and national advancement, and of the advantages that may be expected to accrue, alike to the profession and to the community generally."

TUBULAR MASTS.—The great tubular iron lower-masts for the *Monarch*, 6, iron turret-ship, 5,100 tons, now building, exceed in size any yet made for a ship in the royal navy. The aggregate diameter of the masts is but 2 in. less than the diameter of the masts of the *Great Eastern* steam-ship; but the masts of the *Great Eastern* were sent in pieces, while those of the *Monarch* are whole. The weight of the masts is no less than 53 tons. These ponderous masses were lifted by means of a 25-ton steam crane.

STREET MARBLE.—A new use has been discovered for the lime-lias of the neighbourhood of Street, in Somerset. It has hitherto been used almost exclusively for paving, steps, and rough building purposes, but it is found that it may be so prepared as to form a substitute for, if not actually to vie with, fine marble. It is said to be susceptible of a beautiful polish, and when thus finished, is difficult to distinguish from marble, except under very close inspection. Messrs. Seymour & Son, who possess extensive quarries here, are, according to a local paper, now polishing a large number of lion columns for a new church which is in course of erection somewhere in the west of London.

TRAMWAYS FOR SOUTHWARK.—A double tramway is to be laid down in the London-road, Southwark, the vestry of St. George the Martyr having given a unanimous decision to that effect. The tramway to be adopted, according to the *South London Chronicle*, is that planned by Mr. Haworth, and in satisfactory operation in Salford for three or four years past. The rail for the wheels is in the shape of a gutter with slightly curved sides, is made of wrought-iron, and is about 8 in. wide. Vehicles will be able to run on and off at any place without the slightest inconvenience. Running midway between each set of rails for the wheels is a plain 3-in. rail laid down level with the road, which serves as a guide for drivers. The cost, remarks our authority, is an item in favour of its adoption; for while the estimated cost of paving under the old system is 3,093*l.*, the cost of carrying out the new plan will only be about 3,650*l.* It is also estimated that the cost of keeping the roadway in repair will under the new plan be considerably lessened.

SHEFFIELD ARCHITECTURAL AND ARCHAEOLOGICAL SOCIETY.—The members of this society have made their first excursion of the season. Conisborough was the place selected. A party of twenty-four ladies and gentlemen, accompanied by the president (Dr. Aveling), joined the excursion at starting, and were afterwards met by small parties from Rotherham and Wath. Arriving at Conisborough, the party first repaired to the church, which has lately undergone restoration. The Rev. Mr. Wood, the vicar, kindly acting as conductor, pointed out the objects of interest. Some of the party, including several ladies, ascended to the top of the tower, a task by no means easy. After partaking of luncheon the old castle was visited. Here the Rev. J. Stacey read a paper giving a description of the building, illustrating it with a few small diagrams. The party then went over the several stories of the old keep, the chapel and the fireplaces being particularly noticed. Many of the old masons' marks on the walls, both in the church and castle, were examined. The party then took train to Sprotborough, where the rector, the Rev. S. F. Surtees, conducted them over the church. After having been hospitably entertained at the rectory, they returned by train to Conisborough, and, after partaking of tea at the Red Lion hotel reached Sheffield about ten o'clock p.m.

MONUMENT TO LUTHER.—The monument to the memory of Luther at Worms is to be inaugurated on Thursday, the 25th of June. The *fetes* will last three days—the 24th, 25th, and 26th.

LITERARY FUND ANNIVERSARY.—The dinner on Wednesday last, presided over by the Prime Minister, was a very brilliant and successful affair. About 330 gentlemen assisted, and 150 ladies looked on; the result being, besides their enjoyment, the addition of some 1,400*l.* to the funds of this admirable Institution.

RATS AND MICE.—Recent experiments are said to have shown that squills (*Scylla maritima*), the root of which is much used in medicine, is not only a powerful poison for rodents, but also one they are very fond of. The way of preparing it for the desired purpose is thus described:—

"One of the bulbs is cut into slices, hashed and bruised, then done in a pan with fat, which is afterwards strained through a cloth and poured into broken plates and saucers to be placed in cellars and other places infested with rats, mice, &c. To prevent dogs and poultry from eating of this poisonous compound in stables, pigeon-houses, or farmyards, it may be put into a wooden box, about 1½ ft. long, and having a hole at each end. The rat gets in at one end and goes out at the other, after partaking of the noxious food, which soon kills it. Squills may also be reduced to powder for the same purpose by bruising them in a mortar to a pulp, which is afterwards incorporated with as much flour as it will hold. The paste is then rolled out, as they do for a pudding, then cut into sheets, which are left to dry on hurdles or on sheets of paste-board, and are afterwards pounded in a mortar. The powder thus obtained will keep for years, and may be put into boxes or barrels."

The enticement of the rats into traps ought to suffice, whether that which entices them be poisonous or not. We have found phosphoric paste spread upon thin pieces of bread effectual in ridding a house of mice, but of course it required to be laid out of the way of domestic animals.

THE NEW LUNATIC ASYLUM FOR IPSWICH.—At last week's meeting of the town council the town clerk read the report from the Lunatic Asylum Committee, stating that they had received the following tenders for the erection of the asylum according to the plans approved at the last meeting of the council, viz.:

William Root, plumbers, glaziers, &c., work	21,658 0 0
T. Stear & Son, do. do. do.	1,618 0 0
J. Chincock & Co. stonemasons' work	1,430 0 0
D. & E. Hagger, plumbers, &c., work	1,623 15 0
James Freese, stonemasons' work	1,840 17 0
W. G. Cunliffe, the whole work	20,150 0 0
William Kent, London, do.	20,270 0 0
W. C. Penny, Lewisham, Kent do.	20,685 0 0
Henry Laid, do.	19,980 0 0
Edward Gibbons, do.	19,980 0 0
J. C. Lucas, plumbers, &c., work	2,008 18 8
George Hewitt, the whole work	19,700 0 0
Robert Ireland, stonemasons' work	1,110 0 0

The committee held two meetings for the examination of these tenders, and ultimately resolved unanimously that the tender of Mr. Edward Gibbons should be accepted. The adoption of the report was agreed to by the council. The committee have engaged the services of Mr. Edmond Catchpole as clerk of the works, at three guineas a week. At the same meeting, we may here observe, thanks were accorded to the borough surveyor, Mr. W. P. Ribbans, and to Mr. Catchpole, for their services in the erection of the town-hall.

A RAILWAY FROM SCOTLAND TO IRELAND.—Some years since a joke was perpetrated by the London correspondent of the *Liverpool Advertiser* to the effect that it was intended to extend the Giant's Causeway across the Irish Channel; but without any joke a petition has now been presented to Parliament, signed by Mr. J. O'Neale Neale, of Brook Hill, Devon, and of Middle Temple, barrister-at-law, recorder of Walsall, who states in it,—

"That in the summer of the year 1844 your petitioner was retained as counsel to the Fortruis, Coleraine, and Armagh Railway, and deputed to visit the north of Ireland on behalf of that railway company; that in the course of his investigations your petitioner was struck by the feasibility of making a solid causeway from the Mull of Cantyre in Scotland to Tor Point, near Cape Fair, in Ireland, a distance of only 11 miles; that your petitioner found on inquiry that no unusual difficulties existed to prevent a net of one or more railways traversing across such causeway, the traffic over which would pay a fair percentage on the cost thereof, but the railway panic of 1845 rendered it impossible to proceed further in the matter; that your petitioner is convinced such a causeway with railways so uniting the three kingdoms would restore that fresh life and prosperity to Ireland which would greatly tend to heal all religious feuds and extinguish Fanaticism, while to England it would impart additional strength, security, and honour. Your petitioner, therefore, entreats your honourable House to appoint a Select Committee of Inquiry to ascertain the practicability of making such causeway, and to report thereon to your honourable House."

Such a project is certainly not quite so appalling as a railway across the English Channel.

SAFETY IN MINES.—A correspondent, "R. T.," writes,—"I beg to suggest that explosions in coal-mines could be prevented by transmitting every moment to all parts of the mine an electric spark, so that dangerous accumulations would be impossible. The usual ventilation would not impede it; rain, &c., would not quench it; the pendulum of the nearest church-clock would transmit an intense spark every moment night and day, at a very small cost."

LINNEAN SOCIETY.—One of the most remarkable objects shown at the annual soirée held at Burlington House was an actual specimen of the so-called "vegetable sheep" of Australia. It is a flowering plant belonging to the same family as the dandelion and daisy of our meadows, but, when full grown, forms one huge confluent white mass, so closely resembling a sheep that it frequently deceives even the experienced Australian shepherds themselves. A most interesting collection of new and rare living plants, consisting of orchids, lilies, arums, &c., of exquisite beauty, was displayed in one of the smaller rooms. Amongst the pictures and water-colour drawings we specially noticed a large oil-colour picture (but unfinished) of the Mt. Sdgals, by Mr. Baines, the well-known African traveller; a portfolio of excellent sketches of African scenery and natural history objects, by the late Captain Speke; a collection of highly-finished drawings of animals, by Mr. Wolfe; and a collection of nearly 300 water-colour drawings, illustrative of the British hymenoptera, with some of the details of fructification, enlarged 20,000 diameters, by Mr. W. G. Smith, whose drawings often appear in these pages.

LIVERPOOL ARCHITECTURAL SOCIETY.—At the fifteenth meeting of the present session of this society the first business of the evening was the awarding of prizes for the competition drawings for a village church. The chairman remarked on the industry and taste evinced in the drawings. Mr. J. A. Pictou gave a sketch of what he had observed in the way of architecture in a rapid journey from the north to the south of France, and referred to the great alterations and improvements which had been effected in Paris.

These improvements did not, as some supposed, pay for themselves, and they had entailed on the municipality of Paris a debt of about 16,000,000. He noticed the great attention paid to architectural effect in Paris, in the halls, porticoes, and particularly the staircases, and remarked that he felt ashamed when he contrasted the new municipal offices in Liverpool, with their miserable staircase, with the Hôtel de Ville in any of the second or third rate towns in France. We, in England, were quite behind the French in architectural effect. A paper was read by Mr. H. P. Horner on "Fashion in Architecture," which was followed by a brief discussion.

THE SHEFFIELD OUTRAGES.—A portrait and 600 guineas have been presented to Mr. W. Christopher Leng, editor of the *Sheffield Daily Telegraph*, in recognition of his services in bringing about the Trades Union Outrage Commission of Inquiry in that town. Among the subscribers to the testimonial were forty-two peers, thirty-eight members of Parliament, and 150 justices of the peace. The inscription attached to the portrait stated that the testimonial was given to Mr. Leng "as a public acknowledgment of the ability, courage, and steadfast patriotism displayed by him in exposing a system of trade-union outrages which had existed in Sheffield for many years, injuring both the trade and character of the town, and of his successful advocacy of the appointment of a royal commission of inquiry." Lord Wharncliffe presented the testimonial, and, in doing so, denounced the perpetrators of trade outrages as noisy demagogues who shouted for liberty while striving to do away with it. He recognised in trades unions an agency which had saved the working man from being entirely at the mercy of his master, and blamed the employers for not combining to put down the acts of outrage, and the terrorism which had attached such a foul name to their town. It is stated that Lord Wharncliffe has received a threatening letter from Broadhead, of Sheffield outrages notoriety, in consequence of his lordship having, at a late meeting, pronounced him to be "a cowardly scoundrel." In reply to the threat Lord Wharncliffe has gone further, and declares Broadhead to be "a sneaking assassin." Quite right, too. The fellow ought to be drummed out of the country.

TRANSPLANTING A BIG TREE.—We learn that Mr. Barron, of Elvaston Nurseries, Borrowash, Derbyshire, who has had great experience in transplanting, has this week moved a cedar of Lebanon, upwards of 50 ft. in height, with branches some 40 ft. in diameter, and a stem at a foot from the ground 6 ft. 2 in. in circumference, from Horsey to Acton, by means of one of his large transplanting machines.

A FLYING STEAMER.—Mr. J. K. Smythies, of Paddington, barrister-at-law, proposes to introduce a flying steam-engine, fitted with wings, worked by the action of steam. He reduces the ratio of the weight of the engine to its power by using a tubular boiler with very small and thin tubes. He will use liquid fuel, and carry very little water, condensing the steam by a very light condenser, made, like the tail of a bird, to sustain the bird and steady its flight. The arms of the wings are connected with the piston-rod of the engine, so that the apparatus is raised by the strokes of the wings alone, without light gas, heated air, or other contrivance to give it buoyancy. To this engine he attaches seats for one or more passengers. In the realisation of man's dominion over the air, substances combining strength with lightness will, of course, be made use of. Aluminium is likely to be one of these substances; so are fine steel, cane, whalebone, cork, &c.

OPENING OF A NEW PUBLIC PARK AT SOUTHPORT.—A new public park, thirty acres in extent, has been formally opened by the mayor of Southport, amidst the general rejoicings of the inhabitants and visitors. Southport is a very prettily laid out and improving watering-place on the Lancashire coast, about twenty miles to the north of Liverpool. The park has been laid out from the designs of Mr. Kemp, of Birkenhead, and much ingenuity has been displayed in bringing the original sand-hills, and the little green valleys between them, into harmony with the general plan, so as to avoid the heavy expense of completely levelling and reconstructing the ground. The total expense of the preparation of the park will amount to about 15,000*l.*, and it will be maintained by a special rate. The occasion of the park opening was observed as a general holiday; the streets and buildings were dressed with flags; and both inhabitants and visitors devoted themselves thoroughly to enjoyment.

THE NEW GRAVING DOCKS AT CHATHAM.—The foundation stone of the first of the four large new graving docks which, together with three large floating basins, the whole having a water area of nearly 100 acres, are in course of construction at the dockyard, has been laid by Lady Walker, the wife of Sir Baldwin W. Walker, bart., K.C.B., commander-in-chief at the Nore, and in the presence of a number of spectators. The new docks, basins, factories, workshops, and other buildings now in progress for the enlargement of Chatham dockyard will, when completed, cover an area of upwards of 350 acres, in addition to the 97 acres which comprise the area of the existing Dockyard, rendering this establishment about five times larger than the present dockyard, the entire area being rather more than three-fourths of the extent of the entire City of London. The following are the principal dimensions of each of the four new docks, the foundation stone of the first of which was laid on Tuesday last week:—Length at the floor, 430 ft.; length at coping-line, 468 ft. 3 in.; width of entrance at coping, 80 ft.; width at the centre of the dock, 103 ft.; width on the floor, 42 ft. 6 in.; depth from coping of entrance, 37 ft. 6 in.; depth from coping amidships, 41 ft. 6 in.; depth of water over the sill at ordinary spring tide, 31 ft. 6 in.; depth at neap tides, 28 ft. 6 in. For several months past about 800 workmen have been employed in excavating the site of the first of the docks to a depth of 31 ft., some millions of cubic feet of the stiff clay met with having been removed. Two of the docks and the repairing basin will be completed within two years from the present time. The cement and bricks for the works are manufactured on the spot by convicts, about 1,000 of whom are daily employed for that purpose. During the present season it is intended to manufacture twenty millions of bricks. The whole of the operations connected with the extension works are under the direction of Colonel C. Pasley, Royal Engineers, Mr. Gabrielli's contract being superintended by Messrs. C. E. Daniel and H. J. W. Neville, with Mr. J. Carntrons, clerk of the works, representing the Admiralty.

EXCURSION OF THE BEDS ARCHÆOLOGICAL SOCIETY.—This year the Bedfordshire Archæological Society went to Caldicote after the consecration of the memorial church there. The party inspected Caesar's Camp, near the Sandy railway station, and also the Roman Camp, known as Chesterfield. They afterwards visited Northill church, of which the Rev. J. W. Haddock gave a sketch, and then drove to Ickwell Bury, where Lord Arthur Hervey read a memoir of a member of his family, and the party dined there. The new church of All Saints, Upper Caldicote, was then visited, and the party returned to Sandy, where they visited the church and took tea at Sandy-place before returning to Bedford.

TENDERS.

For a house and shop, No. 15, Crown-street, Finsbury, for Colonel Wilson. Messrs. Haywood & Blashill, architects. Quantities supplied by Mr. D. Cubitt Nichol:—

Myers & Sons	£1,322 0 0
Colls & Son	1,227 0 0
Browne & Robison	1,220 0 0
Axford & Whittier	1,195 0 0
Graham & Sons	1,137 0 0
Newman & Mann	1,098 0 0
Beston	1,080 0 0
Tully	1,075 0 0
Hill & Keddell	1,050 0 0

For the erection of workshops, 247, Bethnal Green-road, Messrs. H. & J. D. Mathews, architects:—

Forrest	£485 0 0
Crowe & Robinson	435 0 0
Sewell & Sons	430 0 0
King & Sons	430 0 0
Ennor	476 0 0
Tully	475 0 0
Barrie	656 0 0

For sundry excavations, putting in foundations, &c., 55, Canonial-street. Mr. Henry Fuller, architect:—

Browne & Robison	£325 0 0
Hill & Keddell	305 0 0
Perry	290 0 0
Axford & Whittier	257 0 0
Prichard	250 0 0
Ashby & Sons	215 0 0
Piper & Wheeler	209 0 0
Sewell	200 0 0
Staines	187 0 0
King & Sons	172 0 0
Woodward	163 0 0

For building a public-house in Lordship-lane, Dulwich, exclusive of fittings, for Mr. B. McLeod. Mr. W. A. Murphy, architect:—

Shapley & Webster	£1,192 0 0
Colls & Son	1,099 0 0
Sharpe & Cole	1,050 0 0
Mitchell	1,000 0 0

For the erection of farm buildings, Reading, for Messrs. Sutton & Sons, Messrs. W. & J. T. Broun, architects:—

Barnicot	£287 0 0
Mathews	230 0 0
Woodroffe	790 0 0
Sheppard	749 0 0
Strong	741 0 0
Dunn	734 0 0
Bloomfield	681 0 0

For the erection of a house and shop, Broad-street, Reading, for Mr. Salmon. Messrs. W. & J. T. Broun, architects:—

Mathews	£791 0 0
Barnicot	790 0 0
Elphinstone	787 0 0
Cartier	785 0 0
Kendell	777 0 0
Bloomfield	775 0 0
East	750 0 0

For decorations, Calcot Park, Berks, for Mr. John U. Bisgrave. Messrs. W. & J. T. Broun, architects:—

Gladden	£297 0 0
Green & King	293 0 0

For rebuilding No. 83, Old-street, Goswell-road, for Mr. Harris. Mr. Joseph B. Moxe, architect:—

Barnett	£700 0 0
Walton	630 0 0
Radkin	537 0 0
Glover	493 0 0
Saber (accepted)	475 0 0

For additions and alterations to Leytonstone House, Leytonstone, Essex, for the Guardians of Bethnal-green. Mr. William Mundy, architect. Quantities supplied by the architect:—

Beale	£1,130 5 10
Read & Son	1,124 0 0
F. & F. J. Wood	1,068 0 0
Hill & Keddell	1,068 0 0
Read	1,063 0 0
Arber	1,051 0 0
Rivett	965 0 0
Forrest	967 0 0
Mason	853 0 0
Hodson	815 0 0

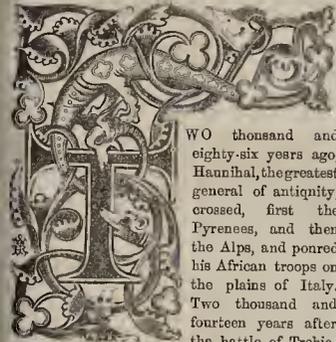

For iron buildings to be erected at Leytonstone, to be used as temporary schools, &c., for the Guardians of Bethnal-green. Mr. William Mundy, architect:—

Cutism & Co.	£14,610 0 0
Tupper & Co.	1,647 5 0
Messers G. & Co.	1,428 0 0
Deuce	1,293 0 0
Griffiths	1,340 0 0
Hemming & Co.	1,300 0 0
Whitford & Co.	1,176 0 0

The Builder.

VOL. XXVI.—No. 1319.

The Engineering of War.

TWO thousand and eighty-six years ago, Hannibal, the greatest general of antiquity, crossed, first the Pyrenees, and then the Alps, and poured his African troops on the plains of Italy. Two thousand and fourteen years after the battle of Trebia, a French artillery officer, by getting a single gun into a position that commanded the fortress of Mont Bard, unlocked the same mountain barrier, and commenced that career of conquest which scarcely paused till it encountered the terrors of a Russian winter, and was only finally checked on the plain of Waterloo. To the master manoeuvre of the greatest general of all time, and to the opening enterprise of the greatest general but one of modern warfare, has now to be added the record of a third not dissimilar adventure—the march of Sir Robert Napier on Magdala.

Viewed in itself, it is the most perfectly conceived and achieved incident in the history of war. We do not say that its accomplishment ranks the successful engineer officer who planned and conducted it on the level of either Hannibal or Napoleon. Times and circumstances must be taken into account, as well as military facts. Neither the Carthaginian nor the French general could dispose at will of the unstinted resources of a mighty empire. The distance which Hannibal had to transport his troops was far less than in our case, but then he had not the aid of a bridge of steam. The troops of General Bonaparte had but to cross the frontiers of their own country, but they were for the most part a starved, ragged, shoeless mob. It was the genius and the glory of the two great invaders of the Valley of the Po to forge their own weapons—to form their own army. England and India have lent their treasure, their skill, and their blood to form the well-ordered and triumphant force commanded by Sir Robert Napier.

It is curious to mark the reappearance of one of the arms of the Punic war. When Captain Dugald Selgaty was so overcome by the ridiculous ideas which he associated with the employment of bows and arrows as somewhat to endanger the cure of his wound, what would he have said if elephants had been proposed as beasts of military burden? Careful students, indeed, have been apt to remark that additions of great bulk and weight to the ordinary impedimenta of marching troops were involved by the use of elephants in the Punic and Pyrrhic wars, in the same way as by cannon in modern warfare. But the combination of the two, and that at the present time,—an Armstrong gun on the back of an elephant, marching over the mountains of Abyssinia in the year 1868,—could

anything have seemed more wildly incongruous a few years since?

The passage of the natural barrier, however, was not a campaign, but the opening of a campaign. With Bonaparte there was no halt till Campo Formio. Rome was declared French at the Treaty of Tolentino. Rome was taken by the French in the following year. The victor of Thrasymene and of Cannæ stopped at Capua. The fatal luxury of Campania demoralised his army. It is always a question among military writers how far the pause of Hannibal was compulsory—a question not likely now to be solved, unless Pompeii yields us further literary treasures. As far as one can decide at such a distance of time and of scene, it seems all but certain that the rapid advance of Hannibal on Rome after the battle of Cannæ, that of Henry of Navarre on Paris after the battle of Ivry, or that of Charles Stuart on London after penetrating as far as Derby, would have changed the course of human history.

Then, again, we do not forget the illimitable resources at the command of the victor of Magdala. But resources, though much, are not all. The man who can rightly dispose of vast resources is apt to be a man of the same stamp as he who can create resources in case of need. And Sir Robert Napier found his main element of delay in the very wealth and abundance of his supplies. He had not the fertile valleys and plains of Lombardy, of Apulia, and of Campagna, from which to draw the food of his troops. He even had to carry hay for his horses, for mules, and elephants. In the protection of his long line of communications, Sir Robert had a difficulty to contend with that was unknown to the great Italian conquerors to whom we have referred. Their advance, in point of fact, was that of a movable column, relying for its support on the contributions it could exact from the country. His was that of an army of invasion. It is true that he had not to fight for every step of his way: had such been the case, the capture of Magdala would have been impossible to ten times the number of troops; but he had to take military precaution against surprise. The *auri sacra flammæ*, the instinct of mankind to pilfer, is as strong among the Abyssinian Christians as it is in any civilised state. Our dusky neighbours would have felt no more "delicacy" than did an honourable Englishman lately referred to in our columns, in helping themselves to all and every article in our baggage-train, if we had only encouraged them by proceeding upon the principle advocated by some of our friends of the Peace Society. We were not fighting our way through an enemy's country, but we were making a military movement of extreme delicacy and magnitude, and one in which no military precaution could be safely—or was in fact—neglected.

This borne in mind, the gallantry, the rapidity, and the crushing success of the blow—a blow dealt with such a long arm—is without precedent in military history. The echo will ring through India and through Africa like that of the tramp of doom itself. Not an Englishman is engaged out of England, in any of those occupations in which it is of importance to him to let his English citizenship be known and respected, who will not feel a couple of inches taller when he reads the tale of the storm of Magdala. Nor is the heroic element wanting on either side. Our men—we (one feels proud to use the pronoun)—fought chiefly against nature. The human foes were as nothing to the hostility of those pathless wilds and those lofty scarpes. The fire of Theodore's troops did little more than serve the purpose of military music to raise the English mettle to that heat at which it is wont to go anywhere or to do anything. But it was different with the barbarian monarch, the descendant of Solomon and the

Queen of Sheba. Savage as he was, he faced Death like a king of men. He turned not from those terrible and utterly astounding steel shells—a projectile that would have been apt to show a point in the character of Agamemnon or of Ulysses that was not suspected by Homer. The *feu d'enfer* opened upon him, but he faced the *feu d'enfer* with as unblenching resolution as if it had been a shower of *bon-bons*. He died a king, to his honour be it spoken—a king, though a savage; and he is entitled to a vote of thanks from the House of Commons for so doing, if it were of any service to him (it might have been more agreeable to certain members to vote it than it seems to have been to do so for our own officers and men); for by his heroic death he has added the only stamp and seal which could render our triumph unquestioned. His fall cannot now be explained away. Sir Robert Napier has carried off his *spolia optima*.

The point of view from which this brilliant and prudently ordered campaign is chiefly interesting to our readers is that from which we have had occasion to deal with all such subjects as those of artillery, fortification, military engineering, and military education. They are subjects germane to our pages. And the great lesson, to us, of the Abyssinian campaign is this: it enforces, not by the voice of calamity, but by the shout of triumph, the truth of that which we have long endeavoured, patiently and modestly, to insist on—the fact that war is changing, not in its nature, but in its method, and that the conduct of war is passing into the hands of the engineer. It is not the fearless and dashing cavalry officer—the *beau sabreur* like Murat,—it is not the unflinching head of squares and of columns, if he have all the courage of Ney,—it is the artilleryist, like Napoleon, or the engineer, like Napier, who will be the general of the future.

For the first time in our history the independent command of a large force has been entrusted to an officer of Engineers. It will not be for the last.

Up to the time of the storm, and with the further exception of the military patrolling or guard of the stores and communications, the invasion of Abyssinia was an engineering task. The laying of the Bordeaux and Bayonne Railway across the desolate Landes bordering on the Bay of Biscay, by an English engineer and by English workmen, was, at a very modest distance, an operation of the same kind. Pioneers were not mere pickets of advance; the whole force had to work as pioneers; they had to make the road over which to go. The enormous military facilities of the railway system were not lost sight of. It seems to us that a little more civil practice and experience would have placed at the command of the general of the forces a longer and more serviceable railway. Considering what can now be done by properly constructed engines for surmounting inclines, considering how much less labour is requisite to excavate, to form, or to embank the narrow track which alone is absolutely necessary for a single line of rails, of perhaps 3 ft. 6 in. gauge, like some of our modern light railways, than to complete a good military road available for the transport of stores and of guns, as well as of cavalry, infantry, and elephants, we think the railway communication might have been more rapidly pushed ahead, to the immense reduction of all the contingent difficulties of the case. Barlow's rails, requiring no sleepers, and requiring, in the season we have just passed through, no ballast, would have been eminently suited for the service of a temporary military railway. Unless in face of very serious obstacles, experience teaches us that such a line might have been run ahead at the rate of more than a mile a day.

It may in this respect he said in reply that it is easy to be wise after the event, and that, in

presence of so brilliant a success, it is becoming to grumble. But there is one point on which we must express surprise—and we rejoice that we are able to do so in the tone of *Fluelen* rather than in that of *Cassandra*.

The intelligence of the fate of *Theodore* reached us in about a fortnight from the date of the event. The preceding intelligence, for some time, had occupied three weeks in transmission. The difference between the two periods may be accounted for partly by military reasons. It must have arisen in *Abyssinia* itself. But, making all allowances for the fact that it was probably the conviction on the part of the commander of the forces that no number of patrols at his disposal would enable him certainly to protect the wires of a field telegraph from the eager pillaging of the natives,—remembering how one of the inhabitants of this quarter of the world endeavoured to welcome Sir S. Baker by making off with his tent from over his head at a first interview,—we can conceive of no adequate reason for the absence of direct communication between the ministerial offices in London and the point of debarkation in the Red Sea. Why was not a special wire arranged for, and, when necessary, laid? What would have been the expense, as a mere matter of pounds, shillings, and pence, compared with the advantage to be secured? With an expenditure going on at the rate of 20,000*l.* per diem, what would have been the commercial value of a saving of some three weeks in every exchange of communication, backwards and forwards, between the general commanding the forces and the minister under whose orders he acted, on the one hand, and his subsidiary base of operations at *Bombay* on the other? Had the telegraph been abandoned when it had conveyed to Westminster the intelligence of the re-embarkation of the last English soldier on the Red Sea, the expense would have been a very wise economy.

But no such expense need have been actually incurred. It would have been only a first outlay, an outlay to be recouped in part, or almost wholly. The disgraceful state of our telegraphic communication with *India* is but too notorious. Independently of the solution of that great industrial question of the day, the centralisation of our telegraphic communications under the control of the authorities of the Post Office, it is clear that we must have more lines of cable to *India*.

The urgent need of instant communication with a half-way point was just one of those occasions of which a great minister would have been prompt to avail himself. We must provide, he would have said, a telegraphic communication, the best possible at short notice, by the time that our troops land. We can make use of the wires hereafter for expediting our despatches to *India*.

The overlooking a provision from the want of which, we may now safely and truthfully say, the whole cost of the expedition might have been douched by the delay of its object for another year, is the more remarkable from the lesson on the subject which we received in 1866. The needle-gun was the arm which decided the battle of *Sadowa*. That was our declaration at the time. A little later it was rather thought to be an exaggeration. Subsequent research has confirmed the truth of the opinion, and all the military writers who have treated the subject now admit that it was the case. But while the needle-gun was the arm used in the actual crisis, the electric telegraph was the instrument which made that crisis possible. The double parallel march through the giant mountains, an extreme effort of military daring, was only rendered possible by the instant, uninterrupted communication of the commanders of the separated *corps d'armée* with the Minister of War at *Berlin*, and thus with one another. As it was, the success is inexplicable,—not the success in the field of the well-armed, well-shod, well-educated Prussian troops against the unprepared and ill-provided *personnelle* that crowded under the Eagle of the Kaiser, but inexplicable that any man with the least knowledge of the art of war, and with the merest handful of troops under his command, should not have endeavoured to strangle the heads of the long-drawn columns before they debouched from those difficult passes. Thus the service rendered to Prussia by the field telegraph is fully equal to that which she exacted from the needle-gun. The two are complements of one another. With increase of precision of range, and of repetition or rapidity of firing in the arm, increase of

rapidity in the conveyance of intelligence is a consistent necessity.

If it should occur—which God avert—which we have to draw the sword in *Europe*, we cannot lay this great lesson too closely to heart. It is a double lesson. We see how the military nations of the Continent go to war; we see how we have done so ourselves: comparing our men, our artillery, our small arms with those of our neighbors, we have no reason for discontent. We are not resting on our oars; we are still making experiments and improvements at unostentatious expense; but in our last great and noble essay we have neglected that powerful instrument by which the armies of the Continent are linked together as by the famous chain of the Saracenic guard, so long borne in the arms of *Albret* and of *Navarre*. It was all very well to deploy before the stronghold of *Theodore* unprovided with a telegraph, but what would have been the result if *Magdala* had contained a *Von Roon*?

Again, for our brilliant advance through *Eastern Africa* we chose our own time. We were absolute masters of the situation in this respect—to stay away or to go—to advance or to retreat. If we should have to fight, or even to stand in armed and grim neutrality, in *Europe*, this will not be the case. To those who are deaf to the warning sounds that issue from every camp and arsenal under the command of *Marshall Niel*, there will be very few hours of delay given to make preparations for a European war. Disarmament or war is becoming a positive alternative; and disarmament—if it takes the tone, “*Yon put down that stick or I'll make yon*”—is a natural pretext for, and ingress into, war. Even in that case we may avoid the vortex. Truly so—and God grant that we may—but the impunity with which we can afford to look on will depend absolutely on the evident power which we possess to make our neutrality respected. And it is now the fact—and we shall do well to take heed of it—that our most brilliant success, a success which has attracted the admiration of our most habitual detractors, has not been unaccompanied by a signal neglect of one of the most valuable instrumentalities which the man of science has ever placed at the service of the statesman.

THE PUBLIC HEALTH GOOD.

THE Registrar-General's quarterly return for the three months ending the 31st of March last gives us the pleasing intelligence that on only two occasions since 1838, when a systematic registration of deaths first rendered statistics of mortality available, has *England* been so healthy during the first quarter of the year, as in that portion of the present year. The annual death-rate in those three months was 22.3 per 1,000 persons estimated to be living, while the average rate in the thirty years 1838-67 exceeded 25 per 1,000. In round numbers, the difference of the death-rate signifies that 15,000 fewer deaths occurred during the first quarter of this year than would have taken place if the average death-rate of the same period in the preceding thirty years had prevailed. The two exceptions above alluded to were the first quarters of 1846 and 1856, when the death-rates were so low as 21.6 and 21.8. In 1850 and 1857 the rate was respectively 22.6 and 23.0; and in the remaining twenty-six seasons of the period above alluded to the rate ranged between 23.5 and 29.1. The average rate of the last ten corresponding quarters, 1858-67, was 25.3.

The popular conviction of the influence of weather upon health has a larger proportion of truth for its basis than many other popular impressions. The thermometer during the winter season is almost as nerving an index of the rate of mortality, as of the temperature. The past winter has been almost unprecedentedly mild;—not that the mean temperature of the three months under notice, although in excess, was so far above the average, but there was an entire absence of continued frosts. Those who notice the weekly returns of deaths in *London*, for instance, may have remarked that whereas in open weather the numbers would range between 1,200 and 1,400, a week or two of hard frost generally sends them up to between 1,700 and 2,000. An improvement in the intelligence and material condition of the working classes, and a more general acquaintance with the best means of protection against severe cold adopted in those countries where low temperatures are regularly

expected, may some day render us more independent of the influence of weather: till then it appears that continued frosts must produce high death-rates.

The mean temperature of last quarter, at the Royal Observatory, *Greenwich*, was 41.4° or nearly three degrees above the average of the same period in ninety-seven years. The rainfall was 6½ in., and nearly 1½ in. in excess of the average of fifty-three years, the whole of the excess occurring in *January*. The weather was somewhat cold during the first fortnight of the quarter, but during the remaining eleven weeks the excess of temperature was almost constant; it was greatest, however, in *February*. There was more than the average amount of movement in the air, but easterly winds were considerably less frequent during *February* and *March* than is usual in those months. These combined meteorological conditions doubtless exercised a very considerable influence upon the mortality.

The total number of deaths registered in *England* and *Wales* during the quarter was 126,095, showing a decrease of 14,000 upon the same period of 1867, and of 18,000 upon 1866. The decrease of deaths is apparent in nearly every part of *England*, the counties of *Leicester* and *Westmoreland* being almost the only exceptions. In rather more than half the whole population of the country living in large towns, the death-rate last quarter was 2.40 per 1,000, against 27.6, the average rate in the ten quarters 1858-67; while in the smaller half, inhabiting the rural districts and small towns and villages, the rate was 20.1, against 23.5 in the same period of 1858-67. It thus appears that the improvement in the health of the country was almost as great in the rural as in the urban districts.

In the eleven large towns of *England* furnishing weekly returns of mortality, comprising nearly all the largest, the death-rate last quarter averaged 2.49 per 1,000. Of these towns *Bradford* and *Hull* enjoyed the lowest rates, 2.20, and 2.21 per 1,000. *London*, with its more than three millions of inhabitants, stands next, with 23.3. The rates in the other towns, ranged in order from the lowest, were as follow:—*Sheffield*, 23.4; *Leeds*, 24.0; *Birmingham*, 24.2; *Bristol*, 25.6; *Newcastle*, 25.8; *Salford*, 28.2; *Liverpool*, 30.0; and the highest rate during the quarter, 31.3, in the city of *Manchester*. Perhaps the most important point connected with these rates is the remarkable improvement in the health of all the *Yorkshire* towns, but especially in *Leeds* and *Sheffield*. *Newcastle* has also been far healthier than in recent years. The rates in *Birmingham*, *Bristol*, and *Liverpool* do not exhibit the same extent of reduction upon recent corresponding quarters, owing to the prevalence, and more or less fatality, of the infantile zymotic diseases, measles, whooping cough, and scarlatina. *Manchester* is conspicuous for its high death-rate; in that city during the first three months of this year more than 800 deaths were recorded which would not have occurred had the death-rate not exceeded that in *London*. The excess of deaths was principally due to the fatality of measles, scarlatina, whooping-cough, and the different forms of fever within the city. Even the most strenuous opponents to the appointment of a medical officer of health for that city will scarcely refuse to acknowledge that this step has not been taken too soon.

The Registrar-General's returns for the first time, a table of the rates of mortality prevailing during last quarter in forty-six large towns, other than those for which weekly returns are published, and containing a population of about 50,000 persons and upwards. Leaving out a few exceptional cases (in which the estimate of population, based upon the rate of increase between the census of 1851 and that of 1861, appears to be unreliable), the rates of mortality in these forty-six towns have a very wide range, between 16 per 1,000 in *Coventry*, and 17 in *Ipswich*; and 32 in *Bolton* and *Ashton-under-Lyne*, and 34 in *Stockport*. In each of the two latter towns the deaths registered in the quarter exceeded the number of births. The publication of these statistics will doubtless excite a little more sanitary activity in many of those towns which have hitherto raised the average rate of mortality in our total urban population without the consequences of a systematic apathy in such matters being brought home to them. We have only to point to the steadily declining death-rates of *Liverpool*, *Leeds*, *Hull*, and of other of our large towns, to show the effect of an awakened interest in their sanitary

condition which has been shown in those towns, in a great measure through the publicity which was given to the waste of life therein prevailing but a very few years ago.

It is beyond question that a more general appreciation of the influence of sanitary supervision upon public health is daily growing, not only in large towns, but in villages and in purely rural districts. It is impossible to estimate to what extent this has already influenced the rates of mortality; but evidence from all parts of the country testifies that in some measure the improved health of last quarter is due to a better outward sanitary condition of the people, as well as to the favourable temperature of last winter.

Infantile zymotics, however, were very fatal in many parts of England during last quarter; measles especially so in Leicester, Hinckley, Whitwick, Stockport, and Liverpool; scarlatina throughout the county of Durham, in Lyncouth, Manchester, and in many of the Lancashire towns. Measles caused 452 deaths in London, against 239 in the same quarter of 1867; and scarlatina, 368, against 339. The fatal cases of smallpox had, however, declined from 526 in 1867 to 280 in last quarter. It is naturally to diseases of the respiratory organs that we must look for the greatest reduction in the deaths last quarter; and of this class those from bronchitis had fallen most. The deaths from bronchitis in London, which had been 3,144 in the first three months of 1867, were only 2,282 in the same period of 1868.

On the whole, the present return must be considered most satisfactory; and, as the death-rate in the first quarter of the year usually furnishes a reliable index of the rate for the whole year, we may fairly hope that, with continued and increasing sanitary intelligence and activity, the year 1868 may prove one of the very healthiest on record.

ON THE UTILIZATION OF SEWAGE BY IRRIGATION.*

Drainage Basins and Conservancy Boards.

ONE of the most formidable of the obstacles which impede the sewage question is the complication arising from the fact that, while most of our principal streams receive in their course the drainage of many towns which have no other outlet, each of these towns has a separate and distinct system of sanitary administration, formed for the purpose of furthering its own peculiar interests, the whole having no more unity or cohesion than the particles forming a rope of sand. From this lamentable feature in the principles of our district government, endless evils originate; for without unity of purpose or will it too often happens that any step in the right direction made by one district is immediately neutralised by the inaction of its nearest neighbour, which, governed by the maxims of the old school, views every innovation as a direct attack upon its exchequer. Isolated and independent local government is doubtless an excellent thing, where such government has no bearing upon the interests of its neighbours, as, for instance, what can it matter to an adjacent community whether the bye-laws of a district insist on a twelve or a nine-inch partition-wall between contiguous buildings? But where broad questions arise, in which the common interests of a multitude of districts are directly concerned, such independent action on the part of each district becomes a curse, and instead of all policies for the common good being fused, they are forced into abeyance by the antagonism of Boards, whose powers for good are thus made impotent. To condemn the vices of independent and irresponsible local government in this respect is but to reiterate the fable of the quarrel between the various members of the human body; without the provident control of the head to keep watch over the combined necessities of the whole structure, it must speedily shrink into a dry and shrivelled anatomy.

The following extract from one of a series of valuable reports that are being issued by the Rivers Pollution Commissioners gives a faithful exemplification of the results of local government in a populous manufacturing district:—

"The rivers Aire and Calder, throughout their whole course, are abused, obstructed, and pol-

luted (to an extent scarcely conceivable by other than eye-witnesses) from Skipton, on the Aire, from Todmorden, on the Calder, down to Castleford. Our inspection was corroborated by incontrovertible and overwhelming evidence; by the engineers to the Aire and Calder Navigation, as also by the men employed in dredging. Pollution by solids—ashes, mud, and other 'pows'—is increasing, and will yearly become worse and worse, unless some remedial measure be rigidly enforced.

It is impossible to treat quite separately the questions of obstruction and pollution. In many cases, where solids are carried into a stream, both injuries are of course inflicted upon it.

The rivers Aire and Calder, and their tributaries, are abused by passing into them hundreds of thousands of tons per annum of ashes, slag, and cinders from boiler furnaces, iron works, and domestic fires; by their being made the receptacles, to a vast extent, of broken pottery and worn-out utensils of metal, refuse brick from brick-yards and old buildings, earth, stone, and clay from quarries and excavations, road scrapings, street sweepings, &c. &c.; by spent dyewoods and other solids used in the treatment of worsted and woollens; by hundreds of carcasses of animals, as dogs, cats, pigs, &c., which are allowed to float on the surface of the streams or putrefy on their banks; and by the flowing in, to the amount of very many millions of gallons per day, of water poisoned, corrupted, and clogged by refuse from mines, chemical works, dyeing, scouring, and fulling, worsted and woollen stuffs, skin-cleaning and tanning, slaughter-house garbage, and the sewage of towns and houses.

The practice of periodically flushing out into the streams the mud which must, under any circumstances, accumulate in goits, culverts, mill reservoirs, or 'lodges,' and canals, is also a palpable abuse."

The amount of annoyance, loss, and danger to public health occasioned by this complication of abuses is beyond calculation. High death-rates prevail; manufactures have been transferred to localities less abused; residential proprietors have been compelled to abandon and let their dwellings; and the beauties of river scenery have undergone a fatal transformation. Although the law professes to give distinct rights to the community in respect of the purity of streams, the vastness of the pollution takes away even the slightest hope of making them good. For an individual proprietor to attempt such legal rectification would be to ruin himself to no purpose, while for a community or a town to attempt it would only be less ruinous and absurd. The former has not only to encounter single-handed the doubtful process of common law, or the filing of a Bill in Chancery, but he must make up his mind to the creation of enemies on every hand, and to be viewed by all his neighbours as a public nuisance,—a consideration which generally imposes an effectual check upon all remedial proceedings on the part of the aggrieved. In the latter case, corporate bodies may indeed deal with their own nuisances as they think proper; but, as the river nuisances created within their own jurisdiction are usually insignificant, compared with those whose effects they suffer, and as the selfishness of mankind cannot ensure the following of such an example, much benefit cannot result; and, therefore, we find that in such cases nothing is done. At Wakefield, for instance, we have an example of river pollution. Before it reaches that town, the river Calder receives the sewage of an area containing 400,000 inhabitants, and the manifold impurities discharged from 1,200 manufactories. This water is drunk by the people of Wakefield after filtration, and so possessed are they of the impossibility of much further defilement that they do not scruple to add to it their own sewage and excrementitious matter before pumping it on to their filter beds."

It is apparent, then, that a stringent law of prohibition is the only method of dealing with the pollution of rivers; and if the multitude of powerful communities whose health, pleasure, and means are daily assailed by this evil, consider themselves mocked by the present statutes, it remains for them to have these swept away, and such a prohibitive measure introduced. It is a grave omission in legislation which places a safeguard over the interests of the proprietors of streams and waters in wild and thinly populated districts, and which yet leaves the rivers of districts abounding with vast and hasty popu-

lations, entirely at the mercy of those who in every conceivable form combine to render them odious to the sight and dangerous to the health of the community at large.

Some portion of this neglect may doubtless be attributed to a drowsy—instinctive in a manufacturing population—of interfering in any degree with the supposed interests of its various industries. Thus, in the northern coal-fields of England, a prejudice has long existed in favour of smoke. "Where there's reek there's brass" is a proverb in these districts, and much disfavour has been shown towards the Smoke Act. The presence of dense black volumes of smoke, issuing from tall chimneys, has become identified with the creation of wealth. But it has been proved, and the proof is now spreading, that "reek" is really an item of waste; and as this idea gains ground the consumption of smoke becomes general.

So in respect of the pollution of rivers, there is still a feeling amongst manufacturers that they should be left undisturbed by legislative prohibitions. But much of this feeling has subsided since the visit of the Rivers Commission to the Yorkshire and Lancashire coal districts. It was clearly proved during the sittings of that Commission that the most noxious portion of manufacturing refuse might be kept out of the rivers by the exercise of care, at a very slight cost, and that in some cases the value of the ingredients regained would leave a profit upon the process of clarification. It was also proved that some branches of the fine woollen and calico trade were migrating from the West Riding of Yorkshire, from no other cause than the scarcity of pure or clear water. The Commissioners pointedly state that in the Aire and Calder districts "the abuses and pollutions of running waters have become almost intolerable, and even trade is seriously injured in consequence."

The forcible interference of legislation is accordingly no longer viewed with such extreme jealousy, and amongst the more scientific and enlightened of the manufacturers such a course is considered absolutely imperative.

It is with a view to the amendment of this disorganised state of affairs that certain Catchment and Watershed Areas of Conservancy have been proposed, whereby the basin of every important stream shall be divided into convenient districts, generally separated by lines of watershed. Over these districts it is proposed that certain Boards of Control, exercising comprehensive powers, shall preside. The duty of such Boards will be to prevent the pollution of running waters by any matter whatsoever interdicted by statute, full powers being given them to pursue the offending party at law, to act in concert with each other, and to act in perfect independence of local interest and prejudice. It is justly argued that until an Act providing for the construction of such Boards be passed no progress in the utilisation of sewage, or the purification of river waters, can be made in the manufacturing parts of Great Britain. It is because this policy was neglected in the interminable discussions on the metropolitan drainage question that the vast and magnificent labours of the Board of Works have not been attended by such perfect results as were anticipated, a neglect which has been tardily amended by the Act relating to the Valley of the Thames.

Mr. W. J. Ffounel, late inspector of the fisheries of England, has recorded his opinion, that there should be a central authority in London, with deputies in the districts, having separate control over separate basins, but with unity of action, and all subject to supreme authority; and also that there should be definite power given to this authority to prevent the pollution of rivers.† It was asked during the sitting of the Committee upon Metropolitan Sewage that if local Boards were put under the jurisdiction of the Home Office, or the General Board of Health, which should in either case have the power to issue a *mandamus* to compel the enforcement of the law, such a course would not be better than to have a central Board in London. But Mr. S. H. Gael, a gentleman profoundly experienced in the preparing of bills relating to the public health, did not approve of the plan suggested, and said it would involve nearly the whole machinery of a central authority, as well as that of a district authority. He also cited the analogous nature of the salmon fisheries legislation, and counselled a similar mode of treatment in respect of

sewage. Under the Salmon Fisheries Act, the Commissioners assign districts to the Boards, who are to carry out the law locally on the salmon rivers and their tributaries, and who have power to prosecute traders and manufacturers whose works pollute the streams.*

Touching the inconvenience which such prohibitory powers over water-courses would effect towards manufacturers, sufficient has been learnt on this subject of late years to show that in most cases it would be merely temporarily. A letter addressed to Mr. Ferrand, M.P., by Mr. Edward Townsend, of Cullingworth Mills, near Bingley, shows what has been done in this regard. The writer says,† "The main feature of the principle we have adopted for the filtration of the dye and soapy waters from our works is, the passing those waters through a bed, 15 ft. to 20 ft. thick, of engine ashes, leaving the solid matters as a crust at the bottom of the tanks, formed of engine ashes; the crust, of course, having to be taken from inside the tanks regularly at stated periods,—say twice or three times per month. This crust makes excellent manure, and we spread it at once on grass and arable land. With especial reference to the sopsends, they go from our wool-warehouses into tanks, very strongly made, and lined with double bricks walled in cement. The suds are then boiled in these tanks and broken with acid. The magma, or thick creamy part, rises to the top. The thin watery part below is run off into the engine-ash filters, percolating through them into the bed, and thus escapes in quite a clear state. The thick part left in the brick tanks is then run into filters made of cocoa-nut matting lined with canvas, and when of the consistency of, say, cream cheese, is wrapped in canvas bags, to be pressed in a steam press, whereby the grease is pressed out, of which we make about 30 cwt. per week, besides a large quantity of solid manure, in the form of oil-cake, which is periodically taken on to the land, and makes very excellent manure. This system of purification is readily done in moderate-sized works. The grease we extract from the soap is now worth 17s. per ton, and is sold to candle and soap manufacturers."

Mr. Rawlinson, late chairman of the Rivers Pollution Commission, has thus expressed his views in a letter to Lord Robert Montague:—

"With respect to Boards to manage drainage areas, I fear any plan of representation embracing even one member from each separate local Board will not prove to be practicable, on account of numbers. Take, for instance, the Aire and Calder drainage area, which is about 800 square miles. There are at present seventy-one local Boards, and will be more. Each such local Board may require to be rated for river improvements, and controlled with respect to outfall sewage; but a Drainage Area Board with only seventy-one members—one from each Board—would be cumbersome for work. There must, however (if representation is to rule the formation of such Boards), be canal, river, land, and mill representatives. I must confess that I do not see the way to purely local Boards for drainage or river areas. The machinery must be in some other form. Rivers require to be improved and preserved from injury, irrespective of county, parish, township, or private boundaries. Permissive power will only mean power to do nothing, as at present. Those who abuse will, for the most part, govern; and, as in the case of the Smoke Act, any Act of a similar kind will, like this, be a dead letter. Of what use is a Smoke Act in Manchester, Salford, Wigan, and other manufacturing towns, where the members of the several corporations are smoke makers? Suppose the factory owners had been required to appoint and pay factory inspectors, how much useful inspection would have been done?"

"I do not like advocating Government interference in river preservation, but I do not see my way without it. Any Board, to be useful, must consist of working members, with ample powers to devise and execute works, to purchase and remove mill-dams, to embank, to drain, and to prevent all forms of abuse on rivers. A drainage-area rate would have to be laid and collected, superintendence should be regular, and an annual report ought to be published. Machinery such as is sketched out will be difficult to establish."

Mr. Rawlinson speaks here with admirable force and justness, which are perhaps somewhat

qualified by the terms of the concluding sentence. With equal force, and divested of all doubt as to the practicability of their suggestions, the Rivers Commission, in their Third Report, reiterate these arguments, the interval of three years' close and exhaustive investigation having but served to strengthen their opinions into immutable conviction. After making a comprehensive sketch of the progress of the woollen and worsted manufactures in the West Riding of Yorkshire, so far as regards the basins of the Aire and Calder, and reporting the evidence taken during the sitting of the Commission, the Report proceeds to state that, "in order to prevent the pollution, and legally control the management of rivers, their basins or watersheds must be placed under supervision, irrespective of any arbitrary division of county, parish, township, parliamentary, municipal, or local Government Act boundaries, or, indeed, of any artificially-established division. Running if the upland waters are polluted by town sewage and by refuse discharged from manufactories, as in the West Riding of Yorkshire, the entire length of a river is necessarily polluted. Towns situated midway, as Leeds, Manchester, Salford, and many other places, will establish and carry out local improvements, and would clarify their sewage and other refuse fluid to little practical purpose, if the towns, villages, and manufactories on the same river with themselves and its tributaries, are not placed under restriction against sending down pollution. Thus, for instance, the corporation of Salford, which occupies one side of the river Irwell, opposite Manchester, entertained the idea of intercepting sewers. Plans were prepared and estimates made, and the project was discussed, but was abandoned on the plea that money expended in Salford alone on such works would not accomplish the purification of the River Irwell, so long as Manchester, and all the great manufacturing towns and mills of Lancashire situated on the river and its tributaries, continued to pollute the running waters of their respective districts. Pollution caused by sewage, and by trades and manufactures, ought, in our opinion, to be prevented at the cost of the community, and persons causing such pollutions. At Croydon, at South Norwood, and at some other towns it has been forbidden by injunction for the local authorities to pass town sewage into running waters below a defined standard of purity, and the result has been, after the failure of all other systems, a clarification of such sewage by irrigation, which not only proves successful for the purpose desired,—namely, to prevent river pollution,—but in its operation is a source of profit to the ratepayers. However that may be, the question of profit or loss in abating nuisances . . . ought not too closely to be taken into account. . . . Towns can as well afford to pay for the means and appliances necessary to render sewage innocuous to running water as they can to pay for the sewers and drains which are necessary to their sanitary well-doing. . . . Every witness we examined admitted the existence of many great evils, and remedial measures are in the evidence over and over again suggested, the reiterated stipulations being that such measures shall be as general as the trades to be affected by them, and that their enforcement shall be by Government authority.

"One conclusion, therefore, forces itself upon any one who honestly deliberates upon the existing state of things in regard to the rivers we have visited, with a view to its permanent improvement. A stronger power than has hitherto been available must be brought to bear, if the present abuse and pollution of streams is to be arrested, and Government supervision and inspection must enforce and strengthen the action of local authorities.

"As previously mentioned, there is plenty of land in the Aire and Calder district suitable for sewage irrigation, and we have no experience of any town or locality where the application of that system would be impracticable. . . . All refuse from dyeworks, mills, factories, tanneries, breweries, malt-houses, slaughter-houses, and the like, should be prevented from being cast into and polluting running waters. No ashes, cinders, slag, waste earth, mud from canals, goiters, and reservoirs, road-scrappings, broken pottery and utensils, bricks and building rubbish, or any other solid calculated to impede the flow of water, raise the bed of the stream, and cause impurity, should be permitted to be cast in, or so to be disposed of on the banks of a river as to be carried in by its water. Sewage interception is always

practicable. Where it can be applied fresh to the land there is least nuisance and least cost to the ratepayers. Where the solids are extracted by mechanical deposition there is pecuniary loss on the operation, and running streams receiving the effluent water are still polluted, the pollution being greater as the volume in the stream is relatively small. No arrangements for treating sewage are satisfactory except its direct application to land for agricultural purposes."

"It is for the interest of manufacturers, as well as of riparian owners, and the community at large, that a preventive law should be equitably but rigidly applied. For such legislation, the successful operation of Lord Derby's Act, which has abolished the nuisance from alkali works, affords a fitting and encouraging precedent.

"Our experience of the weakness inherent in unaided and uncontrolled local authorities, as at present constituted, convinces us that a central Board, appointed by a State department, is necessary to the efficient protection of running waters. For instance, under the Local Government Act, 1858, a local Board may be established, and, after having executed works on borrowed money, the ratepayers may decline to elect a Board; or the members of such local Board, after election, may decline to act, there being no power at the Home Office to compel them to do so. Such power, however, will be absolutely necessary in any conservancy Act to enforce the prevention of river pollution.

"Economy in the work of a central Board for the conservancy of rivers might be probably obtained by enabling it to avail itself of such parts as may be applicable of the existing system of Government inspection, as of factories, mines, alkali works, fisheries, land drainage, &c."

The Commissioners then go on to observe:—
"The duties of such central and district conservancy Boards might be—

1. To aid the Salmon Fisheries Commissioners.
2. To prevent the obstruction of rivers and running waters by casting in of solids or flushing in of mud, as also all forms of river pollution.
3. To take cognizance of all existing weirs, mills, dams, river-walls, embankments, reservoirs, goits, culverts, drains, &c., and of any new works proposed which may affect streams.
4. To hear appeals in cases of local disputes as to works of any character affecting the condition and free flow of rivers."

Sundry geological and other plans accompanying the Report, showing the different basins of the West Riding—those of the Aire and Calder as appertained into sub-conservancy districts.

M. P.

ON BUILDINGS FOR EUROPEAN OCCUPATION IN TROPICAL CLIMATES, ESPECIALLY INDIA.†

The structural difficulties mainly to be anticipated can be, I think, summed up in one word,—want of appliances. There is in India, at least, no want of hands. Labour is plentiful and cheap there, and a surprising degree of some sorts of skill still exists in plenty also, and this is probably more or less true of every place within the tropics where buildings of importance are likely to be needed by Europeans; but any appliances beyond the rudest for raising weights, putting materials in their place, fitting together unwieldy portions of a structure, or even building a scaffold or boisting a block of stone, may be expected to be scarce. In a peculiarly un-English method many sorts of works are well carried on by the natives, who seem to retain, along with the ruder ways of common building, some lingering traditions of arts long almost disused in the cities chiefly occupied by Europeans. A building in progress is, however, a curiously uncouth sight to unaccustomed European eyes. The scaffolding, so irregular and insecure in its appearance, seems only fitted to fall, yet it does its work; vast crowds of half-naked workpeople, those carrying burdens being mostly women, each bearing on her head a light load of what has to be transported; the mason squatting on the stone he has to dress, holding his chisel in the tips of his fingers, and dealing dainty taps with a small hammer, as though he were a sculptor finishing off a marble statue; the smith squatting over his fire, as though his feet must be among the sparks and cinders, as well as his iron; and among them all the dusky overseer with long white robes, and perhaps an

† Jy Mr. T. Roger Smith. See p. 311, ante.

monous red turban, perhaps a tall gilded cap, and on his brow bearing the distinctive mark of his favourite idol, advances with the most obsequious of bows, his posture intended to convey the idea of an entire devotion to your service—not always carried out by his conduct. On such a work as this, busy and active though it be, an iron bolt or a clamp or a joggle, not to mention a powerful crane or a crab, which here it would be the simplest possible thing to have, would be something of a difficulty even in such a city as Bombay; elsewhere it might prove a formidable undertaking, perhaps even an impossibility. Nor is sending things over from this country always a safe and complete resource, although it has to be largely practised. Every one knows how often when such things as ironwork, metal-fittings, &c., are sent on to a building at home, there is something wrong. Bolts going somewhere where a spanner cannot be got on to turn the nuts; things that refuse to match or to fit their place, are serious hindrances even here; but when the original foundry is four thousand miles off, so that either a clumsy makeebiff made on the spot here to be adopted, or a delay of six months has to be endured, before a casting sent in error or broken in transit can be replaced, it is obvious that every complicated appliance ought to be avoided where possible; and where not, that everything of the sort should be put together in this country completely before shipping, and that duplicates of everything liable to damage or loss ought to be provided in abundance. In reference to breakage I may, by the bye, remark that more of it occurs in landing than on the voyage. Castings will travel excellently well if stowed along with plenty of small coal, but their dismemberment should be especially superintended. The necessity of hoisting a large weight or fixing a difficult piece of masonry may prove an insurmountable obstacle; and the employment of anything that would be considered even moderately difficult in this country ought to be avoided, unless the architect have previously ascertained that the means of carrying out his intentions exist at the locality where his building is to stand, as in part they do in the larger cities and most active colonies. In short, in designing for the tropics the architect should suppose that his work is going to be carried out much as Medæval work was done, and without any modern appliances whatever; and how lightly such a limitation need act on a true artist may be easily understood by recollecting how grand and how perfect were the buildings which our predecessors erected in an age when steam-cranes, travellers, and railways were unknown, before iron had been introduced into buildings, and when roads were bad and hoisting little understood.

The materials obtainable in any tropical locality will be sure to differ somewhat from those at home. As a specimen, I will give an account of what is obtainable in Bombay; and here let me say that Bombay must be taken as on the whole a very favourable specimen of an Indian city. It is the capital of Western India, fast becoming the greatest commercial emporium of India; is a city of great wealth, and has a population of about a million, rapidly increasing; and has one of the finest harbours in the world. Whatever, therefore, is wanting in Bombay will not be likely to be better supplied elsewhere.

This island is volcanic, and no stratified stone seems procurable there or for many miles round. The ordinary building stone is a very hard, rough, slate-coloured basaltic trap, quarried with difficulty, all having to be blasted, chiefly used in stones of small size, as rubble, laid with plenty of mortar, and plastered externally. It will make good but rough rubble work if squared up, but much of it proves to be perishable when placed in a building. For dressings and ashlar there is a scanty supply of one or two varieties of yellowish trap stone, called Coorla stone, of a hard, unyielding nature, very difficult to procure in large blocks. A brownish granular limestone, closely resembling the worst qualities of Bath stone, and known as Porehunder stone, is imported by sea from the coasts of Katiwar, a distance of some 300 miles. This is the best available material for masons' work in dressings or architectural features, but it is liable to discolour after being some years in a building. It is often defective, and it is so costly that, on any large work, it would probably be a saving to import Bath or Caen stone from Europe. Native bricks are very dear and small, being thin, like Roman bricks. They are mostly defective, but are available for internal use. Bricks of Eng-

lish pattern are brought to Bombay some thirty miles, from Callian, but are even dearer than native bricks, and not very satisfactory; and I know of one instance, at least, where the facing bricks of a large proposed building have gone from England to Bombay. The fact is that good material and fuel for brickmaking are both equally scarce. A coarse, spongy conglomerate, known as kurliel, is occasionally used for filling-in and internal walling. I believe it to be a species of coral, and it is probable that some coralline material may in many tropical localities be obtained of a serviceable quality. Gravel there is none: for sand there is only sea sand, which at Bombay is not silicious, but ground-up basalt, rounded by action of water. Of course this would be different in many localities. Laminated stone there is none, so that any thin paving stone has to be imported from Europe. A rough paving of the local trap is in use, but is very expensive. Lime and timber are the two materials which alone can be described as really excellent of their kind. The lime is known as chunam, and is obtained mostly from Kunker, a nodulose limestone found in the neighbourhood of Bombay, a small supply of the best quality coming from shells. Where cement is required it has to be imported from England. For some purposes which are served by cement with us,—such as fillets and hips,—a kind of temporary expedient called dammer is made use of. This is a sort of coarse resin mixed with oil, melted, and paid on hot, like pitch, with or without the addition of strips of canvas among it to make it hold better.

Flat terraçed roofs are not so common in Bombay, for the buildings either of Europeans or of natives, as they are elsewhere in the tropics. Where they are used they are ordinarily of chunam, and very thick.

For all carpentry and joinery, Bombay, like other parts of India, has recourse all but exclusively to one material—teak timber. This wood is extremely tough and strong, and can be got in great scantlings. It is hard to work, but has the three cardinal virtues, that the ants do not eat it, the rainy season does not rot it, and, when seasoned in India, the Indian sun does not warp it. Wherever teak is procurable the designer of buildings for the East will do well to employ it alone, unless he is sure that any substitute he proposes will fulfil all three of the above conditions. Timber is often used by the native builders, for such purposes as joists and rafters, in the form of unseasoned round poles, or some other rough shape. The best teak is from Calicut, the next quality from Moulmein. Black wood, which rivals teak in its indestructibility, is only used for furniture. There is plenty of rough timber to be procured for ordinary and temporary purposes, but not proof against the white ant.

The native tiles are an exceedingly bad roof covering; and nothing but the extreme difficulty of obtaining those substitutes which would be an improvement has caused them to be retained in European use. They are of very thin red porous tile, almost semi-cylindrical in section, and about 9 in. or 10 in. long. They are laid course, are laid quite loose on the roofs, and are consequently so easily decayed and damaged that a relaying of them, called tile-turning, is an annual part of the preparation for the wet season. Galvanised corrugated iron has been imported to some extent from England, and is sometimes used as a roof covering; it is not altogether well suited to the climate, but is an improvement on the tiles. Where used for roofing, it ought to be employed double, with an air space of 10 in. or 12 in., with free access for ingress and egress of air between the two skins, and then it is found to form a tolerably cool roof.

All ironmongery has to be of brass to withstand the damp of the monsoon time, and if it is to act at all as Europeans like hinges and latches to act it must come from Europe; so must window glass, and marble or tile pavements. The ordinary material available for floors is a filthy pulp of cow dung, laid by native women, who spread it about with their hands, often jewelled, with great unconcern. I must admit that this unsavoury mess quickly hardens into a good and inoffensive floor; but it requires renewing with fresh applications of the material almost fortnightly. The floors, or chunam floors, are of course preferred by Europeans, but they are disliked by the native servants, all of whom go barefoot, as cold to the feet.

Window glass is, I believe, obtained solely

from Europe, and till lately came only in small panes. Rolled iron joists, to be used in a flooring similar to that of Fox and Barret's patent, are to some extent imported; but the excellence of teak as a material for joists leaves room to doubt whether the ordinary floor, which is constructed with a sort of concrete filling-in between teak joists, is not quite as good. Dennett's arch, perhaps used in connexion with Phillip's girder, and Ransome's artificial stone seem both of them appropriate inventions for use in cities within the tropics, but less available in Bombay than elsewhere, owing to the absence of good sand or gravel, or of any fair substitute. Terra-cotta as a substitute for stone dressings has been to some little extent introduced, and promises to be very serviceable. Lathe are not forthcoming; the split bamboo, which is the best substitute, is liable to be eaten by the white ant, and this, I presume, the chief reason why plastered ceilings are very unusual. Their place is usually filled by boarded, and often by canvas ceilings. Plastering in chunam on walls is coarse and soft. As papering is unsuitable (it would harbour insects), the ordinary finish is an inferior kind of distemper. The saltiness of the sand renders the walls hygroscopic, but if damage from damp could be guarded against, a treatment like the interiors of Pompeii would be the proper internal finish. There is a very superior sort of chunam plastering known as Madras chunam. It very closely resembles fine Parian cement, but is so expensive as not to be often employed.

Plumbers' work is all but unknown in Bombay, except occasionally for water-pipes. Gas-fitting is, however, now in use there, as gas has been lately introduced, and would have now to be provided for in arranging buildings for that city.

I have, I think, in this list, said enough to show that a building intended for Bombay, even if designed in accordance with the climate, but requiring for its erection large blocks of stone, landings, or even much ironwork, or such things as slate slabs, panes of plate glass, or flat tiles for floors or roofs, would have to be modified on the spot, in respect at least of those parts—unless all required was sent out from England; and though, perhaps, some of the localities for which the service of an English designer may be required will be better off than Bombay in some one or two particulars, it is more than likely that they will be worse off in others, so that an acquaintance with the material resources of the place, and the utmost anxiety not to overtax them, is required of every architect of a building for tropical climates.

The administrative difficulty is, however, likely to be greater than the constructive in any case that may probably have to be encountered by any of us, and is much more likely to be overlooked or misunderstood by an architect who has never travelled beyond the limits of Europe.

The available modes of carrying out a building abroad, as at home, are of course either through contractors, or by engaging labour and buying materials. Native contractors of some sort will be found in most large Asiatic towns; and in many places, where there is an extensive European settlement, English or American contractors are to be met with. Where it is probable that the work will be carried on by them, it is important that the documents sent out to explain the architect's intentions should be in such a form as they will understand. Here it may be worth while to add that, at least in India, the documents need not be translated into any foreign language; simple good English will be thoroughly well understood by those natives engaged. Specifications should be clear, distinct, and full, and, above all things, free from such technical words as are not known to be in use in the place where the work is to be done. Drawings should be very full and clear, and should bear on their face written directions as to what is intended by any difficult, or unusual, or intricate arrangement or construction. Simple hills of quantities will ordinarily be valuable, but they should not be taken in much detail. They should also afford more means of tracing on the plans the work which they describe than is usual in England; and where much work has been done under the Royal Engineers, so that the contractors are accustomed to their routine, it may be advisable to throw the bills into the shape ordinarily employed by them, and which are taken very much in the gross, and are arranged to exhibit on the same page the dimensions as well as the result of each of the few measure-

ments made use of. This will be not only advisable, but probably necessary, if the work is under any colonial Government.

In many instances it will not be possible for work in the tropics to be contracted for, and it will be done by day labour. If the English architect has to find some one to take charge of such an undertaking, it will be most desirable to get a superintendent, not only familiar with the work, but also acclimatised to the country, and used to dealing with natives. If these points are neglected, or any one of them, the work will run a great risk of being entirely stopped. Upon the risks due to ignorance of the work I need not enlarge, but it is as well to note that if the superintendent be unfamiliar with the climate and imprudent there is every risk of his being seized with fever, or sunstroke, or some other violent ailment, such as heats a hot climate, especially where there is exposure, and so laid aside; or, if this be escaped, the work may be equally hindered by the superintendent being imposed upon by the craftiness of the natives, or by his blundering through ignorance upon something distasteful to the natives engaged; as, for instance, I have heard of a very extreme case of an entire work being deserted by all the men engaged upon it, owing to the European superintendent having laid his hands on one of the workmen, whose notions of caste were thereby outraged. Such a thing as this may seldom occur, and the narrative may have been exaggerated, but the unwary agent will be extremely likely to be overreached by the craft or overpowered by the caste combinations of natives, which last are quite as formidable as our own trades unions, and even more unanimous in action.

If the work be for any colonial Government, the probability is very great that it will be handed over to an officer of Royal Engineers to carry out by day labour; or, as it is officially termed in India, departmentally. Large numbers of plain buildings, such as barracks, are executed by the officers of this body from their own designs, according to plans and estimates prepared by themselves, they purchasing the materials and employing labour; and their system for doing this work appears to me admirably well organised for this purpose; but any one who has had experience of it will fully understand that neither architecture nor building is the proper function of military engineers, and that as an executive this corps is not suited to the requirements of work of high architectural pretensions, and that it hardly seems giving military officers their proper position to employ them upon the carrying out of any work except from designs prepared by the officer engaged. At the same time that I make these remarks, I must add that this corps contains individual officers who have distinguished themselves in India as architects by their designs and executed works; and that they have been pioneers in the work of constructing in that country buildings for European use. They have excellent facilities for procuring from England such articles of European manufacture as they want, but perhaps have been themselves led by this very facility, and by their example have led others, to neglect the cultivation of the resources of the country. If the proposed work be Government work, it will in some way, probably in every way, be under the Public Works Department, wherever, as in India, such a department exists, and taken in hand by the military engineers of that department; and the great evil which, in that case, the architect has to fear, and if possible to guard against, is his work being wholly or in part modified, set aside, or superseded. To prevent this, the precaution should first of all be taken of being quite sure: that there is nothing which will require necessarily to be set aside,—nothing manifestly unsuited to the climate, to the materials of the locality, or to rude and imperfect workmanship and means of execution. The architect should, secondly, be quite sure that there is nothing which will require necessarily to be added; his drawings, while as little voluminous as he can make them, should be so comprehensive and complete as to furnish every detail, anticipate every question, and supply all needed information. Thirdly, he should be quite sure, that all his documents are regularly in the form customarily used and understood by the engineers, especially his detailed estimate; to use a homely phrase, he should send out the whole thing out and dried. Lastly, he should omit no opportunity of getting any official sanction and mark in the shape of seals or signatures on the drawings, or official and thoroughly formal

minutes and memoranda in their favour, as he can by hook or by crook obtain from any one in authority. The reason of this last suggestion is, that in India, and more or less in all colonies, very frequent changes in administration occur; so that if the official sanction of an officer be not obtained early to anything which he has agreed to and ought to sanction, there is a great risk that he may be suddenly promoted or transferred, and the matter fall into the hands of a successor, who, if not bound by the official action of his predecessor, may take some totally different view, and upset all that has been done. This labour, you will perceive, is greatly in excess of what is required upon an English building up to the time of sending away plans, and it requires to be well remunerated. It is considered, by those best qualified to judge, that if thoroughly well done, the work on a proper set of plans, &c., of this sort, equals all that is wanted here up to the time of making contract, with the addition of about half that which is subsequently done by the architect here during the time of his superintendence of the building.

I may add that the Government of Bombay has officially recognised the scale of professional charges issued by this Institute. It is, however, quite possible that, at least in the case of architects residing and practising in India, these rates ought in fairness to be increased, for it is, I believe, customary for the members of other professions to charge double the English fee for their services. At least, this is understood to be the practice of physicians, solicitors, engineers, &c., at Bombay, and probably therefore will be the rule in other parts of India.

But to return to the agency for executing works. There can be little doubt that in the case of any very large work, the employment of an European contractor of energy and skill furnishes the best guarantee for the good and rapid execution of the work; and any members of this Institute who have heavy works in tropical climates will do well to urge on their clients the great advantage, almost the necessity, for employing the best English contractor who can be found, making liberal terms with him, and stipulating for his sending a representative to be with natives, and already accustomed to a tropical climate. It will, however, only seldom happen that a work is important enough to tempt a good contractor from England, and European contractors settled abroad, or the native contractors, will usually be the agency best to employ; and of these probably native contractors will as often as not be found the most useful; but in either case it cannot be too much impressed on the architect whose designs are to be carried out by hands used mainly to different work, and certainly need to him, that the instructions conveyed by his plans and documents should be very full, very clear, and very unmistakable, and that simplicity should regulate and pervade all his contrivances and arrangements.

There still remains the ultimate question, and the most purely architectural question of all. What aspect, as works of art, shall we, as artists, strive to impress upon the buildings whose arrangement and construction we have been considering? I shall not attempt to examine this question at all in detail, but cannot forbear raising it; for the art of any building is undoubtedly the one element, whatever value we may put upon it, which concerns us architects peculiarly and almost exclusively. All classes of builders require to understand materials and construction. Many non-professional men require to comprehend the arrangement of buildings and organisation of works. Professional men in other branches of the great building art are called on both to comprehend and carry out all these; but it is our special honour that to us is committed the charge of those works which it is desirable to render, not merely serviceable as structures, but impressive as monuments; that of us is expected, indeed, not merely a work of skill, but also a work of art. I hold that the solution of the question lies first in the adoption of a type essentially European; and secondly, in the retention and blending with it of such admissible features as are to be found in the best styles of architecture that have been elaborated already in tropical climates.

Had we a distinctive modern English style, we ought, unquestionably, to use it in our colonies as the Roman did in his colonies, with such changes as local circumstances made necessary. But though this is unhappily denied us, there are in existence distinctive European styles; and I

hold very strongly that as our administration exhibits European justice, order, love of law, energy, and honour, so our buildings ought to hold up a high standard of European art. They ought to be European, both as a rallying-point for ourselves, and as raising a distinctive mark of our presence, always to be beheld by the natives of the country.

As far as I have seen it, most of our building work in the East is not creditable to our taste though it bears witness to our energy and vigour. It is unmistakably European, but of a very bad type. Now, the proper characteristic is not, I hold, the direct imitation of Asiatic types, but the adoption of those European styles which have grown up in sunshiny regions. Such styles are ancient Roman, or even Greek (when good enough materials and workmanship are procurable), or the Renaissance and Gothic of Southern Italy or Spain, or the Early Gothic of Southern France. In treating any of these styles, and still more in treating any more northerly modifications, a leaning towards the peculiarities of the best Oriental styles is desirable. Among these peculiarities, the following may be enumerated as frequently found:—Walls of ample thickness, often covered with a profusion of delicate surface-ornament, frequently beautifully coloured; an absence of such vertical breaks as buttresses, and a prevalence of horizontal cornices and level projections; openings, usually wide and frequent, artistically grouped, often filled in with exquisite pierced patterns; mouldings infrequent balconies and various sorts of corbellings covered usually with carving; roofs of low pitch, flat, or domical walls, often replaced entirely by lines of piers or columns; for the most part, and with some notable exceptions, moderate height, but usually great extent and elaborate surroundings. The whole have an aspect of breadth, richness, shade.

In concluding, I should like to throw out the hint that these peculiarities may be found worked out in the most perfect manner, and with complete adaptation to the exigencies of a fiery climate, in the best of the Mahometan buildings, which mark, as I should like ours to do, the residence in India of a conquering race,—a race, alas! far more artistic than we, and whose works are nobler monuments of art than it can be hoped ours may be. Many of the finest of those fast-decaying and ill-protected works—those at Ahmedabad—are partly represented by means of photography, and so available for study; and if, in addition to affording such information as at least a few of our members may find useful and interesting, I shall have succeeded, by again pointing out these works, which have been already described here, in inducing architectural students to dig in this hitherto almost unexplored mine, I shall have the gratification of knowing that this paper has not been quite barren of results.

COMPETITIONS.

New "Yorkshire Club," York.—The members of the Yorkshire Club, that has been established since 1839, having found that the increase in their numbers necessitated better accommodation than could be obtained in their present home in St. Leonard's-place, and having procured the freehold site now occupied by the house and garden of the Rev. Thos. Richardson (of which the north front faces the Lendal, the west Museum-street leading direct to the Minster, and the south the River Ouse at the point where it is crossed by the Lendal bridge), invited designs in competition from several architects, from which they selected three, and requested their authors to re-compete, as they had somewhat altered the position the erection should occupy on the ground. Of the three second sets of designs the choice fell on that submitted by Mr. G. J. Parwell, of London, who is entrusted with the execution of the works, Messrs. Habershon & Pitt obtaining the premium for the second, and Messrs. Deane & Yeoman that for the third.

Agricultural Hall Company.—The directors of this company having determined to erect a new hall for concerts, dramatic entertainments, and so on, invited a limited number of architects to compete for the design, and the following is the result:—Mr. Peck, the original architect of the hall, to have the work, under certain restrictions; first premium to Mr. Knightley; second, to Mr. Giles.

THE HERALDS' COLLEGE, LONDON.

CONSEQUENT on the formation of the proposed new street from the Thames Embankment to the Mansion House, a small portion of Heralds' College (not the whole, as erroneously supposed), has been taken down, and a new front to it is now being formed. In doing this, the Lion and Unicorn that had long done duty there were placed upon the ground. The accidental position given to them shown by the sketch, led to the following *jeu d'esprit* by one whose initials will be recognized beyond heraldic circles. The writer terms it—

UNSUPPORTED SUPPORTERS.

The Lion and the Unicorn,
Who deign'd, till very lately,
The Heralds' College to adorn,
On pillars tall and stately,

Unceremoniously, one day,
Were hoisted from their stations,
And on the pavement left to stay,
Pending the alterations.

The Lion sadly wanted or,
The Unicorn lack'd argent;
Clearly they 'd ne'er been thus before
"Depicted in the margin."

It therefore seem'd of the offence
A serious aggravation
That folks with arms of less pretence
Obtained full compensation,

While they, supporters of the Crown
For centuries, unaided,
Who had graced standards of renown,
Were to vile flags degraded.

The Unicorn, in language strong,
The Lion laid the blame on:
"Without a growl to bear this wrong
A blot will be your fame on.

If of ns quadrupeds you were
The king, or e'en the regent,
You would be rampant, not beg there,
Like a tame poodle—*sejant!*

As *dexter* 'tis your right to make
Them equal justice minister;
If I should up the matter take,
They'd call the motive sinister.

The British Lion, you! My brain
Whirls round, it so provokes me!
For half-a-crown I'd break my chain—
My collar another chokes me!

'*Dieu et mon Droit*,' no longer may
You boast as your proud motto;
'*Adeu, mon droit*,' you'd better say,
And join Parkins & Gotto.*

So saying, like a vicious colt,
To cut the matter shorter,
He made a sort of demi-roll,
And rump'd his co-supporter.

The Lion winced at the last sneer,
But only gave a whistle,
And said, "My ancient friend, I fear
You've trod upon your thistle."

The motto you to England brought—
Excuse me, comrade, if I sigh
To find you set it now at nought—
Was 'BEAT PARSIVUS.'

Prithce don't let the Herald see
Us, thus 'addressed,' good brother,
When we in every sense should be
'*Respecting one another.*'

In youth I'm willing to admit
More 'combattant' was I, sir;
But then I'd much more pluck than wit—
I'm older now and wiser.

I can complacently repose
Beneath my well-won laurels;
And mean no more to poke my nose
In everybody's quarrels.

Nor does it suit my present views
To roar for every trifle;
I've got—and can, if need be, use—
But won't strain my new rifle.

You seem to have forgotten quite
The world's in constant movement;
And neither King's nor Lion's might
Can long repel improvement.

* *Sol-didant* "sunders" of arms.

London of a new street had need,
And heralds by profession
Were bound to lead, and not impede,
A grand public procession.

The posts we held were on the go,
And fallen soon had seen us,
We had nothing to support, you know—
Not one poor coat between us.

But re-installed in the new court,
And gay with paint and gilding,
We shall our dignity support
With that of the whole huldung.

Facing a street so broad and fine—
When to our seats we've vaulted—
My crown will out a greater shine,
Your horn will be exalted.

So blazon not a long dull roll
Of hickering and bereavements,
Display the power of self-control—
The greatest of achievements."

'Twas all in vain: the Unicorn
Was deaf to explanation,
And, with a toss up of his horn,
Declined more conversation.

J. R. P.

SOCIETY OF PAINTERS IN WATER COLOURS.

THE sixty-fourth exhibition by this Society consists of 297 works, and, as usual, a large proportion of them are very charming. It cannot, however, be called one of their best. The figure subjects are even fewer than usual, and none of the members are at their highest. We are not surprised therefore to hear that the sales, though numerous, are not at present up to the average. Let us note a few of the pictures. 8, "Sans Peur et Sans Reproche," John Gilbert, is a spirited Medieval group, but does not tell its story. The foot of the knight, with full remembrance of what armour is, is obtrusively large. 12, "Wild Fowl, a Flight—Winter," Frederick Taylor. The fowl are full of life and movement, but the aspect of the scene is hardly that of winter. 20, "Rahab (miscalled in catalogue Rachel) Awaiting the Coming of Joshua," F. T. Shields, is the picture of deepest interest in the room. The head, a little too masculine, perhaps, is full of anxious thought: the holding to her of the "line of scarlet thread" cleverly tells what is going on in her mind. 41, "Secondary Colours," G. Rosenberg, a marvellous representation of plums, apricots (the latter a little too yellow), and mossy rocks. In 166, "September," this artist gives another remarkable example of his power of representation. 48, "Monte Rosa from the Rifel," W. Collingwood: a rosy mountain indeed, but for all that an occasional truth. 57, "The Return from Fairy Land," T. R. Lamont. The Ettrick Shepherd's

"Kilmeny, Kilmeny, where have you been?" will be remembered. The mother opens the door; the father stays from chopping wood at the angle; the maiden, with her lap full of roses, is entering. The figure of Kilmeny is so charm-

ingly pretty that one omits to look at weaker parts of the picture. 61, "The Wanderer," Margaret Gillies, has none of the sickly sentimentality that is to be found in many of this clever lady's pictures: it is an excellent work. 64, "Hush!" Walter Goodall: the baby charmingly portrayed. 68, "Harvest Time at Stoke Fleming, South Devon, looking over Slapton Sands to the Start Point," Collingwood Smith: a capital landscape. The same may be said of 78, "The Mull of Cantire," Francis Powell (the ripples tipped by the setting sun), 93, "A Towered City" (solemn and grand), Sammel Palmer; 96, "Laid Up for the Night—on the Thames," J. J. Jenkins. 107, "Morning," Thomas Danhy; 114, "Buttermere—Sunrise," S. P. Jackson; 139, "Over the Hills and Far Away" (with its winding hedge-bordered road), F. Smallfield; "Salzburg" (beautiful Salzburg), Sam. T. G. Evans; and Mr. Newton's large drawing, notwithstanding some commonness in the foreground; 144, "Denbigh Castle," David Cox, jun., and 171 by the same. 163, "Interior of St. Stephen's, Vienna," Sammel Read, looking west, must have special praise; it is one of the finest works of its kind that has been seen for some time. 189, "Oxen Harrowing—Sussex," Basil Bradley. Eight long-horned bestials are pulling a little harrow over mild furrows, a large apparatus for small work. An eminent agriculturist, standing by, maintains that the majority of the oxen must be one hundred years old: it is a clever picture nevertheless. 219, "Fair Daffodils," F. Smallfield: a sweet human face, though the soft blue eyes do not both look quite the same way. 162, "Ave Maria," Walter Goodall; 248, "The Ship's Model," J. D. Watson; and 213, "Well-Sinkers," Frederick Walker,—all call for mention, especially the latter, which is an exquisite drawing.

ST. THOMAS'S HOSPITAL, WESTMINSTER BRIDGE.

THE first stone of the new hospital which is about to rise on the southern side of the Thames, opposite the Palace of Parliament and adjoining the end of Westminster Bridge, was laid on Wednesday last by her Gracious Majesty the Queen. A brilliant sun contributed to success. The road from Buckingham Palace to Stangate was lined with a loving people; and in a very commodious, well-ventilated, and handsome pavilion, erected over the site of what will be the chapel of the hospital, some 3,000 of the more distinguished of them received her Majesty with long-continued plaudits, and watched with interest the short but interesting ceremony. We may say briefly that the interior of the pavilion was planned somewhat after the model of a theatre, with that part which would be occupied by the stage screened off as a reception-room. That portion of the interior space which, in a theatre, might have been the orchestra, pit-stalls, and pit was reserved for the ceremony. All this enclosed space was of one crimson hue. The tall barricade that swept round the arena was painted of that colour, the same to a shade as the crimson carpet and the crimson hangings of the long screen, against which was the crimson-covered dais. Four crimson poles, converging to an apex which was crowned with a cluster of flags, stood in the centre of the floor; and from their midst depended the square and polished block shortly to be lowered on a base, which was covered as to its sides with crimson cloth, while two crimson pedestals were at hand, to support the trowel, mallet, plumb-level, and other implements. On the crimson dais was spread a Persian carpet; and gilt chairs with crimson seats were ranged for the royal party, a throne being in the centre. Above was suspended a blue canopy, surmounted by a gilt crown, and having the same emblem repeated in flat gold hroidery round the border, at intervals with the letters "V. R." Banks of flowers were ranged round the arena, and the embellishment was completed by a pair of royal standards, of long lozenge form, one on either side the canopy. [The canopy was arranged by Mr. J. G. Crace, and with his usual good taste.] It is unnecessary for us to describe the ceremony, but we may say that to an address that was read by Sir John Musgrave, as President of the Hospital, the Queen returned, but did not read, this reply:—

"It is with sincere pleasure that I lay the first stone of the noble buildings which you are about to dedicate to the use of the sick and suffering poor. The hospital of

St. Thomas, founded by my royal predecessor, Edward VI., from the services which it rendered to humanity, naturally attracted the attention of my beloved husband, whose heart and mind were ever interested in institutions of so beneficial a character. It is a solace to me to follow his example in promoting the objects which you have in view, and to trust that your hospital, upon its new site, by the various improvements which experience and sanitary skill may suggest, will secure increased benefits to its suffering inmates, and provide an admirable school for nurses, and for the promotion of medical and surgical science. I thank you for the loyal and sympathising expression of your feeling on the late attempt to take away the life of my dear son the Duke of Edinburgh, and join in your prayers that the same good Providence which preserved him from the assassin will soon restore him in health and safety to his family and country.*

The trowel used was made for the occasion by Messrs. Howell, James, & Co. The handle is of carved rock-crystal, inlaid with scrolls of gold and turquoises, surmounted by the Imperial Crown, in chased gold, set with precious stones, the arched diadems being jewelled with pearls. The blade is silver, with elaborately engraved and gilt arabesques of Italian ornament, and bears the following inscription:—

"This Trowel was used by her Most Gracious Majesty the Queen in laying the first stone of St. Thomas's Hospital, May 13th, 1868."

[The "stone" is a polished block of granite from the Dalbeattie quarries, N.B.]

Mr. Tite, M.P., was prominent amongst the acting governors of the hospital.

The building, as our readers know, is to be erected from the designs of Mr. Henry Currey. A view of it, with plans and descriptive particulars, will be found in our volume for 1865.* The contractors for the works are Mr. Webster and Mr. Perry. The clerk of the works is Mr. Andrew Cleland.

MORRAT HOSPITAL, ST. THOMAS!

MR. PARKER IN ROME.

A LECTURE was given by Mr. J. H. Parker at a late meeting of the British Archaeological Society in Rome, on the Direction and Extant Remains of the Servian Walls. It might be considered as sequel to another on the Construction of Ancient Roman Buildings, given some time previously by the same gentleman on a similar occasion. Mr. Parker holds some theories that are novel, and opposed to those hitherto accepted by Italian archaeologists. An excursion, with the object of visiting *in situ* the antiquities referred to in the lecture, was arranged for the following day, and participated in by a numerous party, who enjoyed the advantage of receiving explanations at the several spots they were conducted to from the lecturer. We may report, briefly, the experiences of that pleasant and instructive day, dedicated to such studies among ruins of remarkable character, but by no means among those most generally visited, or understood, by tourists at Rome.

Important and picturesque remains of the Servian fortifications have been brought to light within recent years, and in most instances as it were accidentally, through works undertaken without any antiquarian purpose. Ancient historians differ in their accounts of the circumstances of the city by that cincture of walls to be attributed to Servius Tullius, and which formed the sole fortification around the earlier inhabited regions during about 800 years—namely, till Aurelianus raised the much more extensive circuit, A.D. 271, which, as restored, and perhaps amplified, by Honorius, A.D. 403, forms the actual girdle of defences to this city, in many parts, indeed, rebuilt by the Popes, to whom is due the entire cincture on the Transiberine or right bank of the river. Dionysius states that the Quirinal hill was first annexed by Numa, the Viminal and Esquiline by Servius; so also Strabo; but Livy ascribes to the latter king the fortifications that included first the Quirinal, afterwards the Viminal, and finally the Esquiline; the project of which works had been originated by his immediate predecessor, Tarquinius Priscus, who was prevented from accomplishing it by the wars with the Latins and Sabines; a second time undertook it, but in vain, shortly before he was cut off by violent death (Liv. l. 1, c. 36, 38). It is possible to reconcile statements that seem contradictory (and for the argument on this subject see Nibby, "Roma Antica," by assuming that Numa annexed some portion only of the Quirinal, Servius the remainder of that hill, and that

Tarquinius Priscus commenced the works completed by his successor, though one writer, Anselmus Victor, ascribes the whole to the former king, except that Agger, with its system of fosses, which all (Pliny alone excepted, who calls it the Agger of Tarquinius) agree in ascribing to Servius. Dionysius, the fullest in describing what he had seen when he visited Rome, about the year 30 B.C., observes how insignificant was the extent of these walls compared with that of the then inhabited city under Augustus, adding that it was difficult to trace their complete circuit, concealed, as they then were in many parts, by other buildings, and that the entire circumference seemed to him not much greater than that of the walls of Athens—namely, 63 stadia, or 7½ Roman miles—a few hundred feet less than the ascertainable measure of these Servian defences.

The first spot visited by the party under Mr. Parker's guidance was the Barberini vineyard, on the northern slope of the Quirinal, and in the valley between that hill and the Pincian, site of the beautiful gardens of Sallust, which eventually became a more important centre, chosen for imperial residence, the favourite seat of several emperors, especially of Aurelian. Here, on the steep hillside, are seen a few courses of antique masonry in lithoid tufa, partly hidden by vegetation, but recognisable as of early Roman work; and from the highest ground we discern the elevation of the Agger, extending southwards, in part overgrown by trees, at one point cut off by the Via di Porta Pia on the Quirinal, its course now traceable through private properties. The ruins next visited are in what was formerly the gardens of the Villa Negroni (where dwelt Alfieri), now the premises of the railway station. Here, in the course of railway works, were found some years ago, the massive substructures of walls in square-hewn blocks, the same lithoid tufa, some of the length of 2·70 metres, the direction oblique, the whole having been buried under a steep bank, evidently a part of the earthworks by which the Agger was supported on the inner side. At the same time were discovered the remains of a gateway, with jambs of ponderous masonry, at once identified as the Porta Viminalis, but which, with strange neglect, was allowed to be demolished—one of the instances of that Vandalism which has not totally ceased in modern Rome! A pleasant spot, notwithstanding utilitarian appropriations, and on every side commanding fine views of city and country, is that estate once of the Negroni Villa. Here, too, are other antiquities, brought to light within late years,—chambers of ruined mansions, built against the bank of the Agger, and on their inner walls are seen, in colouring still fresh, paintings that remind of Pompeian decoration. Those courses of ancient stonework have been numbered, so that each block may be distinguished, and plunder rendered impossible without detection. From hence we proceeded along the little-frequented region between the Viminal and Colian hills to the lower level, where stands S. Clemente, beneath which church, when the more ancient, now subterranean to the more modern building, was re-opened, an extent of walls in square-hewn blocks of lithoid tufa, with a kind of cornice in travertine of still larger masses, was found beneath the chancel of the primitive church, flanking a narrow passage, the opposite side of which is formed by the regular brickwork of a Roman mansion, believed to be the house of the Pope St. Clement III, successor to St. Peter. If, as seems inferable from their character, these walls be indeed a part of the Servian, that cincture must have taken a direction bending inwards from the south-eastern side, and advancing into the Sabura (where S. Clemente stands), which no theorists have hitherto assumed, the accepted maps of the ancient city placing the line far from this spot, and nearer to the Lateran basilica. The southern slopes of the Colian were next visited, and from a solitary road along which rise the picturesque ruinous arcades of the Neronian Aqueduct, we struck off into vineyards and gardens, amidst which it is almost certain that the Servian walls must have passed, though no traces of them be now visible. But other ruins, picturesque and noticeable, little known because not seen from any highway, will here repay the trouble of exploring: the most conspicuous, those of a mansion popularly called "House of Seneca," and in masonry resembling that of the time of Nero, the principal portion, a vaulted chamber in well-preserved *opus reticulatum*, intermixed
